About BJPsych Bulletin

BJPsych Bulletin prioritises research, opinion and informed reflection on the state of psychiatry, management of psychiatric services, and education and training in psychiatry. It provides essential reading and practical value to psychiatrists and anyone involved in the management and provision of mental healthcare.

BJPsych Bulletin is an open access, peer-reviewed journal owned by the Royal College of Psychiatrists. The journal is published bimonthly by Cambridge University Press on behalf of the College. There are no submission or publication charges to authors.

BJPsych Bulletin is not responsible for statements made by contributors and material in BJPsych Bulletin does not necessarily reflect the views of the Editor-in-Chief or the College.

Abstract

For many patients and healthcare providers, the move to virtual psychiatric care has been fast-tracked by the COVID-19 pandemic. In this article, we consider a patient perspective and a provider perspective on the transition to virtual psychiatric care and its strengths and limitations, as well as a call for much-needed future research.

The COVID-19 pandemic has rapidly transformed service delivery, including the delivery of medical care, around the world. As jurisdictions worldwide enacted measures to slow the spread of the SARS-CoV-2 virus, service providers quickly adapted. What was previously a slow expansion of telemedicine and virtual care over the past two decades, with the primary goal of overcoming geographical barriers,¹ became suddenly fast-tracked in a matter of weeks. A rapid transition to virtual psychiatric care, care provided by telephone or video, is one such transformation resulting from the COVID-19 pandemic and the measures implemented to contain it.

Leaders and advocates in the field of telepsychiatry are expecting, and in fact encouraging, these changes to persist post-pandemic.²⁻⁴ The aim of this article is to reflect on the transition to virtual psychiatric care through three lenses:

a patient perspective, a provider perspective and a scholarly perspective, including a call for future research. The patient and provider perspectives obtained for this article reflect individual experiences with the transition to virtual psychiatric care and are not intended to capture the diversity of perspectives and experiences that may exist. The patient and providers have experienced both models of care pre- and post-pandemic onset.

A patient perspective, by Ms Sandra Lubert

“I am a mental health patient with a diagnosis of depression, PTSD and chronic sleep disruption. I have been either ill or in remission for many years and have experienced extensive clinical intervention both before and during the COVID-19 pandemic; that is, both actual, in-person care and virtual, online care. Clearly, a physical meeting between patient and practitioner in a clinical environment is often warranted. Face-to-actual-face is sometimes best, and I am not advocating the replacement of such visits with online care. Further, some of our most vulnerable populations lack access to telehealth and/or virtual technology and for these individuals, it is imperative that we either provide them with the tools required to access proposed alternative care or continue to provide traditional, in-person interventions. Barriers to online care can be significant, salient features and these need to be considered. When a physical appointment is required or even simply preferred, this must be accommodated. I believe that an ideal system of mental health care features a robust, multi-faceted approach which meets the needs of all patients and practitioners. My own mental illness includes severe insomnia and related suicidality. Six weeks ago – right around the onset of the pandemic – I had a psychiatric crisis requiring an ER visit and overnight hospitalization. This urgent, on-site care was life-saving. But I believe that my follow-up care, which has been entirely virtual, has been just as critical. This recent experience leads me to believe that the rapid changes necessitated by COVID-19 have a great deal to teach us about psychiatric care delivery. For me, as a recipient, ‘pandemic-period psychiatry’ (via eVisits) has not only been adequate and helpful, it has in many ways been far more effective than its in-person counterpart. There are three main aspects of online care that have enhanced the overall experience for me: reduced cost, ease of access, and increased flexibility/comfort. From a very practical standpoint, I can state that eVisits have saved me money. I have not had to pay for gas to get to and from appointments, and I have not had to pay for parking. Many patients travel a significant distance in order to see clinicians, and this can be very expensive. Some rely on caregivers, taxis, or public transit. Again, while this may seem insignificant, the cost of transportation can be a major deterrent in seeking treatment, particularly for those on a limited income. Ease of access around virtual care is a huge factor. My mental illness is often incapacitating; when I am in crisis, it is difficult for me to get out of bed, let alone leave my house. Things like getting dressed, planning for travel time, being presentable may seem trivial, but for those struggling with severe mental illness, these obstacles can be insurmountable. The anxiety induced by having to leave the house and get to one’s doctor is sometimes crippling and prevents us from seeking care. When I am in distress, the idea of sitting in a waiting room (often in tears, usually in psychic pain) is intolerable. For those dealing with a physical disability in addition to mental illness, barriers are even more debilitating. When access is restricted, the situation with mental health can become dire. Indeed, it can even become deadly. eVisits have saved me; I have been better able to access consistent, necessary psychiatric care because I can do so virtually from my home. Increased flexibility is perhaps the most beneficial aspect of virtual care. Since the variables of transportation and location are removed, both patient and practitioner are better able to schedule meetings. Modifying appointments has also been far easier to accomplish online, with recipient and caregiver both having immediate access to electronic calendars and other tools. Involving my partner in an eVisit is merely a matter of inviting her to sit next to me at my computer. Both my doctor and I have information at our fingertips if needed. Finally, I feel more comfortable with eVisits. Meeting with my practitioner from my own environment puts me more at ease. Ultimately, this has to do with a levelling effect – it makes me feel like I am more of an equal in the patient–practitioner exchange. Traditional appointments take place in the doctor’s realm – their office, clinic, the hospital... in some ways, this gives them the ‘home field advantage’, as it were. I am in their space. They know where everything is, who everyone is, but it is largely unfamiliar to me. I am a guest. I don’t have my own mug, for tea.”

A provider perspective, by Dr Tea Rosic, psychiatry resident, and Dr Zainab Samaan, staff psychiatrist

“Suddenly, going to the clinic to see patients is a health risk to both my patients and me. I am faced with a precarious balancing act as I find ways to provide adequate psychiatric care to patients who face increasing anxiety, depression, social isolation, and changes in mental status during the pandemic. The novelty of COVID-19, the ever-dynamic guidelines, processes, and instructions, issues of shortage and conservation of PPE, and new risk–benefit equilibria as we consider each clinical decision are all present in ways we have not encountered before. Virtual care has alleviated the risk carried by face-to-face contact but has raised many new challenges. Do I have a printer, fax machine, dedicated telephone line, secure email, and contact information for community pharmacies? Do I know how to schedule appointments without administrative staff support? New medicolegal challenges arise: what if a patient has an urgent psychiatric need, should I be available online 24 h/day? Can we send patients to hospital or are we contributing to risk of transmission and placing patients at greater risk? Not unlike before the pandemic, my patients in greatest need of care often face the greatest barriers in accessing it: limited mobile phone minutes, barriers in access to internet and virtual technologies, lack of privacy. Nevertheless, virtual care has been transformative. Being able to provide much needed care despite the pandemic restrictions is satisfying. Seeing patients through telemedicine modalities has opened the door to better assessments of their environment and allows for easier involvement of other family members when invited. I see patients’ pets and other important aspects of their lives. How often does it occur, in the clinic, that we have no access to updated medication lists, and how much time is spent trying to gain this information before making further treatment recommendations? With virtual visits and medications accessible to the patient in their home, this problem is averted. Virtual care during this pandemic has so quickly transformed how (and from where) we do our jobs. I have greater control over my schedule, working hours are more flexible and I am more available outside of structured clinical time. How these changes will evolve following the pandemic is unknown, but there is much to be learned and gained from this experience.”

A scholarly perspective: the evidence base

Virtual psychiatric care has an established evidence base and has shown effectiveness in a variety of areas, including within different patient populations and in different clinical settings.⁵ Previous research suggests that building therapeutic rapport is just as effective virtually as it is in person.⁵ For clinicians thrust into providing virtual psychiatric care, the strengths and limitations of this model of service delivery are becoming clearer. Recognising and reflecting on these is just as important now as it will be post-pandemic, when organisations and providers decide on the models of care they will offer. In the post-pandemic era, in-person healthcare may indeed become ‘option B’ for many patients.⁶ We are working through the technical issues, concerns about confidentiality and provider payment obstacles that each slowed the advance of virtual care in the past. For many patients, as described above, virtual care provides the easier access, flexibility and comfort that is lacking from in-person, hospital- or clinic-based care. Some patients may be greatly benefited by ongoing virtual appointments.

For all of the potential benefits of virtual psychiatric care, there are shortcomings that must be considered. Physical examination cannot be conducted as usual and there may be challenges in comprehensively assessing physical appearance and functioning in virtual psychiatric assessments. Virtual care may impose additional barriers to assessment for patients presenting with certain symptoms, such as paranoid ideation,^{7,8} although a recent study on the use of telepsychiatry for first-episode psychosis suggests that 50% of patients reported telepsychiatry as a favourable modality for follow-up.^{9,10} Patients experience differential access to virtual platforms and technology, based on socioeconomic and other factors.¹¹ In particular, patients with severe and persistent mental illness may face even greater barriers to accessing care virtually than the general patient population.⁸ Individuals living in close quarters with multiple family members may have insufficient space to talk while maintaining privacy and confidentiality.^{11,12} Older adults and individuals with disabilities may face challenges with access to technology, visual impairment or hearing impairment, creating barriers and gaps in care. Cultural factors in virtual care must be carefully considered and addressed. Patients who require language interpreters may be disadvantaged by virtual psychiatric care.¹³ With the expansion of virtual psychiatric care, we must be particularly mindful of the risk of widening the gap in access to care for patients who are marginalised or otherwise vulnerable. The broader issue of global healthcare access inequities in telepsychiatry is being raised.¹⁴

Research and practice implications

In this article, we aimed to provide both patient and provider perspectives on the rapid and monumental shift to virtual psychiatric care that occurred, seemingly overnight, in many jurisdictions. However, the perspectives shared may be limited in their generalisability for settings outside of a well-funded public healthcare system or in places with limited existing capacity for the provision of telemedicine. We stress that the experiences of unique patients and unique providers, working in diverse clinical settings, managing different clinical presentations and operating in distinct healthcare systems worldwide might be critically different. The global healthcare community will benefit from hearing and learning from diverse experiences and perspectives.

As we rapidly usher in this new era of virtual psychiatric care, concerted efforts must be made to study and learn from our experiences. Research must be undertaken to examine the impact of these changes in psychiatric service delivery for different patient groups and different providers. Ensuring identification of individuals and groups whose needs are not met will be critical. Qualitative research that can capture the depth and detail of our human experiences with virtual psychiatric care will be necessary. Economic analyses of the costs and savings of this model will also be integral. There is some pre-pandemic evidence to suggest great potential cost savings with widespread use of telemedicine – including savings accrued from shorter time spent travelling and waiting, for both patients and providers.^{15,16}

Clinical and research groups worldwide have begun to publish and share their experiences in implementing telepsychiatry during the COVID-19 pandemic for patient populations in various settings, including child and adolescent psychiatry,¹⁷ general out-patient psychiatry^{11,13} and in-patient psychiatry.¹⁸ Surveys of psychiatrists using telepsychiatry during the pandemic indicate benefits such as convenience and flexibility, as well as challenges in relation to the use of technology, impact on confidence in diagnosis and impact on therapeutic alliance.¹³ Authors are giving consideration to the experience of trainees and educators using telepsychiatry.¹⁹

The COVID-19 pandemic propelled us into a new era of virtual psychiatric care, and opened the door to a re-evaluation of how, and why, we provide mental healthcare in the ways we do. This door will remain open, post-pandemic, allowing us to rigorously evaluate, shape and refine our models of care to meet the needs of our patients as best as possible.

1.1.2 The contagiousness of memes: containing the spread of COVID-19 conspiracy theories in a forensic psychiatric hospital

Abstract

COVID-19 has transformed healthcare service provision. In addition to the spread of a virus, there has been an equally concerning emergence and spread of conspiracy theories. Such theories can threaten societal cohesion and adherence to the necessary public health guidance. In a forensic in-patient setting, such difficulties can be amplified. In this paper, we outline the key theory in relation to the development and spread of conspiracy theory memes. We propose primary, secondary and tertiary level responses to tackle the possible generation and spread of harmful conspiracies in the forensic in-patient setting. We consider this to be important, as there is a risk that such beliefs could affect patients' mental health and, in extremis, undermine physical health efforts to reduce the spread of COVID-19.

Forty-four cases of pneumonia of unknown microbial origin were reported to the World Health Organization (WHO) on 31 December 2019.¹ Investigations revealed that the culprit organism was a novel coronavirus, dubbed COVID-19. COVID-19 has spread quicker than experts anticipated; the WHO declared an international state of emergency – a

true pandemic – in early March 2020, as the virus spread rapidly between continents. The human cost has been, and continues to be, vast.

The public health response

The global response to COVID-19 has emphasised the necessity for reduced close contact; hence, the intervention termed ‘social distancing’. To achieve this aim, many governments implemented ‘lockdown’ strategies to limit the free movement of the public, although the precise restrictions and severity of the measures have differed from country to country. The UK government urged people to ‘Stay Home, Save Lives, Protect the NHS’, with only essential travel permitted, restricted mixing of households and citizens at one point limited to a single exercise outing per day. There was a national drive to ‘flatten the curve’, with the stated intention to avoid overwhelming the National Health Service (NHS). A further patriotic message resonated with the public; that is, to protect the most vulnerable in society. Ultimately, the effectiveness of government and society’s efforts to maintain this unconventional and rather antisocial injunction will be measured by the number of casualties.

A forensic mental health hospital facing the pandemic

We are based in a psychiatric medium secure unit (MSU) in the West Midlands, UK. The MSU has capacity for 90 male patients across multiple wards and provides care to men who present with complex risk behaviours and experience psychopathology that warrants treatment under the Mental Health Act 1983 (amended 2007). The reality of COVID-19 within the MSU community parallels the changes seen in wider society. Initially, the virus was an abstract threat. However, measures were quickly implemented to increase hand-washing, social distancing and isolation of symptomatic patients.

At the time of writing, there have been 24 COVID-19 cases confirmed by positive swab in our MSU. Many patients experienced mild to moderate symptoms. However, three individuals required transfer to an intensive care unit for intubation and ventilation. Fortunately, they made a good recovery and returned to the MSU. Those with milder symptoms have been encouraged to self-isolate in their bedrooms. In anticipation of an increase in infections, one ward was designated to be the ‘COVID ward’, to contain the infection within a specific area and minimise further spread.

Clinical practice has changed significantly and it is hoped that, by mimicking national restrictions, the spread of COVID-19 will be contained. However, it is acknowledged that true ‘lockdown’ cannot be instated owing to the necessary travel between wards to maintain essential care.

The Trojan horse: a split between staff and patients?

Patients in the MSU have been required to adjust to novel protocols (use of personal protective equipment (PPE), social distancing, etc.) while also processing the increased limitations on their movements at all times. Such dramatic changes, in the context of access to 24 h news coverage, have understandably heightened anxiety, fear and uncertainty. Of course, this is in addition to the usual physical and relational security provisions, such as air locks, keys and high fences that can be a source of angst for patients.

In these unprecedented conditions, we consider that there is a risk of an ‘us versus them’ dynamic developing, particularly as situational threat is high.² On closed wards, it is plausible that staff are the vehicles of virus transmission, transporting the contagion onto the ward asymptotically, given the incubation period of COVID-19. It is possible that some patients may view the movement of staff as contamination. The usual psychological containment that high staffing levels can provide may now be perceived as hostile, dangerous and unpredictable – when the danger cannot be seen, who is infected and imposing threat to the community? As the staff group fulfil the role of caregivers, a complicated role reversal ensues, as the caregiver is viewed as the source of danger: the Trojan horse entering the fortress.

The emergence of conspiracy theories

We have noticed that conspiracy theories have emerged in tandem with the COVID-19 spread. Conspiracy theories have been defined as ‘attempts to explain the ultimate causes of significant social and political events and circumstances with claims of secret plots by two or more powerful actors’.³ Notably, conspiracy theories are similar to, though distinct from, misinformation and/or ‘conspiracy hypotheses’. Misinformation – false or inaccurate information, often intended to deceive (e.g. ‘fake news’) – can underpin conspiracy theories as it undermines mainstream narratives; conspiracy hypotheses are legitimate counter-narratives that can occur when there is uncertainty about the official story. Again, these can increase uncertainty and trust in a centralised message. The relationship between these phenomena is likely to be fluid.

Research has shown that conspiracy beliefs are common. For example, 60% of Americans believe that the CIA killed JFK⁴ and 46% of leave voters in the EU referendum believed that the vote would be rigged.⁵ There are many other types of theory that gather large follower groups.³ COVID-19 conspiracy theories have included fear of 5G broadband networks and persistent notions that the virus is man-made.⁶

Interestingly, individuals who hold one conspiracy theory are more likely to believe others,⁷ thus suggesting a possible underlying tendency to seek counter-narrative explanations and prefer them to information presented by institutions. Individuals who hold conspiracy beliefs are predominantly male, unmarried and of lower socioeconomic status. They are more likely to have weak social networks and belong to ethnic minority groups. Notably, they are likely to have had adverse childhoods and experience psychiatric problems as adults.⁸ Such demographics are highly consistent with a typical in-patient forensic population.^{9,10}

Particular environmental conditions and psychological processes have been mooted to underpin such beliefs. In a review, Douglas et al¹¹ identified three psychological motivations that led to a preference for conspiracy explanations: epistemic, existential and social. Each has particular relevance to the patient group in an MSU.

The epistemic motivation relates to an individual’s or group’s understanding and knowledge of a phenomenon; conspiracy theories can allow individuals to preserve a sense of understanding in the face of uncertainty and contradiction. These beliefs are noted to become stronger when events are widespread and/or significant,¹² and when simplistic, mundane explanations are perceived as unsatisfactory.¹³ Conspiracy beliefs can foster a sense of cognitive closure when the situation lacks a clear, consistent and understandable official message.¹⁴

When individuals feel anxious, threatened and powerless in the face of danger, they may gravitate towards conspiracy theories to achieve a sense of comfort.^{11,15,16} These are viewed as existential motivations.¹¹ Such powerlessness can be exaggerated by a perception of alienation from decision makers and a breakdown in containment and social order.^{7,15}

Douglas et al¹¹ note that social motivations also contribute to the formation of conspiracy beliefs. Groups that have experienced persecution, for example victims of police harassment¹⁷ or racial discrimination,¹⁸ are more likely to perceive dominant groups as conspiring against them. Research has shown that members of low-status groups are more likely to endorse conspiracy theories than those of higher status.^{15,19} In-group attachments can strengthen in the face of group threat, and ‘collective narcissism’ (an emotional investment in an unrealistic belief about the in-group’s greatness)²⁰ can develop, particularly when underprivileged, undervalued and under threat.¹⁹ This may function to protect the in-group by forming a shared ‘us versus them’ narrative.²¹ Similarly, individual narcissism is understood to emerge as a defence in response to perceived powerlessness; a conspiracy theory is powerful as it ascribes ‘special knowledge’ to the believer, imbuing a safe sense of superiority.²²

Such motivations and psychosocial characteristics are relevant and, in some circumstances, exaggerated in the MSU population. For example, research has linked subclinical delusional thinking²³ and schizotypy^{24,25} to conspiracy thinking. Individuals diagnosed with paranoid personality disorder demonstrate similar conspiratorial thinking.^{26,27} Cognitive/affective mechanisms at play in such samples are also relevant to those at the distressing/impairing end of the psychosis continuum, i.e. those diagnosed with schizophrenia.²⁸ For example, the omission of true cognitive information²⁹ could precipitate a jumping to conclusions (JTC) bias that is associated with the rapid appraisal of ambiguous or anomalous stimuli to form a conclusion without a sound evaluation of evidence.³⁰ Such a bias is evident in subclinical³¹ and clinical populations.³² Moulding et al³³ have identified that holders of conspiracy beliefs are more likely to view the world as threatening. Such schematic views of the world as dangerous³⁴ can underpin the process whereby delusional beliefs – in an attempt to secure cognitive closure – form from misappraisals of anomalous stimuli.³⁰ Of note, a high

proportion of our in-patient population hold – or have held – delusional beliefs.

Disproportionately, MSU in-patients have been exposed to early life danger³⁵ and hold negative schematic beliefs about self, others and the world.³⁶ Psychotic delusions, conspiracy theory beliefs and self-protective distortions have a propensity to surface when conditions are dangerous and uncertain.^{15,16}

The impact of the pandemic within the clinic

Meme theory can help to explain how such ideas spread, particularly in contained environments. Dawkins³⁷ considered memes to be cultural phenomena that pass from one mind to another, and survive (or die) through a process analogous to genetic selection. Goertzel³⁸ noted ‘conspiracy theorizing [*sic*] is a rhetorical meme that transforms scientific controversies into human dramas with villains who can be exposed’.

In the general population, COVID-19 conspiracy theory memes (e.g. 5G phone masts, man-made virus) have gone viral, with some harmful and persistent consequences. More broadly, memes that run as counter-narratives to the government’s explanations and advice affect some people, who may then spread their ideas to others. This may lead to a failure to act according to government guidelines and in the best interest of public health.⁶

We have observed conspiracy theory memes to develop in two distinct ways within the MSU. First, ‘organic memes’ have developed on one ward. These have taken the form of a belief that the pandemic is orchestrated by the hospital staff to restrict leave and delay discharge. Such a belief is likely to have formed with no outside influence and is perhaps good evidence that humans will seek conspiracy theory explanations in isolation to allay epistemic, existential and social concerns.^{11,19} It is our view that, despite several men endorsing this meme to a greater or lesser degree, it will likely wither and fail to spread owing to its fallibility in the face of simple counter-evidence and the physical health restrictions that prohibit mixing of wards (this meme is unlikely to be shared by staff members).

The type of second conspiracy meme is more problematic and harder to contain. These are externally generated conspiracy theories. Such memes may find traction among the internal population by direct or indirect conversations, through telephone contact, media consumption and where there are exchanges of perspectives. It is not possible – or ethical – to stop the introduction of conspiracy theory memes via telephone contact with relatives. However, staff members may be prone to conspiracy beliefs because of their own sense of powerlessness, threat and existential anxiety. As staff members move around the MSU, there is a risk of them spreading conspiracy beliefs to others. Additionally, misinformation might be introduced into the hospital. This new discrepant information may destabilise an already vulnerable in-patient population and prime conspiratorial thinking.

The impact of a COVID-19 conspiracy theory meme outbreak

Healthy secure wards are able to maintain a negotiated homeostasis, whereby clear boundaries and good clinical practice maintain order, safety and containment, while also promoting mental health rehabilitation. Conspiracy theory memes present a threat to this architecture. A possible consequence is a breakdown in trust and cohesion, which would undermine physical and psychological safety, and challenge measures to contain the virus.⁶

Uncertainty and unpredictable danger can be precipitants of anxious threat states. Changes in routine or the introduction of new conditions can trigger a loss of perceived environmental control and subsequent attempts to regain safety. As such, periods of stress and threat require the use of automatic self-protective behaviours and implicit information processing strategies.²⁹ Harmful conspiracy theories or hypotheses can increase uncertainty and decrease trust in authority figures. For many men in forensic in-patient settings, violence or self-harming behaviour has been – or is – an adaptive part of their self-protective behavioural repertoire. When in conditions of threat, such behavioural expressions might manifest to gain control, discharge arousal, communicate distress or elicit care.

Similarly, splitting is a possibility, with competing memes generating an ‘us versus them’ dynamic. As described previously, this is an evidenced component of conspiracy theory motivation, and staff members can become targeted if inequality is perceived (e.g. locked down versus transient, exposed versus PPE). Systemically, these processes can heighten the sense of danger for other residents and group anxiety can escalate. Of course, staff members are not immune to such effects and negative consequences are possible (e.g. burnout, increased punitiveness).

The response

Memes are hypothesised to spread in a manner analogous to a virus.^{37,38} Hence, we propose that a fast, stringent and proactive strategy is required to curb the sharing of unhelpful and false memes. We suggest that the response to ‘prevent’ and ‘treat’ conspiracy theories can be pitched according to the public health approach to diseases: primary, secondary and tertiary prevention.

Importantly, some degree of uncertainty is unavoidable owing to a global lack of clarity regarding COVID-19. It has to be acknowledged that there are few unambiguously *true* known facts about the virus. We do not advocate the suppression of questioning or critical challenge of official narratives. A host of different memes, differing in strength, transmissibility and potential harmfulness, will spread among staff and patients. We recommend that professionals demonstrate clinical judgement to determine if and when intervention is required and listen to alternative perspectives, discussing them in context.

Primary prevention

Primary prevention aims to prevent disease or injury before it occurs. To prevent the development of conspiracy theories within an MSU, we recommend addressing the conditions that lead to such thinking.

We consider the first line of response to be education. Conspiracy theory memes are hypothesised to breed from indecision and uncertainty; gaps in knowledge allow room for a counter-narrative to develop to fulfil a need for cognitive closure¹⁴ and a perception of control.^{11,15,16} We view the regular and consistent dissemination of clear and transparent information about the pandemic, the ‘outer world’ situation and MSU policy to be essential to maximise patients’ knowledge. Information can be adapted to account for complex communication needs, and care plans developed accordingly. Ideally, patients who are vulnerable to being affected by conspiracy beliefs should be identified and bespoke assessments and management plans completed.

The staff group are not immune from conspiratorial thinking. Helping staff members to feel informed requires the consistent dissemination of information in a manner that is accessible to all. Changes in practice should be quickly communicated. Information should be transparent, with an open forum approach to address queries and signpost to relevant resources. In addition, an honest acknowledgement of challenges that individuals and teams will face is necessary to ensure preparedness. To prevent splitting and/or ‘suffering in silence’, regular reflective practice, peer group supervision and *ad hoc* ‘check ins’ can give space for the processing of anxiety and an opportunity to work through uncertainties and questions. Greater use of virtual connectivity has allowed sick or shielded colleagues to sustain communication with core teams, thus maintaining a collective ‘togetherness’.

Research has suggested that it is important that education provided for staff and patients is presented in an ‘even-handed’ manner (i.e. do not dismiss counter-narratives offhand) to prevent the perception of indoctrination or bullying.^{39,40} Failure to do this successfully could lead to the educator being absorbed into the conspiracy belief.⁴¹ Information sharing might take the form of standardised and accessible information boards, regular ward ‘community meetings’ and individual conversations with patients and staff to ensure that they feel informed about events.

In our NHS trust, daily staff briefings have been provided by the chief executive officer. There are daily meetings held by senior management within the MSU to strategise, coordinate a unified response and ensure that information is shared – and then cascaded – evenly throughout the site. In addition, members of different clinical disciplines have adapted their roles. For example, individual psychologists have ‘cohorted’ to provide intensive support for single wards, occupational therapists have provided opportunities for activity and release from the claustrophobic ward spaces and the psychiatric team have employed a ‘shadow rota’ to ensure that sickness does not reduce the provision of emergency care. Collectively, these additions and adaptations to practice can be understood as ‘inoculation’ of the community.⁴² Many of these organisational strategies are likely to be in place to serve other, important needs. However, it is our view that such good practice is also relevant to the aims of this paper.

Secondary prevention

The aim of secondary prevention is to reduce the impact of a disease or injury that has already occurred. We recommend that conspiracy theories already in circulation should be identified at the earliest possible point and the conveyance slowed. The ultimate aim is to challenge unhelpful or disruptive memes that threaten to break down cohesion in the MSU community. Strategies need to prevent re-emergence and reconnect those affected to a less detached position. However, if this is not possible, the focus shifts to containment and reduction of the spread to others.

The infection control response to COVID-19 (i.e. ‘lockdown’ of wards) will inadvertently prevent the cross-contamination of conspiracy theory memes across the MSU site. However, conspiracy theories can infiltrate the community via telephone calls, media and/or staff acting as vectors. It is clearly counterintuitive, unethical and disproportionate to restrict or monitor private phone calls. Secondary prevention should therefore be targeted at the management of memes that are conspiratorial in nature or undermining of national or local COVID-19 policies.

We recommend that changes in anxiety, mood and behaviour associated with conspiracy thinking – or exposure to such ideas – should be observed as part of the usual monitoring of mental state. In the MSU, all patients are regularly reviewed by the nursing staff and forensic psychiatrists, who examine their mental states and the extent of psychopathology. Patients can be given space to explore their thoughts and feelings about such theories; the clinician can then establish whether intervention is required. A ‘COVID-19 formulation-led’ approach to addressing concerns as they arise is recommended.

When discussing conspiracy theories – or related memes – information should be presented in a consistent, clear and accessible manner so that further doubt, ambiguity or reinforcement of the conspiracy does not result.⁴¹ The patient will require adequate knowledge to close the ‘uncertainty gap’. This work may also be achieved through group or individual therapy sessions. In our MSU, we have found that acceptance and commitment therapy (ACT) principles have been beneficial, particularly as these can address issues relating to control and uncertainty.⁴³ In addition, mindfulness practice can help to calm heightened arousal states, release troubling thoughts and teach self-awareness.⁴⁴ As uncertainty is largely inescapable, such therapeutic approaches are preferable to the suppression of all but the most harmful memes. Cognitive remediation strategies can improve reasoning ability⁴⁵ and various non-verbal therapies can help to up- or down-regulate arousal.

Considering the ward as a whole, the maintenance of a ‘safe’ and ‘cohesive’ environment is vital to prevent the harmful effects of conspiracy theory memes. The basis for this is already provided via the implementation of the ‘Safewards’ approach⁴⁶ and positive behavioural support planning.⁴⁷ Indeed, an approach not dissimilar to trauma-informed care could be adopted: ‘pandemic-informed care’ would incorporate the necessary physical health precautions, while also proactively identifying and addressing the emergence of conspiracy theory memes and promoting a clinical awareness of the vulnerabilities of patients who are prone to engage in conspiracy thinking. Pandemic-informed care would also include the provision of staff support and reflective practice.

Some patients who have been exposed to conspiracy theories may become paranoid, anxious or distressed in response to this exposure. If there is a resultant significant decline in symptoms and functioning in which the expression of delusional ideas and other psychotic features is identified, there are a range of pharmacological, psychological and risk-management techniques that may need to be considered.

Tertiary prevention

Tertiary prevention is a strategy to reduce the impact of an ongoing illness or injury that has lasting effects. By definition, many individuals who are resident in an MSU experience complex psychopathology and are vulnerable to anxiety, paranoia and conspiratorial beliefs. Clinicians involved in their care are well advised to consider the impact of ‘lockdown’, uncertainty and competing narratives, and the destabilising effect that each might have.

A multidisciplinary approach is required to incorporate such formulations into care planning and intervention, as has been undertaken across our MSU. In acutely psychotic patients – and those susceptible to relapse – there is a risk that COVID-19-related fears could become enmeshed with pre-existing delusional belief systems. In a patient who becomes absolutely engrossed by conspiracy beliefs to the point that it manifests as a delusion and/or other features of a psychosis and significantly affects their function, an individual, tailored approach must be adopted. The priority

would be the containment of severe pathological symptoms, with consideration given to pharmacological and risk management interventions. In addition, the reinforcement of a consistent and safe environment is necessary to allow the individual to feel secure and grounded. Access to regular, trusted and familiar nursing staff is likely to be important. Arousal-regulating therapy might also be considered. Deterioration in mental state may prompt a review of the patient's current setting. A decision may need to be taken as to whether an acute ward may be more appropriate or higher levels of observations needed. In each case, the acute symptomatology needs to be addressed and, in time, once stable, measures taken to challenge the conspiracy thinking via psychological intervention.

As regards measures introduced to support staff, it is recommended that these are maintained beyond the acute phase of the response. Conspiracy theory memes might retract while the various levels of intervention are in place. However, if support is withdrawn too quickly, a breakdown in communication, increased isolation and potential feelings of abandonment (that accompany burnout) might prompt disharmony and a failure to adhere to the previously outlined necessary actions. This may lead to a second wave of conspiracy beliefs emerging.

Conclusions

These are extraordinary times in society and clinical practice; there is a heavy emphasis on how to identify and manage the physical health manifestations of COVID-19 among the general population, existing patients and the workforce. However, COVID-19-associated conspiracy theory memes also present a societal challenge, which is perhaps exaggerated in a forensic in-patient setting. There is nuance as to what memes should be challenged and the degree to which challenge is made. This is a clinical decision on a case-by-case basis. However, a failure to intervene in an appropriate, effective and ethical manner when memes are potentially harmful could precipitate a breakdown in therapeutic relationships, ward cohesion and the successful implementation of physical health procedures. The consequences of such breakdown relate to mental health deterioration, increased risk behaviours and the failure to curtail the spread of COVID-19. Below, we make suggestions that are consistent with the conspiracy theory literature, which may be helpful to manage the development and spread of conspiracy theory memes (we also consider this guidance to be applicable to other custodial settings, such as prisons): provide clear, consistent and up-to-date information to patients and staff; clearly explain the rationale for change (e.g. new practices/restrictions); empower staff and patients to make informed decisions in relation to care; develop bespoke multidisciplinary COVID-19 formulations for each patient; regularly review patients with reference to their experience of COVID-19; ensure that all clinical environments are 'safe spaces' and that interactions are therapeutically informed (pandemic-informed wards); provide psychological intervention to address uncertainty, change and anxiety, and consider the use of cognitive remediation strategies to enhance reasoning; be prepared to utilise short- and long-term pharmacological and risk-management strategies as required if mental state deteriorates significantly; maintain team cohesion through regular reflective practice, peer supervision and *ad hoc* individual 'check ins'; provide appropriate challenge to conspiracy theory memes, with an awareness of the theory outlined in this paper.

We thank Stephanie Wilson, Sarah Shanahan and Fiona Hynes for reading – and commenting on – draft versions of this paper. Their contributions have improved our work significantly.

pmc Psychiatry P.R.N. is edited by four psychiatrists who are involved in direct clinical care, and it shows in the way the book is configured to focus on practical, pragmatic learning. The use of multicoloured formatting, illustrations, text boxes and bullet points makes for easy reading and quick assimilation. Its small format also allows for easy portability in a handbag or backpack, to serve as a quick reference.

Though positioned as an undergraduate textbook for medical students, it will prove to be equally valuable to trainee psychiatrists, nurses, social workers and occupational therapists. Multiple choice question (MCQ) and objective and structured clinical examination (OSCE) skills are covered, case studies are aplenty and each chapter has salient points highlighted. At the end of each chapter, there is information available in the form of films, plays, novels, papers and useful resources. This second edition builds on the well-regarded first edition (2009), which was highly recommended in the BMA book awards (2010). The 2020 edition adds a chapter on forensic psychiatry. Chapters have been updated to incorporate new research and facts. Accessibility seems to have been a focus, with emphasis on diagrams, pictures and artwork.

The book is divided into two parts. Part 1 offers an overview of psychiatry, including psychiatric assessment, interview skills and psychiatry as a career choice. Part 2 focuses on ‘theory’, with an emphasis on imparting key information on major psychiatric conditions in a lucid, concise manner. Chapters are well laid out, with a uniform template that proffers developmental, neurobiological and sociological perspectives. Cross-cultural aspects of psychiatric illness are included in all the chapters.

I would have liked to see author credits for each chapter individually, but that is a minor quibble.

Strunk’s *The Elements of Style*, first published a century ago, emphasised the rules of writing and language composition. *Psychiatry P.R.N.* reflects advancements in modern publishing, wherein the written word is intertwined with audio-visual and interactive media to enhance learning. I would suggest *Psychiatry P.R.N.* as recommended reading for all psychiatry training grades, as well as consultants who are interested in teaching and training.

- *Brice Pitt, MD, FRCPsych*

pmc Formerly Emeritus Professor of Psychiatry of Old Age, Imperial College, London, UK

Brice Pitt, who died aged 89 on 16 January 2021, was a highly significant pioneer of old age psychiatry, as well as a colourful personality. In 1971, he was a founder member of the informal ‘coffee house’ group of psychogeriatricians, which preceded the RCPsych’s Special Interest Group (now a Faculty) for Old Age Psychiatry. He was the group’s first secretary (1973–1978). As the chair of the subsequent Section (1986–1990), he led old age psychiatry through turbulent debate to achieve government recognition as a distinct medical specialty in 1989. He also chaired the College’s Public Education Committee and, associated with this role, wrote *Down with Gloom! or How to Defeat Depression* (illustrated by Mel Calman). In it, as elsewhere in his writing, he was open about his personal experience of depression.

Brice’s passion for his subject was evident in *Psychogeriatrics: An Introduction to Psychiatry of Old Age* (1974). About this book, he said: ‘I wrote down everything I knew off the top of my head. It was a doddle’. His turn of phrase was often vivid and insightful: psychogeriatricians were ‘a happy band of pilgrims’ who needed ‘occasional militancy [...] to gain a fair share of scant resources, to put them to best use, to make do with too little while wheeling, dealing, and fighting for more’. *Psychogeriatrics* was followed by other books, including *Feelings about Childbirth* (1978), which was based on his MD thesis on post-partum depression (a life-long interest: he was President of the Association for Postnatal Illness at the time of his death) and *Mid-Life Crisis: Its Cause and How to Overcome It* (1980), and they all received international acclaim. These volumes were variously translated into Japanese, Spanish, Polish, Finnish, French, Croatian, Afrikaans and other languages.

Brice was born on 19 December 1931, the son of Norman Pitt, a surgeon, and Emily (née Crawford), a nurse. Brought up in Surrey, he attended Epsom College. In the immediate post-war years, children perhaps conformed more to parental direction than they do today. Brice wanted to be an actor, but his father told him he would have to study medicine. He was unsure how to reconcile this direction with his wishes, but when watching Alfred Hitchcock’s psychiatric melodrama *Spellbound* (1945), he decided that if medicine was to be his destiny, he would be a psychiatrist.

Like his father, Brice went to Guy’s Hospital Medical School in London. David Stafford-Clark, psychiatrist, television personality and author of books on psychiatry for a lay readership, was his teacher. After house jobs came National Service in the Army, first at The Royal Victoria Military Hospital at Netley, then Singapore and Hong Kong. In 1960, Major Brice Pitt moved back into civilian medicine. He opted for psychiatry training at Springfield Hospital in south-west London. There, he treated his ‘first proper old person’. He was ‘perplexed by the richness of the symptomatology’ and perturbed by the attitude that the hospital was ‘like a castle, a good registrar would fend off the elderly, as those who got in were bound to stay [...] dumped by their family’. He objected to excluding people on account of age. Perhaps a childhood memory haunted him: ‘My sainted grandmother had a stroke and threw a knife at me in a tantrum: this affected me profoundly and left me wondering why’.

As a senior registrar, Brice worked with Ford Robinson, who had a ward and day hospital for functionally ill older people at St Clements Hospital, Mile End, London. It was rare in those days to have any dedicated psychogeriatric training. Brice also trained at Claybury, a large psychiatric hospital also in London. It had a ‘tremendous atmosphere emanating from the therapeutic community approach’ nurtured by the ‘superb’ physician superintendent Denis Martin. Brice called Claybury ‘Camelot’, after the mythical fellowship of King Arthur, with all participants equal at the Round Table.

Appointed consultant psychogeriatrician at Claybury in 1966, Brice inherited 400 occupied beds, a catchment area of about 65 000 over-65s, a social worker, a senior house officer and some general practitioner sessions. Local geriatrician Malcolm Hodgkinson said to him: ‘You don’t want a waiting list, you never admit for continuing care, and you don’t want to run a sleepy service’, and he thought: ‘My God, the one thing I do not want ever to be accused of by Malcolm is running a sleepy service’. And he never did. He started by establishing a mixed-sex ward at Claybury, risqué in a gender-segregated hospital. He also introduced routine home assessments for older people, a practice that became widespread. Camelot fell when Martin died. New-style district general hospital psychiatry beckoned, and a prize post at the brand-new Princess Alexandra Hospital, Harlow, lured Brice back to general psychiatry. But in 1971 he returned to psychogeriatrics in Tower Hamlets, where innovation included a collaborative psychiatric–geriatric unit with geriatrician Chris Silver.

In the early 1980s, Brice moved to Barts (City and Hackney), to join psychogeriatrician Alan Gardner, ‘a very obsessive serious fellow, while there is something a bit flighty about me some of the time’, he said. In 1986, he moved again, to St Mary’s Hospital, Paddington, as the UK’s fourth professor of old age psychiatry. While there, he established the Hammersmith Hospital memory clinic, one of the first in the country. This led to him being dubbed ‘Memory Man’ in a local newspaper, for his pioneering work.

Brice also fulfilled his dream to be an actor. With the Tower Theatre Company, he played royalty, noblemen, judges, bishops and Badger in *The Wind in the Willows*. He directed plays and wrote some, including *Anatomy of Melancholy* and *The Memory Clinic*. In 2005, under the pseudonym Beric Norman, he wrote a novel, *Mordred’s Version*, rooted in the original Camelot.

Chaucer would have appreciated his words and humour at the RCPsych’s Old Age Faculty meeting in 2013, when he was presented with its lifetime achievement award: In March, when Spring is nigh, but strong winds blow
The Faculty of Old Age Shrinken blithely go On Pilgrimage, to venues academic
And each and every one a well trained medic To discourse on derangements of the mind
Of older persons, troubled with all kind States of confusion, madness, melancholy –
Yet to my mind the meeting was full jolly [...] His presence at the gathering, to receive meant
His peers’ award for his Lifetime Achievement! [...] Brice was delighted to be offered this award
Which he never knew existed: Thank you, Lord!¹

Brice had a large family. Married three times, he was father of Gareth, Caroline, Tristram and Rosalind, grandfather of Shem, Fiona, Helen and Joshua, and stepfather to children from the marriage of his third wife, Judy. They all survive him.

Contents

- *Brian M. Davies, MD, DPM, FRCP, FRCPsych, FRANZCP*

pmc Formerly Cato Professor of Psychiatry, University of Melbourne, Victoria, Australia

Professor Brian Davies, Victoria's first Professor of Psychiatry, died on 15 November 2020 at the age of 92. As a pioneer of academic psychiatry, he was regarded as a trail-blazer for Australian academic psychiatry who facilitated the training and career development of many successful colleagues. He was appointed to the foundation chair of the University of Melbourne's first academic Department of Psychiatry, taking up the Cato Chair in 1964. He rapidly established the department in the forefront of the specialty. The department that he led quickly gained an enviable reputation for wide-ranging quality research, excellent teaching, and state of the art treatment and caring for patients. To the end of his tenure 26 years later, he steadfastly focused his energies in three main areas: teaching students and postgraduates, service provision and facilitating quality research.

In his typically modest way, Brian attributed the fact that he was able to attract excellent people to accept positions in his department to 'good fortune' rather than the fast-developing reputation of his department as a centre of excellence. The Cato Chair became, arguably, the most prestigious Chair of Psychiatry in Australia, with staff receiving many Australian and New Zealand Commonwealth honours. Many leading psychiatrists, including George Szmukler, Edmond Chiu, David Ames, Graham Mellsop, Sidney Bloch and Graham Burrows, either received their early training or worked as psychiatrists and researchers in his department. His quiet, diffident and, at times, enigmatic nature resulted in a leadership style that enabled department staff to feel free to pursue their research passions while also being gently guided and supported yet nudged when necessary. He led not by acting as a loud front man, forever talking up the achievements of his 'empire', but more as an avuncular encourager and facilitator, open to good ideas but willing to guide and advise when required. The postgraduate psychiatry trainees in Brian's unit learned much from observing him assess patients, quickly and efficiently focusing in on the most salient aspects of their presentation and demonstrating his renowned clinical acumen. To many he became a mentor as well as a teacher. He expected much but also returned loyalty and support.

Brian played a leading role in the group of psychiatrists and business entrepreneurs who conceived the idea of building a modern private psychiatric hospital in Melbourne in 1975. He characteristically played down his pivotal role in setting up and conducting meetings that culminated in the opening of The Melbourne Clinic in 1978. The clinic became Australia's largest private psychiatric hospital. After retiring from the Cato Chair of Psychiatry in 1990, Brian continued to work in private practice, both at The Melbourne Clinic and elsewhere, finally retiring in 2009, aged 81.

Born on 8 June 1928 in Llanelli, South Wales, the son of a miner, Tom Davies, and Lilian (née Drake), a primary school teacher who was passionate about English literature, Brian followed his 6-years-older brother to Cardiff University Medical School. He graduated in 1950, his medical training having included just one lecture in psychiatry. He said: 'I wasn't interested – in those days psychiatry was the last chapter in the medical textbooks – I just wanted to be a physician like my brother'. Having completed training as a physician, Brian asked senior colleagues for advice regarding what should be his next career step. 'Do psychiatry training – psychiatry will be big in 4 years' was the advice. He was able to secure a training position at the Maudsley Hospital in London, where he worked in the unit of Professor Sir Aubrey Lewis, an Australian psychiatrist who had become a towering figure in UK psychiatry. From 1956 to 1964 at the Maudsley and Bethlem Royal Hospital, Brian immersed himself in the newly emerging and exciting field of research into antidepressants. He published world-leading research on tricyclic and monoamine oxidase inhibitor antidepressants.¹

Looking beyond the possibilities of a psychiatric career in Britain, he decided to apply instead for a more interesting academic post, just then advertised – that of Cato Professor of Psychiatry at the University of Melbourne. He, his wife and two children arrived in Melbourne in April 1964, after a 4-week sea journey. His outstanding ability was rapidly

recognised and in 1968 he delivered the Beattie-Smith lecture, the highest honour that Melbourne psychiatry bestows on its leaders. His topic was: ‘Recent Studies of Severe Mental Depressive Illnesses’. He authored a classic student textbook, *An Introduction to Clinical Psychiatry*, which went through four editions from 1966 and remains well-known to a generation of Australian medical students and psychiatrists.

Brian had a quiet manner. He had very little ‘small talk’ and colleagues could sometimes feel that he kept them at a distance. This was more to do with his shy nature than any personal dislike. Persistence in pursuing issues with Brian was often rewarded with knowledgeable and helpful suggestions, advice and encouragement. In recent years he had delighted in reconnecting, at regular lunches, with many former work colleagues from his time as Cato Professor. He remained modest, continuing to be somewhat uncomfortable when publicly praised and never seeking special recognition or honours for himself.

Reading was a lifelong passion for Brian, his taste extending over many genres. He had a love for, and a deep knowledge of, Shakespeare. He also developed an enduring love of golf. He became a skilled and well-known player at Royal Melbourne Golf Club, actively participating until his last year.

In 1951, Brian married Rona (née Waters), a nurse, the start of over 67 years of loving marriage, sadly ended in 2019 with Rona’s death. They had a daughter, Debra, and son, Gareth, together with three admiring grandchildren.

1.1.5 Individual placement and support: cross-sectional study of equality of access and outcome for Black, Asian and minority ethnic communities

Rachel Perkins Rash Patel Amelia Willett Laura Chisholm Miles Rinaldi

Correspondence

Rachel Perkins

(rachel@rachelperkins.london)

date

2022-02

Abstract**Aims and method**

To explore whether people from Black, Asian and minority ethnic (BAME) communities experience equality of access and outcome in individual placement and support (IPS) employment services. Cross-sectional data were analysed of all people with severe mental health problems who accessed two mature high-fidelity IPS services in London in 2019 ($n = 779$ people).

Results

There were no significant differences between the proportions of people who gained employment. The data strongly suggest that people from BAME communities are not differentially disadvantaged in relation to either access to or outcomes of IPS employment services.

Clinical implications

The challenge for mental health professionals is not to decide who can and who cannot work but, how to support people on their case-loads to access IPS and move forward with life beyond their illness.

 - * *Limitations and implications*
 - *Data availability*
 - *Declaration of interest*

pmc It is recognised that people from Black, Asian and minority ethnic (BAME) communities both perceive¹ and experience inequality in access,² experience and outcomes³ within mental health services in England. The NHS Long Term Plan makes a renewed commitment to improve and widen access for adults needing mental health support partly through a new community-based offer. This includes access to employment support for people with severe mental health problems through the expansion of the evidence-based individual placement and support (IPS) approach.⁴

IPS involves a direct, individualised search for competitive employment that avoids lengthy pre-employment preparation or training and does not screen people for work ‘readiness’. It does not exclude people on the basis of diagnosis, symptoms or substance misuse. IPS is a ‘place and train’ approach, rather than a traditional ‘train and place’ approach, to vocational rehabilitation. There are now 27 randomised controlled trials supporting the efficacy of IPS compared with traditional vocational rehabilitation.⁵ National Institute for Health and Care Excellence (NICE) guidance recommends IPS for people with severe mental health problems who wish to gain and retain employment.^{6,7}

Within this context, consideration needs to be given to ensuring that people from BAME communities have fair access to employment support and equal opportunities to gain employment. There has been considerable concern that there is no parity between BAME communities and the White majority in access, experience and outcomes of mental healthcare⁸ and so it is right that we ask questions about the effectiveness of IPS for BAME groups.

Method

This was a service evaluation of two IPS services in London. Formal ethical approval was therefore not required.

The IPS services

To explore whether people from BAME communities experience equality of access and outcome in IPS, two IPS services together serving five London boroughs were selected: Central and North West London NHS Foundation Trust (CNWL) IPS service, serving people using secondary adult community mental health services in the boroughs of Westminster, Kensington & Chelsea, Harrow and Hillingdon (CNWL also provides IPS services in Milton Keynes but data from this service were not included in the current study because this was a relatively new service and our focus was on mature London services); Working Well Trust (WWT) IPS service, which works in partnership with East London NHS Foundation Trust (ELFT) serving people using secondary adult community mental health services in the borough of Tower Hamlets.

These services were selected because they are both mature, high-fidelity IPS services recognised as centres of excellence by the Centre for Mental Health.⁹ Both serve areas of London where there are large BAME communities and they represent the two main models of providing IPS in English secondary mental healthcare services. The CNWL IPS service is provided by the trust and all employment specialists are trust employees and members of multidisciplinary adult community mental health teams. The WWT IPS service is a voluntary sector organisation whose employment specialists are employed by the WWT but integrated into ELFT Tower Hamlets adult community mental health teams.

Data

The two IPS services provided anonymised cross-sectional data on all people with severe mental health problems who accessed their service between 1 January and 31 December 2019. For each person, the following anonymised data were supplied: ethnicity (White, Asian/Asian British, Black/Black British, Mixed, Other) age gender date of accessing the IPS service job outcome (whether the person gained at least one day of open paid employment by 31 December 2019). More detailed data on duration of employment were not available but anecdotal evidence suggests that in practice the majority were employed for a longer period.

Data were also provided by the respective mental health trusts on the ethnicity and gender breakdown of everyone served by their adult community mental health teams for the same time period.

Results

Table 1 shows that $n = 779$ people accessed the two IPS services between 1 January 2019 and 31 December 2019: $n = 412$ accessed the CNWL IPS service and $n = 367$ accessed the WWT IPS service. Ethnicity data were available for $n = 714$ (92%) of these people. Table 1

Number of people accessing the individual placement and support (IPS) services between 1 January and 31 December 2019, by ethnicity, gender and age			
	CNWL IPS service	WWT IPS service	Total
People accessing IPS 1 Jan to 31 Dec 2019, n	412	367	779
Ethnicity, n (%)			
White	134 (36.7)	114 (41.3)	278 (38.9)
Asian/Asian British	77 (21.1)	114 (32.7)	191 (26.8)
Black/Black British	64 (17.5)	63 (18.1)	127 (17.8)
Mixed	38 (10.4)	21 (6.0)	59 (8.3)
Other	52 (14.2)	7 (2.0)	59 (8.3)

Age, years: mean (s.d.), range	37.73 (12.02), 17–65	34.39 (10.74), 18–69	36.16 (11.55), 17–69 ¹

¹ CNWL, Central and North West London NHS Foundation Trust; WWT, Working Well Trust.

Equality of access

To explore equality of access to IPS services for those from BAME communities, for each service the number of people of different ethnic communities accessing the service was compared with the ethnic breakdown of those using secondary adult community mental health services in the boroughs served, using a χ^2 -test statistic for goodness of fit. The ethnic breakdown of those using secondary adult community mental health services was selected rather than general population data for the boroughs served because it is people using secondary adult community mental health services who constitute the population eligible to access the IPS service. The results of these analyses can be seen in *Table 2*. *Table 2* Proportion of people from different BAME communities accessing individual placement and support (IPS) services in 2019 in comparison with their proportions in the population using adult community mental health services

People accessing IPS service, n (%)	People using adult community mental health services, n (%)	People from BAME communities accessing IPS services, %
CNWL IPS service	White 134 (36.7) 2774 (39.6) $\chi^2 = 22.05, P < 0.01$	Asian/Asian British 77 (21.1) 1158 (16.5) 6.6
Black/Black British 64 (17.5) 810 (11.5) 7.9	Mixed 38 (10.4) 936 (13.3) 4.1	Other 52 (14.2) 1335 (19.0) 3.9
Not known/stated 47 (11.4) 1350 (16.1) 3.5	WWT IPS service	White 144 (41.3) 900 (41.1) $\chi^2 = 34.22, P < 0.01$
Asian/Asian British 114 (32.7) 805 (36.7) 14.2	Black/Black British 63 (18.0) 259 (11.8) 24.3	Mixed 21 (6.0) 61 (2.3) 34.4
Other 7 (2.0) 167 (7.6) 4.2	Not known/stated 18 (4.9) 90 (3.9) 20.0 ²	

Table 2 shows that there were significant differences in the proportions of people of different ethnicities accessing the IPS service compared with the respective secondary adult mental health service populations (CNWL IPS service: $\chi^2 = 22.05, P < 0.01$; WW IPS Service $\chi^2 = 34.22, P < 0.01$).

In both services, the proportions of White and Asian/Asian British clients accessing IPS were similar to those in the population of people using secondary adult community mental health community services. However, in both services, the proportion of Black/Black British clients accessing IPS was 52% greater than in the population using secondary adult community mental health services: respectively 17.5% compared with 11.5% in the CNWL IPS service and 18.0% compared with 11.8% in the WWT service.

The proportions of men and women accessing the IPS service did not differ significantly from the proportions using adult community mental health services (CNWL: $\chi^2 = 2.61, P = 0.11$; Working Well Trust: $\chi^2 = 0.14, P = 0.71$).

Equality of outcome

To explore equality of employment outcome of IPS services for those from BAME communities, job outcomes for people of different ethnicities were compared using χ^2 -test statistics. Two separate analyses were performed. The first considered everyone accessing the IPS services between 1 January and 31 December 2019 and whether or not they had gained employment by 31 December 2019. However, some of these people – those accessing the service later in the year – would only have had the opportunity for a very short period of support before 31 December 2019. Therefore, a separate analysis was conducted considering only those who had accessed the service in the first half of the year (between 1 January and 30 June 2019) and had therefore had the opportunity of at least 6 months' support. The results of these analyses can be seen in *Table 3*. *Table 3* Job outcomes by 31 December 2019 by ethnic group

People who gained employment by 31 Dec 2019, n (%)	CNWL IPS service	WWT IPS service	Total	All who accessed IPS 1 Jan to 31 Dec 2019
141 (38.6)	141 (38.6)	107 (30.7)	248 (34.7)	714
(412 people, ethnicity data available for 365)	107 (30.7)	248 (34.7)	355 (49.8)	714
(367 people, ethnicity data available for 349)	248 (34.7)	355 (49.8)	603 (84.5)	714
(779 people, ethnicity data available for 714)	Ethnicity White 47 (35.1) 46 (31.9) 93 (33.5)	Asian/Asian British 35 (45.5) 37 (32.5) 72 (37.7)	Black/Black British 23 (35.9) 18 (28.6) 41 (32.3)	Mixed 15 (39.5) 5 (23.8) 20 (33.9)
Other 21 (40.4) 1 (14.3) 22 (37.3) ² = 2.50, $P = 0.64$ ² = 1.76, $P = 0.78$ ² = 1.46, $P = 0.84$	People who had opportunity for at least 6 months' support by 31 Dec 2019	55 (43.3)	127 (54 (42.2))	128
(139 people, ethnicity data available for 127)	54 (42.2)	109 (42.7)	163 (62.5)	128
(135 people, ethnicity data available for 128)	109 (42.7)	163 (62.5)	272 (84.4)	128

² BAME, Black, Asian and minority ethnic; CNWL, Central and North West London NHS Foundation Trust; WWT, Working Well Trust.

(274 people, ethnicity data available for 255) Ethnicity White 18 (39.1) 29 (46.0) 47 (43.1) Asian/Asian British 8 (40.0) 13 (39.4) 21 (39.6) Black/Black British 6 (30.0) 10 (45.5) 16 (38.1) Mixed 10 (66.7) 2 (22.2) 12 (50.0) Other 13 (50.0) 0 (0) 13 (48.1) $\chi^2 = 5.66, P = 0.22$; $\chi^2 = 2.78, P = 0.59$; $\chi^2 = 1.43, P = 0.84$ ^{3,4}

Table 3 shows that, when considering everyone accessing the service between 1 January and 31 December 2019, 34.7% had gained employment by 31 December 2019: 38.6% in the CNWL IPS service and 30.7% in the WW IPS Service. Considering only those who had the opportunity of at least 6 months' IPS support (those who had accessed the service between 1 January and 30 June 2019), by 31 December, 42.7% had gained employment: 43.3% in the CNWL IPS service and 42.2% in the WW IPS service.

There was no significant difference in the employment outcomes by 31 December 2019 for people from different ethnic backgrounds (for everyone accessing IPS between 1 January and 31 December 2019: $\chi^2 = 1.46, P = 0.84$; for those who had the opportunity for at least 6 months' input: $\chi^2 = 1.43, P = 0.84$). Neither was there any significant difference between the outcomes for people of different ethnicities in either of the services when considered separately.

This equality of employment outcome was found when men and women from different ethnic backgrounds were considered separately. For those accessing IPS between 1 January and 31 December 2019 there was no significant difference in job outcomes between those from different ethnic groups for men ($\chi^2 = 7.62, P = 0.11$) or for women ($\chi^2 = 2.84, P = 0.59$). Similarly, equality of employment outcome was found for people from different ethnic backgrounds in different age groups (up to 25 years of age: $\chi^2 = 1.62, P = 0.81$; 26–40 years: $\chi^2 = 4.38, P = 0.38$; 41–55 years: $\chi^2 = 0.50, P = 0.97$; over 55 years: $\chi^2 = 2.93, P = 0.60$).

Discussion

The data collected from these two mature high-fidelity London IPS services strongly suggest that IPS is equally effective in securing employment for people of different ethnic backgrounds using secondary mental health services. For men and women, young and old there were no significant differences between the proportions who gained employment by the end of the year in which they accessed IPS services. It is not known whether similar results would be obtained in less well-established services – it takes time to implement an effective IPS service. With the NHS England national roll-out of IPS it is essential that routine service monitoring includes access and outcome data broken down by ethnicity to demonstrate the key IPS principle of 'zero exclusion' that ensures services are equally effective across different communities.

Although the proportions of men and women accessing these IPS services did not differ, there were significant differences in the proportions of people of different ethnicities accessing them. These differences do not suggest differential disadvantage for people from BAME communities. Quite the reverse, the proportions of Black/Black British people accessing each IPS services were higher than their proportions in the populations of people using secondary adult community mental health services in the areas (CNWL: 17.5 v. 11.5%; WWT: 18.0 v. 11.8%). However, there are marked differences between the two services: in CNWL the proportion of people from different ethnic communities accessing IPS did not differ markedly, but at WWT there were substantial differences. The reasons for this cannot be ascertained from the data. For example, it may reflect a positive bias in referrals to IPS or a greater interest in work opportunities by the different ethnic communities (perhaps itself reflecting greater deprivation/different employment rates). The data considered here are for those who engaged with the services: it is not known how many were referred

³ CNWL, Central and North West London NHS Foundation Trust; IPS, individual placement and support; WWT, Working Well Trust.

⁴ i.e. accessed IPS between 1 January and 30 June 2019.

but did not engage with the service offered. It should also be noted that the ‘not known/stated’ ethnicity category was higher in CNWL than in WWT/Tower Hamlets adult mental health services.

It has sometimes been suggested that South Asian communities may be protective of people with psychosis and consider employment as a risk. Our study would suggest that this is not the case. It showed no differences in access or outcome for Asian/Asian British people. Similarly, previous research has demonstrated that Asian/Asian British people using IPS services were more likely to be in employment than their White counterparts.¹⁰ However, in our study it should also be noted that, although in CNWL the proportion of Asian/Asian British people was substantially higher among those accessing IPS services than among the adult community mental health services population (21.1 v. 16.5%), in WWT it was lower (32.7 v. 36.7%). It is possible that this difference results from different composition of the Asian/Asian British population (WWT: 80.5% Bangladeshi, 4.9% Indian, 4.1% Pakistani; CNWL: 4.8% Bangladeshi, 41.7% Indian, 13.6% Pakistani). Clearly this area requires greater understanding and a more detailed breakdown of ethnicity than was possible here.

Literature relating to BAME communities and mental health services is replete with examples of disparities in access, experience and outcome of services and, in particular, high levels of compulsion.¹¹ In England, people with mental health problems from BAME communities have been less likely to use employment support services and as a consequence have been less likely to succeed in gaining employment than their White British peers.^{12,13} Morgan et al¹⁴ have suggested that addressing the social needs of BAME patients is likely to lead to improved clinical outcomes and engagement with services. Perhaps increasing the availability of IPS is one good way of doing this?

How IPS works

IPS services are entirely voluntary. In line with the fidelity standards for IPS,¹⁵ an employment specialist is integrated into a clinical team. People using secondary mental health services can access IPS services if they themselves want to work – there is no selection on the basis of diagnosis or supposed ‘readiness’ for work. IPS is personalised and based on the individual’s preferences and choices – very different from typical mainstream employment support programmes. Through shared decision-making, IPS rebalances power and encourages a collaborative dialogue between the employment specialist and the individual. Shared decision-making relies on two sources of expertise: the employment specialist as an expert on supporting individuals with mental health problems to gain and retain employment, and the individual as an expert on themselves, their social circumstances, attitudes to work, and health, values and preferences. Both must be willing to share information and accept responsibility for joint decision-making. The employment specialist needs to provide information about the most effective ways to gain and retain employment. The individual needs to tell the employment specialist about their preferences. As IPS is integrated into the clinical team, the challenge for mental health professionals is not to decide who can and who cannot work but how to support people on their case-loads to access IPS and move forward with life beyond their illness.¹⁶ Two interesting findings arise from this study: a disproportionate number of Black/Black British people were attracted to the IPS services – gaining employment was of importance to them – and there were no significant differences in outcomes for people from different ethnic backgrounds.

Limitations and implications

Clearly, further research is necessary. The naturalistic design of this study is a limitation yet provides a real-world understanding of access to and outcomes from IPS services achieved for BAME communities using secondary mental health services. The data collected here considered only outcomes at the end of the year studied. It is possible that others would have gone on to gain employment had longer-term follow-up been possible. Data on type of employment and job tenure were not collected, neither could people’s experience of using the services be ascertained, and a more detailed breakdown of ethnicity than was possible here would clearly be desirable. However, it is interesting to note that, of the three randomised controlled trials of IPS in England, none has reported outcomes by ethnicity,^{17–19} whereas some of the naturalistic studies have.^{20,21} Although there is a clear need for better quantitative data, the collection of qualitative data relating to people’s experience of using IPS services is necessary to understand some of the differences found and ensure equality of access and outcome for all.

Everyone has the right to be treated with dignity and respect, without discrimination, and to be able to access appropriate mental healthcare when it is needed. Identifying and reducing health inequalities in access, experience and outcomes is essential to the delivery of high-quality mental healthcare. Mental health services have a duty to use data and existing resources to identify inequalities. The present study strongly suggests that people from BAME communities are not differentially disadvantaged in relation to either access to or outcomes of IPS employment support services.

1.1.7 Magical thinking and moral injury: exclusion culture in psychiatry

Chloe Beale

Correspondence

Dr Chloe Beale (chloebeale@nhs.net)

date

2022-02

Abstract

This is an article about exclusion. We might not like to admit it – even fail to realise it – but National Health Service (NHS) mental health service structures have become increasingly focused on how to deny people care instead of help them to access it. Clinicians learn the art of self-delusion, convincing ourselves we are not letting patients down but, instead, doing the clinically appropriate thing. Well-meant initiatives become misappropriated to justify neglect. Are we trying to protect ourselves against the knowledge that we’re failing our patients, or is collusion simply the easiest option? Problematic language endemic in psychiatry reveals a deeper issue: a culture of fear and falsehood, leading to iatrogenic harm. An excessively risk-averse and under-resourced system may drain its clinicians of compassion, losing sight of the human being behind each ‘protected’ bed and rejected referral.

The language of exclusion

Choice of words in clinical work and documentation can betray troubling attitudes, personal values and fears. Given that psychoanalytic theory remains a core component of psychiatric training, we could do better at recognising our own defences. We have developed an entire lexicon of weasel words and magical thinking that we pass between generations and disciplines. It would be hard to come up with an exhaustive list of lies we tell ourselves in psychiatric practice; this does not claim to be one. Neither is this the first time anyone has pointed out the problematic language used in psychiatry.¹ Patients are, of course, acutely aware of the absurdity.^{2,3} There are many which should be easily recognisable to anyone working in National Health Service (NHS) mental health services in 2021 and whose origins demand scrutiny. Perhaps the most widespread example is the language of suicide risk.

Despite all evidence against checklists and risk stratification,⁴ we continue to behave as if risk is both predictable and quantifiable, persuading ourselves that certain stock phrases convey a protective coating. ‘Fleeting thoughts of suicide’, for example, sometimes seen as the precursor to an ‘impulsive’ suicide attempt or act of self-harm. Although it is not without value to record these things in the course of trying to understand someone’s state of mind, it is important to question the attached meaning. In writing ‘no plans or intent’ we make ourselves feel better about the unpredictable nature of suicide, hanging false hope on thoughts that come and go. Rather than admit that someone might end their life but we don’t know when or how, we purport to know it is unlikely to occur. This inevitably leads us to seek reassurance from patients, framing questions about suicide for a negative answer.⁵ Rarely is this more clear than when documenting that someone can (or cannot) ‘guarantee their safety’. It should not be for patients to ‘guarantee’ anything to clinicians – it is our responsibility to hold hope, not for them to promise us a future in which we are not standing before a coroner. It can be painfully obvious when a clinician has alighted on their ‘aha’ moment, the thing that (they believe) proves low risk. Any suggestion that a person has ambivalence towards suicide or actually wants to live (such as voluntarily seeking medical help) risks this interpretation. It is almost as if we take the worst-case scenario and work backwards from there, starting at ‘this person might kill themselves’, followed by ‘how can I prove it wasn’t my fault?’ Our starting point should be the simple recognition of distress and a desire to help. It is that connection on a human level which so often makes the difference to people in crisis. Nobody ever says they were saved by a thorough risk assessment, and certainly not one treated as a stand-alone list of questions delivered without empathy. One wonders if there is another medical specialty in which there is such dogged devotion to a non-evidence-based practice. We seem to pay heed to neither scientific evidence nor personal testimony, available in abundance: ‘When the focus is purely on risk, professionals are often left with the frustration and anxiety of holding the risk, service users are left invalidated and abandoned’.⁶ Bad experiences reinforce learning; inquests and internal investigations can feel adversarial and sometimes ask the wrong questions. Clinicians may feel pressured to say (with the benefit of hindsight) that they would have done things differently; perhaps the only acceptable excuse for having ‘got it wrong’, so to speak, is because we thought the risk was not there. Miles argues that many such problems have their basis in shame, which means that doctors (and other health professionals) ‘become morally neutral, unquestioning automatons, at the mercy of organisational edicts, and fail to advocate for the needs of their patients’.⁷

Further speculation seeks not only to see the future but to determine a person’s motivation. Someone who frequently harms themselves in a way that may or may not have suicidal intentions may be pronounced at risk of ‘death by misadventure’. The implication here is that the patient may die without really meaning to. It is impossible to forecast the drivers and intentions behind a theoretical final act; attempting to do so is designed to alleviate our anxiety about the opacity of the future and introduce a seed of blame on the part of the patient. Similarly, patients may find themselves told they ‘have capacity’ to end their lives, in a perverse justification of medical inaction.⁸ Mental capacity – a concept enshrined in legislation intended to enhance the autonomy and decision-making of vulnerable people – is used to legitimise neglect.⁹ The tendency to stray from objectivity into value judgement is an unfortunate but familiar feature of psychiatric notes, from the truly offensive ‘manipulative’ to the frankly bizarre ‘behavioural’, used to infer that a patient is doing something in a conscious and deliberate manner rather than because they can’t help it. Such terminology does not stand up to scrutiny: not only does it arrogantly assume the ability to precisely determine patients’ motivations and intentions, but it is also nonsensical. All behaviour is ‘behavioural’; one might as well describe breathing as respiratory.

Moral judgement and focus on self-preservation are both ways in which we make the case for denying people care. We do a further massive disservice to patients by assuming they do not see through us, perpetuating the sense of alienation which characterises too many encounters with mental health services.^{2,10}

Systems designed to exclude

We cannot blame individuals for mindless practice without acknowledging the system that has created them. Ours is a culture of senseless fragmentation: separation of addiction and illness, of mental and physical, of mind and brain, of deserving and undeserving. At their very worst, modern mental health services seem to operate on two polarised (but related) values: coercion and exclusion. The former is probably most familiar as a critique of psychiatry as per the recent government White Paper.¹⁰ Time will tell whether statutory reform will lead to the desired aim of reduced coercion. Less talked about, perhaps, than the coercive aspect of psychiatry is the troubling drive to exclude people from services. We exclude based on postcode, diagnosis, complexity, comorbidity. Too much need, not enough need. Risk, lack of motivation, readiness for change, any possible reason to keep people out. We have apparently accepted, without question, the term ‘gatekeeping’ to refer to admission to psychiatric beds, a process that generally involves the agreement of a crisis resolution and home treatment team. While accepting the almost perpetual state of bed crisis in NHS psychiatric services, we should consider what this terminology says about the systemic attitude towards our patients. Our services are fortresses; patients are intruders to be prevented from breaching our defences. There is a rot in a system that views beds as needing protection from patients. Mental health services have developed an ethos of exclusion at an organisational level which naturally drives and perpetuates poor practice at an individual level.

One form of exclusion from care arises out of the false distinction between mind and body. Referrals to secondary care mental health services may be refused if there is a perception that the problem is ‘organic’ unless it fits neatly into a memory clinic remit. René Descartes died in 1650 yet still we subscribe to the dualistic fantasy that mental and physical can be clearly delineated, with health services persistently commissioned in a way that keeps them separated. This has resulted in baseless and ill-defined concepts which dominate practice: take ‘medical clearance’, for example – a requirement that any patient attending an emergency department be reliably pronounced to have no medical condition before having a psychiatric assessment.¹¹ Although nobody would argue that an acute medical condition should not be promptly identified and treated, problems arise when we refuse to assess and manage in parallel. As is now recognised, this leads to inadequate patient care and should not be routine practice¹² (though its grip is tenacious). We ask medical colleagues to ‘exclude organic causes’ of a disturbed mental state, as if it is always possible to do this acutely or to precisely isolate which symptom arises from which condition; as if conditions cannot coexist. In their detailed analysis of the incoherent distinction between ‘organic’ and ‘functional’, Bell et al¹³ conclude that ‘the functional–organic distinction often seems like a tool that helps determine treatment priority dressed up in the language of causation’. Neurologists and other specialists may be as guilty of this as psychiatrists,¹⁴ but we should surely have a greater interest in challenging what is essentially another form of stigma. As long as we rely on outdated pseudo-medical concepts, mental health workers will view ‘physical health’ as a kind of unpredictable bogeyman to be feared and avoided.

A convenient pandemic

Stigma towards people with mental illness in medical settings is well-documented and tackling it a slow process; it was only in January 2020 that the Side by Side consensus statement was published¹³ but the COVID-19 pandemic that hit us just a month later jeopardises its intentions. Driven by the pandemic, there is a vogue for developing acute psychiatric assessment sites away from emergency departments.¹⁵ Across the UK are hastily created diversions for people in mental health crises and it remains to be seen whether these will prove either safe or cost-effective. While acknowledging a genuine need for infection control, the more cynical among us may see certain organisations leaping on the opportunity to do what they have been wanting to for years, which is to exclude psychiatric patients from emergency departments. The party line is that this is a compassionate move: an emergency department isn’t the place for someone in mental health crisis.¹⁶ Arguably, it’s not the most relaxing place for someone with sepsis or a fractured neck of femur either but it’s where most of us would want to be in that situation. When Samuel Shem, in his cult novel about North American internal medicine,¹⁷ coined the term ‘GOMER’ (Get Out of My Emergency Room) he was describing a group of elderly patients with dementia, perceived to use time and resources but never improve or die. ‘GOMER’ refers to the doctors’ reaction when these unfortunate people arrive in their department. However, it seems as if this attitude is even more applicable to people with mental illness, certainly in the 21st-century NHS. Treating psychiatric patients as ‘GOMERS’ is systemically endorsed. A separation of mental and physical emergency locations reinforces the dangerous notion that we can reliably ascertain (even pre-hospital) whether someone needs ‘physical’ care or not.

The pandemic has also focused attention on the concept of moral injury – ‘perpetrating, failing to prevent, or bearing

witness to acts that transgress deeply held moral beliefs and expectations'¹⁸ – in medicine.¹⁹ There is a psychological toll that comes with having to ration resources, transfer patients out of area owing to bed pressures, suspend vital services and see waiting lists grow longer. These have been headline news over the past year,²⁰ yet all are challenges that have faced psychiatry for far longer. Perhaps we have already grown used to excusing exclusion and senseless divisions in order to avoid the reality that services have been systematically cut and we cannot give patients what they need.²¹ The mental health profession has had its compassion eroded by moral injury for longer than we can remember, rationing care for so long that we have come to believe that exclusion is clinically indicated. We claim to be encouraging personal responsibility and autonomy, preventing dependence, avoiding institutionalisation, reducing unnecessary referrals, all of which allows systemic failings to continue. Some of our processes seem almost designed to harm; the ways in which institutional factors have an impact on specific aspects of people's illnesses Kafkaesque. For example, people with eating disorders, among whom the belief that one is 'not sick enough' is common, are literally denied help until they are 'sick enough'.²² People with personality disorder diagnoses who have experienced trauma, rejection and interpersonal discord throughout their lives are rejected by professionals within a system that tells them they should not have time and resources wasted on them.²³ These are not cognitive distortions but grim reality. This culture of exclusion, coupled with the expectation that patients take responsibility to quell clinician anxiety, is a toxic mix.

Rehumanising psychiatry

One consultant psychiatrist pontificating about culture in a journal is not going to drive the kind of genuine change that needs to filter through every layer of our system. Decades of damage requires time to repair, not to mention the buy-in of all parties. Training has a role, from undergraduate level upwards across all professional groups, but organisations must have the guts to implement culture shift rather than a series of slightly altered tick boxes. The more clinicians work side by side with the people who use mental health services (and those who have been excluded from them), the more effective the message. Meaningful training and service development should be truly co-produced; a fundamental problem is the focus on beds and breaches and targets instead of the human story behind each number. Arguably, senior managers who would willingly allow an unwell patient to wait in an emergency department for more than 24 h for the purposes of 'gatekeeping' might take a different view if it were them or a loved one, so should not be permitted to distance themselves from clinical realities. This is not to say that all those working on the front line are faultless patient advocates. Lack of compassionate care for people in mental health crisis pervades emergency services and, although burnout and 'compassion-fatigue' play a role, there are deep-seated negative attitudes towards certain patients. Although co-production is vital, the responsibility for recognising and calling out harmful culture and practices should not fall entirely on the shoulders of those who have suffered it. In short, our profession must open its eyes. Regulatory bodies such as the General Medical Council tell us to 'make the care of the patient your first concern'²⁴ yet we stray from this to prioritise the needs of clinicians and organisations. In a culture of self-protection, exclusion will inevitably become a central aim because, of course, the best way to prevent ourselves from harm is to prevent the 'danger' from getting near us. How have we so comprehensively forgotten to put patients first?

Realism and honesty should be embedded in training, rather than teaching perfect medicine in an imperfect world. Our patients will have more trust in us if we are open about scarcity of resources and restrictions on referrals; if we acknowledge that we cannot provide all we would like to. Instead of pretending that exclusion is clinically appropriate we must name it. However, clinical staff can only safely preach honesty if senior leaders support this endeavour. Although the Royal College of Psychiatrists has produced some welcome position statements and guidelines, this must translate to institutional and organisational change. Senior consultants, managers and academics who do not recognise anything in this article may need to reacquaint themselves with the front line; it will surely resonate with junior doctors, nurses, allied health professionals, students and – most importantly – patients and carers: 'Educating the next generations of clinicians and social workers is vital, but they won't survive immersion in toxic cultures. We need honesty from organisations where poor care and neglect have become systemic and endemic'.²⁵

Patients and carers have been speaking out about exclusion and iatrogenic harm for too long; psychiatrists complaining about blame culture similarly. It is time this was translated into action by those with most power to effect change. Consider this a call to arms: if the content resonates then ensure you do more than shout into your echo chamber.

With thanks to Dr David Foreman for inviting this contribution and for his editorial advice.

1.1.8 Review of antipsychotic prescribing at HMP/YOI Low Newton

Lois Carey Stephen Barlow

Correspondence

Lois Carey (Lois.Carey@nhs.net)

date

2022-02

Abstract

Aims and Method

The purpose of this review was to establish whether the prescription of antipsychotic medication in HMP Low Newton was safe, rational and consistent with current best practice. A search of the electronic healthcare records was performed on 14 March 2018 to identify all the women in the prison who were prescribed antipsychotic medication, and then data were collected from the records.

Results

A total of 46 out of 336 prisoners (13.7%) had been prescribed antipsychotic medications; 29 of the 46 patients (84.8%) were also prescribed other psychotropic medications at the same time. Quetiapine was the most frequently prescribed antipsychotic and was also the most likely to be prescribed for off-label indications. Less than one-third of all antipsychotic prescriptions were for psychotic disorders.

Clinical implications

The rationale for prescribing all antipsychotic medication, especially for off-label indications, should be clearly documented and reviewed regularly within the prison by the mental health team and psychiatrist.

pmc .. _sec1:

Introduction

HMP Low Newton is one of 13 women's prisons in England, and houses approximately 350 inmates aged 18 years and above. It manages a mixed population of remand and short-term sentenced prisoners and those serving longer sentences, including a significant number serving life or indeterminate sentences. The turnover is high (approximately 70 receptions per week) and psychiatric morbidity is common.

Women in prison are five times more likely to have a mental health problem than women in the general population, with 78% exhibiting some kind of psychological disturbance on reception according to the 12-item General Health Questionnaire.¹ A study of remanded prisoners found 11% to be acutely psychotic on reception.²

At any one time, the mental health team in HMP Low Newton provides support to about a third of the population, about a quarter of whom have complex mental health needs.³ The team conducts triage assessments for approximately 20 new patients each week. There are three sessions of clinical input from a psychiatrist, which, given the constraints on access to prisoners, amounts to approximately 6–8 h direct clinical contact per week. There are no other prescribers within the team. Primary care services are provided by an independent organisation, G4S Healthcare.

Antipsychotics are potent drugs, primarily licensed for the management of schizophrenia, mania and other severe psychotic disorders. They have the potential to cause a wide range of acute and long-term side-effects, some of which can be serious, including parkinsonism, neuroleptic malignant syndrome, obesity, diabetes, cardiotoxicity, sudden death, hormonal changes, electrolyte imbalances, convulsions and blood dyscrasias.

Although they can also be prescribed in both psychiatric and general practice for the relief of stress, anxiety and psychological distress, those licensed for this purpose, which include chlorpromazine, olanzapine and haloperidol, should only be used in the short term. There is no evidence that antipsychotics have any demonstrable long-term benefit in the management of personality disorders.⁴ Despite this, off-label prescribing is increasingly common and has been identified as a cause for concern.⁵

There is a growing body of literature highlighting the misuse potential of some antipsychotic medications, particularly quetiapine.^{6,7} There is also increasing awareness of the risks of harm from misuse and diversion of prescribed medicines in prison. These extend beyond the effects of the drugs themselves to include bullying, threats and coercion, and debt.^{8,9} Deaths from the misuse of prescribed drugs, including antipsychotics, are rising. The numbers of deaths caused by antipsychotics in 2017 saw an increase of just over 5% from 2016, which equates to a rate of 2.1 per 1 million population.¹⁰

Aims/objectives

The purpose of this review was to ascertain whether the prescription of antipsychotic medication in HMP Low Newton was safe, rational and consistent with current best practice. We considered best practice guidance from the National Institute for Health and Care Excellence and adopted the following principles. Antipsychotic medication should only be prescribed if there is a clearly documented, evidence-based rationale, consistent with the drug's licence and/or best practice guidelines. Patients receiving antipsychotic drugs should be regularly reviewed by specialist mental health services. No patient should be prescribed more than one antipsychotic or equivalent doses above *British National Formulary* (BNF) limits.

Method

This review was registered with and approved by Tees, Esk and Wear Valleys (TEWV) NHS Foundation Trust clinical audit department.

All medical records within the prison are held on an electronic system, and all prescribing is done electronically. A search of the electronic healthcare records was performed on 14 March 2018 to identify all the women in the prison who were being prescribed antipsychotic medication on that day. Their healthcare records were then reviewed by the authors to identify: patient's age date of reception into HMP Low Newton antipsychotic prescribed and dose prescriber's professional status date of prescription diagnosis or indication for prescription (where recorded) other psychotropic medication past or future contact with mental health services.

Within TEWV NHS Foundation Trust, 'off label' is defined as the use of a medicine that has a marketing authorisation for an indication (condition), at a dose, via a route or for a patient category (e.g. age) that is not listed in the Summary of Product Characteristics for that medicine. Therefore, any antipsychotic prescription that met this criterion was defined as 'off label'.

Results

The prison roll for that day was 336. Forty-six women (13.7% of the total population) were identified as having a current prescription for antipsychotic medication.

Age distribution

The ages of the women taking antipsychotic medication ranged from 22 to 55 years, with a mean and median of 35 years (*Fig. 1* and *Table 1*) This was consistent with the age profile of the population as a whole within the prison.³ *Fig. 1* Age in years of the women prescribed antipsychotic medication *Table 1* Age distribution Age, years Patients, N <21 021–30 1631–40 1741–50 11 >50 2

Length of time in prison

The number of days each patient had been in HMP Low Newton on the date of the audit ranged from 4 to 2430, with an average of 363 days. The distribution suggested distinct groups, with the majority having spent less than 180 days in the prison and a second significant group having been in for more than a year, reflecting the fact that the prison houses both a transient population of remand and short-sentenced prisoners and a more stable population serving longer-term sentences (*Table 2*). *Table 2* Length of time in prison in days Time in prison, days No. of prisoners <91 1191–180 11181–270 4271–360 6 >361 14 Range 4–2430 days Average 363 days

Reception

The majority of patients (26, 56.5%) had been admitted directly from the community; 19 (41.3%) had come from other prisons and one (2.2%) had been discharged from a psychiatric hospital.

Antipsychotics prescribed

The antipsychotics prescribed are shown in *Table 3*. By far the most popular antipsychotics were quetiapine (20 patients) and olanzapine (16 patients). Other antipsychotics prescribed were risperidone (three patients), flupenthixol (two patients), aripiprazole (two patients), sulpride (one patient), chlorpromazine (one patient) and zuclopenthixol (one patient) (*Table 3*). *Table 3* Antipsychotics prescribed Antipsychotic No. of patients Quetiapine (inc. modified release) 20 (43.5%) Olanzapine 16 (34.8%) Risperidone 3 (6.5%) Sulpride 1 (2.20%) Flupenthixol 2 (4.30%) Aripiprazole 2 (4.30%) Chlorpromazine 1 (2.20%) Zuclopenthixol 1 (2.20%)

No patients were prescribed doses above BNF limits. One patient was prescribed two antipsychotics, zuclopenthixol and aripiprazole, after it was recommended that aripiprazole be started for hyperprolactinaemia secondary to zuclopenthixol.

Prescriber

Thirty (65.20%) of the prescriptions for antipsychotics were started by a psychiatrist. These included 12 (26.10%) started in HMP Low Newton during the current period of imprisonment; three (6.50%) had been started in another prison but during the current period of imprisonment, and 15 (32.5%) had been started in the community or during a previous period of imprisonment. Sixteen (34.80%) prescriptions were prescribed by a general practitioner (GP) or primary care services.

Polypharmacy

One patient was prescribed aripiprazole for hyperprolactinaemia in addition to zuclopenthixol. Only seven patients (15.2%) were not prescribed any additional psychotropic medications.

The amounts and types of other psychotropic medications prescribed are summarised below (Tables 4 and 5).
 Table 4: Number of additional psychotropics prescribed
 Additional psychotropics: No. of patients: 07127210324050
 Table 5: Type of additional psychotropics prescribed
 Type of drug: No. of patients: No. of scripts
 Specific agent: Scripts for agent
 Antidepressant: 2932
 Mirtazapine: 13
 Sertraline: 7
 Trazadone: 4
 Fluoxetine: 3
 Venlafaxine: 2
 Amitriptyline: 1
 Duloxetine: 1
 Paroxetine: 1
 Opiates: 1414
 Methadone: 1
 stabilisers/anticonvulsants: 33
 Depakote: 1
 Lamotrigine: 2
 Stimulants: 22
 Atomoxetine: 1
 Dexamphetamine: 1

One patient was prescribed a total of five psychotropic medications, comprising zuclopenthixol depot injection, aripiprazole, atomoxetine, sertraline and clonazepam. This patient had been returned to prison from a medium secure unit and had a diagnosis of emotionally unstable personality disorder (EUPD) and attention-deficit hyperactivity disorder.

One patient was prescribed three psychotropic medications (duloxetine, lamotrigine and buprenorphine) in addition to quetiapine. Medication had been started in HMP New Hall, and the diagnosis recorded was depression and EUPD.

Indication and diagnosis

The BNF licensed indications for each of the prescribed antipsychotics prescribed are summarised in Table 6.
 Table 6: BNF licence indication for each antipsychotic prescribed
 BNF licence indication: Aripiprazole, Chlorpromazine, Flupenthixol, Olanzapine, Quetiapine (inc modified release), Risperidone, Sulpride, Zuclopenthixol
 Schizophrenia/psychosisxxxxxxx, Maniaxxxxx, Short-term management of agitation/excitement/anxietyxx, Depressionxx, Bipolar prophylaxisx, Nausea/vomiting/tics/hiccup, Short-term use for aggression in patients with Alzheimer'sx

Patient notes were reviewed to identify recorded diagnoses or indications for each patient who had been prescribed an antipsychotic. The reasons recorded in the notes are summarised in Tables 7 and 8.
 Table 7: Documented indication for each antipsychotic medication in the notes
 Quetiapine: Olanzapine, Risperidone, Sulpride, Flupenthixol, Aripiprazole, Chlorpromazine, Zuclopenthixol
 Total: EUPD 104211120, EUPD + PTSD 213, EUPD + depression 112, EUPD + psychosis 22
Psychosis/schizophrenia 23117, Drug-induced psychosis 33, Bipolar 213, Mood stabilisation 213, Depression 0, Psychotic depression 11, Anxiety/paranoia 112, Number 201631221146
 Table 8: Licenced versus off-label indications documented in the notes for each antipsychotic prescription
 Antipsychotic (N): Licensed indication (N), Off-label indication (N)
 Quetiapine (20): Depression (1), Anxiety/paranoia (1), Psychosis/schizophrenia (2), EUPD (10), Bipolar (2), EUPD + PTSD (2), Mood stabilisation (2), Olanzapine (16): Psychosis/schizophrenia (5), EUPD (4), Drug-induced psychosis (3), EUPD + PTSD (1), Anxiety/paranoia (1), Bipolar (1), Depression (1), Risperidone (3): EUPD (2), Psychotic depression (1), Sulpride (2): EUPD (1), Anxiety/paranoia (1), Flupenthixol (2): Psychosis/schizophrenia (1), EUPD (1), Aripiprazole (1): Psychosis (1) (hyperprolactinaemia), Chlorpromazine (1): EUPD (1), Zuclopenthixol depot (1): EUPD (1)

Less than a third (13/46 = 28.3%) of the prescriptions for antipsychotics were for psychosis (including affective psychoses), and three were for bipolar affective disorder. The remainder were for non-psychotic conditions.

Sixteen of the 46 prescriptions were within the licensed indications. Of the 30 (65.2%) that were prescribed for off-label indications, half (15/30 = 50%) were quetiapine (Table 9). Fisher's exact test was used to determine the significance of this and gave a *P*-value of 0.3496, which is below the typical cut-off for statistical significance (*P* < 0.05).
 Table 9: Number of off label prescriptions for quetiapine in comparison to other antipsychotics
 Licensed indication: Quetiapine 515, Other drugs 1115

Two-thirds of the prescriptions where non-licensed indications were recorded in relation to quetiapine were for EUPD (10/15 = 66.6%), plus additional two for EUPD and post-traumatic stress disorder (12/15 = 80%).

Contact with mental health team

The average length of time between arrival in HMP Low Newton and review by the mental health team was 30.2 days (range 0–310 days). This is summarised further in *Fig. 2*. The average number of days between arrival and review for the seven patients who were seen more than 31 days after coming to HMP Low Newton was 166 days, which suggests that these patients tended to have longer sentences and did not present with symptoms until later in their sentences. Of the 46 patients, 36 had been reviewed by a psychiatrist, five were on the waiting list to be seen, one had declined input as they felt mentally stable and four had no follow-up planned. The average time between review by the mental health team and review by a psychiatrist was 87.97 days. This is broken down further in *Fig. 3*. *Fig. 2* Length of time between arrival in HMP Low Newton and review by the mental health team *Fig. 3* Length of time between review with the mental health team and review with a psychiatrist

Of the five patients on the waiting list for the psychiatrist, four had been seen by the mental health team for the first time in the 10 days prior to the sample collection date (14 March 2018). One patient had been on the waiting list since January 2018 and had been waiting 8 weeks so far for an appointment. Of the four patients that had not been seen by the psychiatrist and were also not on the waiting list to be seen, 50% (2/4) continued to be followed up by the mental health team. All four of these patients were prescribed quetiapine which had been commenced prior to coming to prison. The characteristics of these four patients are outlined in more detail in *Table 10*. *Table 10* The characteristics of the 4 patients prescribed antipsychotic medications but not under psychiatrist review

Patient 1	Patient 2	Patient 3	Patient 4
Age (years)	36	35	49
Time in HMP Low Newton (days)	120	141	163
Received from HMP New Hall	Community	Community	Community
Antipsychotic	Quetiapine	Quetiapine	Quetiapine
Other psychotropics	Mirtazapine	Methadone	nil
Antipsychotics commenced	Prior to reception	Prior to reception	Prior to reception
Diagnosis	EUPD	Psychotic episode	EUPD
Follow-up by mental health team	No	No	Yes

Summary of findings

On the day of the survey, 46/336 prisoners (13.7%) were prescribed antipsychotic medications. No patients were prescribed high-dose antipsychotics. Only one patient was prescribed more than one antipsychotic, and the rationale for this was clearly stated. Twenty-nine of the 46 patients (84.8%) were prescribed other psychotropic medications, most commonly an antidepressant and/or an opiate. Two patients (4.34%) were prescribed four or more psychotropic medications. Both of these had diagnoses of EUPD. Approximately a third of prescriptions were initiated by primary care/GP. Of the 65.2% of prescriptions initiated by psychiatrists, approximately half were started during the current period of imprisonment. Quetiapine was the most frequently prescribed antipsychotic and was also the most likely to be prescribed for off-label indications. Less than a third of all antipsychotic prescriptions were prescribed to treat psychotic disorders. The most common non-licensed indication for antipsychotics being prescribed was EUPD, which accounted for approximately half of all the prescriptions. The average length of time between arrival in HMP Low Newton and review by the mental health team was 30 days, with the majority being seen in less than 7 days. Forty-one of the 46 patients (89.1%) had prior or planned appointments with the psychiatrist.

Discussion

This review identified a number of positive findings: no patient was prescribed high-dose antipsychotic therapy; only one patient was prescribed combination antipsychotic therapy, and in this case the second agent was commenced for a side-effect of the first and had been initiated by a psychiatrist who remained involved in the patient's care. The majority of patients were reviewed by the mental health team with 7 days of reception and had prior or planned appointments with the psychiatrist to review their medication.

The review highlighted a high rate of off-label prescriptions for antipsychotic medication within the prison. The study confirmed that this was particularly the case with quetiapine, which, given the high rates of misuse of this drug within the prison, is of concern. Although there was no clear reason for this, one can speculate that, owing to the high number of female prisoners reporting difficulties with 'mood' and 'voices', quetiapine is chosen because of its reported benefits

in relation to ‘mood stabilisation’, as well as its antipsychotic effects. There is also, however, a likelihood that this medication is often requested by the prisoners for its ‘tradeable’ status and potential for misuse.¹¹

There is a high rate of polypharmacy in relation to psychotropic medication, which can increase the risk of side-effects and physical health complications. All but two of the patients were prescribed no more than three psychotropic agents. Again, this is likely to be due in part to a high rate of comorbid substance misuse within the prison population. Furthermore, there is a tendency for patients to prefer medication over alternative treatments such as psychological intervention.

Psychological therapies are identified as the primary treatment for patients with personality disorder.⁴ At HMP Low Newton, a variety of psychological services are available. These include the 12-bedded Primrose Unit, for women with severe personality disorder, which forms part of the Offender Personality Disorder Pathway, and a Psychologically Informed Planned Environment wing. The prison forensic psychology services offer a range of assessments and treatments, and the scope of this work is driven by consultancy with offender management units and offender managers within the community. Finally, there is the prison mental health team, who work in line with trauma-informed care principles and can offer a range of individual and group therapies. However, there is often a waiting list for such services, and potentially suitable prisoners often do not remain within the prison long enough to start and complete identified treatments before release or transfer.

Although a large proportion of the prescriptions were issued by a psychiatrist, it is noted that approximately half were commenced in either in the community or during a different prison sentence. Therefore, it is possible that some patients are reissued prescriptions without a thorough review of need, current mental state and other prescribed treatments. Also, the records indicate that often little consideration is given to whether the patient has adhered to medication in the community and so, often, this is simply re-prescribed if it is on the GP summary. The guidelines in relation to use of antipsychotic medications for minor symptoms, such as anxiety, stress or agitation, are clear that it should be a short-term measure only. However, such prescriptions are often continued for prolonged periods without a critical review. This tendency may be exacerbated in the prison population by transfers to other establishments, early release, failures to engage with the mental health team, and a relative lack of attention paid to the initial timing and indications for prescribing.

Recommendations

The patient’s diagnosis and/or the indication for each prescription should be clearly recorded at the point of prescription in the running case record and in the medication section of the electronic notes system. In order to reduce the rate of off-label prescribing, all patients arriving at the prison who are prescribed antipsychotic medication on or shortly after reception should be brought to the attention of the psychiatrist and the mental health team manager. All of these patients should be allocated to a secondary care worker and given an appointment to see the team psychiatrist. The secondary care nurse should obtain all relevant past records. The psychiatrist should conduct an initial case review note and advise on either withdrawing or continuing antipsychotic medication prior to the review. Particular attention should be given to patients who have a primary diagnosis of EUPD, particularly those for whom antipsychotics have been prescribed for the relief of minor symptoms, such as stress, anxiety and insomnia. The presumption should be that medications for these reasons should only be prescribed in the short term, and this should be clearly explained to the patient. Care should also be taken with patients who have a history of substance misuse, or of secreting and hoarding medication, as this often indicates involvement in trading. If patients have not adhered to antipsychotic medication in the community, then it should not be automatically re-prescribed on reception without review by the mental health team or psychiatrist. Prescriptions for quetiapine should be kept under regular review and withdrawn unless there are clear reasons for continuing to prescribe. This review should be repeated after a year to assess the effects of these measures on off-label prescribing.

Lois Carey is a consultant forensic psychiatrist at Roseberry Park Hospital, Middlesbrough, UK. **Stephen Barlow** is a consultant forensic psychiatrist at Roseberry Park Hospital, Middlesbrough, UK.

1.1.9 Interview with Dr Jan Wise

Abdi Sanati

date

2022-02

Contents

- *Interview with Dr Jan Wise*

pmc Dr Wise is a consultant in general adult psychiatry working in inner city London. I first met Dr Jan Wise around 15 years ago through another colleague. At that time, Dr Wise was already active in the British Medical Association (BMA). I found his knowledge of medicolegal and contractual issues vast and unparalleled. I have always admired his wisdom and his structured approach in solving problems. He remains active in the BMA and is currently the chair of BMA Medicolegal Committee. What made him stand out for me was his work on physician burnout, something I faced a few years ago. Dr Wise is also active at international level. He is elected to the Board of European Psychiatric Association. In addition to that he is also an Honorary Member of the World Psychiatric Association and Distinguished International Fellow of the American Psychiatric Association. I caught up with him to discuss issues such as pressure on psychiatrists and his international work.

Thank you very much for agreeing to this interview Dr Wise. You mentioned in your article that going an extra mile endangers staff and patients. Could you elaborate on that statement please?

We are a finite resource. We are human. We are limited and we are fallible. So, even under normal circumstances, there's a limit to how long we can stay on the board, clerking a patient, how long we can sit in casualty comforting the truly distressed psychotic patient who is ripping their hands to shreds, trying to escape the manacles the police have put them in. And this is a never-ending tide. There is always a need to care, there is no end to the misery that is out there, that we want to address. And if we do not place limits on ourselves, we will wear ourselves out. Even before COVID-19, we wore out faster than we were replaced. If I'm going to say that more succinctly, 'We will never run out of patients, we will run out of you'. So staff have got to look after themselves, to avoid burnout, the moral distress that we're seeing at the moment. We hear from the BMA and in surveys that there are unprecedented numbers of doctors in general – not just psychiatrists – who want to leave, who want to reduce their hours, who don't want to do this.

Thank you, another thing that comes up is the danger of being at risk of clinical negligence charges.

Yes. People go into medicine because they want to help others, and that urge to help often clouds our judgement. Things are much better now than they were 25 years ago when some of us started. With exception reporting and reduced hours, we are less often in the scenario of people being so tired that they fall asleep at the nursing station. But what we forget is that the General Medical Council is going to hold you to the standards of the reasonable doctor with your experience. So if you're underperforming because you're excessively tired, whether that's from a long shift, having young children, or sick relatives that you are caring for, if you make a mistake, being tired is unlikely to be a defence. So, when people stay beyond their shift, or they have covered a night because the trainee was sick and there was no one to come in, we need to protect ourselves by letting the system know we are not fit to deliver care, because making an error by staying behind really puts your registration at risk, let alone the very unpleasant process of a relative or a patient deciding to sue you, because you made a mistake.

Thank you. Reading your work on this topic is very interesting. It seems that going the extra mile has been celebrated as something of value, you're expected to say it in interviews that you are willing to go the extra mile. It is expected from us now.

And that's the problem. If someone said they would never go the extra mile that would be a disaster for the profession and for the person. The Royal Army Medical Corps has as its motto *In Arduis Fidelis*, faithful in adversity. And in unusual circumstances, I would hope we would pull together for something like the Clapham rail disaster, Grenfell Tower or Piper Alpha, and we would all be there. But when it is not unusual, when it's not even every month, but it's every week, then it's wholly inappropriate to go even the extra 10 metres, because it just allows the government to underfund the service. And eventually people won't be able to go the extra distance and all patients will suffer, because we didn't say enough is enough.

You have written about it in the context of the whole of profession of medicine. How do you specifically see it in psychiatry?

Well the good news is, we have excellent training in boundaries, so it's relatively easy working in a profession where people aren't going to die if you don't do it, to have less porous boundaries than someone working in emergency medicine or oncology. I think the trainees are beginning to see from some consultants how to have an appropriate work-life balance. If they go the extra distance on Monday, they go short on Tuesday, Wednesday or Thursday, but on one day that week, they leave early to make up for the extra delivery. I think that is becoming easier. But what I hear, from colleagues and from other services like child and adolescent mental health services, are phrases like we need to get better at saying we are not commissioned to do that. Doing something that we are not commissioned to do, is to deliver it for free. Which means we are not delivering what we were commissioned to do unless we are delivering more hours than we should be. In a very concrete way, restricting yourself to what is commissioned in the time that is commissioned, and making it clear why you are doing that, helps managers argue for the funds they need. It is very simple for management to say it takes 12 man hours a day to deliver that and you have only commissioned 8 man hours, and many consultants are making it clear that they have used to give you 12 but they do not feel appreciated, so they are now only doing what you pay for.

One thing I liked about your writing is emphasis on contracts, because we are contracted to deliver something, but many of us go beyond our contracts and feel it is a moral duty to do so.

There are many different types of expectations. Everyone has an internal model of what they would like to be, different from what they are. One of the goals of therapy is to get people to marry those models because it leads to more happiness. The reason I mention that is, I would really hope that just as we say to an adolescent that peer pressure is not a good reason to give up your virtue prematurely or to take drugs, I don't see why peer pressure is a good reason to overdeliver, to stay late or start early. Now, as you've mentioned, there are other pressures, we have expectations on ourselves. If you're a perfectionist and everything has to be just so, it is a real struggle to make it perfect with the resources we have now. It was a real struggle 10 years ago, and we do not have now what we had 10 years ago.

I was thinking that if the service is well-functioning, does it need people to work beyond their contract?

It very much depends upon how one defines well-functioning. Deming, an economist, said that every system is perfectly designed to get that to give the results it gets. If the staff are working to their contracts then they are not overdelivering. If that delivers what was commissioned then that is 'well-functioning' – but it may not be a 'good service'. But I am not sure we will ever have an average service that achieves that because, on average, consultants across the UK are working 4–6 hours a week beyond what they're contracted to do.

Another issue is physician burnout, as you mentioned doctors are burning out. And one thing that I fear is that in the post-pandemic National Health Service (NHS), we will have even more and more burnout. I do not think giving more money would fix it.

In the short term, the pandemic has been absolutely horrendous. It's been horrendous for its acute devastation, but also because it has eroded rest and recreation. People cannot travel, and rest and recreation is more than just not being at work. It is seeing our loved ones, seeing friends and family, going and doing those interesting things that feed the soul and spirit. There are also positives from the pandemic. We have learned that we don't need endless meetings, or to be in the same room for procedural issues. It kills creativity.

You can't do research development across Zoom. Unless you already have a really strong relationship with your peers, it's very difficult for those ideas to zing around the room to snowball and become something truly exhilarating and exciting. So we do need in-person meetings, but we are no longer losing hours to get to a room that we feel obliged to sit in to listen to something for 45 min when we really need to only hear 10 min. That actually is great for democracy like medical staff committees or local negotiating committees, because it means that you can do them more often. So the time before a response has been given is dramatically cut. You can have your consultant body complaining about the on-call rota or raising issues about trainees safety or highlighting that there's a personality conflict with a clinical director much faster than ever before. So I agree that it is exhausting, that everybody is tired, but it has given some real opportunities for change, including the realisation that there's got to be more to life than work.

That is very true. Staying on the issue of burnout, I remember that in a conference some leading scholars put the responsibility of burnout on the individual. If the individual walks away they wouldn't burn out. What about the role of the system?

I think you are referring to the sense that resilience in a way, blames the person for not being able to cope. And it is very difficult to build resilience in a disaster. The NHS does not have enough resources, if there were more staff, more time, less demand, we wouldn't be burning out like this. If you think about burnout as the consequence of friction between personal aspiration and what can be delivered, we know that the NHS is like a supertanker, it takes years to change its directions. It takes over a decade to train a new consultant. So, if we want to keep on doing things the way we're doing them, people are going to burn out, we will fail. We should be creative, for instance using nurse prescribers, or physician assistants, changing our view about handling risk. There are tasks that can be dropped or allocated to rapidly trainable members of staff that would change their day-to-day jobs. None of us do the mundane activities we did 20 years ago, or even 10 years ago. They've been devolved to other staff. I'm concerned that when we take back some of those administrative duties such as booking or changing appointments, even with an app, it is inefficient. So it's helping people to think about why does it feel useless, what is the frustration and how does one fit within that? That, I think, is the key to maintaining longevity in the service, which is critical in a way it wasn't previously; people are now going to be in psychiatry till 67 years of age, probably 69 for those who are starting now, because the state pension age will go up, rather than leaving at 55 with mental health officer status.

Do you think the mental health officer status should be reinstated?

Yes, from a pragmatic perspective. However, if they do not change the pension rules, then when people hit 50 years old or thereabouts, they will need to go part time, which is a good thing. We have a paucity of child and adolescent services in north-west London. There are charities interested in growing the independent sector provision, and they were very, very concerned that this would harm the NHS. A couple of us spoke with them, pointed out the waiting lists and the barriers to providing more. And it helped them understand that were they to point out to relatively new consultants that they can work in the independent sector for part of the time, in a multidisciplinary team, they will actually grow capacity to treat an underserved proportion of the population. There are also those who've retired with mental health officer status who are available, and there will be those who need to reduce their provision to the NHS because of breaches of the annual allowance, who are also available. So independent provision is not necessarily at the detriment of NHS provision, it can be positive for patients and positive for staff.

It's interesting because NHS and the private sector are presented as the polar opposites, and private is seen as kind of the dark side. I think a healthy private service could help the NHS.

Absolutely. If people have a reasonable alternate source of income they're not beholden to a single master, they're able to point out inappropriate working conditions, lack of respect or the shameful physical environment. Why should patients and staff have to put up with substandard facilities? There is no reason why we shouldn't support independent

provision, which is not in direct conflict with the NHS, e.g. the independent sector can't really provide adequately for psychosis. Although I do hear a growing view that the NHS can't provide adequate care in metropolitan areas.

One thing I have witnessed is the constant reorganisation of the services, and what do you think is the effect is on psychiatrists?

Well one of the effects is understanding it's a life cycle event. The first time it happens, you're full of enthusiasm, it's going to solve these problems. The second time, well, maybe they just didn't do it right the first time. The fifth time, your main concern becomes, how am I going to get a solo office. Will I still have a secretary? One's enthusiasm for the delivery of clinical care can erode with time, I exaggerate for dramatic purposes. In the last reorganisation we had, I delivered a piece of work pointing out that the manpower calculations for the metrics that were planned meant that staff would have no breaks in a week. This was nursing staff, so that was inappropriate. The revised metrics still meant that they only got half an hour's break in the week! So, consultants still have an important role in reorganisation. But we need to bear in mind that the primary purpose is often not what we're told this is for. It is politically driven, it hides budget or manpower cuts. Consultation must be meaningful; to paraphrase, no change to me, without me!

And how do you see the increase in bureaucracy in psychiatry? That is one of my pet hates, I have to admit.

It goes hand in hand with an increasing conviction that if you measure everything, you can prevent the things you want to prevent. One of the biggest drawbacks I found of electronic records is the loss of the narrative. I am fully aware that this may be harking back to an inglorious past that was never present. But when I look at case files for medicolegal reports, I see the old discharge summaries, and someone's life is explained in glorious detail. It's very difficult to piece that together nowadays from an electronic patient record. There are advantages, one can cut and paste the highlights quite easily. But it then appears to be that all one is reading is cut and paste, for the large part.

One thing that I always ask about is clustering, and the way patients are reduced to clusters.

Yes. Some people have gone as far as identifying clusters with diagnosis. And how is that going to help them when we start using ICD-11!

It's interesting you mentioned narrative. One thing, as psychiatrists, we used to be trained in, was psychopathology, which emphasises narrative. And it's kind of being pushed out of the curriculum. And that is, I think, to the detriment of psychiatry. What do you think?

It is sometimes surprising the lack of scepticism that I see in trainees. Why is this patient presenting in this way at this time? It's relatively easy to say why in this way, but there's not enough attention to why at this time. We underrecognise the degree of secondary gain that can be present. Whether it's problems with neighbours, benefits or family. Often, that is the secret to understanding why there's a deterioration now.

You are very involved with European psychiatry. Reading some articles from mainland Europe, I think there is a gap between UK and European psychiatry, and we need to actually get more together.

Definitely. One of the things that's very odd about looking at other systems is, it's really easy to idolise them or denigrate them. So for years, I was going to the American Psychiatric Association for clinical excellence and the European Psychiatric Association for connections, networking and friendship. As time went on I realised that the USA does have truly outstanding Centres of Excellence. But the average UK psychiatrist, in my view, was better than the average USA psychiatrist. Looking at Europe, what came across was the importance of cultural differences and local circumstances. You do need unique solutions for different places. In Iceland in the middle of winter, when you can barely travel to the next building because of the snow and the wind and the ice, meant they were world leaders in telepsychiatry 30 years ago. And then you compare that with Denmark, who had a huge influx of refugees during the Yugoslav War, but a tremendous shortage of translators, they started using telepsychiatry for interpreters for psychological treatments for post-traumatic stress disorder. There are different approaches to hospitalisations, so Italy has a very low rate of compulsory hospital admissions compared with the UK. It's being exposed to these that leads you to see important clinical differences that arise from legal and political differences. It also highlights what can go horribly wrong if you don't pay attention to the politics.

I think politics also manifests itself in defensive practice. The fear of going to Coroner's Court. It's something that worries me that we will be more defensive, and it doesn't serve patients well.

It is an attempt to protect oneself against an unknowable risk. As Professor Wasserman has stated, one can reduce suicide at a population level, but not at an individual level. If you very thoroughly treat every single patient, the same number are probably still going to die, but for most people, that is so horrible that they can't run with it. One of the things I've noticed is by accepting that there is a risk that cannot be eliminated, and once one's done what one can do, and been clear about therapeutic risk, there are usually fewer adverse outcomes. Partly because you've put the risk on the table and said we've done what we can do, that there is a chance it will go horribly wrong, but if we don't take this risk it will never get better, or by being clear the risk is not one that psychiatry can solve, or is commissioned to solve.

1.1.11 Transference-focused psychotherapy as an aid to learning psychodynamic psychotherapy: qualitative analysis of UK psychiatry trainees' views

Orestis Kanter Bax Georgios Nerantzis Tennyson Lee

Correspondence

2022-02

Abstract

Aims & method

Learning psychotherapy can be difficult and stressful. We explore core trainees' ($n = 5$) views on undertaking a psychodynamic psychotherapy training case using transference-focused psychotherapy (TFP), in an East London NHS Foundation Trust supervision group. We used framework analysis of focus group interviews to examine trainees' concerns, their views about this experience and its impact on general psychiatric practice.

Results

Trainees described various concerns on starting: providing an effective intervention, insufficient experience and training-related pressures. However, they found that TFP addressed some of them and was helpful for learning psychodynamic psychotherapy. Difficulties around the countertransference remained at end-point. Trainees suggested that introductory teaching and learning through observation might be worthwhile.

Clinical implications

Trainees' experience suggests that an evidence-based operationalised approach such as TFP can be integrated into the core psychiatry curriculum as a psychodynamic psychotherapy learning method. Trainees report benefits extending to other areas of their practice.

Transference-focused psychotherapy (TFP) is an evidence-based, manualised¹ treatment for borderline personality disorder,^{2–4} with modifications for narcissistic personality disorder.^{5,6} Developed from Otto Kernberg's contributions on borderline personality organisation,^{7,8} it offers a structured approach to the treatment of severe personality disorders.

TFP offers operationalised technical guidance based on modified psychoanalytic principles that are helpful for the general psychiatrist.⁹ We hypothesised that there are specific TFP characteristics (*Box 1*) that may be facilitators for a meaningful training experience in the UK, especially in the context of training in the National Health Service (NHS) and the drive for developing suitable skills for a patient population with severe personality pathology. TFP has been used in psychiatric residency training in Australia and the USA with positive learning outcomes for residents.^{10–12} It has recently been introduced in the UK as a modality for the supervised experience of trainees and this is the first reported study describing trainees' views. *Box 1* About transference-focused psychotherapy

Transference-focused psychotherapy (TFP) is a psychodynamic treatment grounded in contemporary object relations theory and supported by randomised controlled trials. Its main premise is the central importance of transference analysis, as manifested in the 'here and now' of the therapeutic relationship, in relation to the integration of fragmented psychological structures (borderline personality organisation). The treatment is operationalised in a treatment 'manual'¹ that provides the technical framework (strategies, tactics and techniques) to be used by the therapist. Key modifications from traditional psychoanalysis include an emphasis on a diagnostic 'structural assessment', lesser frequency (1–2 sessions/week), more active participation by the therapist, and focus on the treatment frame and treatment objectives as negotiated in the treatment contract (with limit setting when self-destructive behaviours occur). In line with its psychoanalytic origin, TFP examines various communications at different levels (verbal, non-verbal, countertransference) and aims to help the patient understand and resolve unconscious conflicts and work towards greater personality integration.

Background

The role of psychodynamics in medical education and psychiatric training curricula dates from the beginning of psychoanalysis.¹³ Tensions between the medical model in psychiatry and the psychoanalytic paradigm remain.¹⁴ The Royal College of Psychiatrists (RCPsych) places importance on psychotherapy learning in core and higher psychiatry training in the UK.¹⁵ Core trainees need to meet psychotherapy-specific curriculum competencies: participation in Balint-type or case-based discussion groups and supervised psychotherapy experience. Completion of core training and examinations lead to RCPsych membership and eligibility for progression to higher specialty training. The aim is not for all trainees to progress to medical psychotherapy specialism, but for psychiatrists to be psychotherapeutically informed.¹⁶

Trainees' views on case-based discussion groups¹⁷ and cognitive-behavioural therapy (CBT)¹⁸ indicate that these are valued as part of their training development. Psychodynamic psychotherapy has been used for learning psychodynamic principles and for the long-case requirement.¹⁹ Reports indicate that starting out in psychodynamic psychotherapy is daunting²⁰ and related ideas are challenging but valuable.^{21,22} The General Medical Council's Medical Psychotherapy Report (2013) has triggered further research on psychotherapy training needs. There is accumulating evidence about specific specialist approaches and their usefulness for the trainee psychiatrist.^{23,24}

Aims

This study was set up to identify the baseline and end-of-therapy views of core trainee psychiatrists in East London NHS Foundation Trust (ELFT) regarding a TFP approach to their psychodynamic long case. We investigated (a) concerns about starting out, (b) recommendations regarding training needs, (c) the perceived advantages and disadvantages of using TFP and (d) its impact on current and future psychiatric practice.

Method

Five core trainees in the same supervision group were identified and invited to participate in the study. They were informed that participation was voluntary, that the interviewer of the focus group discussions would be independent from their supervisory structure and that transcripts would be anonymised before analysis.

We conducted two focus group interviews with the participants, one at the start and one at the end-point of their training case. We employed a framework approach^{25–27} owing to its suitability for analysis of textual data, particularly semi-structured interview transcripts. The focus group interviews were facilitated by a clinical psychologist with no background in TFP. The interviewer asked five questions designed to investigate the study's initial aims. Two were asked a baseline: What are your main concerns about starting a psychodynamic long case? What would you find most helpful in starting a psychodynamic long case? and the remaining three at end-point: What are the advantages of using TFP for your first psychodynamic long case? What are the disadvantages of using TFP for your first psychodynamic long case? How has the experience of having used TFP on a psychodynamic long case affected your current and ongoing psychiatric practice? Open, non-suggestive prompts repeating the question and inviting further elaboration or participant dialogue, and a prompt at end-point inviting trainees to think back to their baseline concerns, were permitted. Discussions were audio recorded, lasting 75 and 60 min each. We transcribed recordings verbatim and anonymised transcripts ahead of independent familiarisation with the data by the interviewer and the lead author. Line-by-line open coding was conducted independently by the two, who subsequently compared labels, resolved differences through discussion, homogenised themes and jointly produced the resulting indexes and charts. Additional deductive review of the transcripts, mapping of themes, analysis and interpretation were completed jointly in a final stage by two of the authors and the interviewer.

All participants (in year 2 and year 3 of training at baseline), two males and three females, provided consent to the study. All had already completed the academic and basic clinical part of their training for their level (psychotherapy lectures, case-based discussion groups) and all but one had completed their CBT short case. None had formal psychodynamic psychotherapy experience or had worked in a personality disorder service and all were expected to undertake preparation for the training method (*Table 1*). All joined the baseline focus group interview and one did not take part in the end-point interview. All met their training expectations, and all except one (the patient discontinued psychotherapy early) completed their case after 1 year. *Table 1* Characteristics of the transference-focused psychotherapy (TFP) training method

Characteristics	Details
Format of clinical experience	Individual TFP once a week
Duration	1 year
Allocated patients' characteristics	Personality disorder diagnosis: borderline personality disorder or narcissistic personality disorder (as assessed on SCID-II DSM-IV). ²⁸
	Moderate to severe pathology.

Moderate to severe pathology.

Informed consent for session audio-recording of all sessions for training purposes. Patient preparation requirements Assessment, preliminary contract setting²⁹ and goal setting completed by the specialist service.

Trainee-led contract finalisation takes place in a preliminary meeting after allocation. Trainee preparation requirements Familiarisation with the TFP 'manual'.¹

Orientation to the supervision process and regular preliminary attendance of the group. Supervision characteristics Facilitated by a consultant psychiatrist in medical psychotherapy and accredited TFP teacher.

Format: group. Frequency: once weekly.

Duration: 1 h.

1:1 preparation and progress review meetings with the supervisor at start, midpoint and end of case.

Review and supervision of audio-recorded sessions.

Review of end-of-case formulation report

Cases related to this study were assessed prior to allocation and consideration was given to reducing the risk of patient drop-out. Patients allocated had borderline personality disorder or narcissistic personality disorder diagnoses and scored in the lower range of the Global Assessment of Functioning (GAF) (scores of 51–10), indicating serious impairment.

The study was registered as a service development project and was granted approval by the East London NHS Foundation Trust Ethics Committee.

Results

Major themes from our analysis matched the questions asked. The subthemes derived from the data, and we present findings in two sections, each following analysis of the respective interviews. The first section (Trainees' concerns) addresses the first two aims of our study using baseline data (*Table 2*) and the second (Trainees' views) the last two, with end-point data (*Table 3*). *Table 2* Thematic analysis: focus group (5 participants) views at baseline Themes Subthemes (1) Concerns about taking on a long case Providing an effective intervention Insufficient experience and training Training-related and other pressures (2) Recommendations about taking on a long case Practical training skills Improvement in supervision Introductory teaching Common scenarios and basic tips Access to personal psychotherapy *Table 3* Thematic analysis: focus group (4 participants) views at end-point Themes Subthemes (1) Advantages of using TFP Clarity about the nature of psychotherapy Improved ability to manage the therapeutic encounter Facilitates long-case supervision Facilitates long-case preparation Facilitates learning psychodynamics (2) Disadvantages of using TFP General/unspecified limitations Limitations related to countertransference management Difference from the psychiatric model (3) Impact on initial concerns about taking on a long case Reduces anxiety about doing it wrong Reduces anxiety about doing it right Reduces anxiety about the patient discontinuing psychotherapy early Reduces anxiety about making interventions Facilitates formulating/planning treatment No effect on concern about lack of effectiveness Positive effect on concern about lack of effectiveness No effect on concern about training commitments (4) Effects on psychiatric practice Positive effect on the clinical encounter Positive effect on understanding of personality disorder Positive effect on working in team Positive effect on education and training skills¹

Trainees' concerns about starting a psychotherapy long case and their recommendations

“I have never even seen any kind of talking therapy happen [...] normally in medicine you sort of at least see something, like someone put in a cannula or someone take a history’ (participant 1).” “[...] that’s probably quite difficult for us to swallow, being medical, ’cause I think you always think there needs to be some sort of result, whereas maybe there isn’t always some big result that you want, but in our heads we probably think that every time there should be, so this puts more pressure on you’ (participant 3).” Trainees expressed concerns at baseline about treatment effectiveness and lack of competency: ‘the intervention I am doing, how therapeutic is it?’ (participant 5); ‘is it a waste of time?’ (participant 1). They said they had no previous training and experience, no direct observation of treatment delivery, a limited theoretical and conceptual map and limited familiarity with the field: ‘you don’t even know how you are supposed to sit’ (participant 1); ‘I don’t have that deep knowledge of psychoanalysis to really understand what I’m doing’ (participant 2). This left them with uncertainty, a sense of lack of purpose, inadequacy and unpreparedness. They were concerned about the quality of care they delivered, potential errors in treatment delivery, negative treatment effects and causing harm to the patient: ‘I am a bit worried about saying the wrong thing and sort of causing damage,

I guess people who have actually trained in therapy would be less likely to' (participant 3); 'the feel of failure is quite strong: is it gonna be your fault?' (participant 5).

Additional pressures originated from their wish to complete their long case in a timely manner for training progression: 'one of the big concerns is about the [patient] dropping out before doing enough work to complete the case' (participant 2). They discussed the emotional and personal commitments to the patient and the task in hand, and reported pressures relating to the continuity and intensity of contact and a sense of isolation. Some trainees mentioned having had no personal psychotherapy as an added concern.

Given perceived limitations in the current format for preparation for the long case and the limited duration of supervision sessions, trainees recommended introductory teaching (theory and technique) and suggested focusing on practical skills and observational learning (audio, video, simulation and expert demonstration methods): 'seeing someone having psychodynamic work in practice' (participant 2); 'a few key [tips]: tell me in three sentences what am I supposed to be doing when I start' (participant 1). They also noted that anxiety management skills would be useful.

Trainees views on learning psychodynamic psychotherapy using TFP and its impact on psychiatric practice

"I think I was really worried that I was going to do it [psychotherapy] wrong or not be able to do it or not know what I was doing [...] I think the more you do it you realise there isn't really a right and wrong [...] I think you have a lot more anxiety about it before you start' (participant 3)." "at the beginning [I didn't] see the point of a trainee doing a long case if you have no interest in going into doing psychotherapy training as an SpR [specialist registrar], but I think it has changed my clinical practice [...] I would hope it's not something I would forget or lose as I go through the career' (participant 4)." "you get a sort of more rounded view of how they [patients with personality disorder] feel, I think that they suffer more [...] and I understand what it's like for them a bit more' (participant 1)." At the point of completion of the long case, trainees discussed the positives and negatives of using TFP, its impact on their initial concerns and day-to-day psychiatric practice.

They reported an overall positive effect on their initial concerns: TFP reduced anxiety about competence, harming the patient, the patient discontinuing psychotherapy early and making therapeutic interventions. They remained worried about the effectiveness of psychotherapy. There was no impact on their concerns about competing training pressures.

Trainees said that TFP provided clarity about the nature and purpose of psychotherapy and it made the theory more accessible and less obscure. They also spoke about TFP enabling a focus on the patient–therapist relationship 'in the here and now', and their increased ability to focus on affect, challenge engagement on a cognitive level, address recurrent transference and countertransference patterns and manage the negative transference: 'I think it is clearer what you are supposed to be doing with TFP' (participant 4); 'It helps you mentalise yourself a bit more in the session' (participant 3); 'with TFP alone I guess you are quite protected in some way, because however [the patients] respond even if it is quite negative, this could be a positive thing, 'cause there was a lot of affect in the room, there is a lot of material' (participant 3).

They reported that the treatment contract and frame provided a shared sense of purpose for themselves and the patient, reduced their anxiety about interventions and activity in the session, and enabled them to manage risk, address acting out and better understand the patient's expectations: 'I think the TFP frame was useful in [...] thinking about why that happened without it feeling really personal' (participant 2); 'in TFP you are more allowed to bring up breaks to the contract – with my patient I felt much more comfortable to do this' (participant 4).

Finally, they shared a view that TFP enables preparation at baseline and ahead of each session, allowing them to recall sessions and report them in supervision in a structured way. They said it facilitated the use of supervision within time constraints by offering a shared language and reference framework, which allowed them to track affectively important material, understand and feedback in supervision the challenges to the frame and the patient–therapist relationship: '[TFP] framed how I would relate the session back to the group' (participant 2).

In terms of the shortcomings of TFP, they felt that its focus on the transference neglected other important relationships in the patient's life and limited the variety of potential directions for the therapy. They reported that the expectation of therapist activity and the manualised model produced performance and adherence anxiety: 'I was quite anxious

at least for the first 10 sessions to make sure I was on model' (participant 2). Some trainees said that TFP theory and practice was difficult to link and that the marked difference from the psychiatric model, in combination with their limited exposure to psychoanalytic theory, was a limitation for using the model. They said that the challenges in managing countertransference-related difficulties were not fully overcome by using TFP. They described negative therapist feelings produced by the focus on the transference, and difficulties with maintaining therapeutic neutrality. They also mentioned experiencing uncertainty in the face of patients developing positive feelings, attachment to the therapist, genuine affective contact and psychological progress: 'I feel like my patient has made progress and that he is being genuine and the more he is like that, the more difficult it is for me to know what to do' (participant 3).

Trainees noted that TFP experience improved their daily psychiatric practice and working with patients in various general adult psychiatric settings: 'I find it easier to be clear about the point of us meeting and to maintain the boundaries around that, whereas before when I first started I always found it hard to keep my clinic sessions down to the right length [and to] be clear with them and myself about why we are meeting' (participant 2). They felt it improved awareness and management of transference/countertransference 'in the room' in such settings, made interactions with patients (especially those with a personality disorder) less stressful and improved their ability to manage boundaries, set therapeutic goals and contracts, promote openness, instil hope, manage time, risk and acting-out, and liaise with specialist services. They felt that TFP improved their understanding of the nature of personality disorder and the patients' subjective experience: 'It gives you a better hope' (participant 1); 'I think you just have [...] more understanding of it [personality disorder]' (participant 3); 'I think I am more confident [...] managing assessments or interactions [...] being boundaried and also commenting on things that I might not know how to comment on before and being quite open with the patient in a professional way' (participant 3).

They said that working in teams was positively affected through an improved ability to supervise teams, and to recognise and address colleagues' and teams' strong affective reactions to interactions with patients with personality disorders: 'you are able to have that discussion [about frustration and acting out] with your colleagues, like PLNs [psychiatric liaison nurses]' (participant 2); 'using the TFP sort of structure [to think] about actually why is this anxiety being raised, why is the team acting in such a way' (participant 4). They reported that their experience provided transferable skills for tutoring and education and improved their understanding of the role of psychotherapy in the curriculum.

Two participants said this experience motivated them to seek further experience in psychotherapy.

Discussion

Trainees with no previous experience in psychodynamic psychotherapy expressed intense anxieties related to the prospect of providing this intervention for the first time. They described ambivalence about the value of psychodynamic psychotherapy at baseline, professional self-doubt and training-related pressures. The interview after completion of their long cases indicated that some of these anxieties are alleviated and that TFP has overall positive effects for trainees, extending into their general psychiatric practice, though with some limitations.

Describing therapist difficulties is a core area of the psychotherapy literature but there are few publications specifically identifying what psychiatry trainees find difficult.^{20,30,31} Our study group's anxieties partly match the available taxonomy for psychotherapists' (both novice and seasoned) struggles.³² This pattern of self-doubt, recognised for the novice therapist,³³ is to be expected also for the trainee psychiatrist in the early stages of development but may improve with professional progression.³⁴ This trajectory of change is supported by our findings of some improved anxieties at end-point. Trainees report increased confidence about doing psychotherapy and working with patients with personality disorders in the general psychiatric setting.

Manualisation in psychodynamic psychotherapy is an emerging trend.³⁵ Trainees hold contrasting views about this aspect of TFP. On the one hand, they reported that the specific treatment framework promoted learning psychodynamic principles in a structured manner and facilitated supervision. On the other hand, they said it produced performance anxieties. Importantly though, trainees reported that it helped with management of risk and acting out. There are limitations relating to persistent scepticism about the effectiveness of psychotherapy, ongoing difficulties in managing the countertransference, TFP's psychoanalytic origin, which trainees feel unfamiliar with and consider at odds with the established medical model, and training-related pressures. It is noteworthy that trainees felt helped in managing their countertransferential feelings in psychiatric settings rather than in their psychotherapy work. This both indicates the

complexity of use of the countertransference in psychotherapy and suggests the potential contribution of a psychoanalytically informed training such as TFP for psychiatrists in their daily work.

Evidence indicates a high rate of early dropout in patients receiving psychotherapy.³⁶ This is less prevalent in psychiatric training³⁷ but important to consider, given the impact on training progression. TFP was reported to affect concerns about doing psychotherapy, but it did not affect the experience of training-related pressures.

Given the increasing complexity of the population seen in secondary care, finding suitable training cases may be difficult. Cases treated in this study had moderate to severe personality disorder. TFP may facilitate a pragmatic approach to training within the current NHS service limitations. Four of the five trainees were able to complete their cases and described making good use of the intervention. Supervisors may wish to consider trainees' competence when allocating cases³⁸ and be aware of the difficulties relating to the focus on the transference, trainees' performance anxieties, pressures about 'being on model' and the lack of access to personal therapy.^{39,40} Trainees reported that using a TFP approach partially reduced levels of anxiety about doing psychotherapy with a subgroup of patients with complex problems.

Supplementing supervision with other modes of preparation and learning, with a focus on direct observation, audio-visual material^{41,42} and simulated learning should be considered for incorporation into standard supervision groups.

Strengths and limitations

This is the first study in the UK to examine the views of core trainees about doing a long psychotherapy case using TFP as the modality of choice. TFP has been recently introduced in the country and its use for training purposes in the NHS only recently started. We provide an early description of trainees' views about this evidence-based treatment, linking it with training-specific needs.

Limitations in this study are inherent to the study design and the small number of participants, typical of the size of supervision groups in core training. Theoretical saturation in the analysis may be suboptimal because of the small sample size,⁴³ but limited use of TFP in the UK for training purposes did not allow the inclusion of further focus groups at this time. We studied the views of trainees in a single supervision group, in one locality within one NHS trust. The preparation and supervision were specific to this locality and the generalisability of findings is limited by this. We anticipate that as use of the model grows in the UK, opportunities will arise for further studies of trainees' views that may in addition explore patients' experience of TFP.

We safeguarded against positive bias by explicitly separating the training evaluation process from participation in the study from the outset. Participation in the study was optional. The long-case supervisor did not facilitate the focus group discussions, and the transcripts were anonymised to limit the supervisor's ability to identify a specific trainee's comments and views and to limit self-censorship and selective reporting. The participants were explicitly invited to report their views about the negatives of using TFP to further mitigate this risk and they indeed shared a range of opinions. The risk that the focus group responses may have been biased by the participants' perceived expectations of their supervisor is nevertheless present. Attrition at end-point (one trainee did not participate in the end-point focus group) also reinforces the risk of positive bias in the results presented.

Recommendations

Findings from our study of trainees' views about using TFP support the use of this model for core training purposes. Learning psychodynamic psychotherapy can be difficult and stressful, and this model of training delivery addresses some of the concerns of the starting trainees. We recommend that the use of TFP can help improve their confidence about the effectiveness of psychodynamic psychotherapy and their capacity to treat patients and manage clinical encounters, and can facilitate their use of supervision. There are additional reported collateral benefits for the developing psychiatrist, in terms of working with patients with personality disorders, understanding of psychodynamic aspects in psychiatry, working in teams, and improving education and training skills.

Learning psychodynamic psychotherapy remains a fundamentally challenging endeavour that requires working with and tolerating uncertainty. The problem of some trainees experiencing a dissonance between established psychiatric

training and the psychoanalytic principles used by TFP remains, and further integration between disciplines is still required.⁴⁴ TFP does not offer a magic bullet for the intrinsically complex nature of learning psychodynamic psychotherapy. However, our study suggests that it addresses some of the trainees' anxieties about taking this task on.

On the basis of these findings, we recommend that the RCPsych considers using TFP in its core training curriculum for meeting the psychotherapy long-case requirement. Our findings are in keeping with evidence from the international paradigm about the usefulness of TFP for psychiatry training purposes.

We thank the five participant trainees, Dr Patrick Grove for his contribution to the study, and Drs Matthew Roughley and Iain McDougall for their helpful comments on the final manuscript.

Orestis Kanter Bax is a Senior Trainee in Adult Psychiatry and Medical Psychotherapy with Deancross Personality Disorder Service (East London NHS Foundation Trust) and Essex Partnership University NHS Foundation Trust. He is also a research associate at the Centre for the Understanding of Personality Disorder (CUSP), London, UK. **Georgios Nerantzis** is a Senior Trainee in Adult Psychiatry currently training at East London NHS Foundation Trust and a research associate at CUSP, London, UK. **Tennyson Lee** is a consultant psychiatrist in medical psychotherapy, clinical lead at Deancross Personality Disorder Service (East London NHS Foundation Trust) and co-director of CUSP, London, UK.

Data availability

The data that support the findings of this study are not available to share due to ethical considerations about the privacy of the participants.

T.L. conceptualised and designed the study. O.K.B., G.N. and T.L. contributed equally to drafting the manuscript.

This research received no specific grant from any funding agency, commercial or not-for-profit sectors.

1.1.12 No wrong door: addressing injustices and achieving better mental health-care provision for under-18s in acute physical healthcare settings

Virginia Davies

Correspondence

Virginia Davies (v.davies3@nhs.net)

date

2022-02

Abstract

The distressing reality that mental healthcare for children and young people in acute trust settings in the UK is woefully underprovided is not news. But with acute trust debts being written off, hospital trusts and commissioners of services have a timely opportunity to address this age- and condition-based discrimination.

Delivering a just service for under-18s depends on attitude, resources and adequate knowledge of the tasks involved. This article aims to describe the current landscape, summarise the arguments for better integrating mental healthcare into physical healthcare settings, articulate the tasks involved and the challenges for commissioning and providing, and finally share examples of current service models across the country.

Ultimately, commissioning and provider choices will be constrained by resource pressures, but this article aims to underscore why commissioning and providing a portmanteau ‘no wrong door’ hospital service for children, young people and families is worth the headache of thinking outside old commissioning and provider boxes.

pmc In 2019, the National Confidential Enquiry into Patient Outcome and Death (NCEPOD) report into the mental healthcare of young people in the UK¹ concluded that: mental healthcare was not given the same level of importance as physical healthcare in general hospitals. General hospital staff were not receiving enough support from mental health professionals in the general hospital setting, particularly with regard to risk management.

Despite these damning findings, the report did not advise commissioners how they could use their purchasing power to exact a more equitable provision of mental healthcare for young people in hospital settings. Unhelpfully, in terms of systems change, many of NCEPOD’s recommendations can be implemented at a ‘tick box’ level, through superficial changes to job definitions and training plans.

And, having stated in 2015 that ‘What is particularly worrying is that children with physical, learning or mental health

needs are telling us they have poorer experiences [in hospitals]’,² Ted Baker, the Care Quality Commission’s chief inspector of hospitals, noted in the 2020 Assessment of Mental Health Services in Acute Trusts (AMSAT) report³ that: “Physical and mental health care have traditionally been delivered separately. While investment and improvements in mental health services are welcome, physical and mental health services will only truly be equal when we stop viewing physical and mental health as distinct. Services need to be built around all of people’s needs and not determined by professional or interest groups.”

He continues: “Many of the people attending acute hospital emergency departments with physical health needs may also have mental health needs. These people are in a vulnerable position and need to be treated with compassion and dignity. This must be in a way that makes them feel safe and upholds their human rights. In our report, we raise concerns that people with mental health needs are not always receiving this level of care. How well they are treated in an emergency department, or elsewhere in an acute hospital, is often linked to the importance that mental healthcare is given by the trust board. Acute trusts must do more, but they also need support from mental health trusts to develop better and more integrated approaches to care.”

AMSAT makes some welcome recommendations for integrated care systems and acute trusts; however, with no absolute commissioning directives regarding ‘whole person’ hospital care, most trusts will choose to overlook this central aspect of patients’ – and especially children’s – care.

The tendency for adult and physical health priorities to set the agenda within acute trusts means that children and young people with mental health needs seem always to be last in the queue. This is despite the well-known rates of comorbidity between long-term physical and mental health conditions in children (*Fig. 1*)⁴⁻⁷ and the immediate, let alone long-term, resource implications of failing to address these psychiatric comorbidities.⁸ Fig. 1 Prevalence of mental disorders in children with specific physical complaints. From Meltzer et al, p. 74.⁴ © Crown copyright 2000, see <http://www.nationalarchives.gov.uk/doc/open-government-licence/version/3/>.

The levers of integration

As AMSAT points out, if integrated treatment of mind and body is to be achieved, it must be underpinned by effective service-level agreements between stakeholders. The principles that guide such contracts were well articulated in *Side by Side*,⁹ published in February 2020. This UK-wide consensus statement, agreed by the Royal Colleges of Psychiatrists, Nursing, Emergency Medicine and Physicians, calls on all parties to work together to better care for patients with mental health needs in acute hospitals.

‘Best care’ is characterised by: reciprocal competencies in each staff group, physical and mental joint ownership of the care of children and young people while in the hospital co-location of physical and mental health staff.

Addressing the second and third aspects, reciprocal competencies and joint ownership of care, can be relatively easy, but as Ted Baker observed in AMSAT: ‘Where high-quality leadership for better mental health in acute trusts was lacking, we saw how there was more likely also to be a lack of appropriate training to support staff and poor working relationships between acute and mental health trusts.’³

Reciprocal competencies

Exchange programmes for junior doctors and nurses are already in place in some areas. Likewise, many health practitioner training programmes now contain modules offering reciprocal competency qualification, and frameworks such as the UCL competency framework¹⁰ allow staff to register as having reached various competencies in relation to mental health training. This model could be used to determine levels of mental health competency and capacity within the acute trust workforce. Those aiming to improve capacity in this area should be aware that the ‘We Can Talk’ training¹¹ used by many trusts to help staff to feel better equipped to talk about mental health problems with children and young people, detect safeguarding issues and provide signposting is not a child and adolescent mental health services (CAMHS) competency framework. Consequently, adoption of this training across a trust should not be used to distract from inadequate mental health staffing. Both are needed: upskilling of physical health staff, as well as direct employment of specialist mental health staff.

Joint ownership

Joint ownership of patient care can be interrogated by examining a trust's pathways and protocols. These agreements can usefully confirm which team will take lead responsibility for a young person's care. Children and young people who have used hospital emergency departments during mental health crisis describe how the experience of feeling unwanted at a time of particular vulnerability puts them off returning.¹² Given increasing rates of self-harm and suicide in young people,^{13,14} this is not a desirable outcome.

Co-location of staff

The biggest challenge to achieving genuine side-by-side working is co-location of physical and mental health staff. This is not simply a problem of estate management and a lack of space – it is because co-location of mental and physical healthcare provision presents a challenge to the very notion of what an acute hospital is about. Acute trust functioning and the commissioning of services within hospitals remains mired in an outdated notion of physical healthcare. Within this conceptualisation, physical health is divorced from the unconscious and from emotional and irrational reactions to physical ill health and disease, let alone family psychological factors, and care packages are linear processes.

Key considerations in commissioning integrated care for children and young people

Four main areas need to be considered when negotiating contracts for integrated acute trust care for under-18s: the range and complexity of mental health tasks to be addressed; commissioning discontinuities and fragmentation between adult and child, mental and physical, local and regional/national/international services; funding sources for non-patient-facing activities, including staff support and professional development; ensuring a single 'front door' for children and young people and their families.

Tasks to be addressed

Broadly speaking, three mental health tasks need to be managed in the acute trust setting: crisis/emergency mental health presentations; non-urgent psychiatric or psychological problems; systems issues regarding complex cases. *Box 1* gives more detail. *Box 1* Mental health tasks relating to under-18s to be managed in the acute trust setting

Crisis/emergency mental health presentations. These presentations involve under-18s in the emergency department or on the ward who need urgent joint assessment, alongside physical monitoring with or without treatment. Some individuals may need an emergency place of safety within the hospital. They might include children and young people with self-harm and attempted suicide, psychosis, acute confusional states (delirium), eating disorders and sudden deterioration in behaviour in the context of autism spectrum disorders or intellectual disability. A significant proportion will have safeguarding needs. Some children and young people will have psychiatric needs related to physical health medicines (e.g. intensive care medicines) or their physical condition (e.g. brain injury).

Non-urgent psychiatric or psychological problems in in-patients, day patients or out-patients. This group might include children and young people with medically unexplained physical symptoms such as pain or paralysis, those experiencing major emotional reactions following a newly diagnosed long-term condition, for example non-adherence with medication in asthma or insulin-dependent diabetes mellitus, those with a psychiatric condition in the context of a long-term physical condition, such as attention-deficit hyperactivity disorder in the context of epilepsy, and those subject to medical child abuse/fabricated and induced illness.

Systems issues regarding complex cases. Physical health staff dealing with cases involving complicated systems dynamics or complex child or parent psychopathology need access to support, training and consultation from expert mental health colleagues to effectively manage the staff effects that can ensue. These can include conflict within teams (splitting), accidental medical harm of children and young people, inadvertent collusion with abusive parents and staff burnout. Mental health staff embedded with their physical health colleagues can run reflective groups, facilitating psychological processing and providing in-context staff support. Such reflective groups have been shown to reduce staff sickness and burnout in physical healthcare staff.^{12,13}

Commissioning discontinuities and fragmentation

Commissioning discontinuities and fragmentation are rife for under-18s in hospital, with 16- and 17-year-olds most disadvantaged despite having the highest rates of psychological morbidity (*Fig. 2*).¹⁵ *Fig. 2* Under-18s requiring emergency mental health assessment in the emergency department of one London teaching hospital over the period 2013–2019.

The age discontinuity between paediatric commissioning and CAMHS commissioning, especially given the former's non-alignment with educational transition points, is surely an area for urgent attention by integrated care systems (ICSs) (*Box 2*). ICSs are tasked with breaking down barriers to care as part of delivering the National Health Service's long-term plan,¹⁶ but with the COVID-19 pandemic having changed the commissioning landscape, how will the new block contracts affect this? *Box 2* Ensuring that 16- and 17-year-olds are not forgotten Paediatric commissioning finishes at 16, but CAMHS commissioning finishes at 18. The physical arrangement of acute trusts, with most paediatric emergency departments and wards having an age cut-off of the 16th birthday, means that the over-16s end up in environments that are far from young-person friendly. Having no in-house under-18s mental health staff to visit them in these 'inappropriate' settings doubly disadvantages the under-18s; their adult equivalents are far more likely to have access to in-house liaison psychiatry teams, since commissioning for adult mental healthcare in hospitals is more advanced than that for under-18s.

How does the commissioning arrangement work when a hospital functions not only as a local 'district general', but also as a regional, national and possibly international specialist referral centre? Most acute trusts have arrangements in place for costing physical healthcare packages involving national and international patients, but these rarely take into account potential mental health needs. Greater recognition needs to be given to this side of the 'business' and financial packages developed accordingly.

Funding for non-patient-facing activities

Funding sources for non-patient-facing activities, including staff support, are vital for the sustainability of any integrated service. Significant amounts of non-patient-facing activity are involved in the first two tasks listed in (*Box 1*): dealing with crisis/emergency mental health presentations and non-urgent psychiatric or psychological problems. A 75-min crisis consultation will often require as much time again, often more, liaising not only with other hospital and primary care staff, but also other agencies, especially social care and education, as well as adult mental health if parental mental illness is a factor. Emergency tariffs rarely cover the hours of work involved or the numbers of mental health staff who may need to be involved. Tariffs need to contain adequate funding for staff with sufficient knowledge of child and adolescent mental health to complete this important liaison work, and payment by results has often meant that provider trusts end up running these services at a loss.

Mental health staff are also important for delivering staff support, something that has become very obvious during the current COVID-19 pandemic. Plenty of evidence exists for the benefits on staff well-being of reflective practice,^{17,18} but this is rarely factored into commissioning agreements between acute providers and commissioners.

Ensuring a single 'front door'

Finally, how does the commissioning arrangement ensure that children and young people and their families are not having to visit multiple 'front doors' and tell their story multiple times? Having on-site, integrated mental health staff ensures not only that under-18s and their families have an experience of one extended team caring for them, meaning that any mental health professional coming to see them has a good sense of their physical context and is already well-briefed on their possible mental health difficulties, but, perhaps more importantly, that they can access mental healthcare even if they come from a family or culture where attending CAMHS or having mental health problems is difficult to accept or act upon, and where a separate visit to a mental health clinic simply will not happen.¹⁹ Equally, if the young person's family of origin is chaotic and/or their emotional and behavioural presentations stem from neglect or abuse, the hospital provides a one-stop shop. This offer is unlikely to be the case if commissioning relies on in-reach from local CAMHS.

Developing a just and best-fit model

Having reflected on how a local hospital service might deliver or not on good care as articulated above, commissioners and providers planning to establish or enhance integrated hospital care for under-18s within the next commissioning cycle might want to consider the following. Is/will the team be multidisciplinary (more common in paediatric liaison/children's psychological medicine teams) or unidisciplinary (as in crisis teams or paediatric psychology services)? Are/will the team members be employed by the acute trust or by the mental health trust, with honorary contracts with the acute trust? There are pros and cons to each. Does/will the funding come via block contracts or activity-based, condition-specific funding streams? The mental health needs of children and young people are often inchoate and less amenable to being fitted into diagnostic boxes or care bundles. Embedded staff, able to respond to the queries of paediatric staff or the sudden call for help with a child's behaviour or family's emotional response, are invariably more useful than staff tied to specific conditions or workstreams. Who does/will do the commissioning? Local children's mental health commissioners are responsible for ensuring adequate 24/7 emergency provision, but who will take on responsibility for in-patient, day-patient and out-patient provision? Will this be agreed on a cost-per-case basis with local children's mental health commissioners or will the acute trust agree tariffs with local, regional and national commissioners that include mental health activity? The latter is certainly more sustainable in terms of paediatric mental health service financial viability. Does/will the mental health service involve one team or a multitude of different units within the hospital? In some hospitals, the paediatric psychology service functions separately from the paediatric mental health team (which may be called a paediatric liaison team or children's psychological medicine team), and in some hospitals, the paediatric psychologists are not joined in one service, but are simply members of their condition-specific paediatric teams.

Examples of some current models for under-18s mental health provision

With these considerations in mind, commissioners and providers can examine which of the following models is best for their acute trust/s. Services at these example trusts are further outlined in the Appendix. An acute trust-employed under-18s mental health service covering the emergency department, wards and out-patients. The team delivers in-house training, staff support and reflective practice. This model is followed at the Whittington Hospital, London. A mental health trust-employed emergency department psychiatric service (adult practitioners) and CAMHS crisis team which sees under-18s emergency department presentations and those admitted for less than 24 h. An acute trust-employed paediatric (i.e. under-16s) mental health team sees all other cases, including crisis admissions of more than 24 h. A paediatric mental health team delivers in-house training, staff support and reflective practice. This is the model at the John Radcliffe Hospital, Oxford. A mental health trust-employed emergency department service, with an on-site under-18s mental health team during normal working hours. An on-site mental health team sees certain groups of in-patients and out-patients as part of acute trust-funded, condition-specific service level agreements (e.g. for Tourette syndrome), as well as 'generic' in-patients and out-patients if funding is agreed on a cost-per-case basis by local commissioners. There is a large acute trust-employed, condition-specific paediatric psychology service, separate from the mental health team. A paediatric psychology service delivers in-house training, staff support and reflective practice. This model is followed at the Evelina Children's Hospital and St Thomas' Hospital, London. An acute trust-employed under-25s out-of-hours mental health emergency team as well as CAMHS in-reach during normal working hours. An acute trust-employed community counselling service providing in-reach or outpatient services for children on wards or out-patients, as well as paediatric staff support. This model is followed at the Blackpool Victoria Hospital, Blackpool.

A binary choice?

In effect, commissioners and providers working within integrated care systems have two broad choices when they consider mental health provision for children, young people and families in acute trust settings: an embedded, multi-disciplinary children's psychological medicine team, staffed by practitioners such as paediatric psychologists, child and adolescent psychiatrists, child mental health nurses, child psychotherapists, physical therapists and social workers, all directly employed by the acute trust and working across all settings; two separate mental health teams, one employed by the mental health trust and seeing crisis/emergencies (uni- or multidisciplinary, with nurses usually providing the unidisciplinary input) and one employed by the acute trust seeing all other patients (uni- or multidisciplinary, with psychologists usually providing the unidisciplinary input).

In an ideal world, where team boundaries are minimised, the first model is preferable. Such embedded services allow children, young people and families access to timely mental healthcare, when and where they need it, with staff versed in their physical health needs and without the long waits that currently plague access to CAMHS. Clinical scenarios involving acute behavioural disturbance on paediatric wards or the need for urgent and ongoing psychiatric care for children and young people in intensive/high-dependency care cannot wait around for funding requests that take weeks to agree. Equally, children and young people with disabling unexplained physical symptoms may not appear to mental health commissioners to be 'mental' and legitimate recipients for funding (not fitting usual CAMHS eligibility criteria), so then fall between posts.

It is hoped that this article gives commissioners and providers the questions and framework to query current arrangements and to ask themselves: Can children, young people and families in my integrated care system expect a unified care offer when they walk through the front door of our local acute trust/s? Will acute trust care costs be contained by having timely mental, as well as physical, healthcare available to the large cohort of under-18 in-patients and out-patients with long-term conditions for whom we are responsible? Will under-18s under our care genuinely find that there is no wrong door when they find themselves requiring hospital care?

I thank both my reviewers for their helpful comments, as well as all those who commented informally in the production of this document, in particular Dr Peter Hindley, who prompted me to get on and write about this area, and Dr Sebastian Kraemer for support with the early drafts.

Virginia Davies, MRCP, FRCPsych, MRCGP, is a consultant in paediatric liaison in the paediatric mental health team at the Whittington Hospital, London, UK, and chair of the Royal College of Psychiatrists' Paediatric Liaison Network.

This research received no specific grant from any funding agency, commercial or not-for-profit sectors.

None.

Detailed service descriptions

Blackpool Victoria Hospital, Blackpool

The Child & Adolescent Support & Help Enhanced Response (CASHER) service offers emergency assessment to young people under 25 from 5 pm–10 pm on weekdays and from 10 am–10 pm on weekends and bank holidays. CASHER provides support for young people 365 days a year. CASHER also provide an on-call night time service via their dedicated number (07810 696565) and will come into the hospital to see young people outside of their usual working hours. Each shift is staffed by two mental health staff, one CAMHS-trained and one not. Staff from local CAMHS opt into the staffing rota, which is run by the hospital bank. This avoids any issues with rota absence due to annual leave or sickness. CASHER also offer weekend clinics and drop in sessions for those in crisis. Over 16s are admitted to the adolescent unit or adult medical wards whenever necessary.

CASHER also run an 'Intensive Home Support' service (CASHER RAIS) which provides immediate support to young people who may have presented at accident and emergency or are currently on waiting lists for other services. CASHER

RAIS ensures that young people are not left unsupported at any stage during their care. CASHER has also adapted their face to face REACH-OUT Groups that are held in the more deprived areas of Blackpool, Fylde & Wyre by supporting online sessions via Zoom with colleagues from Lancashire Children's Services as well as Attend Anywhere for Blackpool Teaching Hospitals online sessions.

CASHER close links to local services including CAMHS and YoutherapY, which are both run by the acute trust. YoutherapY, to which in- and outpatients can be referred or can self-refer, has counsellors working with paediatric staff and children, young people and families in the hospital, as well as working in community sites.

Evelina Children's Hospital and St Thomas' Hospital, London

South London and Maudsley NHS Foundation Trust's National and Specialist Paediatric Liaison Service is a multi-disciplinary team focusing on young patients with comorbid medical and psychological conditions (<https://www.slam.nhs.uk/national-services/child-and-adolescent-services/paediatric-liaison/>).

The team receives referrals from across the UK and internationally for certain conditions and also provides assessment and treatment of in-patients at the Evelina Children's Hospital and St Thomas' Hospital. The service comprises four consultant psychiatrists, a clinical nurse specialist, a family therapist, a counselling psychologist and specialist training doctors.

Staff are employed by the local mental health trust, with funding coming from a mixture of sources, including portions of the local CAMHS block contract, cost-per-case funding for in- and out-patient work from mental health commissioners and acute hospital funding via service level agreements related to particular conditions, such as tics and Tourette syndrome.

Oxford University Hospitals Children's Psychological Medicine (CPM) service

Oxford University Hospitals Children's Psychological Medicine (CPM) service is primarily staffed by paediatric psychologists, with 2.2 whole-time equivalent child and adolescent psychiatrists. All staff are employed by Oxford University Hospitals NHS Foundation Trust (OUH). OUH has a large adult psychological medicine service, and the child and adolescent psychiatrists are managed within this larger group of adult psychiatrists. OUH's John Radcliffe Hospital is a trauma centre and it receives children who have sustained complex trauma following suicide attempts.

All CAMHS emergencies presenting to the emergency department are seen by the emergency department psychiatry service, which is provided by the local mental health trust. Any children needing in-patient care beyond 24 h, e.g. for medical treatment of an overdose, are then managed by CPM. The adult psychological medicine consultants provide out-of-hours Responsible Clinician cover for all children and young people detained at OUH. The child and adolescent psychiatrists do not undertake any out-of-hours work.

CPM and psychological medicine are funded by out-patient and in-patient tariffs. Some work is funded using best practice tariffs, some by service level agreements with specific teams and some is paid for by monies coming in for medical student teaching. Oxford's Children's Hospital also purchases generic CPM child and adolescent psychiatrist input using money from their overall budget, charged by OUH to commissioners. Any new service development has a small amount immediately factored into the costings to cover CPM or psychological medicine costs.

Whittington Hospital, London

Whittington Health NHS Trust's paediatric mental health team (PMHT) at the Whittington Hospital, London, is staffed by psychiatry, nursing, family therapy and psychotherapy (see <https://www.whittington.nhs.uk/default.asp?c=25315>).

The service offers liaison input to the paediatric team, in-patients and out-patients, and crisis assessments and management in Whittington Hospital's emergency department and the paediatric ward. The service also supports staff on neonatal intensive care.

The PMHT is part of acute paediatrics. The latter is commissioned within the context of the national contract for acute hospital services. Since the PMHT is not a commissioned service, it has to be funded out of the paediatric budget. Whittington paediatrics have been commissioned under Payment by Results for a number of years, with income generated from attendances / admissions. However, this has changed as part of the Covid finance / contracting arrangements and services are now paid for as a block contract. The contract amount is fixed and based on historic expenditure and demand trends.

1.1.13 Improving attitudes toward electroconvulsive therapy

Oakley Cheung Marc Baker Paul Tabraham

Correspondence

Marc Baker (marc.baker@port.ac.uk)

date

2022-02

Abstract**Aims and method**

Electroconvulsive therapy (ECT) often causes fear in the general public because of media representation and negative reported side-effects. This study evaluates a new video focusing on experiences of ECT and how this can aid communicating medical information to the public. Knowledge and attitudes toward ECT after watching the video were compared with a group that received no information and a group that read the current NHS leaflet on ECT. The role of empathy was also considered as a covariate.

Results

The video was the only condition found to positively affect knowledge and attitudes toward ECT. The video was especially beneficial to those that possessed low perspective-taking trait empathy.

Clinical implications

These findings demonstrate the video improved knowledge and attitudes toward ECT compared with current material or no information. We suggest that the addition of personal experiences to public information adds perspective, improving overall attitudes toward health treatments.

Electroconvulsive therapy (ECT) is a mental health treatment involving the use of electric currents to induce a seizure,¹ and is used to treat life-threatening depression, catatonia and severe, long-lasting mania that is resistant to medication.^{1,2} However, ECT raises fear among the general public,^{3–5} largely because of its dramatization in the mainstream media.^{2,5–8} Concerns are, however, not entirely based on fiction, as some patients have reported adverse psychological side-effects as a result of ECT treatment, implying possible signs of trauma response.⁹ The National Health Service (NHS) information for patients undergoing ECT consists of a science-based leaflet from the National Institute for Health and Care Excellence (NICE),¹ despite research suggesting that healthcare education may be better received alongside contextual and emotive evidence.^{9,10} Gold Coast Health in Australia implemented these principles, focusing on adding contextual evidence for the benefits of ECT,¹¹ but there is no empirical evidence as to whether this approach improved perceptions of ECT.

From a psychological perspective, trait empathy is one factor which may affect someone's ability to relate to the per-

sonal accounts of those receiving ECT. Both cognitive and affective empathy have a positive relationship with the ability to perceive emotional content.¹² Specifically, cognitive empathy can facilitate ‘perspective-taking’ capabilities.¹³ Following the use of the video produced by Gold Coast Health,¹¹ the Southern Health NHS Foundation Trust developed a similar tool to foster more accurate perceptions of ECT. This study is the first to empirically test whether the use of the emotion-based information improves perception of ECT compared with the current leaflet. We aimed to test whether the new video fulfils its purpose to promote a more positive attitude and better knowledge of ECT in the UK public, and whether trait empathy plays a role in any effects.

Method

Ethics

Ethical approval was given by the University of Portsmouth Undergraduate and Taught Postgraduate Psychology Department Research Ethics Board (clearance number 2019-036).

Design

The experiment used an independent groups design. Participants were randomly allocated to one of three conditions based on type of ECT information (no information, science-based leaflet or emotional video). The dependent variables were mean scores on the ECT knowledge and attitude questionnaire. Two subscales of the Interpersonal Relativity Index (IRI), perspective-taking and empathic concern, were used to control for differing levels of trait empathy in the participant sample.

Participants

Participants were recruited by volunteer sampling. Posters were advertised around the University of Portsmouth, asking for volunteers to complete an online survey about ECT; these were not aimed at psychology students, but they were not excluded from taking part. Participants that were not students were recruited by sending a request for participation to local community facilities. The survey link was further sent by the non-student participants to their own colleagues, to increase the number of non-student participants. Participant ages ranged from 18 to 67 years ($N = 146$, mean age 31.94 years, s.d. 13.49). The sample comprised 51 men and 95 women, and both students ($n = 39$) and non-students ($n = 107$). *Table 1* shows the mean age and gender and student ratios for each condition. *Table 1* Participant demographic information

Condition	Mean age in years (s.d.)	Female:male participants	Students:non-students
No information	34.40 (14.37)	29:23	10:42
NHS leaflet	30.98 (12.74)	36:24	17:34
New video	29.98 (13.24)	29:13	11:31

Participants were asked to disclose any experience with ECT, and any mental illness that might qualify an individual for ECT. Some participants disclosed previous experience with ECT ($n = 64$), with a significant proportion ($n = 21$) receiving their knowledge from film or television. Some participants disclosed previous experience of mental health problems ($n = 84$), with the majority ($n = 63$) having experience with severe clinical depression.

Materials

The survey consisted of a revised version of the IRI,¹⁴ an ECT attitude and knowledge questionnaire¹⁵ and two types of information on ECT use as treatment for mental illness.

IRI

Two subscales from the revised version of the Basic Empathy Scale¹⁴ were used to measure trait empathy: empathetic concern and perspective-taking. The scales were rated using five-point Likert scales, with a high score representing higher trait empathy scores.

ECT attitude and knowledge questionnaire

The ECT scale consisted of both an attitude and knowledge subscale. Each statement was scored on a six-point scale, with high scores indicating a more positive attitude or correct knowledge of ECT.

Information on ECT use in mental health treatment

A public information leaflet was taken from the NICE guidance for the prescription and administration of ECT in depression, mania and catatonia.¹ This leaflet contains mainly scientific evidence of the efficacy and use of ECT. For this study, the sections ‘What is NICE?’ and ‘What are depressive illness, mania, schizophrenia and catatonia?’ were omitted. A video intervention was developed by the lead author and Southern Health NHS Foundation Trust based on a successful educational video created by Gold Coast Health, Australia.¹¹ The video focuses on the experiences of patients, nurses and caregivers with ECT. The video is available to the public at: <https://vimeo.com/369525494>.

Procedure

All participants completed the survey online and provided written informed consent before taking part. Participants were first asked about any experience with ECT and any mental health conditions, and then completed the IRI. They were then randomly allocated to one of three information conditions: no information, the current NHS leaflet or the newly developed video. Participants in the leaflet and video condition were presented with the educational material and asked to watch/read carefully before completing the knowledge and attitudes to ECT questionnaire. Participants in the no information condition only completed the knowledge and attitudes to ECT questionnaire.

Results

Descriptive statistics

Figures 1 and 2 show the distribution of the knowledge and attitude scores in each of the three information conditions. The median scores indicate participants in the video condition had more correct knowledge and a more positive attitude. Importantly, in the attitudes to ECT factor only the video condition showed a median score above the mid-point, indicating a positive attitude. Receiving no intervention or the ECT leaflet had distributions that sat mostly below the mid-point for both knowledge and attitudes, thus meaning the video condition was the only form of intervention likely to encourage accurate knowledge and facilitate a more positive attitude toward ECT when compared with receiving no information or the current leaflet. These findings suggest that video information is the most positive tool of the three studied. *Fig. 1* Distribution of electroconvulsive therapy knowledge scores across each information condition (points represent individual participant ratings). *Fig. 2* Distribution of electroconvulsive therapy attitude scores across each information condition (points represent individual participant ratings).

The role of empathy in the success of the ECT educational material

To analyse the data further, a one-way multivariate analysis of covariance (MANCOVA) was conducted on ECT attitude and knowledge data comparing data from each information condition. Empathetic concern and empathic perspective-taking used as covariates. A significant multivariate effect of information type was found (Wilks' $\lambda = 0.84$, $F(4, 280) = 6.36$, $P < 0.001$), with a small effect size. Empathic perspective-taking was a significant covariate in the multivariate model (Wilks' $\lambda = 0.95$, $F(2, 140) = 3.44$, $P = 0.035$), with a small effect size. No significant effect of empathetic concern was found on perception of ECT.

The significant omnibus MANCOVA justified separate univariate ANOVA on the dependent variables. There was a significant effect of information type on knowledge scores ($F(2, 141) = 11.68$, $P < 0.001$), with a small effect size. *Post hoc* pairwise comparisons with a Bonferroni adjustment revealed that knowledge scores were significantly higher in the video condition compared with the leaflet condition ($P = 0.01$) and receiving no intervention ($P < 0.001$). There was also a significant effect of information type on attitudes to ECT scores ($F(2, 141) = 11.45$, $P < 0.001$), with a small effect size. *Post hoc* pairwise comparisons with a Bonferroni adjustment showed attitude scores to be highest in the video condition when compared with the leaflet condition ($P = 0.003$) and receiving no intervention ($P < 0.001$). There was no significant difference observed between the leaflet and receiving no information for either knowledge or attitudes to ECT.

Perspective-taking was found to be a significant covariate for attitudes to ECT only ($F(1, 141) = 5.06$, $P = 0.026$), with a small effect size. This suggests the increase in positive attitude to ECT after watching the video exists after controlling for the underlying trait empathy. It also suggests empathic perspective-taking accounts for a very small but significant portion of the variance in attitudes to ECT. *Figure 3* shows the relationship between emotional perspective-taking on ECT attitudes in each of the three conditions. Although the regression line for the video was similar across the range of perspective-taking scores ($\beta = 0.06$, s.e. 0.25), there was a small positive relationship for the NHS leaflet group ($\beta = 0.29$, s.e. 0.16) and the no information group ($\beta = 0.30$, s.e. 0.21). When perspective trait empathy was high, attitudes toward ECT in the three information conditions were similar; when perspective trait empathy was low, attitudes toward ECT scores in the new video condition were higher than the NHS leaflet and no information conditions. From this, we can infer that the style of intervention had little effect on those already high in trait empathy; however, for those with low trait empathy, the video proved beneficial for improving perceptions of ECT. *Fig. 3* Relationship between perspective-taking and attitudes toward electroconvulsive therapy in each of the information conditions.

The role of gender and student status on the effect of ECT educational material

To check the data for potential biases arising from gender and student status, an independent group MANCOVA was conducted on ECT attitude and knowledge scores comparing data from each information condition. Gender (male/female) and student status (student/non-student) were used as covariates. A significant multivariate effect of information type was found (Wilks' $\lambda = 0.87$, $F(4, 280) = 5.10$, $P = 0.001$), with a small effect size. Gender was a significant covariate (Wilks' $\lambda = 0.92$, $F(2, 140) = 6.19$, $P = 0.003$), with a small effect size. No significant effect of student status was found on perceptions of ECT. The significant omnibus MANCOVA justified separate univariate analysis of variance on the dependent variables. There was a significant effect of information type on knowledge scores ($F(2, 141) = 2.88$, $P < 0.001$), with a small effect size. *Post hoc* pairwise comparisons with a Bonferroni adjustment revealed that knowledge scores were significantly higher in the video condition compared with the leaflet condition ($P = 0.01$) and receiving no intervention ($P < 0.001$). There was also significant effect of information type on attitudes to ECT scores ($F(2, 141) = 8.87$, $P < 0.001$), with a small effect size. *Post hoc* pairwise comparisons with a Bonferroni adjustment showed attitude scores to be highest in the video condition when compared with the leaflet condition ($P = 0.005$) and receiving no intervention ($P < 0.001$). There was no significant difference observed between the leaflet and receiving no information for either knowledge or attitudes to ECT. Gender was found to be a significant covariate for knowledge of ECT ($F(1, 141) = 12.38$, $P = 0.001$), with a small effect size, and attitudes to ECT ($F(1, 141) = 6.35$, $P = 0.013$). This suggests that the increase in knowledge and a more positive attitude to ECT after watching the video exists after controlling for gender. It also suggests gender accounts for a small but significant portion of the variance in knowledge and attitudes toward ECT.

Discussion

ECT knowledge and attitudes

Our findings suggest that both knowledge and attitudes to ECT can be significantly improved using contextual and emotive information. Only the video condition improved knowledge and attitudes to ECT, whereas the leaflet currently used by the NHS did not improve either knowledge or attitudes compared with no information. For both the no intervention condition and the leaflet condition, participants sat below the mid-point for attitudes and on or below the mid-point for knowledge, suggesting that they were still inclined to perceive ECT negatively. These findings suggest that, compared with other styles of intervention, the video would work best to educate patients and carers on the use of ECT to treat mental health illnesses. These results support current literature which suggests that interventions focusing on more emotional, real-life experience may be more effective for perception improvement than using factual information alone.^{13,15,16} It should be noted that all the main and covariate effects were small, and the distributions in all three experimental conditions had participants that perceived ECT both positively and negatively. This suggests that although the video may help to improve perceptions of ECT, it is not a 'silver bullet', and might best used alongside other informational material. Future research should assess whether combining the leaflet and the video improved the perceptions above and beyond the video alone.

An alternate explanation for our results may be the modal differences between video and written information; the introduction of a dynamic stimulus may have been enough to demand more attention from participants than reading a leaflet. Some research has suggested showing patients a video can reduce anxiety around healthcare treatments more than written information.¹⁷ To address this, it would be important to examine whether a similar improvement in knowledge and attitudes is found irrespective of how the content was delivered. It should also be noted that although the efficacy of ECT is outside of the scope of this research, there is still large debate as to whether there are any noticeable and long-lasting benefits to undergoing ECT.^{2,3,7,18} Additionally, meta-analyses report high relapse rates among many patients.¹⁹ There are some ethical considerations on whether improving attitudes toward ECT is acceptable if the benefit of the treatment is, in some cases, limited and relapse is likely.

The role of trait empathy

We hypothesised that trait empathy would offer some explanation as to why emotional content was more effective compared with scientific information. We found that perspective-taking influenced attitudes to ECT, but this was only the case for participants who received no information or the NHS leaflet; those with higher perspective-taking trait empathy had a more positive attitude to ECT. Perspective-taking had no effect on attitudes to ECT in the video condition. Therefore, participants with high perspective-taking scores had similar attitudes to ECT in all three conditions, whereas participants with lower perspective-taking empathy had a more negative perception of ECT in the leaflet and no information groups compared with the video group. The video, therefore, seemed to directly improve the attitude of participants who had lower perspective-taking abilities. The proposed reason for this is that the video directly adds context to ECT as a treatment. This allowed participants with lower perspective-taking empathy to relate to the treatment or participants in a similar way to those participants with high perspective-taking empathy.

This explanation seems to be consistent with evidence from neuroimaging studies, which has demonstrated a link between perspective-taking ability and the ventromedial prefrontal cortex,²⁰ a brain area that is also critical for perception and reaction to the suffering of others.¹⁹ Thus, scoring higher in perspective-taking may make an individual more likely to be able to imagine the suffering of those experiencing severe mental health problems, which explains why they may react more positively to ECT even with limited information around the treatment. Furthermore, adding context in the form of another person's account can elicit a more empathetic response from participants when making decisions,²¹ and that the empathy elicited is generally more appropriate when context is present;²² this suggests that the context in the video may have encouraged a more empathetic response to the content, even for those who do not naturally empathise with another's situation

Alongside the significant covariate effect of trait empathy, gender was found to be a separate significant covariate for both knowledge and attitudes. We suspect that the known gender variation in empathy²³ can partly explain why gender was a significant covariate. This information provides grounds to suggest further research is conducted into the effect

of an emotional, video-based stimulus, and whether any specific gender effects exist in relation to the efficacy of these training materials.

Clinical implications

These findings provide a deeper insight into the use of education to improve perception of ECT, with emotional stimuli proving to be the best method for information delivery, especially for people with low perspective-taking empathy. Overall, better knowledge of people's experiences with ECT may ultimately mean less fear and apprehension among the public.²⁴ The results of our findings can be used as a recommendation for both the NHS and the wider health sector on how to structure and deliver their informational material. A critical point seems to be that personal accounts and context are important in the effective delivery of health information.

Limitations and suggestions for future research

This study focuses on ECT, which carries a large amount of stigma.^{6,8} Going forward, it could be interesting to explore whether the effect exists with other health treatments with potential negative public perceptions. Some alternative treatments still have stigma attached,⁴ and contextual evidence may be the key to improving perceptions of these treatments for mental health illnesses. The results provide grounds to recommend that more emotive content should be introduced when educating the public about mental health. Suffering from a mental health disorder can still affect your ability to find work and maintain relationships.²⁵ Further, certain disorders, such as schizophrenia and psychosis, are still hugely feared by the general public.²⁶ Introducing a context and personal experiences to these illnesses helps to distinguish between mental health in the real world and the overdramatization of disorders fed to the public by the media.²⁷ Making the distinction between individual and symptom could help integration in society, improve quality of life and aid recovery for those with a mental illness.

The authors would like to acknowledge Karen Osala, Hannah Watts and Mark Pointer from Southern Health NHS Foundation, for help in producing the video; and Dr Tade Thompson from Solent NHS Trust, for his guidance during the conceptualisation stage of this research.

Data availability

This study was preregistered on 6 November 2019 on the Open Science Framework. Data and details of the preregistration are available at the following link: <https://doi.org/10.17605/OSF.IO/SY6AP>.

O.C. was responsible for initial conceptualisation of the study and its hypotheses, direction of the ECT video and oversight of its production, designing and conducting the study, analysis of results and end write-up of the study. M.B. provided general guidance through all experimental processes and edited the final manuscript. P.T. provided a critical clinical perspective and comments.

This research received no specific grant from any funding agency, commercial or not-for-profit sectors.

- *Response to: Does COVID-19 pose a challenge to the diagnoses of anxiety and depression? A psychologist's view*
 - *What is the problem?*
 - *Who is responsible?*
 - *What are the alternatives?*
 - *Collective trauma and a collective response*
 - *A conclusion*

pmc In her recent article, Johnstone (Bulletin, September 2021) writes critically about how we have responded professionally to the effects of the COVID-19 pandemic. While it is easy to agree with some of what she has to say, much of her argument consists of a series of assertions that are neither entirely accurate nor logically connected to each other or to her main contention.

What is the problem?

Johnstone's central claim is that by using psychiatric diagnosis we label things as abnormal that are in fact normal. The opening example of handwashing and cleaning is unfortunate because it is unconvincing – hardly anybody spends 'most of the day' doing it and there is more to the diagnosis of OCD than cleaning: resistance, ritualising, other compulsions and so on. Certainly, the use of florid metaphors about tsunamis and pandemics of mental disorder is unhelpful, and research does show that much unhappiness and anxiety during the pandemic has proved to be transient. But then many illnesses, including those caused by the COVID-19 virus, can be transient and non-disabling – it doesn't mean they aren't illnesses. Every doctor, including every psychiatrist, knows the value of watchful waiting: the question is how we respond when symptoms are not transient or non-disabling. When Johnstone talks about 'people with a psychiatric history', I take it to mean people who most psychiatrists would regard as having a long-term mental disorder. We can agree that 'It is untrue and even patronising to assume that everyone in this group will fail to cope', but does any psychiatrist actually assume that? More fundamentally, Johnstone is opposed to the idea of psychiatric diagnosis (and

not just of anxiety and depression) because it rests upon defining mental illness in relation to social norms while (as she and her colleagues have argued elsewhere) masquerading as being analogous to the more legitimate processes of medical diagnosis. It is an error to assume that medical diagnosis is radically different in all respects: it does for example recognise social causes (cigarette smoking, hazardous drinking, unhealthy eating, physical inactivity) and defines some of its most prevalent disorders such as hypertension, hyperlipidaemia and diabetes mellitus according to deviation from norms. More important is the question of whether the states so diagnosed are harmful and, if so, whether intervening is beneficial.

Who is responsible?

I found it difficult to suppress a smile at Johnstone's jibe about the self-serving nature of articles promoting the importance of research in the areas of expertise of the authors. But it is too narrow to name only academics and Public Health England as the actors in a debate about the nature of public mental health – professional bodies, the pharmaceutical industry, politicians and journalists are among others who set the agenda and the tone. The emergence of the phrase 'mental health' is an interesting topic in its own right, and one way to view its effects is to see it as a vehicle for medicalisation of distress. It might, however, be as useful to think of it as effect rather than cause of the individualisation of societal problems – a phenomenon that has deep cultural roots and consequences that go beyond psychiatry into penal policy, welfare provision and education.

What are the alternatives?

It is a category error to propose formulation as an alternative to diagnosis – the latter is a descriptive statement, whereas the former provides an explanatory framework, a point illustrated by the training requirement that psychiatrists are expected to be able to make a biopsychosocial formulation and management plan as well as coming to a diagnosis. It is not news that the onset of many mental disorders is preceded by adverse life events and difficulties – research in this area goes back half a century – or that the content of some people's illnesses reflects these experiences. However, bundling together all mental disorders as 'various forms of distress... that are understandable responses to adversities' does not do justice to the issues. Not everybody reports life adversities before onset; the nature of adversity may be reflected in the content of some but not all conditions; life adversity does not explain the differences in form of the various mental disorders; there is a strong genetic risk for some disorders. It is difficult to know what it means to say that mental disorder is 'what we do' in response to threats, but in my reading it is hard to see it as other than dismissive of the reality of mental illness.

Collective trauma and a collective response

There is a disconcerting *volte face* at the end of Johnstone's piece. Having presented the argument that what we are seeing in the pandemic is essentially normal, part of a meaningful response to stress and not to be pathologised, we are finally offered the idea of collective trauma – defined as an experience that overwhelms our usual ways of coping. If states like anxiety and depression are to be thought of as arising because of this overwhelming of usual ways of coping, how is that different from the way that psychiatrists think about what they are likely to call mental disorders? Only, it seems, in the reluctance to use a descriptive vocabulary that distinguishes between different conditions – as if it is a trivial matter whether somebody is hearing voices, embarked upon life-threatening self-starvation or unable to touch a newspaper for fear it will give them a fatal infection. How are we supposed to use this way of thinking to help people now, while they and we wait for a fairer society? Local peer networks may indeed help some, but they won't suffice for the severity and diversity of problems we face. One of the central tensions of healthcare is that we can recognise that health and illness have social determinants, but as clinicians it is individuals that we see. Isn't a question of picking one or the other – both are important, and I think most psychiatrists understand that.

A conclusion

Surely we can all agree about some things: it is important not to medicalise distress that does not merit such an approach; social adversities are important risks to our mental well-being, and government policies in recent years have both exacerbated these risks and done much damage to society's ability to help those most in need as a result of them; professionals in healthcare have a responsibility to speak out both for individuals in need and also about the social conditions that contribute to their difficulties. These simple and powerful messages are obscured by wrapping them, as here, in a muddled polemic animated as much as anything else by anti-psychiatry sentiment.

1.1.15 Transforming MRCPsych theory examinations: digitisation and very short answer questions (VSAQs)

Karl Scheeres Niruj Agrawal Stephanie Ewen Ian Hall

Correspondence

Ian Hall (ian.hall4@nhs.net)

date

2022-02

Abstract

Many examinations are now delivered online using digital formats, the migration to which has been accelerated by the COVID-19 pandemic. The MRCPsych theory examinations have been delivered in this way since Autumn 2020. The multiple choice question formats currently in use are highly reliable, but other formats enabled by the digital platform, such as very short answer questions (VSAQs), may promote deeper learning. Trainees often ask for a focus on core knowledge, and the absence of cueing with VSAQs could help achieve this. This paper describes the background and evidence base for VSAQs, and how they might be introduced. Any new question formats would be thoroughly piloted before appearing in the examinations and are likely to have a phased introduction alongside existing formats.

pmc Examinations are now being delivered on online platforms in many undergraduate and postgraduate contexts. The COVID-19 pandemic has accelerated this, as digital platforms have the potential to enable examination delivery during lockdowns, or if trainees are isolating or in quarantine, without social distancing concerns. Education is also becoming increasingly international, and the MRCPsych examination is both sought after and has been delivered in international centres for many years. However, travel to examination centres for both staff and candidates is expensive, and significantly increases its overall carbon footprint.

The Royal College of Psychiatrists has therefore decided to deliver its theory examinations via digital platforms as from Autumn 2020, using a combination of artificial intelligence and in-person online proctoring (equivalent to traditional invigilators) to ensure that high standards of probity are maintained. The examinations will initially be delivered using the two existing question formats, multiple choice questions (MCQs) and extended matching questions (EMQs). However, digital platforms enable the use of new question formats that may allow more comprehensive coverage of the syllabus (the syllabus can be found at: <https://www.rcpsych.ac.uk/training/exams/preparing-for-exams>). We know that assessment has a powerful effect in driving learning,¹ and multiple choice question formats may encourage rote learning from question banks. We will thoroughly evaluate any new question formats before we introduce them into the MRCPsych examination, but we would hope that they would encourage deeper and more holistic learning strategies that would better equip our future psychiatrists to have the biggest impact on the mental health of their patients.

Choosing examination formats for the MRCPsych

When setting an examination, some of the key factors² that need to be considered when assessing its utility are shown in *Table 1*. Each of these factors have to be weighed up against each other, with differing weightings according to the purpose and type of assessment. Table 1 Key factors to be considered when assessing the utility of an assessment (adapted with permission from reference²)

Factor	Questions asked	Validity	Does the examination test what we want it to test?
Reliability	Are the results repeatable and accurate?	Are external sources of error other than candidate ability accounted for and reduced?	Educational impact
What is the impact of the examination upon trainees' learning?	Does it lead to deeper learning and long-term retention?	Acceptability	Is the examination acceptable to those sitting it and other stakeholders?
Cost	Are costs reasonable?		

MCQs are a format that lends itself to reliability through standardisation of answers and ease of evaluation of large numbers of candidates via machine marking. Although MCQs have been used since the inception of the MRCPsych in 1972, historically, short answer questions (SAQs) and essays were also utilised; these were phased out as individual marking of SAQs with increasing numbers of candidates was taxing, and there were questions about the reliability of essay marking.³ The format of MCQs evolved from initial true/false answers to the single best answer or 'best of five' in use today, as well as the use of the EMQs, in which there is a theme, several stems and a greater number of options, more easily assessing the application of knowledge.⁴ The MRCPsych is a high-stakes examination, with important consequences for candidates, our patients and society in general. In common with all high-stakes postgraduate medical assessments based in the UK, it is regulated closely by the General Medical Council, and all changes to format and structure must undergo prospective approval by them.

Given these concerns, the reliability of the MRCPsych must be extremely high, so that no trainee passes without the requisite ability. Fortunately, the written papers have excellent reliability (with Cronbach's alpha, a measure of reliability, consistently >0.85), but some have questioned whether this has happened at the expense of validity.^{5,6} Has the depth of clinical context and its application been lost? Perhaps we fail to reward those trainees who undertake in-depth study of complex issues, such as aetiology, ethics and the history of psychiatry.⁵ The main criticism of MCQs is a 'cueing' effect, whereby candidates are cued by the correct answer, rather than actively recalling it.⁷ There is evidence that requiring candidates to *construct* an answer, such as in SAQs, produces better memory than tests that require recognition.⁸ Additional issues with MCQs may include various 'test-taking' behaviours, such as eliminating wrong answers to arrive at the correct one, guessing from the options available and seeking clues from the language used to deduce the correct answer independently from the knowledge required.⁹

MCQs end up testing recognition memory, and recall is significantly affected by this cueing effect. Creating a good MCQ with valid and meaningful distractors (incorrect options) can be extremely hard. Poor-quality distractors can make guessing more rewarding. There are a number of areas of the syllabus where it is impossible to write valid

distractors, and as a consequence, clinically meaningful knowledge may not be examined and more obscure areas, where MCQs may be easier to write, are more likely to be tested.

As mentioned above, it is intuitive and commonly recognised that the assessment drives learning.¹ Areas of the syllabus that are more commonly examined are therefore more likely to be studied by trainees. Assessment factors contribute to strategies used to study,¹⁰ which could influence the trainees' overall learning and the extent of knowledge achieved. Developments in technology have allowed easy access to online MCQ 'question banks'. Many trainees therefore focus their effort on practicing these questions, rather than focusing on core learning and developing deeper understanding.

The costs of taking the MRCPsych for candidates are high¹¹ because of the high cost of the infrastructure behind the examination, e.g. the professional examinations team, detailed psychometric analysis, and supporting the psychiatrists who volunteer their time freely to create and quality-assure questions, and analyse the results. For several years now, the examination is budgeted not to make excessive surpluses, but if this inadvertently happens, the surplus is directed to the trainees' fund, which has previously funded the creation of the Trainees Online learning resource, among other projects. Moving to digital platforms may reduce costs to trainees as they no longer need travel or accommodation, and potentially could reduce overall costs as no physical venues are required; however, this is uncertain, and the costs of commercial contracts for software, training and ongoing IT support may counteract this.

Digitisation of examinations

The COVID-19 pandemic led to a rapid and unpredicted introduction of online examinations for the MRCPsych, although the College had plans to begin moving toward digitisation before the pandemic. Although there is a relative paucity of literature on online examinations,¹² one small study, in which a direct comparison of online examinations versus paper examinations was made, showed equivalent reliability and validity.¹³ In terms of candidate performance in online versus paper examinations, the few studies directly testing this have shown no significant differences.^{13,14} Candidates' perception of online examinations are often favourable, and one study found reduced anxiety when taking online compared with traditional paper-based examinations.¹⁴ Possibly, the fact that candidates are not able to see their peers might account for this. However, it is clear that the rapid introduction of digitisation for the MRCPsych caused considerable anxiety in trainees; the same study¹⁴ recognised that the first sitting of online examinations can cause anxiety, which later subsides with familiarity upon repeated testing.

Very short answer questions

Very short answer questions (VSAQs) are a novel format of written questions.^{15–19} A VSAQ consists of a short question for which an answer is required to be manually entered on computer screen from free recall, as open text. There are no options provided to choose from as in MCQs/EMQs. Generally, the answer would be only a few words. *Box 1* shows some examples of how VSAQs may look. Any correct response will attract one mark and any incorrect response will attract zero marks. Examination software would be programmed to recognise multiple versions of correct answers, using smart algorithms. These would allow different versions of a correct response to be recognised. For example, the first question in *Box 1* provides an example of several possible correct answers for that question; all of these answers would attract a full mark, and centre around the idea of a reduction or suppression of the default mode network. The software would additionally be programmed to highlight any answer that is a non-exact match (approximate) to any possible correct answers, and these will be manually reviewed by a designated and trained examiner to ascertain whether that represents a correct response. This will ensure that any unforeseen versions of correct responses will not go unrecognised and unrewarded. That response will then be saved in the list of correct answers for that question for any future examinations. Examiners will also review all other marking done by the computer, to ensure accuracy. Minor spelling errors or typos (e.g. 'inhibited' rather than 'inhibited') will not be penalised and will be picked up during the review process. VSAQs also allow for two entirely different but correct answers, as illustrated in the second example in *Box 1*. In this example, again, either of the responses will attract a full mark. *Box 1* Very short answer question examples. Example 1: A very short answer question with different versions of the correct answer: How does the 'default mode network' react in a healthy brain when one performs a goal-directed task? Correct answers may include, but are not limited to: Decreased activity Reduced activity Inhibited Suppressed Switched off Example 2: A very short answer question with different correct answers: Name the neurotransmitter mechanism thought to be responsible for clozapine-

induced hypersalivation. Correct answers would include: Alpha 2 receptor antagonism, Muscarinic M4 agonism. Again, differing versions of these correct answers would be accepted, e.g. α_2 adrenergic antagonism.

The free recall tested by the VSAQs can be more easily focused on clinically relevant topics, and allow freedom to assess a wider spectrum of the syllabus where MCQs may be impossible to write. This should encourage trainees to refocus on core learning through textbooks and primary papers, and make their knowledge base more clinically relevant in the long term.

In the studies to date, VSAQs have been shown to have higher reliability than MCQs, and reduce the cueing effect.^{15–17} They may improve validity by testing nascent knowledge and clinical skills, rather than the ability to pass examinations.¹⁵ In one study of 300 medical students,¹⁵ 69% of students undertaking VSAQs felt that they were more representative of how they would be expected to answer questions in actual clinical practice, and about half felt that they would change their learning strategies in response. However, these studies were conducted on undergraduate medical students and may not be generalisable to postgraduate psychiatry trainees. Additionally, as far as we are aware, there has not been any published data that uses VSAQs from a high-stakes examination such as the MRCPsych, although at least one other College are considering their introduction for UK medical trainees.²⁰ Finally, as VSAQs require recall rather than recognition, candidates appear to universally score lower in them when compared with MCQs;^{15–19} this must be carefully accounted for in the standard setting process that sets the pass mark, so that standard setting judges are aware of likely lower scores in comparison with MCQs, particularly in first iterations of the test when they are lacking comparative past data. To account for this, there would be pilot questions tested and a full analysis undertaken to inform future standard setting.

Trainees' views on digitisation and VSAQs

The opinion of psychiatry trainees was obtained via a presentation by the Chief Examiner, Dr Ian Hall, to the Psychiatric Trainees' Committee. The Examinations Sub-Committee's Trainee Representative also sought feedback on the Psychiatric Trainees' Committee collaborative platform, 'Workplace'. The questions submitted to the College's webinar, 'MRCPsych Exam – Changes to exam delivery this Autumn', attended by over a thousand psychiatry trainees and supervisors, were also reviewed in summarising concerns with regards to the digitisation of the theory examinations.

Psychiatry trainees raised several concerns with regards to the digitisation of the theory examinations (*Table 2*). In the context of sitting the examinations from home, a common theme was how technical issues, such as insufficient internet connectivity, would be resolved, what support would be available to assist with this, and how the College would ensure candidates were not disadvantaged as a result of technical issues. Trainees also expressed concerns as to how cheating would be identified, particularly the potential to 'trick' proctoring technology, to prevent inflated examination marks disadvantaging other trainees. Similarly, they expressed concerns that trainees may be falsely accused of cheating if they write notes or look away from the screen. The concerns regarding cheating are in keeping with the published literature of both candidates' and examination setters' perceptions of online examinations.¹² Trainees also noted that some trainees' home environments may be unsuitable for sitting examinations, because of caring commitments or house-sharing arrangements. Trainees were also keen to understand how candidates with dyslexia and other specific learning needs would be accommodated. Furthermore, trainees expressed an expectation that examination fees would be reduced in the context of digital examinations. *Table 2* Common themes of trainees' concerns and responses

Concern	Responses
Technical issues, e.g. internet connectivity	The College partners with third-party software providers who have both expertise and a track record in high-stakes online examination delivery. Trainees are encouraged to test the resilience of their internet and device in advance, using provided software. Software developers design software to account for brief interruptions, and protocols exist for more significant technical issues.
Cheating, proctoring and false accusations	All alerts from the artificial intelligence software proctoring are reviewed by a live proctor. Final decisions about cheating are made following rigorous review by the Examinations Sub-committee, and subject to the normal appeals process.
Unsuitable home environment	Candidates can choose any suitable workstation with reliable internet to take the examination, e.g. a family member's or friend's house, a work or university computer.
Examination should not be reduced to a 'spelling test' in very short answer questions	Variations in answers and spelling mistakes will be accounted for, and examiners would review incorrect answers, including typos and spelling errors.

Despite the concerns raised, trainees generally appeared to agree with the prospect of the digitisation of the theory examinations, even outside the current context of COVID-19. However, many expressed a strong preference for these

to be conducted in test centres to prevent technical issues or cheating, and to ensure candidates with home settings unsuitable for sitting examinations were not disadvantaged.

With regards to the introduction of VSAQs, the trainee response was generally positive. Trainees felt it addressed their request for a greater emphasis on the testing of core knowledge and that VSAQs were better at testing the application of knowledge than the current format. However strong concerns were raised with regards to the examinations not becoming a 'spelling test', and particularly that this may disadvantage candidates with dyslexia, other specific learning needs and international medical graduates. They noted that not all spelling errors are of equal clinical significance and where it is clear that a candidate's intended meaning is correct, that this should be accepted as a correct answer.

Conclusions and future directions

The digitisation of examinations is inevitable, and the pace of change has been rapid as a result of the COVID-19 pandemic. For the MRCPsych theory papers, this could bring several improvements in terms of examination delivery, such as improved convenience and access to the examination, and faster processing of results. However, it also brings opportunities for improving assessment. We hope that a careful, phased introduction of alternative question formats such as VSAQs will enable a more comprehensive sampling of the examination syllabus, a greater focus on core knowledge and promote deeper, more holistic and integrated learning strategies. We know that these issues are of importance to trainees and clinical educators alike.

Any change like this requires comprehensive evaluation and testing, and because this is a high-stakes postgraduate medical qualification, the UK General Medical Council will need to prospectively approve any changes.²¹ As mentioned above, before any partial introduction, we plan to pilot questions on trainees and conduct an extensive psychometric analysis of the results. This would include an equality analysis to assess the impact on differential attainment in protected groups. The successful delivery of such a change requires comprehensive stakeholder engagement, and none are more important than the doctors training in psychiatry who take the examination; we plan ongoing consultation with trainees. We must also ensure that our training programmes prepare candidates thoroughly, with supervisors and tutors being up to date with new assessment methodologies and the reasons for their introduction. There would be the potential for online learning platforms to assist trainees with the new style questions. Stakeholder feedback has been largely positive on the face validity of VSAQs, in promoting the acquisition of knowledge that will be useful in clinical practice, and so help deliver better healthcare for people with mental health problems.

We thank the trainees who contributed their views to this paper, both from the Psychiatric Trainees' Committee and those who attended the webinar.

1.1.16 Lack of respect and balance

Margaret White

date

2022-02

Contents

- *Lack of respect and balance*

pmc This editorial and current issue of BJPsych Bulletin do nothing to be ‘respectful and balanced’ about issues of trans health. Reprinting the article which caused the controversy in the first place means that it is exposed to a wider audience, and instead of having a counterbalancing view in another article, it has the article by Griffin et al which contains a number of anti-trans talking points. Anything which is supportive of trans people or current best practice standards for trans health is relegated to the letter pages. None of the authors of the two articles are gender identity specialists; they have instead mobilised their credentials in other areas to claim expertise in an area where they have none. The voices of trans people are either absent or denigrated as some kind of online-based groupthink.

Trans health is its own research field, and there are plenty of researchers that the *Bulletin* could have reached out to for a counterbalancing view. Instead, they have amplified anti-trans voices once more, with a sop that those with opposing views could write a letter or propose an article.

I am not seeking to silence debate, and acknowledge that this is a controversial area. However, issues around trans health are treated particularly poorly in the *Bulletin*. Would the *Bulletin* accept having two papers on women’s mental health written solely by men who had no expertise in women’s mental health, or two papers on ethnic minority mental health written solely by white people who had no expertise in ethnic minority mental health? If not, why is it acceptable for this to happen for trans people?

1.1.17 Vivienne Cohen, MRCS, LRCP, FRCPsych

Kate Lockwood Jefford

date

2022-02

Contents

- *Vivienne Cohen, MRCS, LRCP, FRCPsych*

pmc Formerly Senior Lecturer and Consultant Medical Psychotherapist, St Bartholomew's Hospital and Medical College, London, UK

Vivienne Cohen, who has died at the age of 94, was a visionary, award-winning psychiatrist at the forefront of the developing fields of National Health Service (NHS) psychotherapy and group analytic treatments. A talented protégé of the pioneering psychoanalyst and military psychiatrist S.H. Foulkes, and the first female doctor to train in group therapy, she was a founder member of the Institute of Group Analysis (IGA) and developed one of the earliest out-patient psychotherapy departments, establishing creative links between the NHS and IGA that remain today. Her passion for training doctors and allied professionals earned her an international reputation as a teacher and supervisor.

Born Vivienne Wolfson on 1 November 1926 in London, she attended the first Jewish primary school in north-west London – co-founded by her father in 1932 – but, as war forced the family to move between London and grandparents in Hove and Ayrshire, her secondary education was fragmented across eight different schools. Vivienne studied determinedly to catch up, alongside looking after her younger sister and baby brother, early evidence of her indefatigable commitment to education and caring for others.

Her parents – and the entrenched patriarchy of the time – expected her to leave school at 14 and train as a secretary, but Vivienne had other ideas: she wanted to be a doctor. She recruited her strong-minded paternal grandmother, who argued that Vivienne was ‘too clever’ to leave school. Her parents listened.

In 1945, Vivienne won a state scholarship to University College – one of three London medical schools that accepted women – entering a pre-clinical year where one in five students were female, and completed clinical training at West London Hospital Medical School, founded to prioritise access to women. A fellow student described her as ‘principled, steady with purpose, full of ideals, brilliant and insightful, but always with a spirit of fun and humour’. In 1950 she won the Rudolf Konstan prize for medicine and she qualified in 1951.

Entering the Maudsley Hospital in 1957 as a trainee, Vivienne met Foulkes, renowned for developing innovative group treatments at the Military Neurosis Centre at Northfield. ‘Michael’, as he was known to family and close friends, became her lifelong supervisor, mentor and friend. In 1962, after working for Professor Linford Rees – a ‘marvellous’ experience where she taught and supervised psychiatric social workers – she was appointed chief assistant psychotherapist to Foulkes in his service at St Bartholomew's Hospital. After Foulkes retired in 1963 she led the service single-handedly at consultant level, expanding and improving provision to growing numbers of referrals by providing treatment both directly and from medical students and trainee psychiatrists and non-medical psychotherapists under her supervision.

In 1978 Vivienne was formally appointed consultant medical psychotherapist and senior lecturer – a rare academic post in psychotherapy – at St Bartholomew's Hospital and Medical College, and continued to build and organise the service to become one of the most reputable in the UK. In 1983 she won a national award – the first prize of this kind for psychotherapy – for her ‘imaginative’ audio-visual study of group therapy technique and practice for training purposes. In 1985 she received a Levenhulme Teaching Fellowship to support her programme of supervised clinical placements for non-medical IGA trainees. These ‘internships’ were highly competitive, as they provided a wealth of clinical experience and expert supervision, as well as enhancing the service's group treatment capacity alongside individual, couple and family therapies. In 1987 this model won her a Barnett Prize for efficient use of NHS resources.

Vivienne was a senior member of staff at the IGA and served on many local, national and international committees with an emphasis on service provision and training. She was invited frequently to teach abroad, including Denmark, Italy and Australia, and ran an intensive group therapy course in Israel. She published extensively on groups in major

journals¹ and textbooks^{2,3}, covering many aspects, including supervision, training, NHS provision, cultural factors, large groups and organisational dynamics. Her vision and commercial and organisational skills played a key part in securing the building in Daleham Gardens, NW3 that is still home to the internationally renowned IGA today.

In 1955 Vivienne married Sam Cohen, a liaison psychiatrist and former professor of psychiatry at the Royal London Hospital. It was a supportive relationship with mutual regard for their respective specialties: Sam's ward milieu drew on therapeutic community principles and Vivienne published on psychological aspects of medical conditions. Sam died in London in 2004.

Vivienne eschewed private practice, preferring to work in the NHS providing what people needed, not what they could afford. Following retirement she set up a charitable foundation to fund a group psychotherapist post in the City & Hackney Psychotherapy service. When the service relocated to premises near Homerton Hospital, staff wanted a new, distinct name and, in August 2014, Vivienne Cohen House was opened at an event she attended with family, describing herself as 'bowled over'. The chair of East London NHS Foundation Trust thanked Vivienne for her contribution to psychotherapy for residents of the City of London and Hackney over half a century, nurturing the service from its origins, sharing her skills and knowledge with patients, colleagues and trainees. Many of her trainees working today will remember their first experiences of psychotherapy supervision for her astute recall of clinical detail and her tactful creation of both personal and clinical insights in the warm ambience of her office.

Charming, vivacious and sharp, Vivienne Cohen was an independent thinker and courageous doer, a dedicated clinician and inspiring teacher. Always direct and honest, she saw herself not as a pioneer or 'anything special',⁴ but as someone who did what needed to be done.

Loved and admired by her children Michael and Elisheva, five grandchildren and many great-grandchildren, Vivienne was excited by the next generation, encouraging them to pursue their dreams and celebrating their achievements.

Since retirement, she divided her time between Israel and London and enjoyed opera, museums and ballet.

In January 2021, Dr Vivienne Cohen passed away at home in Israel with her family around her.

With thanks to Dr Cohen's family, Mark Salter, John Schlapobersky and Gyles Glover.

1.1.18 Author's reply

Norman Poole

date

2022-02

Contents

- *Author's reply*

pmc I thank Dr Margaret White for the letter in response to my recent editorial 'Publishing controversy'. It raised important challenges. Why have the trans health papers been published online and in print even though written by non-specialists in gender identity, and should opposing views be relegated to the Correspondence section? First, all papers published online also appear in the paper journal eventually. To do otherwise would have marked these papers out as

somehow different. Dr White does not wish to silence debate, but not publishing in print form as usual would be a form of censure even if not censor. Although this is a controversial and contested area, the papers did not express extreme views. In fact, Marci Bowers, president-elect of the World Professional Association for Transgender Health, recently raised concerns similar to those expressed in the *Bulletin* papers. However, we remain keen to present all opinions so have commissioned papers from gender identity experts, which are making their way through the editorial process. When the papers by Griffin et al and Evans were published on First View, they quickly attracted several complaints with demands for their retraction, which as explained in the editorial was not appropriate. Those authors were invited to write opposing articles but unfortunately, for their own reasons, none took up the offer. Hence our decision to publish all the available letters alongside the original papers so readers can evaluate the arguments for themselves. I hope this and the forthcoming papers assures Dr White that no one's voice is relegated to the correspondence section in the *BJPsych Bulletin*, but letters, such as Dr White's, are also an invaluable element of discourse.

1.1.19 Self-harm and suicide in adults: will safety plans keep people safe after self-harm?

Allan House

Correspondence

Allan House (a.o.house@leeds.ac.uk)

date

2022-02

Abstract

Safety planning is recommended as a part of the response to everybody who presents after self-harm, although there is surprisingly little evidence for its effectiveness. There is potential for such plans to be experienced as unhelpful if patients are not genuinely involved in their production and if the plan does not include information about meaningful sources of support. Staff training is needed to ensure that plans are delivered in a collaborative way and self-harm services need to be improved nationally if such plans are to be effective.

- *Self-harm and suicide in adults: will safety plans keep people safe after self-harm?*
 - *What is safety planning?*
 - *How effective is safety planning after self-harm?*
 - *Could safety planning have detrimental effects?*
 - *Can we mitigate the potential harms of poorly managed safety planning?*
 - *Declaration of interest*

pmc It has been known for a long time that the risk of suicide is greatly increased after hospital presentation due to self-harm.¹ England's National Suicide Prevention Strategy recognises this risk and its 2017 report 'expanded the scope of the National Strategy to include self-harm as a new key area for action'.² This welcome policy change brings with it a dilemma – how to respond to self-harm as a suicide risk while at the same time responding to its many other meanings. Suicide is perhaps the worst outcome in psychiatry and inevitably captures our attention – can we develop our services to respond to the risk without at the same time allowing the 'risk-reduction' aspect of service provision to overshadow the rest of the process of care? The recent Royal College of Psychiatrists (RCPsych) report *Self-harm and Suicide in Adults* (CR229)³ can be read as an attempt to answer this question.

What is safety planning?

The RCPsych's report is forthright in stating that there is more to assessment after self-harm than judging suicide risk and that management should involve a 'holistic psychosocial approach' at the core of which, at least in the short term, is making a safety plan. According to the report, such a plan comprises: individual strategies or activities to instil hope; calming or distracting activities; restriction of access to common means of suicide; and contacts for social and crisis support.³ It has to be said that some of the illustrative activities seem a bit weak for the work they have to do – looking at a photo of a great view or doing Sudoku for example – but if the plan is genuinely co-produced then its elements might be expected to make sense to the person to whom it applies.

There are a number of similar approaches to that proposed by the RCPsych, and something very similar forms a part of the risk management plan endorsed by the National Institute for Health and Care Excellence (NICE) as an essential component of the response to self-harm.⁴ On the face of it, it seems like an uncontroversial recommendation that everybody should indeed have something like a safety plan: does that initial impression hold up to closer scrutiny, especially in relation to the dilemma under discussion here?

How effective is safety planning after self-harm?

The first thing to say is that, given how roundly they are endorsed by the RCPsych, there is surprisingly little evidence to support the use of safety plans as a means of reducing repetition of self-harm. In fact, CR229 cites only one supportive study,⁵ a retrospective case-note review of 48 cases from the USA. Elsewhere, a small randomised controlled trial ($n = 97$) of active-duty US Army soldiers⁶ reported, in a comparison of a crisis response plan versus a 'contract for safety', an effect on self-reported attempted suicide at 6 months (3/64 v. 5/33 participants). A recent review of suicide prevention interventions⁷ reported a positive effect on subsequent self-harm rates but the positive outcome for that part of the review is accounted for by only two studies: one⁸ is a study of men in active military service which used multiple outcomes and reported a reduction in self-reported attempted suicide but not in emergency department attendances for self-harm. The other⁹ is a non-randomised comparison of Veterans Affairs hospitals; 90% of participants were men with 'suicide-related concerns' and the primary outcome (a composite measure of 'suicidal behaviour') was found in 3–5% at 6 months. The results of these studies are not only unconvincing but they are not generalisable to the UK self-harm population.

Of closer relevance to the position of UK clinicians seeing people after an episode of self-harm is the non-randomised Emergency Department Safety Assessment and Follow-up Evaluation (ED-SAFE) study,¹⁰ which reported self-reported suicide attempts but not all self-harm episodes, citing a 12-month difference of 20.9% (treatment as usual) v. 18.3% (intervention) – a result that is by no means definitive given the study design. The only UK randomised controlled trial of a comparable intervention¹¹ – called a volitional help sheet, with many of the features of a suicide prevention plan – found no difference in 6-month self-harm repetition rates between usual care and the new intervention.

Could safety planning have detrimental effects?

Does the lack of evidence of effectiveness matter? Isn't such a common-sense action worth implementing regardless of limited evidence of its effectiveness? The reason to be cautious is that there are non-trivial possibilities of unwanted outcomes from a misapplication of the approach – misapplication, that is, in the way the plan is introduced, how it is negotiated and what are its specific components. If adverse consequences are to be avoided then they need to be considered by the service during the planning and delivery of suicide prevention plans after self-harm.

One possible problem arises from the degree to which the implementation of the suicide prevention plan is left to the person who has self-harmed. The first four of the six suggestions under the heading 'sources of support' in the RCPsych report relate to marshalling social or informal supports,³ yet we know that people who self-harm find it difficult to confide in others^{12,13} and may be struggling with mood disorder and difficulties with problem-solving – problems that can exacerbate difficulties in calling on the assistance of others. The social network can be a positive resource or, on the other hand, a source of the adversity underlying self-harm, and it is not easy to get a clear picture during a single brief encounter: the result is that it can be neglected or misunderstood, especially during an assessment oriented towards the identification of individual pathology. Personal accounts, especially given by those with a history of repeated self-harm, indicate that conversations with staff can emphasise strongly this assumption of individual responsibility, for example by referring pointedly to the person's mental capacity.

The second substantial problem arises from the organisational context within which planning usually takes place. In truth, service provision for many people after self-harm is poor. Typically, self-harm, despite its associated suicide risk, is not seen as falling within the remit of community mental health teams or Improving Access to Psychological Therapies (IAPT) services and yet there are very few specialist clinics. Again, from accounts of people with personal experience, this general lack of provision is exacerbated by the prevalence of the unhelpful concept of non-suicidal self-injury¹⁴ – a diagnosis that suggests (misleadingly) that the individual is at low risk of suicide and that can therefore make accessing services difficult because the problem is not seen as sufficiently severe.

The worst case, then, is that a clumsily negotiated or unilaterally developed safety plan, coupled with inaccessible professional aftercare, leads to a sense of being left alone in managing the impulse to self-harm and its attendant dangers. We do not know the frequency with which these negative outcomes occur, because the relevant research has not been undertaken.

Can we mitigate the potential harms of poorly managed safety planning?

One of the recurring complaints about self-harm services is that risk assessment is so often delivered as a thoughtless box-ticking exercise. To avoid safety planning going the same way it has to be delivered as a genuinely collaborative effort. A pre-printed form with little space for personalisation will not convey the right message or serve the purpose. Staff who are going to be undertaking safety planning should therefore be trained in techniques for joint planning – which may be drawn from those with expertise in techniques such as shared decision-making.¹⁵

Quality improvement projects should be aimed not just at monitoring comprehensiveness of coverage; they could usefully explore the experience of safety planning from the perspective of people who have attended hospital after self-harm – including their level of personal involvement in the content and their sense of the usefulness of the plans. A starter might be the measure developed by NICE.¹⁶

Making safety planning meaningful depends on the accuracy and usefulness of nominated sources of support, and yet informal sources can be difficult to identify and engage in a single session after an episode of self-harm, while professional sources (such as specialist services) are not available in most places, even at the level of telephone follow-up. If we are to be serious about making self-harm 'a key area for action' then we must press for proper professional services for those seen after self-harm – to allow immediate follow-up for help responding to current circumstances and in the longer-term to offer therapeutic support for change. It is these services that will allow resolution of the dilemma of care – making risk reduction meaningful without allowing risk management to define the healthcare response to self-harm.

Research is needed to determine the effectiveness and safety of safety planning, as an adjunct or alternative to standard assessments and follow-up planning. Research in other areas has usefully shown that an important moderator of out-

comes is the degree to which there is genuine collaborative engagement of patients with planning,¹⁷ and such process evaluation would be an important component of any future evaluation.

Allan House is Emeritus Professor of Liaison Psychiatry in the Leeds Institute of Health Sciences, School of Medicine, University of Leeds, UK. His research interests include the overlap between physical and mental disorder, medically unexplained symptoms, suicide and self-harm.

Abstract

Aim and Method

To determine the effect on decisional-related and clinical outcomes of decision aids for depression treatment in adults in randomised clinical trials. In January 2019, a systematic search was conducted in five databases. Study selection and data extraction were performed in duplicate. Meta-analyses were performed, and standardised and weighted mean differences were calculated, with corresponding 95% confidence intervals. The certainty of the evidence was evaluated with GRADE methodology.

Results

Six randomised clinical trials were included. The pooled estimates showed that decision aids for depression treatment had a beneficial effect on patients' decisional conflict, patient knowledge and information exchange between patient and health professional. However, no statistically significant effect was found for doctor facilitation, treatment adherence or depressive symptoms. The certainty of the evidence was very low for all outcomes.

Clinical implications

Using decision aids to choose treatment in patients with depression may have a beneficial effect on decisional-related outcomes, but it may not translate into an improvement in clinical outcomes.

pmc .. _sec1-1:

Depression and decision-making

Depression is the most frequent psychiatric disorder and the third most frequent cause of disability-adjusted life-years.^{1,2} The majority of patients with depression are eligible to receive treatment, which includes different psychological and pharmacological interventions^{3,4} that seem to have similar efficacy.^{5,6} However, patients with depression frequently have low access⁷ and adherence to depression treatment.⁸

Patients with depression want to receive more information about their disorder, and participate in their health-related decisions.^{9,10} In this sense, shared decision-making is an approach for patient-centred care that seeks to actively involve patients in the decision-making process of choosing between two or more medically acceptable and evidence-based treatment options.¹¹ It is hypothesised that active patient involvement empowers the patient and could improve treatment adherence and satisfaction rates, which may result in better treatment effectiveness.^{12–14}

Decision aids in depression

Decision aids are the main tools used to facilitate shared decision-making and support patients in making informed choices.¹⁵ These materials are developed in different formats (paper, video, web-based tools, etc.), and describe the condition and the benefits and harms of each treatment option, and encourage patients to identify which outcomes are the most important for them when making a choice.^{16,17} Usually, these interventions have to be adapted according to specific population needs, considering the context of their application.¹⁸ The decision aids mainly seek to improve patient knowledge, decisional conflict and patient–clinician communication.¹⁹ Additionally, they have also been studied to explore their clinical effects, such as treatment adherence²⁰ or reduction of symptoms.²¹

Although the use of decision aids may cause benefits such as higher treatment adherence and, therefore, higher clinical improvement, it may also cause harm, such as an increased level of patient stress.²² In addition, people with major depressive disorder could have abnormal decision-making behaviour in a social interaction context because of an altered sensitivity for reward and punishment, reduce experiences of regret and poor decision performance.²³ This situation could also affect the use of decision aids in patients with depression.

Regarding decision aids for depression treatment, there is still concern about the benefit–harm balance, although some studies have assessed their effects. Therefore, this systematic review aimed to search for randomised clinical trials (RCTs) to assess the effects of decision aids on the shared decision process and clinical outcomes in adults with depression.

Method

The protocol for this systematic review has been registered with the International Prospective Register of Systematic Reviews (PROSPERO; identifier CRD42019121878). This study was approved by the Institutional Review Board of the Human Medicine Faculty of Ricardo Palma University (CE-8-2019).

Literature search and study selection

For this systematic review, we included all RCTs that included adults with any type of depression. These RCTs must have compared a group that received a decision aid that aimed to help patients decide about their treatment for any kind of depression treatment (as a stand-alone intervention, or as the main element within a complex intervention) with a group that did not, and directly assessed any beneficial or adverse effects in adults with depression. We excluded RCTs that had as population only pregnant women because they have different risks that should be considered when deciding whether to use antidepressants.²⁴ Also, we excluded conference papers. There were no restrictions on language or publication date.

Decision aids were defined as tools or technologies used to help patients make informed decisions by offering information about treatment options, and help them to construct, clarify and communicate their values and preferences.²⁵ However, sometimes it is difficult to differentiate from other information-based interventions.²⁶ To define if the proposed intervention was a decision aid, we used the six-item qualifying criteria for decision aids developed by the

International Patient Decision Aid Standards Collaboration, as it provides the definition standards for decision aids: (a) describes the health condition or problem for which the index decision is required, (b) states the decision that needs to be considered, (c) describes the options available for the index decision, (d) describes the positive features of each option, (e) describes the negative features of each option and (f) describes what it is like to experience the consequences of the options.²⁷

The decision aid assessed by the RCTs needed to meet all six criteria to be included in our systematic review.

A literature search was performed in two steps: a systematic review of five databases, and a review of all documents cited by any of the studies included in the first step. For the first step, we performed a literature search in five databases: Medline, EMBASE, Scopus, Web of Science and ClinicalTrials.gov. We used terms related to decision support, decision aid, decision-making, depression and clinical trials. The complete search strategies for each database are available in Supplementary File 1 available at <https://doi.org/10.1192/bjb.2020.130>. The last update of this database search was performed on 5 January 2019. Duplicated records were removed with EndNote version X8 for Windows (Clarivate Analytics, Thomson Reuters, New York; see <https://endnote.com/>). After that, titles and abstracts were independently screened by two pairs of independent reviewers (C.A.A.-R. with M.E.D.-B., and N.B.-C. with C.J.T.-H.) to identify potentially relevant articles for inclusion. This was performed with the online software Rayyan version 01 for Windows (Qatar Computing Research Institute, Qatar Foundation, Qatar; see <https://rayyan.qcri.org>).²⁸ Disagreements were resolved through a discussion with a third reviewer (J.H.Z.-T.). Then, the full text of potentially relevant articles were assessed to evaluate their eligibility. This process was also independently performed by two researchers. The complete list of excluded articles at this full-text stage is available in Supplementary File 2.

For the second step, two independent reviewers (M.E.D.-B. and N.B.-C.) assessed all documents listed in the references section of the studies selected in the first step, and collected all articles that fulfilled the inclusion and exclusion criteria.

Data extraction

Two independent researchers (C.A.A.-R. and M.E.D.-B.) extracted the following information from each of the included studies into a sheet of Microsoft Excel version 2018 for Windows: author, year of publication, title, population (inclusion and exclusion criteria), setting, intervention (name, type, the methodology of application and length of use), comparator (name, type, the methodology of application and length of use), time of follow-up and effects of decision aid in all included outcomes.

Intervention information was collected with the Template for Intervention Description and Replication (TIDieR) checklist.²⁹ The checklist originally was designed for pharmacological interventions; thus, we included only the following items, adapted for more complex interventions: name of intervention, rationale, location of delivery, materials, procedures, who provided, modes of delivery (grouped or individual), frequency (sessions) and possible options to choose within the decision aid. In case of disagreement, the full-text article was reviewed again by the researchers, to reach a consensus.

Study quality and certainty of the evidence

Two independent researchers (C.A.A.-R. and N.B.-C.) used the Cochrane Risk of Bias Tool for RCTs to assess systematic errors (or bias) in the design, conduct, analysis and reporting of the RCT that could potentially underestimate or overestimate the results.³⁰ We followed the instructions stated in the Cochrane Handbook for Systematic Reviews of Interventions and evaluated selection bias, performance bias, detection bias, attrition bias and reporting bias to assess each of the six domains of the tool as low, high or unclear risk of bias, by each RCT included in the systematic review.³¹

To assess the certainty of the evidence, we used the Grading of Recommendations Assessment, Development and Evaluation (GRADE) methodology,³² which classifies it in a very low, low, moderate or high certainty of the evidence each outcome in the systematic review. This classification is based on the following criteria: risk of bias (evaluated through the Cochrane Risk of Bias Tool), inconsistency (heterogeneity between the RCT results and in terms of population, intervention, comparator and outcome; additionally assessed by the I^2 test), indirectness (how different are the included RCTs to the question of interest) and imprecision (width of the confidence interval). The certainty of the evidence

was assessed for all meta-analysed outcomes and non-meta-analysed outcomes that were important for decision-making. Additionally, when two or more RCTs assessed the same outcome, but a meta-analysis was not performed, we summarised the individual data of each RCT narratively, and then assessed the certainty of the evidence following the recommendations proposed by Murad et al.³³

Statistical analyses

We performed meta-analyses to summarise the results of the RCTs that evaluated the same outcomes. When outcomes were measured with different scales across studies, we calculated standardised mean differences (SMD) to compare and meta-analyse these studies; otherwise, we calculated weighted mean differences (WMD). For outcomes that had been measured more than once, we only considered the final measurement to perform the meta-analyses, as suggested in the Cochrane Handbook.³¹ We assessed heterogeneity with the I^2 statistic, and we considered that heterogeneity might not be significant when $I^2 < 40\%$.³¹ We considered it appropriate to use random-effects models in all the meta-analysis because of the overall heterogeneity in terms of population, intervention and comparators.³⁴ We executed a sensitivity analysis, taking into account contradictory results within studies. We did not consider to exclude studies with high risk for bias for sensitivity analysis, because all the included RCTs had at least one domain of the Cochrane Risk of Bias Tool with a high risk of bias. Also, we did not execute a subgroup analysis because of the low number of studies by each meta-analysis. Publication bias was not statistically assessed because the number of studies pooled for each meta-analysis was less than ten.³⁵ The data were processed with Stata version 15.0 for Windows.

Results

Studies characteristics

We found a total of 3309 titles. We removed 804 duplicates and screened a total of 2505 titles, of which 41 were evaluated in full text. Of these, 35 were excluded (reasons for exclusion are detailed in Supplementary File 2) and six were included.^{17,36–40} Additionally, we evaluated 255 documents cited by any of the six included studies, from which no additional study was included (*Fig. 1*). *Fig. 1* Flow diagram (study selection). RCT, randomised controlled trial.

Patient characteristics

In the included RCTs, the number of participants ranged from 147 to 1137. Regarding the study setting, three studies were performed in primary care centres,^{17,38,39} one in out-patient clinics³⁷ and two were performed remotely (one intervention was sent by mail to the participants³⁶ and one was an online intervention⁴⁰). With regards to depression diagnosis for inclusion criteria, two studies used the Patient Health Questionnaire-9,^{38,39} one study used the DSM-IV,³⁷ one study used the DSM-IV and the ICD-10,¹⁷ one used self-report criteria⁴⁰ and another did not specify the diagnosis criteria.³⁶ Also, only one study specified the severity of depression according to the inclusion criteria.³⁸ Characteristics of each included study are available in Supplementary File 3.

Interventions and comparators

Interventions were heterogeneous across studies; four studies used visual decision aid (leaflets, booklet, cards or DVD),^{36–39} and two studies used a computer-based decision aid (webpage or artificial intelligence).^{17,40} Regarding the decision aid application: in two studies, physicians applied the decision aids,^{38,39} in two studies the decision aids were self-applied,^{17,36} in one study the decision aids were applied by a pharmacist³⁷ and in one study decision aids were applied by artificial intelligence.⁴⁰ All decision aids presented possible options regarding the patient's depression treatment. Specifically, four decision aids presented options for the use of antidepressant drugs, psychotherapy/psychological treatment or watchful waiting.^{17,37,39,40} Furthermore, two decision aids presented options for start, stop, increase or switch antidepressant treatment.^{36,38} Intervention's characteristics are detailed in Supplementary File

4, using the TIDieR checklist. Regarding the control group, in five studies, participants received either usual care or no intervention, and in the remaining study, the decision aid was compared with an informative intervention.⁴⁰

Outcomes

Included RCTs assessed a wide variety of outcomes, including decision-making process outcomes, such as decisional conflict, information exchange, patient knowledge, patients involvement in decision-making, decision regret, etc. Decisional conflict is known as the degree of patient insecurity about possible consequences that occur after deciding their health,⁴¹ and information exchange assess the communication between doctor and patient about their illness and its management when there is a need to decide on patient's health.⁴² Additionally, there are also clinical outcomes (such as depressive symptoms, adverse effects, treatment adherence and health-related quality of life). All the measured outcomes and definitions, by each RCT, are presented in *Table 1*. Table 1 Outcomes evaluated in the included studies Aljumah et al, 2015³⁷ LeBlanc et al, 2015³⁸ Loh et al, 2007³⁹ Simon et al, 2012⁴⁰ Perestelo-Perez et al, 2017¹⁷ Sepucha et al, 2012³⁶ Adherence: Morisky Medication Adherence Scale (0–8 points) Adherence: Patient self-report and pharmacy records to categorise patients' adherence (Yes or no adherence) Adherence: single question: 'How steadily did you follow the treatment plan?' (1–5 points, Likert scale) Adherence: single question (0–100 standardised points) Decisional control preferences: Control Preference Scale Adverse effects: mortality Health-related quality of life: EuroQol-5D in Arabic version (0–100 points) Decisional conflict: Decisional Conflict Scale (0–100 points) Consultation time: documented in minutes by the physicians, following each consultation (minutes) Decisional conflict: Decisional Conflict Scale (0–100 points) Decisional conflict: Decisional Conflict Scale (0–100 points) Patient involvement in the decision-making process: Observing Patient Involvement in Decision-Making scale (0–100 points) ^a Knowledge: self-developed questionnaire (0–100 points) Patient involvement in the decision-making process: Man-Son-Hing-instrument (patient perspective) Knowledge: self-developed questionnaire (0–100 points) Knowledge: self-developed scale of knowledge of treatment options (0–8 points) Knowledge: self-developed questionnaire about depression and methods for managing depression symptoms (0–100% correct answers) Depressive symptoms: Montgomery–Åsberg Depression Rating Scale (0–60 points) Depressive symptoms: PHQ-9 Depressive symptoms: Brief PHQ-D Decision regret: Decision Regret Scale (0–100 points) Treatment intention: question: 'If you had to choose a treatment right now, what treatment would you choose?' ² Results not presented in the paper.

Risk of bias

Regarding the risk of bias, mostly all RCTs detailed random sequence and allocation concealment. Two RCTs presented a high risk of attrition bias because they some participants were lost to follow-up. Furthermore, three RCTs had an unclear risk of bias for selective reporting. All six RCTs failed to blind the outcome assessment, and five RCTs failed to blind personnel and participants (*Fig. 2*). *Fig. 2* Risk of bias in the selected studies.

Effects on decision-making process outcomes

When pooling the RCTs, we found that decision aids had a beneficial effect on information exchange (two RCTs; WMD 2.02; 95% CI 1.11–2.93), patient knowledge (four RCTs; SMD 0.65; 95% CI 0.14–1.15) and decisional conflict, which refers to patient insecurity about the possible consequences that occur after deciding their health (three RCTs; WMD 5.93; 95% CI 11.24 to 0.61). Additionally, we found no statistically significant effect on doctor facilitation (two RCTs; WMD 1.40; 95% CI 4.37 to 7.18).

Regarding the outcome of patient involvement in the decision-making process, two RCTs present their results for this outcome, but each of them used a different instrument and perspective of assessment. Loh et al³⁹ used the Man-Son-Hing scale (patient perspective) and found a statistical difference between study groups (mean difference 2.5; 95% CI 1.6–3.4). Alternatively, LeBlanc et al³⁸ used the Observing Patient Involvement in Decision-Making scale (evaluator perspective), and also found a statistical difference between study groups (mean difference 15.8; 95% CI 6.5–25.9).

The remaining decision-making process outcomes were assessed only by one RCT, and we did not find differences between the study groups in terms of length of consultation,³⁹ decisional control preference (between passive, active or shared)¹⁷ and decision regret.⁴⁰ However, we found a beneficial effect to be sure of the intention to choose a treatment (sure or not sure),¹⁷ in the treatment satisfaction,³⁷ in the decision aid satisfaction³⁸ and the preparation of patients for decision-making.⁴⁰

Effects on clinical outcomes

We did not find beneficial effect on treatment adherence (three RCTs; SMD 0.20; 95% CI 0.31 to 0.71), and depressive symptoms (three RCTs; SMD 0.06; 95% CI 0.22 to 0.09) (*Fig. 3*). Also, one RCT evaluated one adverse effect, mortality, and reported no adverse effects in both intervention and control arms,³⁶ and another one found no differences between study groups for health-related quality of life.³⁷ *Fig. 3*(a) Forest plot of decision aid for decisional conflict, higher is worse. (b) Forest plot of decision aid for patient knowledge, higher is better. (c) Forest plot of decision aid for depression symptoms, higher is worse. (d) Forest plot of decision aid for treatment adherence, higher is better. (e) Forest plot of decision aid for doctor facilitation, higher is better. (f) Forest plot of decision aid for information exchange, higher is better. SMD, standardized mean differences; WMD, weighted mean differences.

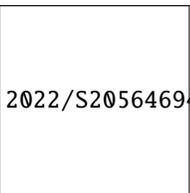

Sensitivity analysis

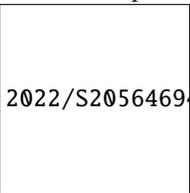

Three of the performed meta-analyses had important heterogeneity ($I^2 > 40$). Of these, only the meta-analysis performed for treatment adherence (three RCTs; SMD 0.20; 95% CI 0.31 to 0.71) included studies with contradictory results. Thus, we executed a sensitivity analysis for this outcome, excluding the RCT by Simon et al,⁴⁰ because its results contradicted the other results of the two RCTs by Loh et al and Aljumah et al.^{37,39} The global effect of this sensitivity analysis, with only two RCTs, was an SMD of 0.50 (95% CI 0.29–0.70).

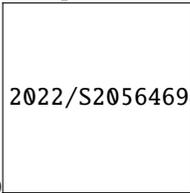

Certainty of evidence

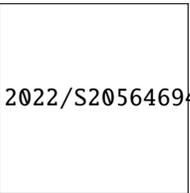

We created a Summary of Findings table, using the GRADE methodology to assess the certainty of evidence. For this, we included those outcomes that were considered important for the patient and/or their practitioner. We found that the evidence for all these outcomes was of very low certainty, mainly because of high risk of bias, inconsistency and imprecision of RCTs (Table 2). Table 2 Summary of findings to evaluate the certainty of the evidence, using the GRADE methodology

Discussion

We included six RCTs that evaluated the effects of decision aid in adults with depression. These studies were heterogeneous, had small sample sizes and presented with a high risk of bias. When pooling the RCTs, we found benefits in some outcomes such as decisional conflict, patient knowledge and information exchange, but not in clinical outcomes such as depression symptoms or treatment adherence. All of the outcomes included in the Summary of Findings table had very low certainty of evidence.

The interventions used in the six included RCTs fulfilled all the qualifying items from the International Patient Decision Aid Standards Collaboration criteria.²⁷ However, there was heterogeneity regarding the type of decision aids used (including leaflets, booklets, cards, DVD, a webpage or artificial intelligence), treatment options in the decision aids and by whom they were administered (physicians, pharmacists, researchers or the patient themselves). This heterogeneity is expected because the use of the decision aids largely depends on context, and has to be adapted according to population needs.¹⁸ However, the fact that there were not even two studies that used the same decision aid affects the capability of synthesis and interpretation of the pooled results.⁴³

Regarding the quality of the included RCTs, participants were not blinded because of the intervention's intrinsic nature. This represents an important source of bias as the perception of subjective outcomes could have been influenced.⁴⁴ Additionally, most RCTs used a no-intervention group as the control without placebo. However, using an information-based intervention about treatment options for depression without a decision-making process as a control group in the RCTs would have helped to prevent the complex intervention effects, and ensure that the effects of the decision aid are not explained only by higher attention from a health professional.⁴⁵

Regarding the effects of decision aid, our pooled estimates suggest no effect in clinical outcomes, as described by a previous review that assessed decision aid in patients with mood disorders and found no effect with depressive symptoms,⁴⁶ and by another systematic review that assessed decision aid for screening tests and found no effect in treatment adherence.⁴⁷ These results could be explained by a linear and logical sequence that we propose. First, the decision aid gives the information to the patient about depression and its treatment options, which explains the 'knowledge' improvement. Then, the patients are more capable of discussing the disease and their treatment options with

³ EuroQol-5D, European Quality of Life-5 Dimensions; GRADE, Grading of Recommendations Assessment, Development and Evaluation; RCT, randomised controlled trial; s.d., standard deviations.

⁴ Higher points are better.

⁵ Blinding of allocation, personnel and/or outcome assessment was not detailed in the publication. Incomplete data are reported.

⁶ Sample sizes were small (<400).

⁷ Selective reporting was not evaluated as the protocol was not available.

⁸ $I^2 > 40\%$.

⁹ 95% confidence intervals include 0.5 value.

¹⁰ Higher points are worse.

the health professional, which explains the ‘information exchange’ improvement. Later, the patient feels capable of making a choice, which explains the decrease in ‘decisional conflict’. After making a choice, the patients receive their treatment and feel satisfied with their decision, which improves the ‘sure of the intention to choose a treatment’, the ‘treatment satisfaction’ and the ‘decision aid satisfaction’. Lastly, it would be expected that all of these achievements are translated into clinical outcomes: a higher treatment adherence and subsequent reduction of depressive symptoms.

However, regarding this last point, other factors could influence clinical outcomes. Adherence could be affected by accessibility to the treatment, the way the patients perceive the effectiveness of the treatment, severity of the disease, etc.⁴⁸ Additionally, depressive symptoms could be affected by the treatment adherence itself, the adequacy of the chosen treatment for the clinical characteristics of the patient and other psychosocial factors.⁴⁹ In addition, some methodological issues could explain the results. None of the studies included in the meta-analysis of depressive symptoms, and only one of the three studies included in the meta-analysis of treatment adherence were designed to assess those outcomes, so there could have been a lack of power to find a difference between study groups.

The pooled analysis found no effect of decision aids on treatment adherence (SMD 0.31 to 0.71). This meta-analysis included three RCTs.^{37,39,40} One of them⁴⁰ contradicted the results of the other two, in addition to having the smallest sample size and the highest risk of bias (as a result of attrition bias and small sample size). Thus, a sensitivity analysis removing that RCT found a beneficial effect of decision aids for treatment adherence (SMD 0.50; 95% CI 0.29–0.70). Thus, we cannot exclude a possible positive effect of decision aids on treatment adherence, which has to be assessed in future studies.

On the other hand, we did find beneficial effects in decision-making process outcomes, such as decisional conflict, information exchange and patient knowledge, similar to a previous review.⁴⁶ These three outcomes are expected for a decision aid designed to facilitate the shared decision-making process. Five^{17,36–38,40} out of six RCTs assessed decision aids developed to enhance patients’ involvement in the decision-making process, support their choices, empower them and improve their knowledge about their therapeutic options. Consequently, the decision aid’s main objective may determine the outcomes (decision process or clinical outcomes) it will affect. Future studies assessing decision aid clinical outcomes must assess a decision aid specially designed to improve clinical outcomes, such as treatment adherence, depressive symptoms and quality of life.

Altogether, our results suggest that the use of a decision aid in patients with depression may have an effect on knowledge, information and decision-related outcomes. However, its effect on adherence is doubtful, and there seems to be no effect on depressive symptoms. Although we found a very low certainty of the evidence, stakeholders are needed to decide in this regard. Healthcare institutions must consider the costs, acceptability and applicability of this intervention in their context. Additionally, healthcare professionals must consider the balance between desirable and undesirable consequences of the decision aid’s application, and acknowledge the patient information and involvement as decisive components for the shared decision-making process,^{50,51} to make a decision applicable to each particular patient.

Limitations and strengths

Our study included a small number of heterogeneous studies. However, we decided to conduct a meta-analysis to test the hypothesis about the overall effect of decision aid in patients with depression, for a better decision-making process.⁴³ The certainty of the evidence was very low for all the prioritised outcomes, which demonstrates the need for more well-designed and adequately reported RCTs with higher sample sizes.

On the other hand, this systematic review has important strengths: it followed the Preferred Reporting Items for Systematic Reviews and Meta-Analyses statement and was inscribed in the PROSPERO database. Also, we performed a comprehensive search strategy across multiple databases, without language restriction, and across articles that cited each of the found studies, which allowed us to find all studies reported in previous systematic reviews^{46,47} and other studies that were not found in these reviews. Lastly, we evaluated the certainty of evidence with the GRADE methodology.

In conclusion, we found six RCTs that evaluated the effects of decision aid in adults with depression. Evidence of very low certainty suggests that decision aids may have benefits in decisional conflict, patient knowledge and information exchange, but not in clinical outcomes (treatment adherence and depression symptoms). More RCTs are needed to adequately assess the effects of decision aids in patients with depression.

pmc I do indeed agree with the statements in Professor House's final paragraph and with several of his other points, for example, that there are many vested interests in the debate about public mental health, and that we can see the term 'mental health' itself as both effect and cause of the individualisation of societal problems. Indeed, it is that individualisation – not, as he seems to assume, the psychiatric profession itself – that my critique is aimed at. I have always argued that all professions, including my own, need to be aware of the limitations and potential harms of their

theories and practices. That is why I raised concerns not just about over prescribing, but about ‘formal psychological interventions [which may be] unnecessary for most and can actually be harmful if implemented too early.’

I find Professor House’s final phrase ‘...a muddled polemic animated as much as anything else by anti-psychiatry sentiment’ the most worrying part of his response. This kind of language suggests that he has moved beyond rational and evidence-based argument, into *ad hominem* dismissal. It invites a fight rather than a debate, and since I do not identify as ‘anti-psychiatry’ (whatever that means) I have no desire to take up such a challenge. I will simply observe that the areas in which I take a different position from him are fundamental, legitimate and increasingly common. For example, clinical psychologists’ professional guidelines on formulation state that it is ‘not premised on a functional psychiatric diagnosis’.¹ Professor House is free to use the term differently but not to simply rule other definitions out of court. Yes, we need to offer immediate help to individuals as well as addressing adversities, but that help does not have to be based on unproven medical assumptions about the nature and origins of their distress. Yes, there are social causal factors and unclear boundaries in some physical health conditions, but no one is arguing that diabetes is a mental health problem; common sense tells us that this analogy doesn’t work, despite the claims of anti-stigma campaigns and some professionals. And so on.

In 2017, a United Nations report noted ‘The urgent need to... target social determinants and abandon the predominant medical model that seeks to cure individuals by targeting “disorders” and recommended that ‘Mental health policies should address the “power imbalance” rather than “chemical imbalance”’.² Rather than allowing ourselves to be distracted by attempts to defend a failed paradigm, we all urgently need to work towards this future.

Abstract

Undergraduate psychiatric education is essential for the training of medical students and for their recruitment into psychiatry. A significant shortage of graduates choosing a career in psychiatry has been recently documented, and this trend might have many causes. When medical students have positive experiences of teaching, elective placements and exposure to psychiatric patients, their attitudes towards psychiatry are significantly better. Therefore, there is a need to improve the quality of undergraduate training courses in psychiatry. Innovative teaching strategies are suggested, including the use of movies, virtual reality, simulated patients and multiprofessional training wards.

pmc Undergraduate education in mental health is an essential part of the training of medical students. Given the high prevalence of mental health problems in the general population, all practitioners should have the basic skills to identify and manage mental disorders.¹ According to the World Psychiatric Association (WPA), undergraduate psychiatric education aims to improve the quality of mental health education and, consequently, the quality of care provided to people with mental disorders.

Furthermore, high-quality undergraduate education in psychiatry is crucial for the future recruitment of medical students into psychiatry as a specialty. In the past 10–15 years the percentage of graduates choosing a career in psychiatry has been significantly reduced.² Possible explanations for this negative trend include the low quality of teaching, stigma towards people with mental disorders and negative attitudes of medical doctors towards psychiatry.³ In particular, it could be that some aspects of the psychiatric discipline, such as the use of compulsory treatment and the presence of negative stereotypes attached to psychiatrists, may have an adverse effect on both recruitment and retention of medical students in psychiatry.^{3–5} In some European countries, students may consider a placement in psychiatry as ‘low priority’.⁶

However, students’ attitudes towards the discipline change if they have positive teaching experiences, elective placements and direct contact with patients with mental disorders. Several strategies have been proposed for improving the attitudes of medical students towards psychiatry. These include direct contact with patients (particularly those who get better after treatment), an emphasis on the evidence-based treatments and approaches used in psychiatry, and a close relationship with consultants and senior trainees during their education. Therefore, to overcome stigma and the negative image of the discipline, in 2009, the Royal College of Psychiatrists in the UK suggested organising periodic meetings between medical students and licensed psychiatrists throughout medical school and the development of an *ad hoc* mentoring programme.⁷

Furthermore, receiving an adequate undergraduate psychiatric education may be useful not only for students interested in psychiatry, but it could also help those who want to pursue a different medical career. In particular, undergraduate psychiatric education may teach them the communication skills, and explain concepts and thought processes necessary to understand patients and their disorders from biological, psychological and sociocultural viewpoints.

Improving the quality of undergraduate education can support the process of de-stigmatisation of psychiatry, since medical students can develop correct and unbiased opinions regarding the discipline, which in turn can play a significant role in ameliorating the healthcare services provided to patients with mental health problems (or related physical complaints) in other medical settings.

Taking a worldwide perspective, this paper aims to: (a) describe the characteristics of undergraduate training in psychi-

atry; (b) discuss the most relevant unmet needs of undergraduate training in psychiatry in medical schools; (c) outline some innovative strategies to improve undergraduate psychiatric education.

Characteristics of undergraduate training in psychiatry

Undergraduate psychiatric training greatly varies across different countries and university sites. Some medical schools include psychiatry programmes as optional, and others have only 2 weeks of mandatory formal training in psychiatry.⁸ A recent survey promoted by the International Federation of Medical Students' Associations (IFMSA) in collaboration with the WPA noted that psychiatry education is mandatory in 81 out of the 83 surveyed countries, and is an elective course only in two countries (Ethiopia and Nigeria).⁹ Furthermore, the duration of classes on theory significantly varies across countries (e.g. from just 1 day to more than 30 days); Nigeria and Burkina Faso do not have any practical classes at all. Even in Western countries, some medical schools offer only 4 weeks of training in psychiatry.⁹ Undergraduate psychiatric training in the USA is longer than it is in Asian and Pacific regions. Methods for evaluating students' knowledge and competencies also vary among countries, although the most common way of assessing it is multiple choice questions. The format of teaching does not significantly vary, with most medical schools offering a combination of lectures, bedside teaching and computer-based learning.⁸ Overall, the survey conducted by IFMSA shows that undergraduate psychiatric education is not given enough prominence in undergraduate medical curricula.

Unmet needs and the way forward for undergraduate training in psychiatry

A number of unmet needs in undergraduate psychiatric education have recently been highlighted in the literature. In particular, the limited availability of tutors, highly trained faculty members and clinicians at several sites is adversely affecting the quality of provided and perceived undergraduate training.¹⁰

Second, in some contexts, limited resources are a significant obstacle to good-quality training, especially in relation to access to adequate facilities and evidence-based educational materials.

Many traditional educational methods are not easily applied in undergraduate psychiatric education (e.g. some patients may be reluctant to disclose their mental problems to students because of delusional thoughts; others may feel that the presence of a third person breaks the therapeutic alliance with their psychotherapist). Furthermore, in many sites, students have limited access to psychiatric patients at the bedside, and thus gain little practical knowledge of many psychiatric disorders.¹¹

Therefore, novel methods to teach psychiatry should be put in place and trialled. It is beyond the scope of this paper to systematically review all the innovative teaching models used in psychiatry, so we have selected some of the most promising approaches to outline here.

Simulation techniques offer one innovative solution. Techniques such as student role-play and simulated patients have been found to improve the communication skills and empathy of undergraduate medical students and seem to be very well accepted.¹² These techniques are used to teach history taking and formulating a management plan and can depict challenging clinical situations (e.g. acutely agitated patients) or rare syndromes, which would otherwise be neglected during training.¹³

Another innovative solution is the use of movies as an educational tool. Watching movies and videos with students may allow them to discuss misconceptions about mental disorders in a relaxed setting (i.e. not in the patient's presence) and whether the clinical descriptions are accurate or not. Using videos to teach particular topics to medical students has been shown to result in improved recall of those situations.¹⁴

The Psychiatry Early Experience Programme (PEEP) was proposed in 2015 in the UK. Medical students are paired with specialists in psychiatry, to shadow them while on-call and for one regular day shift during each of their jobs.¹⁵ By joining the programme, students are exposed to a wide range of mental health problems and develop insight into psychiatric trainees' work. The students can also attend lectures given by psychiatric experts and clinical sessions with patients. The programme looks very promising, as confirmed by the fact that many students who joined it developed more positive attitudes towards psychiatry and seemed less reluctant to choose psychiatry as a speciality.¹⁵

In 2019, the American Psychiatric Association launched the Psychiatry Student Interest Group Network (PsychSIGN), a networking initiative that includes students interested in psychiatry. It provides resources and mentoring opportunities for students to help them to deepen their interest in the field.^{9,16}

Interprofessional training wards offer another innovative teaching opportunity. These enable students and trainees from different health professions to work in collaboration to manage the medical treatment and rehabilitation of real-life patients, taking a multidisciplinary perspective.

Finally, another aspect to be improved is related to providing feedback to medical students at the end of their rotation in psychiatry. A recent study carried out in Sweden using a structured feedback tool found that medical students were more satisfied at the end of the rotation period if they had received structured feedback on their internship.¹⁷

Conclusions

Undergraduate training in psychiatry is essential for psychiatric education and practice. Providing good-quality undergraduate training increases students' interest in mental health, reduces stigma towards people with mental illness and increases students' confidence in working with people with mental health problems.^{1-3,18}

Initiatives aiming at improving psychiatric education during the early years of medical school have been well received and have been found to be effective in changing the attitudes of medical students towards the discipline. Novel techniques using virtual reality, movies and simulation can help increasing the psychiatric knowledge and practical skills of undergraduate medical students, without affecting patient confidentiality and the therapeutic alliance.

This work has been conceived within the activities of the WPA Section on Education in Psychiatry, whose members are acknowledged for their ongoing commitment and support in improving the quality of undergraduate education in psychiatry.

Data availability

Data availability is not applicable to this article as no new data were created or analysed in this study.

- *Malik Hussain Mubbashar, MB BS, FRCP (London), FRCP (Edinburgh), MRCP (Glasgow), FCPS (Pakistan), FRCPSych*

pmc Formerly Professor and Head of the Institute of Psychiatry, Rawalpindi, Principal, Rawalpindi Medical College and Vice-Chancellor, University of Health Sciences, Lahore, Pakistan

Malik Hussain Mubbashar, the leader of psychiatry in Pakistan for a generation and a pioneer in the development of community mental health services and psychiatric research, died on 10 August 2020, at the age of 75 years. His work in the establishment of community mental health services served as a model for such services in low-income countries throughout the world. Initially, local men were recruited and trained to provide services to those identified in need. This was soon followed by school programmes, which enlisted head teachers, persuading them to include information about mental disorders in their curricula. Professor Mubashar was remarkably innovative in his approach, for example, recruiting children to identify people in their village who might benefit from seeing a doctor and arranging travel for them. His research activities were always both scientifically rigorous and highly relevant to the needs of people with mental health problems in areas where specialist services were thin on the ground or non-existent. He carried out a community survey of stress and psychiatric disorder in rural Punjab, a prevalence study of psychiatric morbidity among the attendees of a native healer in Rawalpindi, as well as a unique randomised trial of the impact of a school mental health programme in rural Rawalpindi, Pakistan. He had a highly productive publication record, authoring or co-authoring many peer-reviewed papers as well as 28 books.

He was highly effective as a teacher. At the Rawalpindi Medical College (RMC), where he was Principal for some years, he reorganised undergraduate education, introducing problem-based learning. As Vice-Chancellor of the University of Health Sciences, Lahore, he made the study of behavioural sciences mandatory in undergraduate medical education. He was responsible for the postgraduate psychiatric training of large numbers of junior doctors, for many of whom he arranged further training in the UK, especially with Professor David Goldberg in the Department of Psychiatry at the University of Manchester, with whom he developed a special link. When they achieved consultant status, many of his former trainees would put up a photograph of Professor Mubashar in a prominent position in their departments. He was also active in obtaining legal rights for people with mental illness in Pakistan. After years of incessant effort, he was instrumental in the passage of the Mental Health Ordinance 2001. His interest in promoting public policy in favour of the mentally ill more generally motivated him to make links with whoever was President of Pakistan at the time.

His influence in psychiatry extended well beyond national boundaries. His Institute of Psychiatry in Rawalpindi was recognised as a World Health Organization (WHO) Collaborating Centre for Mental Health Research and Training, of which he was the Director. Among many other international positions, he was chair of the Global Mental Health Network, Global Forum for Health Research at WHO, Geneva. The WHO Community Mental Health Programme was his brainchild, and he had a particularly influential link with the development of such programmes in the WHO Eastern Mediterranean region.

Malik Hussain Mubbashar was born in Lahore on 1 August 1945, the son of Miraj-ud-din Malik and Shahzadi Anwar. His father was a government employee in the irrigation department. After completing his medical training at King Edward Medical College, Lahore, in 1968 with honours, he underwent further medical and then psychiatric training in London at Guy's Hospital with David Stafford-Clark. While in England he passed the membership examinations of three UK medical colleges. He was strongly motivated by having seen in childhood the ill-treatment of the mentally ill.

On return to Pakistan in 1972, he was appointed to the Central Government Hospital, Rawalpindi. However, to his disappointment, the administration of the hospital made it abundantly clear that he was not welcome as a psychiatrist and refused him any clinic space to see psychiatric patients. Manifesting his inevitable grit, as he did throughout his career, he set up his table and chair under the shade of a tree in a neglected, remote corner of the hospital. Within 8 years, his department had grown into an Institute and then into a WHO Collaborating Centre.

His administrative talents and leadership qualities were rapidly recognised. Professor Mubbashar was closely involved with the College of Physicians and Surgeons Pakistan (CPSP), becoming Dean of the newly formed Faculty of Psychiatry. He was elected President of the Pakistan Psychiatric Society. He served as Principal of the Rawalpindi Medical College before going on to become the Vice-Chancellor of the University of Health Sciences, Lahore.

During his lifetime he was accorded many honours. Two of the highest civilian awards of the Pakistani government, Hilal-e-Imtiaz and Sitara-e-Imtiaz, were conferred on him. The CPSP's gold medal for psychiatry, the most prestigious medal in the field, is named the Malik Hussain Mubbashar Gold Medal.

In his spare time, he enjoyed visiting rural areas and trekking.

Professor Mubasshar is survived by his wife Dr Yasmin Mubbashar, whom he married in 1973, children Sabooh, Aamna, Zainab, Saima, Fatima, Maryam and Imtiaz (five of whom are psychiatrists) and 15 grandchildren.

pmc Ruth Paddon has written a short biography. It is devoid of self-pity and rancour; it has a simple, pellucid style that I found very moving.

She describes coming through childhood abuse, anxiety and parental illness to reach an early adulthood that appeared promising. She then developed depression and psychosis (and anorexia) and had several hospital admissions. Her initial life plans and expectations were not fulfilled but she made use of other options that became available, including moving to Italy. Adverse experiences are clear but not harrowing, there is no bitterness despite the pain, and she thanks those who have supported her. The personal descriptions are complemented by family photos which locate her and her family as ordinary human beings.

As a psychiatrist, I often reflect on how little time I spend with each patient: maybe 15 minutes a week for an in-patient and 30 minutes every 3 months for an out-patient. Meanwhile, they are hearing voices or experiencing negative thoughts most of the time every day. Paddon gives a very balanced view: it is clear that most of her time is without professionals but she is positive about all the staff she mentions; she values the specific role they have to play (particularly when performed with warmth and friendliness). She is clear about the more extensive (and different) help she has had from her family (particularly siblings).

I knew Ruth Paddon in a professional capacity many years ago. I found it personally educational to see how I figured (briefly) in her life and compare it with my experience of being her psychiatrist.

This book is very readable and it is relatively short (34 pages of text and 10 of photos). I would recommend it to psychiatric staff, patients and relatives equally. It is a balanced, genuine and accessible account of a life that has been intermittently diverted or temporarily held up (the 'stillness' of the title) by depression and psychosis.

It is currently available only to order from the publisher (email: info@tempoallibro.it).

1.1.24 Mamoon Rana, MA, MBBS

Affia Qazi

date

2021-06

Contents

- *Mamoon Rana, MA, MBBS*

pmc Psychiatric trainee, North East London NHS Foundation Trust, UK

Dr Mamoon Rana, a much loved, highly regarded, enormously valued and committed junior psychiatrist, died at the age of 48 years of COVID-19 on 16 April 2020 after a short illness.

Mamoon was born in Punjab, Pakistan, the youngest of four children. She graduated from Lahore Medical College, worked in her native country for some years, after which she and her husband emigrated to the UK. She secured a training post in psychiatry in 2018 and embraced the discipline with huge enthusiasm. She had a lovely bed-side manner and great listening skills. At an early stage in her career she showed a keen interest in teaching and was often to be found with medical students on the wards instilling them with her newly acquired knowledge of psychiatry. Her eagerness for learning was infectious. She had enormous potential and there is no doubt she would have contributed enormously to the field of psychiatry.

Mamoon was a calm, caring and loving person, who was intelligent, witty and full of life. Her husband, Dr Azeem Qureshi, an anaesthetist at Newham University Hospital, describes her as a remarkable woman who gave hope and joy to those around her. She was also a very good cook and a devoted mother.

Mamoon was buried in East London, her family in Pakistan being unable to attend her funeral owing to the coronavirus travel restrictions. She is survived by her husband Azeem, and their 8-year-old daughter Narmin.

1.1.25 Lynn Sinclair Gillis, MB ChB, MD, FRCPsych

Joan Raphael-Leff

date

2021-06

Contents

- *Lynn Sinclair Gillis, MB ChB, MD, FRCPsych*

pmc Formerly Head of the Department of Psychiatry, University of Cape Town, and consultant psychiatrist, Groote Schuur Hospital, Cape Town, South Africa

Lynn Gillis, who died recently at the age of 96 years, was, over a long period, one of the leaders of academic psychiatry in South Africa. In the 1960s and 1970s, he was a pioneer of community psychiatry and set up numerous community psychiatry services, mostly led by nurses. Under his guidance, a day hospital was established in 1963 in Cape Town, allied to a community service and psychiatric social club, which promoted continuity of care for patients in the community. This linked outreach provisions with psychiatric advocacy, aiming to destigmatise mental illness. Out-patient clinics were established at most hospitals and peripheral clinics in many parts of the country, which catered mostly for patients who had been discharged from hospital. Later legislation in 1976 made formal provision for a community service in country areas associated with particular psychiatric hospitals. Over time, an active Division of Child and Adolescent Psychiatry was established in Cape Town's Red Cross War Memorial Children's Hospital.

Courageously defying apartheid segregation, Lynn integrated staff across wards. In 1968, he carried out a significant research project into the rate of mental illness and alcoholism in the multiracial groups of people in the Cape Peninsula. Later, he organised a community service for alcoholism, and a specialised geriatric service, the first in South Africa. In 1980, he was appointed to head the newly established Social Psychiatry Medical Research Council Unit, which focused on research in community-based mental health. In collaboration with Professor Julian Leff of the UK Medical Research Council, he carried out a number of studies of the social precipitants of relapse in schizophrenia. Their studies revealed massive discrepancies in the lived experience of the different racial groups.

Lynn's clinical teaching and research laid the foundations for the existing Department of Psychiatry at the University of Cape Town, now a leader of psychiatric research on the African continent. Professor Dan Stein, the current Head of the Department, recalls that 'the clinical, teaching, research, and social responsiveness strengths of the existing Department are in no small measure due to his pioneering work'. As well as clinical work and carrying out research, Lynn wrote several books dealing with different aspects of clinical practice in psychiatry and psychiatric education. Towards the end of his life he published a series of reflections on his rich and varied experience.

Lynn was born on 1 February 1924 to Jewish parents who had migrated from Kretinga in Lithuania. His father, Julius Gillis, was a dentist who grew competition roses as a hobby. His mother, Annie Gillis (née Lynn), was a concert pianist who gave music lessons locally. He was first brought up in the small South African town of Kroonstad in the Orange Free State. As a result, he spoke vernacular Afrikaans (a language he deemed second only to Yiddish in its rich array of metaphors and flamboyant curses) with fluency. At the age of 9 years, a year after the family had moved to Johannesburg, he contracted scarlet fever. His experience in the Children's Fever Hospital may have influenced his later ideas about hospitals as institutions.

He entered Witwatersrand medical school in 1941. He interrupted his medical studies to enlist as a medical assistant in the South African Medical Corps, serving in makeshift hospitals in North Africa and Italy. Returning to South Africa in 1945, he completed his medical studies, qualifying as a doctor in 1948. After qualification, he worked until 1962 at Tara Hospital, Johannesburg, a pioneering mental health facility where he was influenced by the indomitable Dr Mary Gordon, a migrant from Russia. In the 1950s, Lynn took a break from Tara to hold positions at both the Maudsley Hospital in London and St Francis Hospital, Haywards Heath in Sussex. In 1962, he was recruited to fill the position of founding Head of the Department of Psychiatry and Mental Health at the University of Cape Town and first consultant at Groote Schuur Hospital (posts he held for 27 years).

During his career, Lynn won numerous awards, among them the Salus Medal (silver) for Meritorious Service to Medicine (1989) and the Merit Award for Outstanding Services, Medical Association of South Africa (1990). He also held many positions of responsibility, including President of the South African National Council for Mental Health (1969–1970, 1976–1978, 1981–1983) and President of the College of Psychiatrists of South Africa (1969–1971). He was an elected member of the International Brain Research Organization (1977–1989), President of the South African Geriatrics Society (1978–1980), President of the South African Gerontological Association (1982–1993) and Chairman of the National Research Programme on Ageing of the South African Population, Human Sciences Research Council (1987–1991). He was a founding member and later Fellow of the Royal College of Psychiatrists (1971).

Although a reserved man, Lynn's warmth, compassion and mischievous humour influenced several generations of psychiatrists, psychologists and allied practitioners as much as his professional capacities as inspirational teacher, mentor and author of many publications. He had a long-lasting effect on his trainees, many of whom rose to eminence in South Africa, the USA and the UK. Today, they still acknowledge the lasting legacy of his singularly trusting style of leadership, which fostered personal initiative. Ever curious, his awareness of the many contradictions and unconscious processes of the human mind drew Lynn to psychoanalysis, and he pursued a lifelong interest in Buddhism. He always

had a subtle appreciation of beauty, art and music. In retirement he studied sculpture and became a prolific creator of many austere carvings in marble and rare woods. An enthusiastic mountaineer, he remained remarkably healthy and agile until his last years. He was lucid and fiercely independent to the end of his full and fulfilled professional and artistic life. He died on 24 May 2020.

His wife Shirley (née Lurie) died in 2015 after they had been married for 64 years. One daughter, Susan, died in 2012. He leaves a daughter Jennifer, four grandchildren and three great grandchildren.

The ‘*Cognitive Sports Therapy Manual*’ is a 120-page book centred on holistic, fundamental concepts, such as ‘mind, body, breath’, for supporting mental health. It is based on 12-week practical courses and support groups (available at www.cognitivesportstherapy.com), designed by a founding Multi Disciplinary Team composed of psychiatric, general practice, yoga and exercise professionals. It includes the use of non-medical jargon and practical tools, such as a gratitude journaling, screening tools, care planning, worksheets and calendar logs, for tracking personal progress related to ‘mind, body and breath’ exercises.

This type of manual is timely, particularly given the emerging robust evidence base for the therapeutic role of ‘lifestyle psychiatry’ (e.g. exercise, nutrition, sleep, stress management and adverse health behaviours) within severe mental illness. The back of the manual makes reference to some of these key papers and texts.

Within front-line psychiatry work, the use of some of these proposed, alternative therapeutic methods is well aligned with the preventative direction of the NHS Long Term Plan. This may prompt traditional Multi Disciplinary Teams to include professionals who can optimise such lifestyle factors (e.g. physiotherapists), particularly when patients with severe mental illness cite lack of staff support as a major barrier to physical activity engagement.

Despite idealism toward holistic interventions, we also have evidence from pragmatic trials led by [Gaughran et al](#) (<https://doi.org/10.1186/s12888-017-1571-0>), demonstrating the challenges of embedding positive lifestyle factors for severe mental illness. Therefore, this type of manualised approach may be more suited as a well-being strategy for those with higher levels of motivation. Further, I believe that the book should have included a screening function or content related to the risks of over-reliance on exercise as a coping mechanism, as we know this can result in exercise addiction and associated dysfunctional eating behaviours.

In summary, I enjoyed reading this manual and knowing that there are professional initiatives exploring holistic, lifestyle factor optimisation that can benefit individuals across the mental health spectrum.

1.1.26 Veganism and eating disorders: assessment and management considerations

Sarah J. Fuller Andrea Brown Jeanette Rowley Jade Elliott-Archer

Correspondence

Sarah Fuller (sarah.fuller@nhs.net)

date

2022-04

Abstract

The number of people following a vegan diet in the UK is increasing. Eating disorder clinicians are anecdotally reporting that more of their patients with anorexia nervosa are wanting to follow a vegan diet. The relationship between veganism and eating disorders is unclear. A fictitious scenario is used to explore these issues. An approach is described that clinicians may follow to help patients to understand the potential relationship between their eating disorder and veganism. The human rights issues this involves are also explored. It is hoped that this article will make readers more aware of this complex issue and the impact it can have on engagement with services and on treatment options.

pmc .. _sec1:

Clinical scenario

You are a trainee in a tier 4 specialist eating disorders unit (SEDU) and a 22-year-old female has been admitted under section 3 of the Mental Health Act 1983 (MHA) with a body mass index (BMI) of 12.7 kg/m², having lost 7 kg in 5 weeks. She has had amenorrhoea for 2 years. She was diagnosed with anorexia nervosa at age 17, requiring a 6-month admission, also under section 3 of the MHA, to a general tier 4 child and adolescent mental health unit. Since age 18, she has followed a strict vegan diet, whereas her family do not. She says her reasons for adopting this are ethical: a concern for the environment and animal welfare. Her family have questioned this, citing the timing of her illness and some lifestyle choices that conflict with veganism, such as using cosmetics containing animal products.

The SEDU has been unable to provide a full vegan diet. As a result, she is refusing to eat. For the past 72 h she has retired to bed and is only drinking water. At present, her physical health observations are stable. In the morning handover, the nursing staff request a professionals' meeting following the unit's policy regarding refusal to eat.

Questions to consider: What is the relationship between veganism and eating disorders? How can clinicians assess this? What are the patient's rights with regard to dietary choice on the in-patient unit? What are the nutritional considerations of a vegan diet? What are the implications for refeeding patients who are vegan?

Discussion

The complex relationship between veganism and restrictive eating disorders

The Vegan Society defines veganism as: "A philosophy and way of living which seeks to exclude – as far as is possible and practicable – all forms of exploitation of, and cruelty to, animals for food, clothing or any other purpose; and by extension, promotes the development and use of animal-free alternatives for the benefit of animals, humans and the environment. In dietary terms it denotes the practice of dispensing with all products derived wholly or partly from animals."¹ Compared with vegetarianism, veganism requires extensive dietary and lifestyle restrictions to avoid any product derived from animals.

Clinicians who support patients with restrictive eating disorders such as anorexia nervosa will be aware of the number of ways that patients can restrict their diet, ranging from total caloric restriction and self-diagnosed dietary allergies/intolerances to socially acceptable dietary restrictions such as vegetarianism or veganism. The link between vegetarianism and the development of eating disorders is well established in the literature.²⁻⁶ These researchers suggest that some individuals with restrictive eating disorders adopt a vegetarian diet to limit the available dietary choices or to justify a choice that is lower in calories. However, this apparent link may be due to methodological problems encountered in some of these studies. For example, eating disorder screening tools would not be able to differentiate between dietary restraint from being vegetarian or restraint driven by an eating disorder.^{7,8}

For decades, diets have claimed to assist weight loss by advocating different forms of restriction. It is known that following diets can be the trigger to developing eating disorders in vulnerable individuals.⁹ A recent example of a popular diet is the 'clean eating movement', which advocates eating freshly prepared, unprocessed foods and recommends eating more plant-based foods. This movement is highly active on social media, with prominent influencers advocating diets, often with no qualifications to do so. If taken to an extreme, this can lead to 'orthorexia'. Orthorexia describes a presentation in which the person becomes pathologically obsessed with eating healthy food.^{10,11} The term, coined by American physician Steven Bratman, does not appear in any of the classifications used in psychiatry but is used in practice to describe this presentation. For some patients, the overlap between healthy eating, dieting, clean eating, orthorexia and veganism is blurred.¹²

In the past 10 years, the number of people following a vegan diet in the UK has increased and veganism is particularly common in younger age groups,¹³ females¹⁴ and those living in urban areas.¹⁵ It is estimated that ~1% of the UK population now follow a vegan diet.¹⁶ Clinicians may be worried that veganism shares aspects in common with restrictive eating disorders, controlled dietary exclusion and checking of food labels. Some researchers have suggested that the theoretical link between dietary restriction seen in eating disorders is mirrored in veganism.^{17,18} Furthermore, the individuals who are more likely to adopt a vegan diet have demographic overlap with those at risk of developing an eating disorder.

At present there is a lack of research into veganism in individuals who have restrictive eating disorders. Some studies have shown that those following a vegan diet are at lower risk of developing pathological eating disorders,¹⁹ whereas others have highlighted that former adolescent vegans may be at increased risk of extreme ‘unhealthful’ weight-control behaviours.²⁰ However, adolescence is a period in which an individual starts to become independent of their family, become more socially conscious and develop their self-identity. Many young people adopt dietary patterns that are different from their families’ and therefore clinicians need to be aware of the distinction between healthy curiosity or lifestyle choices and eating-disordered behaviours.

We conducted a flash survey, via SurveyMonkey, on 1 March 2018 to identify how many patients receiving either specialist eating disorder unit (SEDU) treatment or day hospital treatment identified as vegan on admission. In total, 65 specialist services responded, representing 1008 patients with eating disorders. Within adult services, rates of veganism were reported as 46/419 (11%) in the SEDUs and 11/173 (6.4%) in the day hospitals. In child and adolescent services, the rates were 37/230 (16%) in the SEDUs and 15/186 (8.1%) in the day hospitals. These rates are higher than the national reported prevalence¹⁶ of 1% and this initial finding suggests that more research is needed to identify the actual prevalence within SEDUs.

Approach to assessing vegan diets in people with eating disorders

Clinicians should be mindful of two key questions when trying to distinguish whether an individual is following a vegan diet for ethical reasons or not. First, are ethical choices seen in non-food aspects of life, such as clothes, toiletries and use of free time? Second, is there a pattern of increasing dietary restriction, such as starting off with healthy eating, then vegetarianism and finally veganism, or were ethical concerns present before the dietary restriction began?

What are the patient’s legal rights regarding dietary choice within SEDUs?

When balancing medical decision-making with human and equality rights, clinicians should be aware that veganism is classed as a non-religious belief protected under Article 9 of the European Convention on Human Rights (the right to freedom of thought, conscience and religion).²¹ Case law and guidance^{22,23} indicates that for a belief to engage Article 9 it must: be sincerely held be a belief and not an opinion/viewpoint concern a weighty and substantial aspect of human life and behaviour attain a certain level of cogency, seriousness, cohesion and importance be worthy of respect in a democracy, compatible with human dignity and must not conflict with the rights of others. These criteria can be referred to when trying to understand whether a patient’s vegan beliefs are distinct from their eating disorder. It is worth noting that the beliefs of an individual cannot be decided or overridden by others, and only a court can decide whether the belief complies with the criteria.

The Human Rights Act 1998 (section 6) stipulates that a public body must not act in a way that is incompatible with a Convention right. In practice this means that patients have a right to their beliefs being respected by the organisation providing care. Providing vegan food for patients who request it would therefore ensure compliance with this obligation. However, there are defences to allegations under section 6, including, for example, vegan food not being in the best interests of the patient and whether the patient is deemed to lack capacity to make important healthcare decisions.

There are two forms of discrimination, direct and indirect. Direct discrimination occurs where, contrary to section 13 of the Equality Act 2010, certain groups/people are treated differently because they hold a particular philosophical belief. Indirect discrimination can take place where, contrary to section 19 of the Act, there is an apparently neutral policy that applies to all but has the effect of disadvantaging certain groups/people (e.g. those expressing their philosophical belief in veganism). This means that if a SEDU has an inflexible catering regimen that does not allow for veganism, it leaves the unit open to legal action stating indirect discrimination. In claims arising, an objective justification for the inflexible regime will be required. Clinicians do have a potential defence to individual claims of indirect discrimination if life-saving treatments are required, for example nasogastric tube feeding, given that there is no appropriate vegan enteral feed available at present.

What nutritional considerations need to be taken into account in vegan diets?

With appropriate expertise and planning, there is no reason why a vegan diet should not be well balanced and sufficient to meet the nutritional needs of any individual. Vegans need to ensure that they eat a wide variety of foods and find suitable plant-based alternatives for meat and dairy products. However, research suggests that there are specific nutritional vulnerabilities within a vegan diet that require particular attention or supplementation.²⁴ This has led some European countries to suggest that vegans have blood tests every 3 months to monitor their nutritional status.²⁵ Current guidance in the UK (<https://www.nhs.uk/live-well/eat-well/vegetarian-and-vegan-diets-q-and-a/>) is for vegans to take an appropriate vitamin and mineral supplement to ensure that their nutritional needs are met.

The key nutrients of concern are vitamin B₁₂, vitamin D, iodine, selenium and omega-3 fats.²⁴ People who have a restrictive eating disorder may not be able to eat a sufficient quantity and variety of foods and consequently they may become deficient in these and other nutrients. Close monitoring of patients' biochemistry is therefore advised to identify whether they are deficient in any nutrients.

What are the implications for refeeding patients who are vegan?

It is possible to refeed a patient on a vegan diet. Following a vegan diet is not an identified risk factor for the development of refeeding syndrome. However, it is important to be aware that, in some cases, like-for-like adaptations to catering menus may result in a vegan patient having to eat a larger volume of food. This may result in psychological distress as they compare their portions with those of their non-vegan peers. It may also be problematic for patients experiencing delayed gastric emptying that results in uncomfortable bloating and pain.^{26,27}

Clinicians should also be aware that, if treatment is required for micronutrient deficiency (such as calcium, phosphate or magnesium) due to refeeding syndrome, some vegan alternatives may not have the equivalent nutritional value or bioavailability.^{28,29} It is well worth having discussions with the local pharmacy to ensure that supplies of such micronutrients are available and their characteristics are summarised for use in out-of-hours and other urgent situations. However, in life-threatening emergencies, treatment should be given.³⁰

There is currently only one prescribable supplement drink registered as vegan friendly in the UK (AYMES ActaSolve Smoothie®), but this is not nutritionally complete and it is also not suitable for enteral feeding.³¹ However, if nasogastric tube feeding is required, given the absence of any vegan enteral feeds, clinicians should be aware that many vegans will often accept foods that contain minimal amounts of animal products, for example a soya-based enteral feed in which the only ingredient that is not vegan may be a vitamin such as vitamin D. In cases where a person refuses to accept this option, and they are deemed not to have the capacity to make such a decision, legal advice should be sought for clarification and support.

Reflections and considerations on the clinical scenario

In the clinical scenario introducing this article the patient is at high risk of refeeding syndrome and is likely to be cognitively impaired owing to starvation. There is still an option to work with her to re-establish regular eating on a fully vegan diet, which would be the least restrictive option under the MHA. Irrespective of whether the veganism is independent of her eating disorder or not, facilitating a vegan diet in line with her beliefs will result in her feeling understood and will allow the therapeutic relationship to be repaired. Any discussions about the relationship between veganism and her eating disorder can take place when she is no longer at medical risk and is able to engage cognitively.

This scenario does pose the question: do patients with eating disorders have the right to follow a vegan diet while admitted to a SEDU? Indeed, our flash survey highlighted that not all units are able to provide a vegan diet – 15/21 adult SEDUs (71.4%) and 10/13 child and adolescent SEDUs (76.9%) that responded could not – i.e. the option of following a vegan diet while receiving tier 4 treatment is not yet universal. However, the survey did not enquire into the difference between vegan diets being available versus vegan diets being offered in practice.

Veganism is becoming much more common and it is defined as a protected characteristic under the Equality Act 2010. Therefore, SEDUs need to find ways to adapt to meeting vegan beliefs just as religious beliefs are accommodated. It is

unlikely that a SEDU would expect a person of Jewish faith to eat pork, for example. Provision of a complete vegan diet plan incorporating all the nutrients required to avoid refeeding syndrome and promote healthy weight restoration is possible but requires the input of a specialist dietitian.

The British Dietetic Association's Mental Health Specialist Group has endorsed an internal document to help dietitians understand whether the decision to follow a vegan diet is likely to be linked to an eating disorder or is a genuine lifestyle choice that pre-existed someone's illness (this document is not yet available outside of the BDA). In some instances, veganism can help a person recovering from an eating disorder, allowing them to discover new foods and ways of cooking, change the way they perceive food and embrace the vegan subculture. For others it may be an opportunity to restrict their diet and maintain their eating disorder.

Practical management

In the short and medium term, i.e. during this patient's admission, her veganism can be respected but also challenged in a therapeutic way, as it is not clear that her decision to follow a vegan diet is not linked to her illness. It is important to remember that being malnourished is associated with poor cognitive flexibility, so it might be more appropriate to address this once appropriate and regular nutrition is well established. At that stage, working with the unit's dietitian, it can be challenged with modifications to her meal plan and social tasks involving eating outside of the unit with family and friends. The aim would be to expand the variety of her diet while maintaining a weight at which her body is functioning and no longer experiencing any symptoms of poor nutrition and to challenge aspects of her veganism that may have been hijacked by her anorexia nervosa. In the long term, her community eating disorder team can continue to work with her and her dietary choices as is usual practice.

Treating someone with anorexia nervosa requires that the person's religion or belief is respected while at the same time ensuring that the person is not discriminated against in terms of the quality of treatment they receive. This can produce a quandary owing to the lack of vegan sip feeds and enteral feeds, which may be required under certain circumstances. In life-saving situations some patients may be prepared to accept non-vegan treatment options. In the meantime, pharmaceutical companies are being encouraged to produce vegan alternatives.

Certain situations, such as treatment under the MHA, which could include compulsory nasogastric feeding or treatment with non-vegan medication, produce ethical dilemmas. On the one hand, the therapeutic relationship with the patient is already under strain; on the other hand, treatment could be life-saving. At present, and in the absence of equivalent vegan enteral feeds and medicines, the best that can be done is to treat the patient as you would any other, while being as collaborative as possible and minimising the use of non-vegan options.

In March 2019, a consensus statement was published outlining guidance for practitioners in the UK treating vegan patients with eating disorders.³⁰ This will help services to provide appropriate treatment for these individuals.

The real people involved

The fictitious case scenario is based on the reflections of a real patient and a carer. We obtained informed consent from both to create the scenario and to publish their anonymised reflections here.

A patient's reflection

“My veganism has always been respected in 20 years of [NHS and private] treatment, and even when tube feeding/supplements were required I had a product that was soya based and only had one element that was derived from animals. Wherever possible, my medication also was free from animal ingredients. My diet was limited and often “safer”, but I wanted the opportunity to challenge myself with foods I could enjoy socially within the restrictions of my illness. After 5 years in the community, I had an admission where I felt that I was detained in part due to the unit's anti-vegan policy. I gave up. Not being listened to led to a standstill in my treatment – it was “them versus me”. Veganism was the only thing stronger than my illness: I would drink a litre of oil over a teaspoon of cow's milk. I needed

tube feeding and the idea of a cow's milk-based feed was difficult to accept. My body felt like a graveyard. My mental health, identity and soul were damaged and instead of fighting anorexia I was fighting the system.”

A carer's reflection

“I am 100% convinced that my daughter's request to follow a vegan diet was driven by her illness. Through her whole life I had ensured that the family had a healthy and balanced diet which included treats and party food. In our house, no food was a “bad” food. Prior to being diagnosed with anorexia, she first announced that she wanted to cut out meat, then fish, then eggs. Within three months she wanted to become vegan. We embraced family treatment and had many tantrums along the way regarding her veganism. We are now in a good place and she has admitted, guiltily, that she never wanted to be vegan and her illness drove her to pursue this as a way of restricting.”

We would like to thank both the patient and the carer, who are not related, for their contribution to this paper. Both have asked to remain anonymous.

Conclusions

We have highlighted the increasing incidence of veganism at a national level and the flash survey has suggested increased incidence within the eating disorders population. Concerns about animal welfare, environmental considerations and health impacts appear to be driving this change. There has been little research into veganism and eating disorders and more research is needed. A fictitious case has been used to explore the approach clinicians can take to support a vegan patient with an eating disorder. This included considerations on the relationship between the eating disorder and veganism, refeeding on a vegan diet and the legal implications for patients on a SEDU. The anonymous perspective of a patient and a carer highlight the multifaceted issues inherent in recovery from an eating disorder and the nuanced role veganism can play. Wherever possible, treatments for people with eating disorders should be person centred and therefore this is an opportunity to adapt meal plans, offer appropriate supplements and engage vegan patients in their treatment.

pmc We agree with the comment regarding how ethnic minority is an independent effect with respect to differential attainment; however, this paper tried to focus on the subgroup showing the largest effect size, IMGs.

The comment regarding IMGs of White ethnicity is an illustration of the above (ethnicity: moderate effect on differential attainment; 'IMG-ness': large effect on differential attainment), so we are grateful you have helped us to make this point more explicit. However, we think the central point of our paper remains – that IMGs need special focus as, unlike ethnicity, to be an IMG is not a protected characteristic, so interventions to support IMG might not be deemed to be a priority or even a need. Overall, we consider that this is complex and delicate, with many further layers of intersectionality, including gender, sexual orientation and social background, but it is promising that more and more work, including yours, is beginning to address the many issues affecting IMGs working in the UK.

1.1.28 Risk, demand, capacity and outcomes in adult specialist eating disorder services in South-East of England before and since COVID-19

Agnes Ayton David Viljoen Sharon Ryan Ali Ibrahim Duncan Ford

Correspondence

Agnes Ayton (suchagnes@gmail.com)

date

2022-04

Abstract

Aims and method

This is a longitudinal cohort study describing the demand, capacity and outcomes of adult specialist eating disorder in-patient services covering a population of 3.5 million in a South-East England provider collaborative before and since the COVID-19 pandemic, between July 2018 and March 2021.

Results

There were 351 referrals for admission; 97% were female, 95% had a diagnosis of anorexia nervosa and 19% had a body mass index (BMI) <13. Referrals have increased by 21% since the start of pandemic, coinciding with reduced capacity. Waiting times have increased from 33 to 46 days. There were significant differences in outcomes between providers. A novel, integrated enhanced cognitive behaviour therapy treatment model showed a 25% reduction in length of stay and improved BMI on discharge (50% v. 16% BMI >19), compared with traditional eclectic in-patient treatment.

Clinical implications

Integrated enhanced cognitive behaviour therapy reduced length of stay and improved outcomes, and can offer more effective use of healthcare resources.

pmc .. _sec1-1:

National background

In the 2019 Health Survey for England, 16% of adults aged 16 years (19% of women and 13% of men) screened positive for a possible eating disorder. This included 4% (5% of women and 3% of men) who reported that their feelings about food had interfered with their ability to work, meet personal responsibilities or enjoy a social life.¹ This is almost a threefold increase since 2007.² These findings may be surprising, but are consistent with international epidemiological data.³

In parallel, hospital admissions in England of people with eating disorders have increased from 4849 in 2007–2008 to 19 116 in 2018–2019.⁴ This shows an almost fourfold increase in demand, and there has been no investment in specialist eating disorder in-patient services during this time. Approximately 70% of people needing hospital admission are adults with anorexia nervosa.

On 6 November 2020, after the inquest into five avoidable deaths, the coroner for Cambridgeshire and Peterborough, concluded that National Health Service (NHS) treatment for patients with anorexia nervosa is ‘not a safe system’ and risks ‘future deaths’.⁵ These statements mirror the 2017 Parliamentary Health Service Ombudsman (PHSO) report.⁶ Three years ago, the PHSO made several helpful recommendations, including reviewing medical education, improving the workforce, ensuring the parity of funding of services across the age range and strengthening coordination of care. There has been limited progress since.⁷

Child and adolescent eating disorder services have received substantial investment since 2015,⁷ and progress toward meeting the referral to treatment waiting time standard has been monitored (<https://www.england.nhs.uk/statistics/statistical-work-areas/cyped-waiting-times/>). These standards require child and adolescent eating disorder services to begin out-patient treatment within 1 week for urgent cases and 4 weeks for non-urgent cases. However, neither the standards nor monitoring are in place for adults, and the much-awaited funding into community eating disorder services has not yet reached the front line. Adult in-patient eating disorder services are part of specialist services and have been commissioned by NHS England. Over the past few years, NHS England has initiated a shift of commissioning to regional NHS collaborations, with the intention of transformation of care pathways focusing on the health of local populations, with the aim of improving outcomes and cost-savings.

Aims and objectives

In this paper, we describe demand and capacity for hospital treatment of patients with severe eating disorders in the Healthy Outcomes for People with Eating Disorders (HOPE) provider collaborative in South-East England since July 2018, and examine the effects of the COVID-19 pandemic. In addition, we compare the outcomes between different in-patient services, using the traditional eclectic treatment model with a new integrated enhanced cognitive behaviour therapy (I-CBT-E) treatment across the care pathway.

Method

This is a longitudinal cohort study, involving all patients with eating disorders referred for admission from a total population of 3.5 million in South-East England. The study has been approved by the Oxford Health NHS Foundation Trust Audit Department. Patient consent was not needed for the study.

The HOPE provider collaborative

The HOPE network was one of the first pilot sites of adult eating disorders selected by NHS England. It was established in shadow commissioning form in July 2018. The main goal of the network was to bring together in-patient and community services from several organisations providing in-patient and out-patient services for adults with eating disorders. Initially, the network included a total population of 5.2 million.

The footprint was reduced in September 2019, and the following partners have remained in the provider collaborative: Oxford Health NHS Foundation Trust (Oxfordshire, Buckinghamshire, Swindon, Wiltshire), Berkshire Healthcare NHS Foundation Trust, Gloucestershire Health and Care NHS Foundation Trust and the Priory Group (in-patient provision in Bristol).

The total population of the geographical footprint is 3.5 million. Oxford Health NHS Foundation Trust provides 14 beds in Oxford, and 6 beds in Marlborough. In addition, Oxford has six day patients and Marlborough has four. Berkshire and Gloucestershire have day services for 8 and 12 patients, respectively. The Bristol Priory is an independent partner in the provider collaborative providing specialist eating disorder beds; however, as it has a national contract with NHS England, their beds are not aligned with the HOPE provider collaborative.

This provider collaborative has developed a more collaborative and joined-up approach to admissions and discharge planning, with the aim of improving access closer to home and joint working between in-patient and out-patient teams. A weekly joint clinical activity panel consisting of senior clinicians from each organisation and a single point of access for all referrals has been established, to ensure that decisions about admissions are made by highly experienced clinicians. Referrals and outcomes have been systematically monitored since July 2018, for the whole geographical area.

There was also an agreement to monitor outcomes, and compare the NHS England standard eclectic model of care⁸ with a new, integrated stepped-care model using I-CBT-E in Oxford, building on the pioneering work of Dalle Grave et al.⁹ I-CBT-E offers a single evidence-based psychological model delivered by a multidisciplinary team, starting before admission and continuing across the treatment pathway (40 sessions in total). A detailed I-CBT-E formulation ensures continuity, consistency and a personalised treatment plan.

The COVID-19 pandemic has significantly affected capacity as a result of infection control measures across the care pathway. In-patient and out-patient services needed to reduce the number of people in poorly ventilated and crowded buildings. Day services had to be closed because of environmental and staffing challenges. Furthermore, remote working may have caused delays in recognition of deterioration of non-cooperating patients (both in primary and secondary care).

Demographic and clinical data

This paper analyses data from the partners who have been part of the provider collaborative since the beginning (Oxfordshire, Buckinghamshire, Wiltshire, Gloucestershire and Berkshire) for the period from July 2018 to 1 April 2021. The data collected concerns referrals, including demographic and clinical information, such as diagnoses and severity of physical risk related to malnutrition, and outcome of referrals, including length of admission and travelling distance. Body mass index (BMI) was recorded on referral, admission and discharge for those admitted. No additional outcome data was recorded for patients not admitted.

Statistical analysis

Descriptive statistics were conducted to describe the demographic and clinical characteristics of the referred patients. Categorical variables were compared by χ^2 -test, and continuous variables by independent t -test and ANOVA, using SPSS for Windows version 22.

Results

Between July 2018 and 1 April 2021 there were 351 referrals for admission; 97% were female and mean age was 29.6 ± 11 years. According to DSM-5 severity ratings, 56.3% had extreme anorexia nervosa, 20.8% had severe anorexia nervosa, 17.9% had mild-to moderate anorexia nervosa, 1.8% had severe or extreme bulimia nervosa and 3.2% had other specified feeding or eating disorder. Approximately 65% of referrals were urgent or emergencies since the establishment of the provider collaborative. Urgency of referral was determined by the risk to the patient's health and safety, including level of malnutrition and risk to self; 19% of referrals had a BMI < 13 , which is an indicator of potentially life-threatening malnutrition, and a further 37% had extreme malnutrition. This pattern of referrals remained unchanged after the COVID-19 pandemic, but the absolute numbers increased by 21%.

There were no significant differences in mean age (29.20 ± 10.5 years v. 30.1 ± 11.9 years), gender (97% v. 99% female), diagnosis (95% v. 96% anorexia nervosa) or need for compulsory admissions (84.6% v. 83.4% informal), before or since the COVID-19 pandemic.

The impact of the COVID-19 pandemic on the outcome of referrals

Before the COVID-19 pandemic, 63.6% of patients were admitted, which has increased to 65% since the COVID-19 pandemic (Table 1). The number of patients waiting has increased by 20%. However, this is likely to increase further with time, as the in-patient capacity for admission is insufficient, not just within the footprint, but also nationally. The reason for no admission was usually because of the patient refusal and/or ongoing out-patient treatment. Approximately half of these patients were admitted following a second referral. Table 1 Outcome of referrals before and since COVID-19 (number of patients and percentages)

	Before COVID-19	Since COVID-19	Total
Not admitted	65 (38%)	55 (35%)	120 (36%)
In-patient unit in the HOPE provider collaborative area			
Cotswold House Oxford	50 (29%)	50 (32%)	100 (30%)
Cotswold House Marlborough	15 (9%)	22 (14%)	37 (11%)
Bristol Priory	9 (5%)	12 (8%)	21 (6%)
Out of area			
Priory OOA	15 (9%)	14 (9%)	29 (9%)
NHS OOA	14 (8%)	3 (2%)	17 (5%)
Cygnet	4 (2%)	2 (1%)	6 (2%) ¹

Before the COVID-19 pandemic, 43% of referrals could be admitted within the network, which has increased to 54% since the COVID-19 pandemic. The Priory Group provided 5% of admissions within the geographical area and a further 9% out of area.

Waiting times and travelling distance

The distance from home to hospital increased during the COVID-19 pandemic (from 41.4 ± 60 miles to 56 ± 78 miles). Eight patients were admitted to Priory Glasgow because of a lack of bed availability in England. Waiting times increased from 33 ± 44 days to 46 ± 43 days (t -test = 0.03)

Even pre-COVID-19, the HOPE network already had a large demand/supply mismatch, with insufficient specialist beds within the network and lengthy waiting times even for patients with extreme or life-threatening malnutrition. This causes a vicious cycle of delayed and high-risk referrals requiring urgent admissions. Figure 1 demonstrates the variation in waiting times before and since the COVID-19 pandemic. It shows huge variations, even for the most high-risk patients, reflecting the reduced capacity in the system. One of the additional challenges is the lack of striated beds, which makes it difficult to meet the needs of patients who present with a high level of behavioural disturbance resulting from comorbidities such as autism spectrum disorders or personality disorders. Fig. 1 Waiting times for admission depending on severity of malnutrition.

¹ HOPE: Healthy Outcomes for People with Eating Disorders; OOA: Out of area placement; NHS, National Health Service Providers.

The reduced specialist in-patient and day treatment capacity has had a significant impact on community teams in the footprint. Because of the lack of prompt access to specialist eating disorder units, approximately 19% of patients have required acute admission to general hospitals for emergency medical treatment. This represents a 20% increase during the COVID-19 pandemic, when acute hospital capacity is also reduced.

Differences between in-patient providers

Before the COVID-19 pandemic, there were significant differences between individual in-patient services in terms of length of stay (Supplementary Table 1 available at <https://doi.org/10.1192/bjb.2021.73>).

As part of the establishment of the provider collaborative, Cotswold House Oxford has been pioneering the implementation of an integrated stepped-care treatment, based on an intensive CBT-E model developed between Professor Fairburn in Oxford and Dr Dalle Grave in Italy.¹⁰ The model advocates integration of NICE-approved psychological treatment across the care pathway, with clear goal-oriented, time-limited admissions, followed by day and out-patient treatment. Given the differences between the Italian healthcare system and the NHS, we adapted the model by including a crisis admission pathway for those patients who refused full weight restoration but agreed to informal treatment. The details of the treatment will be discussed in a separate paper.

Here, we summarise the comparison between the outcomes of patients who were admitted to the Oxford unit and other specialist units that use the current standard eclectic treatment approach promoted by NHS England. Previous internal service evaluation of the Oxford pilot programme before the COVID-19 pandemic showed improved outcomes, reduction of restrictive practices (such as needing to use nasogastric feeding under restraints), improved patient outcomes and reduced length of stay. Despite the challenges, this has been maintained through the COVID-19 pandemic (Table 2): 50.5% patients reached a BMI >19 compared with 16% in all other providers ($\chi^2 = 0.000$). Table 2 Comparison of the traditional eclectic in-patient treatment with the Oxford pilot programme (integrated CBT-E)

In-patient treatment model	n	Means	d	Significance (two-tailed)
Referral BMI	Integrated CBT-E	9014.72	0.050	0.377
	Eclectic model	9214.51	0.96	
Discharge BMI	Integrated CBT-E	8818.22	0.0001	
	Eclectic model	8417.01	0.89	
Length of admission (days)	Integrated CBT-E	8885.154	0.01	
	Eclectic model	92107.268	0.8	
Home mileage to in-patient unit	Integrated CBT-E	7620.62	0.000	
	Eclectic model	7967.180	0.5	
Age (years)	Integrated CBT-E	9032.213	0.005	
	Eclectic model	9427.558	0.80	
Waiting time for admission (days)	Integrated CBT-E	8933.48	0.95	
	Eclectic model	9233.14	0.3 ²	

Discussion

To our knowledge, this is the first paper providing a systematic analysis of referral patterns, access, waiting times and outcomes for adults with eating disorders requiring specialist in-patient treatment in England. The main strength of the study is the systematic data collection for 2.5 years, across a large geographical area with a population of 3.5 million. As the joint data collection had been established in July 2018, we have also been able to analyse the impact of the COVID-19 pandemic on this patient population and corresponding services. Although regional, our data derive from a large geographical area, representing 6% of the population of England, so we believe that our findings are representative of most adult eating disorder services elsewhere in the country.

Referrals have increased by 20% since the COVID-19 pandemic, and this has resulted in increasing number of patients needing admission to acute hospitals and further away from home. Waiting times for admission were long even before

2

the COVID-19 pandemic, and <50% of patients could be admitted close to home. Of those admitted, approximately a third were placed out of area. Out-of-area placements are well-known to cause distress to patients and families, and have been shown to have longer length of stay and poorer outcomes.¹¹ Most worryingly, even before the COVID-19 pandemic, patients with life-threatening malnutrition had to wait several weeks for admission, and this timescale has increased further since the pandemic, placing patients, staff and provider organisations at risk.

Although current national-level data by NHS Benchmarking on bed occupancy in hospitals suggest that demand is not dangerously high, this is not an appropriate indicator of how pressured specialist eating disorder services are across the care pathway. Infection control requirements and workforce impact of COVID-19 mean that the majority of NHS services are running at reduced capacity. Many services are struggling with reduced staffing levels resulting from the COVID-19 pandemic. Furthermore, in specialist eating disorder services, monitoring risks and ensuring patient flow between in-patient, day and out-patient services has become much more challenging in an already pressurised system.

The physical environment is important to ensure patient and staff safety. The Royal College of Psychiatrists has been campaigning for improving mental health estates and facilities.¹² This has become even more pressing since the COVID-19 pandemic: improving services to meet increasing demand requires capital investment into NHS mental health services

Following the high-profile reports into avoidable deaths, there has been an acknowledgement that adult community eating disorder services need to be funded to reach parity across the age range,^{6,13} and this is reflected in the new NHS England commissioning guidance for adult eating disorder services. However, this is still aspirational, and many adult patients struggle to access care or face long waiting times. This may explain the high number of patients in our network referred to hospital with a BMI of <13, in a life-threatening emergency, which has increased by 20% during the COVID-19 pandemic. This is a concern, as although the Royal College of Psychiatrists published the ‘Management of Really Sick Patients with Anorexia Nervosa’ (MARSIPAN) guidelines to improve patient safety in emergencies,^{14,15} their implementation has been inconsistent in acute hospitals, as shown by the recently reported tragedies. This is partly because of the limited training of eating disorders for doctors and allied health professionals, an area of concern that was identified by the PHSO.¹⁶

Although it is possible that the much needed investment into adult community eating disorder services in the next few years will reduce the need for in-patient treatment in the future, this is going to take several years. In-patient provision needs to be increased to meet current demand, which has quadrupled since 2007–2008 in England.⁴ Furthermore, recent national epidemiological data¹ indicate increasing prevalence across the lifespan, and this is consistent with increasing referrals to the community teams and the increasing rates of hospital admissions. NHS-led provider collaboratives will only succeed if funding meets the need in the population served.

However, it is important to consider the significant variations in length of stay and short-term outcomes between providers. Our findings are consistent with previous research. In 2013, a UK-wide cohort study of adult specialist eating disorder units reported an average length of stay of 182 days and an average discharge BMI of 17.3,¹⁷ with only 22% reaching a BMI of 19 by discharge. In our study, only 16% of patients admitted to a unit offering standard eclectic treatment reached a discharge BMI >19, as opposed to 50% in the I-CBT-E pilot programme (within a 25% shorter length of stay), Discharge BMI is an important predictor of medium- and long-term outcomes.^{18,19} Although this was not a randomised controlled trial, the treatment model is based on a previous randomised controlled trial, and published manuals.^{9,10,20,21}

The findings of the Oxford pilot programme (I-CBT-E) utilising an evidence-based and integrated stepped-care approach suggests that, with service transformation, reduced length of stay, improved patient outcomes and reduced restrictive practices are achievable. This can ensure use of existing limited in-patient capacity more effectively, and suggests a significant opportunity for cost-savings. This is particularly important, as a large proportion of patients in the cohort had an illness duration of >10 years. Our findings replicate previous studies from Italy,^{22,23} and suggest that the model is generalisable to the NHS. However, adaptation would require the redesigning of care pathways, staffing levels and skill mix. CBT-E training is freely available online (<https://www.cbte.co/for-professionals/training-in-cbt-e/>) and has been tested in previous research.²⁴

The main limitations of our study are that we only had BMI as a consistent indicator of outcome at discharge, and that the comparison between in-patient providers was not based on randomisation. However, randomisation would not have been practically possible, given the limited capacity and the dispersal of beds in a wide geographical area in England

and Scotland. Further work with our partners will explore more details of the longer-term psychosocial and health economic outcomes.

A multicentre, randomised controlled trial would be desirable, but it is important to note that the current NHS England standard contract is based on expert opinion rather than trial evidence, or robust outcome monitoring.

Clinical implications

It has been frequently stated that anorexia nervosa has the highest mortality of any mental disorder affecting young people and adults.^{25,26} We should not accept this: people should not die of anorexia nervosa or any eating disorder, as they are treatable mental disorders.²⁷ Severe complications, such as malnutrition, are safely reversible, even in the most extreme cases.

The I-CBT-E model is based on a cohesive, integrated stepped-care approach for people with severe eating disorders, and wider implementation in the NHS has the potential to both improve short-term and long-term outcomes, with the added benefit of cost-savings. A national audit of demand, capacity and treatment outcomes would help to establish the need for specialist eating disorder beds, as well as explore the differences between various treatment models. There is an urgent need for capital investment into NHS mental health facilities to ensure a safe environment for patients and staff in the light of the COVID-19 pandemic.

We are very grateful to all of our partners for submitting the data, Beris Cummings and Este Botha for data collection and Dr Andrew Ayton for proofreading.

- *David Walter Millard, FRCPsych, MD, MA (Mus)*

pmc Formerly Consultant Psychiatrist, Oxfordshire Mental Healthcare Trust, and Lecturer in Applied Social Studies, University of Oxford, UK

David Millard, who died on 13 January 2021 aged 89, had a varied career as a practitioner, teacher, academic and historian. The idea that a patient's social context could be altered in such a way that it enhances recovery from mental illness was at the heart of his work. The practical manifestation of this idea was the therapeutic community movement. David's interest in what makes groups and institutions tick resulted in a career that was framed by psychiatry, but which, in the middle period, took what was, at the time, an unconventional multidisciplinary path.

David was born on 9 February 1931 in Gloucestershire to Walter, a biology teacher, and Gladys Jarvis, a nurse (and a descendent of Thomas Hardy). One of David's school reports berated him for spending so much time on music, but his parents' occupations were influential in his choice of medicine. Following qualification from the University of Birmingham Medical School, he had intended to pursue a career in surgery, but Harold Macmillan and Suez intervened and a short service commission as a doctor in the Royal Army Medical Corps followed. On return, his career changed direction and he embarked on psychiatric training at Rubery Hill Hospital in Birmingham. There he experienced the therapeutic community run by John Yerburch, which shaped his future interests and career choices. He moved to Sir William Trethowan's professorial unit at the Queen Elizabeth Hospital in Birmingham, where he established a therapeutic community on Ward North 5A. Returning to Rubery as a young consultant, he was instrumental with others in building a third therapeutic community. However, after just 4 years, in 1970, his enthusiasm for the workings of multidisciplinary teams, growing academic interests and enjoyment of teaching led him to take the unusual step of relinquishing his consultant post in Birmingham to become Lecturer in the Department of Applied Social Studies at the University of Oxford. This reflected his interest in bringing psychiatry and social work together. The students were trainee social workers and probation officers. A devout Christian, he also taught Psychology of Religion for the Faculty of Theology and was for 20 years a Council Member and chair of the Institute of Religion and Medicine.

Through his continuing interest in the new and evolving Association of Therapeutic Communities (founded in 1972), David became the inaugural convener of its research group, followed by 8 years as joint editor of the *International Journal of Therapeutic Communities*. A prolific contributor to this and related fields, his MD thesis *Collected Writings on the Therapeutic Community* (1995) included an important contribution on the life and work of Maxwell Jones. This was reprinted in *150 Years of British Psychiatry 1841–1991: The Aftermath* (1996), edited by Hugh Freeman and German Berrios.

In 1979, under Sir Richard Doll's wardenship, David was invited to be one of the 18 Founding Fellows of Green College Oxford. He held posts as Senior Tutor and later Dean of Degrees. His devotion to the College was to last for the rest of his life. On retirement he was made an Emeritus Fellow of the College.

During his years teaching in the Department of Applied Social Studies, David maintained his clinical interests as an honorary consultant in Michael Gelder's newly formed professorial unit at the Warneford Hospital in Oxford, where he provided a psychodynamically informed out-patient service, including teaching medical students in the clinic. Gelder's

style of rigorous structured exploration of psychiatric diagnosis and the ambitiousness of academic medicine was not really to David's taste – but he enjoyed seeing patients too much to give up clinical work.

He retired from academic work in 1991 but continued his connection with NHS psychiatry, taking on a substantive post as consultant in old age psychiatry in 1994, which was to last for 6 years.

In Oxford his wide interest in social processes within institutional contexts led to his involvement in the governance of local organisations concerned with the elderly and with delivering often innovative services to psychologically vulnerable people in the community. Always interested in the most disadvantaged, David nurtured organisations that looked for restorative pathways, such as those for the homeless and people involved with the criminal justice system.

David was a careful, thoughtful listener. His wise advice – 'If it's not clear, get more information' – lies at the antithesis of decisive medical action in the absence of certainty, but was a constant reminder to go the extra mile for the patient. He led, but did not drive his teams to make better, broader, decisions. His espousal of flat hierarchy, drawn from the same humility that drew him to therapeutic communities, endeared him to staff of all disciplines.

An able cellist, pianist and musician with a keen interest in historical instruments, including constructing his own clavichord, David obtained an MA in Music following retirement. His dissertation, on musical feminine endings – in which an additional unexpected step is added and the penultimate chord is the strongest – betrayed his deep interest in the psychology of resolution.

He married Heather, by whom he had two children (Julian and Hilary). They divorced in 1976. He then married Sheila, a psychiatric social worker and group analyst, whose attention he attracted by his performance in role-play as an elderly grandmother at a conference.

In his later years he suffered from vascular dementia. It was fitting that, in his final illness, his wife was supported in his care by doctors, nurses and institutions whose development David had influenced: he reaped as he had sowed.

He is survived by Sheila, his two children, his two step-children (Peter and Laura) and his sister Ann.

2022-04

Contents

- *Response to: Lagunes-Cordoba et al 'International medical graduates: how can UK psychiatry do better?'*

pmc The paper by Lagunes-Cordoba et al¹ makes important points in relation to differential attainment in psychiatry. However, we note the statement: 'we note that technically the term "IMG" applies to a White British citizen who studies abroad and returns to work in the UK, yet such an individual is less likely to face attainment gaps'. This may not be entirely true, depending on what one means by 'attainment' in this context. We previously published a study

using data drawn from the UK Medical Education Database (UKMED), which investigated educational performance and success at recruitment into specialty training for UK International Medical Graduates (IMGs). These are doctors who are UK citizens but have obtained their primary medical qualification outside the UK. We showed that, on average, ratings at the Annual Review of Competence Progression were poorer for UK IMGs than non-UK IMGs. Nevertheless, UK IMGs were more likely to be successful, compared with IMGs, when applying for a specialty training post.² This finding obviously raises issues of fairness, and effectiveness, in postgraduate medical selection. We would also wish to draw attention to our own recently published study of differential attainment in the MRCPsych examination, which was not cited in the paper, though highly relevant.³ This demonstrated that differential pass rates at the Clinical Assessment of Skills and Competencies existed for candidates (both UK graduates and IMGs) who identified as being from minority ethnic groups, even after controlling for the influence of performance on knowledge-based components of the examination. Similar findings were previously reported by Esmail, for the Clinical Skills Assessment component of the MRCGP.⁴ At the time we suggested that these differential pass rates were likely to have complex underlying causes but urgently required investigating and addressing. Understanding and addressing differential attainment is clearly a matter of social justice but is also essential to the well-being of the National Health Service, its patients and the overseas-qualified staff it has traditionally relied on. Therefore, we felt it was important to draw attention to our own findings, which we believe have contributed to understanding this important but sensitive area of workforce research.

1.1.31 Recognition and management of depression in early psychosis

Zainab Bashir Sian Lowri Griffiths Rachel Upthegrove

Correspondence

Dr Sian Lowri Griffiths

(s.l.griffiths@bham.ac.uk)

date

2022-04

Abstract**Aims and method**

Depression in first-episode psychosis (FEP) is highly prevalent and associated with poor outcomes; it has become increasingly recognised and adopted in national and international guidelines for psychosis. Using a 26-item questionnaire, this study aimed to explore if this shift has led to greater recognition among UK psychiatrists, and more effective management of depression in FEP.

Results

Of the 297 respondents, 54.4% observed depression occurring in chronic psychosis, with the least number of respondents (17.7%) identifying depression occurring frequently during FEP. Although there was reasonable agreement in the use of antidepressants as a first-line treatment for depression (70% prescribing antidepressants), there was uncertainty around assessing depression and delineating from psychosis symptoms, and particularly negative symptoms.

Clinical implications

Evidence-based treatments for comorbid depression in psychosis will lead to clearer national guidelines, allowing for optimal management of depression in early psychosis, potentially leading to improved outcomes for these individuals.

pmc Depression is prevalent in first-episode psychosis (FEP), with rates of up to 70% at illness onset.¹ It is associated with a higher risk of relapse,² poorer functional outcomes^{3,4} and suicide.⁵ Although the National Institute for Health and Care Excellence (NICE) recommends monitoring for depression within psychosis, specific guidance on the treatment of comorbid depression has been limited, until recently.^{6,7} The lack of large-scale controlled trials investigating the effectiveness of adjunctive antidepressants⁸ has perhaps resulted in considerable variation in prescribing practices.^{6,9} A study of 80 000 international psychiatrists showed little consensus on the best management strategy for treating depression in schizophrenia; a third of clinicians reported that they rarely or never prescribe antidepressants in combination with antipsychotics.^{9,10} Since this publication in 2001,⁹ depression as a common occurrence in psychosis has become more widely recognised.^{11,12} Monitoring for depression in psychosis is featured more commonly in national and international guidelines,⁷ and the recent British Association for Psychopharmacology updated consensus statement is the

first UK guide to include specific pharmacological treatment recommendations.¹³

We aim to understand whether there has been an improvement in clinician awareness of depression in psychosis; this may have an impact on effective management, particularly in the early stages of psychosis, where treatment is likely to be more effective.¹⁴ Using a survey which was distributed to UK psychiatrists, this study aimed to explore the level of recognition and management of depression through the course of FEP.

Method

Participants

Participants were members of the Royal College of Psychiatrists, which is a professional organisation of psychiatrists based in the UK. The sample therefore comprised psychiatrists of various ages and career stage, from those in training to consultant level. Although there are around 8700 psychiatrists registered at the Royal College of Psychiatry, the survey was targeted at, and only distributed to, the general adult faculty. Participants were given the opportunity to enter into a prize draw to win £200 worth of Amazon vouchers.

Measures

Management of Depression in Psychosis questionnaire

The Management of Depression in Psychosis questionnaire is a shortened version of Siris et al's original questionnaire.⁹ It was felt to be the most suitable as it was designed to evaluate clinician awareness and management approach. It also allows for comparison of trends of psychiatric practices in assessing and managing depression in psychosis over time. The questionnaire has been adapted to focus on the identification of depression and prescribing in the early course of psychosis. For the purpose of this study, recognition of depression is defined as assessing for the three cardinal symptoms of depression, namely low mood, anhedonia and anergia. The questionnaire was built into Survey Monkey for ease, practicality and anonymous online administration. The questionnaire was completed anonymously and comprised 23 questions relating to the following: demographic characteristics of the respondents (e.g. gender, years since graduation, specialty/subspecialty and region of practice); recognition of symptoms relevant to the diagnosis of depression; depression time course in psychosis; factors and symptoms that prompt the prescription of antidepressants; evaluation measures; and treatment selection and practice (e.g. medication dose and duration).

Procedure

The questionnaires were completed over a period of 2 months after being granted ethical approval and agreed sponsorship by University of Birmingham (REC Reference: ERN_18-1658). Participants were provided with information about the study, informed of the voluntary nature of their participation, and reminded that responses were anonymous with the option to opt in for the prize draw. Written informed consent was obtained from all participants.

Data analysis

Data were downloaded from Survey Monkey (see http://www.surveymonkey.co.uk/r/Depression_in_psychosis_survey) and inspected using a Microsoft Excel (365 for Windows) worksheet. Descriptive statistics were explored using SPSS version 24 for Windows.

Results

In total, there were 297 respondents; although on average, it was observed that a third of the participants who completed the survey also skipped at least one question in the questionnaire. A total of 52% were male, and on average, the sample had 21 years (s.d. 11.5) of practice since graduating from medical school. Responses by geographical regions were as follows: London (13.4%), South-East (12.4%), West Midlands (11.9%), South-West (11.9%) and Scotland (11.9%). We had the least responses from Wales (2.6%), Northern Ireland (2.6) and East Midlands (3.6%), and 26.8% of participants did not give a response. The majority of the respondents were clinicians that practiced within community settings (67.7%).

Observed prevalence and time course of depression in psychosis

A total of 41.2% of participants had a case-load of which patients with psychosis comprised >50%; 46.6% had between 5–50% and 1.3% had <5%. The majority of respondents reported observing depression occurring concurrently with chronic stable psychosis (54.4%), and 23% reported depression occurring concurrently with acute relapse. With regards to depression emerging in the initial phase of illness, 19.1% observed depression within the prodromal phase to the acute psychotic phase; 32.4% reported depression emerging as the first acute episode of psychosis resolves, and 17.7% of respondents reported observing depression during the first episode of psychosis.

Assessment and diagnosis of depression in psychosis

Respondents were asked to select the first five most relevant symptoms they consider in diagnosing depression in psychosis: 93.2% identified low mood, 68.3% identified anhedonia, 57.1% identified suicidal thoughts, 53.2% identified poor motivation and 48.3% identified interest in life as a symptom. Please see *Fig. 1* for the full breakdown of symptoms reported by respondents. *Fig. 1* Breakdown of main symptoms identified by respondents to diagnose depression in psychosis.

The majority of participants reported not utilising a specific interview system to inform a diagnosis of depression in psychosis (96.6%). In terms of employing depression evaluation measures, 35.1% of respondents reported using none, 39.1% used the Beck Depression Inventory, 28.5% used the Hamilton Rating Scale for Depression, 17.2% used the Brief Psychiatric Scale and 9.3% used the Calgary Depression Scale for Schizophrenia (CDSS).

Recognition and management of depression in psychosis

Participants were asked about which clinical guidelines they used to aid the recognition and management of depression in psychosis: 61.5% of respondents used NICE guidelines, 50.0% used the Maudsley Prescribing Guidelines, 27.6% used British Association for Psychopharmacology guidelines and 12.0% used *BJPsych Advances* (previously known as *Advances in Psychiatric Treatment*) articles; the remainder mainly used clinical experience.

Treatment approaches

Antidepressant therapy

The majority of respondents reported that antidepressant medication would be their first line of treatment for psychosis with comorbid depression (69.5%), 32.5% indicated cognitive-behavioural therapy, 12.3% reported a 'watch and wait approach' and 7.4% would reduce the dose of the prescribed antipsychotic medication.

In terms of factors that would prompt prescribing of an antidepressant, 84.2% reported a family history of depression, 40.4% reported poor interpersonal and social skills, 39.2% reported 'living alone' and 29.8% reported a 'recent loss or rejection'. Key symptoms prompting a prescription of an antidepressant medication included hopelessness (80.1%), low mood (76.5%) and suicidal ideation (75.5%).

With regards to antidepressants prescribed in early psychosis with comorbid depression, selective serotonin reuptake inhibitors were generally preferred; the majority of respondents opted for sertraline (85.4%), followed by mirtazapine (49.8%), fluoxetine (45.4%) and venlafaxine (33.7%). Interestingly, 28.8% of participants opted for citalopram and 15.1% opted for escitalopram. Please see *Fig. 2* for the proportions of antidepressants prescribed. *Fig. 2* Proportions of antidepressants reported to be prescribed as first-line treatments for depression in early psychosis

Antipsychotic therapy

Participants were asked about antipsychotics they routinely prescribe for young people with early psychosis. Atypical antipsychotic agents were the most commonly prescribed: 66.0% of respondents opted for aripiprazole, 54.2% opted for olanzapine, 52.2% opted for risperidone and 44.3% opted for quetiapine. Clozapine was selected by 9.9% of respondents. Please see *Fig. 3* for the proportion of antipsychotics prescribed. *Fig. 3* Proportions of antipsychotics prescribed by respondents.

Drug combinations and treatment duration

In terms of conjunctive antidepressant and dopamine antagonist prescribing, 55.7% reported they would not frequently prescribe this combination, 35.8% reported often prescribing and 8.5% affirmed that they very often prescribe this combination.

A total of 13.5% of respondents stated that they would completely avoid mirtazapine and olanzapine in combination, with a handful citing reasons such as weight gain and oversedation; 14.4% stated they would actively avoid citalopram and antipsychotics in combination, with some citing reasons such as increased risk of corrected QT interval prolongation; and 42.3% reported that there were no combinations that they would actively avoid.

With regards to duration of therapy, 47.8% of respondents estimated expecting clinical benefits within 2–4 weeks of adding antidepressant to dopamine antagonist therapy, 43.3% thought it would likely take 4–6 weeks and 7.5% predicted improvement in 6–12 weeks. The majority of participants (77.5%) felt that antidepressant therapy should continue for 6–12 months once the individual showed a satisfactory response, 15.7% felt that therapy should continue for >12 months and 8.3% felt that therapy should continue for 3–6 months. In terms of physical health monitoring when coprescribing, 77.9% monitored heart rhythm via electrocardiogram, monitored blood chemistry (prolactin, glucose and lipid profile), 73.4% monitored bloods (prolactin, glucose and lipid profile) and 42.9% undertook a physical examination. However, 18.2% reported that no physical health interventions were carried out.

Non-pharmacological treatment approaches

On average, most respondents prescribed non-pharmacological therapies for depression in FEP, with 82.1% opting for psychoeducation and cognitive-behavioural therapy, 67.2% opting for psychosocial interventions and 42.3% opting for family interventions. A further 10.5% of participants reported prescribing electroconvulsive therapy, and a handful opted for lifestyle interventions and supportive psychotherapy.

Reflections from respondents

Overall, about a third of the participants highlighted difficulty in delineating negative symptoms of psychosis from depression during a period of psychosis. Others described the complex interactions of positive and cognitive symptoms that are hard to disentangle, as well as the possibility of an affective illness occurring as the primary driver for psychosis. Many respondents expressed keenness in offering psychology or psychotherapy, but cited problems with availability at the time of need.

Discussion

This study aimed to gauge the level of recognition and management approaches used by UK psychiatrists to manage and treat depression in psychosis. With depression in psychosis now being adopted in national and international clinical guidelines,⁷ we wanted to explore whether any change in recognition has led to more effective management of depression in those with psychosis, particularly in the early stages of illness.

Overall, the majority of respondents (69.5%) indicated the use of antidepressant medication as a first line of treatment for young people with psychosis and comorbid depression. There was reasonable agreement among clinicians on the contextual factors and key symptoms that would prompt a prescription of antidepressant medication. For example, the majority of respondents reported low mood and anhedonia as the major symptoms for diagnosing depression (93% and 68%, respectively), with 45% also identifying anergia as a core symptom. Over 80% of participants reported that they would routinely prescribe a selective serotonin reuptake inhibitor (sertraline in particular). This indicates a reasonable agreement between clinicians on the best strategy for managing comorbid depression with psychosis. These findings demonstrate a possible shift in the management strategy since Siris et al's⁹ earlier publication, where a third of clinicians reported that they would rarely prescribe antidepressants in adjunct to antipsychotic medication.

Although previous studies have reported 70% prevalence rates of depression at illness onset,¹ our study showed fewer respondents (19%) identified depression as occurring frequently in FEP; instead, 54% reported observing depression occurring with stable psychosis. This might suggest that depression in the early phases of psychosis is still underrecognised; this is concerning, given that young people in particular are at heightened risk of suicide within the first 12 months following the initial episode of psychosis.^{15,16} However, it must also be acknowledged that the findings from our survey are reliant on the memory of clinicians, with a potential for recall bias, and so the accuracy of these findings may be challenged.

Despite a consensus on treatment strategies for depression, what became apparent from the survey was the uncertainty around assessing depression and delineating from psychosis symptoms, and particularly negative symptoms. Interestingly, a large proportion do not employ structured interview schedules to inform their assessment, which could aid this delineation. In particular, the CDSS was only used by 9% of respondents. The CDSS is a short and easily used instrument, designed specifically for the assessment of depression in psychosis, as it distinguishes between negative and positive symptoms.¹⁷ Better promotion of these evaluation measures may be warranted.

There were also reports of challenges faced by clinicians in determining if the symptoms were part of an affective component of the psychotic episode, potentially highlighting the need for a better understanding of the diagnostic uncertainty and course of depression in early psychosis.¹⁸

Over the past two decades, there appears to have been a shift in prescribing of antipsychotic medications – particularly from the first generation (typical) to second generation (atypical) agents.¹⁹ This is also reflected in our survey, where the majority were prescribing atypical agents such as aripiprazole, olanzapine, risperidone and quetiapine, compared with 4.9% and 3.9% of respondents prescribing haloperidol and zuclopenthixol. Thus, there appears to be a particular preference toward the antipsychotics believed to have the least side-effects, but not with recognition that some antipsychotics may have more antidepressant properties,²⁰ or possibly promote depression, such as haloperidol.¹³

In regards to coprescribing in the present study, most respondents reported that there were no combinations of antidepressants and antipsychotics that they would actively avoid; however, some did express actively avoiding citalopram and antipsychotic in combination, with some citing risk of prolongation of the corrected QT interval. A similar percentage reported they would actively avoid a combination of mirtazapine and olanzapine because of increased risk of weight gain and sedation. In line with this, the majority of respondents (>70%) stated that they provided routine physical health monitoring when coprescribing. These findings indicate that clinicians are perhaps more cognisant of the potential physical health problems caused by antipsychotic medications, and may suggest proactiveness in mitigating such risks. Although this finding is encouraging, recent data shows that only 32.3% of individuals with severe mental illness in England receive a full physical health check.^{21,22} Given the lowered life expectancy of individuals with schizophrenia, the current NICE recommendations advocate for annual physical health checks for all individuals with severe mental health problems.²³ Improving physical health monitoring should remain a top priority.²²

Implications for clinical practice

Our results may indicate further training and embedding of routine assessment tools into clinical practice is needed to further increase the recognition and management of depression, which, if achieved, could improve outcomes. Indeed, this finding is in keeping with the wider literature on the difficulty of promoting the use of instruments, such as the CDSS, into routine practice.²⁴ A suggestion may be to embed these instruments into electronic patient records, and include monitoring of comorbidities as part of quality improvement programmes, and national audits such as the National Clinical Audit of Psychosis.²⁵

Study strengths and limitations

This study was the first to explore clinician recognition and management of depression in young people with FEP. Although the survey was completed by 297 clinicians, responses were underrepresented in certain parts of the country (particularly Wales, Northern Ireland and East Midlands), and overall response rate was low. On average, a third of the participants who completed the survey also returned incomplete questionnaires, affecting the overall representativeness of the information provided.

This study relied on the clinician reflecting on their previous practice, awareness and general approach, and they were provided with multiple options for each question. As such, there is a potential for recall bias. Furthermore, some questions were focused on depression within psychosis more generally, meaning that responses were less specific to depression in FEP. It is also very likely that clinicians within the Early Intervention Service and those with more interest in this field may have been more involved in the survey. An Amazon voucher was also offered as an incentive for participation, again, further introducing a respondent bias.

Another limitation was in disseminating the survey. Because of regulations governing the Royal College of Psychiatry, emails were only distributed to members registered under the General Adult Psychiatry faculty. The questionnaire was not disseminated to other psychiatric disciplines that may have been relevant, such as Child and Adolescent Mental Health Service, and Forensic or Learning Disability subspecialties. Finally, the survey was UK-based, with a low response rate. Further research is required to understand whether these practices are uniform in a larger sample of participants, and across different countries, particularly in the USA and Europe.

In conclusion, although there is now more consensus on recognising depression in early psychosis strategies, there continues to be variations in the approach toward its assessment and management (e.g. in the use of specific interview schedules or evaluation measures to assess depression in those with psychosis). Although our findings are tentative, given the low response rate, the survey indicates that adjunctive treatment is being administered by most clinicians; however, some expressed difficulties in differentiating between depression occurring in relation to psychosis and negative symptoms of psychosis, and there was little consensus on treatment duration and time of expectation of response. Embedding of structured assessment tools into routine practice, in addition to devising clearer national guidelines based on large definitive trials, would be instrumental in improving future practice in early psychosis, potentially leading to improved outcomes.

We thank the Royal College of Psychiatrists for supporting our research by distributing our study information to its members. We also thank the clinicians who took time to participate in this study.

Abstract

Can delusions, in the context of psychosis, enhance a person's sense of meaningfulness? The case described here suggests that, in some circumstances, they can. This prompts further questions into the complexities of delusion as a *lived* phenomenon, with important implications for the clinical encounter. While assumptions of meaninglessness are often associated with concepts of 'disorder', 'harm' and 'dysfunction', we suggest that meaning can nonetheless be found within what is commonly taken to be incomprehensible or even meaningless. A phenomenological and value-based approach appears indispensable for clinicians facing the seemingly paradoxical coexistence of harmfulness and meaningfulness.

pmc The prevailing clinical view of delusions in the context of psychosis, as reflected in the cognitive literature, supports the central proposition that delusions are the result of disturbances of reasoning and that they represent maladaptive appraisals about the world one inhabits. Such inferences are often taken to be grossly outside of the realm of psychological comprehension and, for the most part, inherently dysfunctional. In some cases, this can lead to prejudiced attributions of bizarreness, irrationality and meaninglessness. Very few empirical studies have investigated the relationship between delusions and meaningfulness. In addition, since the so-called ‘operational revolution’ in psychiatry, a tendency to focus on notions of disorder, disability and distress has often led to a reduced attention to issues of subjectivity, personhood and meaningfulness within the experience of illness. Through presenting this case study, we wish to bring these issues back to the fore.

The case of Harry, the ‘happiest man in the world’

Mr Harry is a 33-year-old gentleman who has been complaining of being the target of a worldwide conspiracy for the past 5 years. He explains that one day, he was in his room and he was picking his nose. The cameras in his room recorded it and this was uploaded to the internet; now everyone in the world, especially those in the USA, are talking about it. People in the streets make signs like scratching their nose or straightening their hair, as an indication to him that they have seen his videos and know about him. He believes that there is a hierarchy of people who are taunting him, and this hierarchy goes up to the Illuminati and the Queen. He thinks that there are lizard people in charge of the Earth that have made people believe that the Earth is round, when in fact it is flat and ends at the Arctic and Antarctic (where there are ice cliffs beyond which we are not allowed to go). He believes that people are being told lies since the day they are born, and two- and three-dimensional imagery are used by the National Aeronautics and Space Administration to fool people into believing what they see is real, just like in the film ‘The Truman Show’. Harry thinks that scientists are trying to fool humanity by leading us away from religion. Satan is taking over the world and the Earth is moving at 6660 miles per hour.

During a consultation with one of the authors (R.R.), Harry explained how he knows all this: ‘My senses have shown me that nothing is real, there is nothing outside this world, just infinite space’. These experiences are unique to him and he feels very special as a result, as nobody else has access to the truth. He reported watching YouTube videos that have proven all his theories, and now fully understands what the world is really like. He is the happiest man in the world and states that every day is filled with novelty and excitement. Harry finds it surprising that people are blind to all this, and have nothing better to do in their lives than following him around, listening to his thoughts and controlling him. However, he has now learnt that he can reply back and influence their thoughts positively, which has made him feel more powerful than he has ever felt. Harry denies ever feeling threatened or anxious when he found out about the conspiracies, although he has not been able to work because of this outside interference. When asked further about the challenges of conducting a life under the control of others, Harry replied: “‘If I went out one day and I realised that

people weren't expecting me to be there, it would be a real shock again ... I would be ... I don't know ...?! I got so used to people expecting me to be there and lash out with them ... I would feel alone again, which is what everyone else feels, like alone. So people are like a family for me, it's like a safety blanket, they make me feel so comfortable now ... If I found out that they are not watching me and reading my mind, I would feel alone and crazy like everyone else. To feel like I have everyone following me around, whether it's negative or positive, that alone is a force of power ... knowing that you can influence people's minds in the right way, I feel like Jesus (of course I'm not) but why not believe?"

Clinical encounter

Harry was referred to Early Intervention in Psychosis services via his general practitioner, after revealing the unusual situation in which he found himself. He was prompted to seek help by his family, who were concerned about his mental health, although he did not believe he needed help. Rather, he thought that everyone else was deluded for not realising what was really happening. At the time of the first interview with the psychiatrist, Harry was described as a very pleasant, cooperative gentleman, and caring father. Upon examination, his content of thought was characterised by ever-increasing systems of conspiratorial views of the world and described as bizarre – including, for example, the idea that the Queen is a lizard in disguise. This was associated with a mild degree of formal thought disorder and decline in social and occupational functioning. There was no evidence of marked changes in mood, hyperactivity or other signs of elation. Harry described 'voices' talking to him and about him, although when asked the direct question of whether he was 'hearing' voices, he denied this. Risk to others was considered to be low, whereas a potential vulnerability to others was highlighted.

Given the presence of clear positive psychotic features and impairment in functioning, suggesting first-episode psychosis, Harry was informed about treatment options and antipsychotic medication was prescribed. At the following appointment, Harry reported non-adherence with his medication. He said that he had realised there was a microchip inside him that was being used by others to monitor him and read his mind. People were making signs at him, following him around, thus he needed to 'deal with them'. He insisted that he was 'completely in control' and that those who were persecuting him were the ones needing help. While discussing medication, he became irritable and started accusing staff of considering him 'crazy'. He was not amenable to persuasion or reasoning. To avoid escalation, the clinician had no option but to let him leave for his home.

Management options were discussed, and clinicians were divided between those who felt that Harry's symptoms should not be necessarily considered pathological, and those who felt that his presentation would fulfil the criteria for compulsory admission to hospital. This latter understanding was motivated by the clear evidence of mental disorder, a detected risk of him acting out on his beliefs that others were persecuting him, potential risk (but no evidence of this) to his children and failed attempts to treat him in the community. Initial diagnostic considerations made by the treating clinician were in keeping with a diagnosis of schizophrenia. However, this diagnosis was challenged by others, who suggested that his delusions were better explained by a delusional disorder or, more simply, were in keeping with the influence of cultural factors and were not pathological at all. Harry remained convinced throughout that his experiences were real, that he was the happiest man in the world and that clinicians had no good reason to 'label' him as mentally ill or recommend a compulsory admission. Unfortunately, the disagreement led to significant subjective distress reported by Harry, a breakdown in the therapeutic relationship, disengagement from the team and other adverse social consequences, including denial of access to his children for a period of time.

Questions concerning current conceptions of delusions

This case is illustrative of more general, unresolved issues concerning current conceptions of delusions, which have a knock-on effect on the clinical encounter with deluded patients (irrespective of their diagnosis, but potentially more relevant in the case of schizophrenia). In particular: What exactly is pathological about delusions? This is briefly discussed in *Delusional complexities*. Are delusions the source of the problem or a response to the problem? This is addressed in *The phenomenological approach to delusion formation*. Can delusions have and give meaning? An overview of the small body of relevant literature is offered in the corresponding section. Our inquiry into meaning in this context takes a subjectivist naturalist perspective on the conception of 'meaning'. Meaning refers here to the extent to which one's life is subjectively experienced as making sense, and as being motivated and directed by valued goals.

We temporarily leave diagnostic challenges aside and explore possibilities for a cross-disciplinary dialogue between philosophy and psychiatry concerning the nature and meaning of delusions, with direct relevance for clinical practice. Implications for the clinical encounter are discussed in the final section.

Ethical considerations

The reported patient agreed to the publication of the case study and provided written consent. All steps were conducted in accordance with the regulations of Coventry and Warwickshire Partnership NHS Trust and the Declaration of Helsinki. Written approval for the publication of the report was obtained from the Research & Innovation Department, Coventry and Warwickshire Partnership NHS Trust.

Delusional complexities

Delusions are core psychopathological features of severe mental illness. They are present in the vast majority of patients at first presentation to early intervention services across affective and non-affective diagnoses within the psychosis spectrum.¹ They are often associated with great distress, depression and harm, representing a significant therapeutic challenge for clinicians.^{2,3} Despite extensive literature on the potential psychological, neurocognitive and phenomenological underpinnings of delusion formation,⁴⁻⁶ there is no consensus as to what causes delusions or why they are maintained despite their harmful consequences. Furthermore, cross-disciplinary attempts to define their puzzling nature remain inconclusive – perpetuating the philosophical debate between doxasticists (who regard delusions as beliefs) and non-doxasticists (who regard delusions as other than beliefs).

In psychiatric practice, given the absence of clear biological markers, the distinction between delusional and non-delusional ideas is not straightforward. Although meta-analyses of the available data corroborate a connection between reasoning biases and the occurrence of delusional ideas,⁷ they do not provide an explanation as to why delusions have the specific thematic content that they have, nor do they establish clear evidence for a causal relationship. Given the difficulties in defining what kind of phenomena delusions are, and in identifying the aetiological factors involved in their formation and maintenance, the clinical examination and study of delusions continue to focus on their (apparently more reliable) doxastic features. Such features predominantly consist of negative epistemic attributes such as falsehood/incorrectness, fixity/resistance to counterargument and counterevidence, and implausibility of content.⁸ For example, the DSM-5 defines delusion as: “‘A false belief based on incorrect inference about external reality that is firmly held despite what almost everyone else believes and despite what constitutes incontrovertible and obvious proof or evidence to the contrary. The belief is not ordinarily accepted by other members of the person’s culture or subculture (i.e. it is not an article of religious faith). When a false belief involves a value judgment, it is regarded as a delusion only when the judgment is so extreme as to defy credibility. Delusional conviction can sometimes be inferred from an overvalued idea (in which case the individual has an unreasonable belief or idea but does not hold it as firmly as is the case with a delusion)’ (p. 819).⁹”

However, as philosophers have already made clear, overreliance on these criteria is often not a successful strategy when trying to distinguish pathological beliefs from everyday irrational beliefs.¹⁰ For instance, prejudiced, superstitious or self-enhancing beliefs are all often ill-grounded and impervious to counterargument, yet they do not warrant a psychiatric diagnosis or compulsory treatment. In the case of Harry, these criteria evidently fell short and clinicians immediately noticed how similar Harry’s belief were to those held by ‘flat earthers’ and other fringe communities with heavy influence across social media. What then makes such beliefs different from those of patients affected by schizophrenia? When do beliefs become a symptom of mental disorder?

Focusing on the psychological and sociological features (such as distress, harm and dysfunction) associated with certain unusual convictions might be a better way forward for clinicians. However, this pragmatic approach, relying on criteria of clinical utility, hides other significant and ethically loaded challenges.¹¹ For instance, how do we equitably decide on the threshold of harm or potential harm that deserves a psychiatric diagnosis and/or warrants treatment against someone’s will? Such a decision will necessarily involve a value judgement on the part of the clinician not only about what might be harmful to another person in relation to their behaviour, but also in relation to their own feelings (e.g. levels of distress), sociocultural background, previous life circumstances and future goals. Disregarding the value-laden context that shapes the lived experience of delusional phenomena might increase patients’ vulnerability to suffering

epistemic injustice.¹² Harry for example, appeared to be adequately fulfilling his parental role and repeatedly denied feeling distressed, anxious, worried or depressed. A battery of psychological tests showed no clinically relevant anxiety or depression; rather, they revealed surprisingly high levels of meaning in life (see discussion below). On the other hand, his level of social and occupational functioning is moderately low. Harry is unable to maintain a stable occupation and what seems to be giving a special significance to his experience (i.e. the fact that he has special access to the truth) is effectively making him an outcast from society.

Clinicians therefore seem to be faced with a case of meaningful dysfunction. The person's beliefs seem to impose a limitation on their objective ability to keep consistent employment (social dysfunction). Concurrently, they also seem to enhance the person's sense of agency and belonging, and no distress is reported with regards to either the beliefs or the ensuing impairment. Does such a condition deserve clinical attention? Does it require pharmacological treatment? Despite being grounded within a delusional experience, could such feelings play a protective role against depression and anxiety?

It is clear that, although the concept of delusions as 'false beliefs' is commonly taken for granted within mainstream psychiatry, their complex nature remains difficult to grasp. As a result, the threshold for pathology or dysfunction continues to be set on pragmatic grounds relying on criteria of severity and degree of distress/functional impairment. However, in certain cases, it seems that the clinical utility of pragmatic criteria is limited by a clash with the framework of values of the individual patient. This begs the key question of what constitutes a meaningful or functional life, and leads us further into the relationship between facts and values in psychiatry.¹¹

Although many of these questions remain open and in need of further philosophical investigation, an important response in the past 20 years has been the renewed interest in phenomenological approaches to psychopathology. This has been accompanied by a revival of the legacy of Karl Jaspers and other classical authors, such as Minkowski, Bleuler, Conrad, Blankenburg, Mayer-Gross and J.S. Strauss, among others.^{13–17} The phenomenological approach argues that, particularly in the case of schizophrenia, there is a qualitative difference between 'true' delusions and delusion-like ideas, and that a more precise and in-depth characterisation of changes in the experience of self and lived world is needed if we aim to distinguish non-disordered analogues from clinically relevant forms of psychopathology.

The phenomenological approach to delusion formation

Various phenomenologically informed authors have challenged the view that delusions are beliefs (see *Table 1* for some excerpts from the contemporary phenomenological literature). In contrast with the doxastic (i.e. belief-based) position, phenomenologists have understood delusions to be either something of a completely different nature from beliefs (this is the 'non-doxastic' view), or they have suggested that this discussion is beside the point as it is failing to engage with what is most fundamental to delusion.¹⁸ Jaspers himself wrote: 'To say simply that a delusion is a mistaken idea which is firmly held by the patient and which cannot be corrected gives only a superficial and incorrect answer to the problem. Definition will not dispose of the matter' (p. 93).¹⁹ Table 1 Conceptions of delusions from a phenomenological perspective 'For the phenomenologist, delusion is typically understood not as an individual belief [...] but as a mutation of the ontological framework of experience itself.' (p. 633)²⁰ 'It follows that delusions, at least in this scenario, are not simply anomalous beliefs or perceptions. [...] They have a type of intentionality that differs from mundane experiences of believing, remembering, imagining or perceiving.' (p. 153)²¹ 'One might indeed argue that the so-called 'delusional beliefs' are not beliefs in the epistemic sense at all, for they lack the basis of a shared intentional relation to the world.' (p. 25)²² 'Schizophrenic delusions typically reflect a fundamentally altered existential-ontological structure of subjectivity.' (p. 173)²³ 'When a subject enters into a delusional state, he or she is entering into an alternative reality. [...] one can enter into a delusional reality just as one can enter into a dream reality, or a fictional reality, or a virtual reality.' (pp. 255–6)²⁴

Following Jaspers, much phenomenological research has drawn attention to the subtle and all-enveloping changes that are often described by patients with delusions during the 'prodromal' or 'pre-delusional' stages. Jaspers refers to this experience as 'delusional mood' or 'delusional atmosphere', and describes it as follows: "'Patients feel uncanny and that there is something suspicious afoot. Everything gets a new meaning. The environment is somehow different—not to a gross degree—perception is unaltered in itself but there is some change which envelops everything with a subtle, pervasive and strangely uncertain light. A living-room which formerly was felt as neutral or friendly now becomes dominated by some indefinable atmosphere. Something seems in the air which the patient cannot account for, a distrustful,

uncomfortable, uncanny tension invades him' (p. 98).¹⁹

In Jasper's view, the subsequent emergence of a specific belief content can only be understood in the context of a 'transformation in our total awareness of reality'.¹⁹ Such fundamental transformation can, in some cases, give rise to what he calls 'delusion proper' or 'primary delusions' to distinguish them from 'delusion-like ideas'. Although the latter kind of delusional beliefs can be understood as an excess or lack of certain known emotional states or responses (such as fear, melancholy, suspiciousness, anxiety and wonder), the former kind of delusions remain largely incomprehensible in the face of empathic or common-sense attempts to grasp their meanings.

Just as Harry mentioned the film 'The Truman Show' to aptly communicate his puzzling experience of infinite space, many patients talk about living in a 'real simulation' or a 'fake reality' to convey the sense of unreality that surrounds them. In these moments, they often describe changes in their subjective experience of the lived world, including the dimensions of time, space, objects, atmospheres and other persons.²⁵ For example, time or movements might be experienced as accelerated or slowed down, objects may appear two-dimensional as if they were artificially projected on the backdrop of a theatrical scenery, and other people may look like mannikins, puppets or robots wearing a mask.²⁶ This is similar to what Renee describes as an all-embracing atmosphere of unreality in her memoir: "Objects are stage trappings, placed here and there, geometric cubes without meaning. People turn weirdly about, they make gestures, movements without sense; [...]. And I - I am lost in it, isolated, cold, stripped purposeless under the light. A wall of brass separates me from everybody and everything. In the midst of desolation, in indescribable distress, in absolute solitude, I am terrifyingly alone; no one comes to help me. This was it; this was madness [...] Madness was finding oneself permanently in an all embracing Unreality' (p. 33, abridged).²⁷

Although this can be perceived in some cases as an exciting and illuminating experience (such as in Harry's case), most often the delusional atmosphere is fraught with dread, anxiety and a sense of uncertainty. Patients often describe an increasing tension coupled with an unbearable sense of impending doom.

In his seminal work, the German psychiatrist Klaus Conrad calls this initial phase 'trema' (stage fright) – emphasising the suspenseful and expectational character of the experience.²⁸ Even Harry reported that it all came as a shock for him, calling into questions everything he knew about the world since the day he was born. This state of perplexity seems to trigger an urgent quest for meaning, as highlighted in many first-person reports and clinical accounts.²⁹ The delusion then provides the long-sought meaning that dissipates anxiety, perplexity and confusion. In this moment, which Conrad calls the 'apophany' or 'aha experience', the person promptly makes sense of what was previously only alluded to. This new (delusional) meaning alleviates the unbearable sense of dread previously felt. The soothing effect provided by the experience of finding 'a fixed point' to cling on is described well by Jaspers: "This general delusional atmosphere with its vagueness of content must be unbearable. Patients obviously suffer terribly under it and to reach some definite idea at last is like being relieved from some enormous burden [...] the achievement of this brings strength and comfort, and it is brought about only by forming an idea, as happens with health people in analogous circumstances' (p. 98, abridged).¹⁹

Framed in this way, the newly developed delusional framework can be understood as establishing a new 'order' within the 'disorder', one which can alleviate negative feelings of anxiety or induce intense feelings of wonder. This allows the person to re-establish a pragmatic connection with the world, although this can come at great expense because of the difficult integration between the shared sociocultural world and the delusional reality. Rather than being the source of the problem, the emerging delusional narrative (i.e. what we currently identify as belief) may be better interpreted as a secondary response to anomalous experiences which call into question our most fundamental assumptions about ourselves, the world and the meaning of life.

Can delusions have and give meaning?

After a period of disengagement with services, Harry agreed to continue working with the team, although he refused to interact with staff initially involved in his care. Because of the research interests of one of the clinicians (R.R.), Harry was invited to talk about his experiences, and he happily completed a small battery of self-administered psychological tests that measure depression (Calgary Depression Scale for Schizophrenia),³⁰ anxiety (Generalized Anxiety Disorder seven-item scale)³¹ and meaning in life (the Purpose-in-Life Test (PILT), the Life Regard Index (LRI) and the Multidimensional Existential Meaning Scale).^{32–34} These assessments revealed high scores across three measures of meaning in life (indicative of a strong sense of coherence (SOC), purpose and significance), and low scores on the depression and anxiety scales, suggestive of absent levels of depressive or anxious features (see *Table 2*). Table 2 Self-administered measures of depression, anxiety and meaning in life conducted in the case study Measure Total score - Details of measures Calgary Depression Scale for Schizophrenia 36 is commonly used to identify clinically significant depressive symptoms Generalized Anxiety Disorder seven-item scale 0 Scores of 5, 10 and 15 are taken as the cut-off points for mild, moderate and severe anxiety, respectively Purpose-in-Life Test 96 Range 20 (low purpose) to 100 (high purpose) Life Regard Index 68 Range 14 (low life regard) to 70 (high life regard) Multidimensional Existential Meaning Scale 99 Range 15 (low existential meaning) to 105 (high existential meaning)

There is no doubt that Harry's experiences have brought about a significant change in the way in which Harry sees himself and the world around him, albeit one that others cannot recognise. As we can gather from his account, it all came as a shock, a powerful revelation of what life is really like. Whether this change is one that can be understood by others as 'having meaning' (i.e. making sense) and 'giving meaning' (i.e. contributing to a sense of purpose and significance) is a far more complex issue, but one worthy of further investigation and one that carries significant implications for the clinical encounter. From Harry's perspective, this new order seems to provide a coherent explanation for his experiences, while also enhancing his sense of direction in life and enthusiasm regarding the future.³⁵ There is, however, a remarkably small amount of empirical research that has examined such issues, which we briefly review below.

In a study by Roberts,³⁶ a group of patients with chronic schizophrenia displaying elaborated delusional systems was administered the PILT and the LRI. The author compared the scores obtained by actively delusional patients with chronic schizophrenia with a matched sample of other chronic patients, who were previously deluded but were now in remission. Psychiatric rehabilitation nurses and Anglican ordinands were also included as non-clinical comparison groups. Results showed that patients with elaborated delusions had a very high level of perceived purpose and meaning in life (and low level of depression and suicidal ideation), and PILT/LRI scores were significantly higher than those found in patients with chronic schizophrenia in remission. The group in remission felt both more depressed and found their lives less meaningful than those with active delusions. Scores in the actively deluded group were also similar to those found in the Anglican ordinands comparison group and higher than those found in the nursing group. Another study³⁷ investigated the relationship between the SOC and delusional experiences in individuals with schizophrenia, using self-report scales for delusions, SOC, depression and expressed emotion. SOC among participants experiencing acute delusion was found to be similar to the average scores found in the general population, but a reduction in SOC was found in the remission period, suggesting decreased well-being among those with reduced delusional intensity. These findings led Bergstein et al³⁷ to speculate about the subjective meaning-enhancing effect of delusional systems, and the potential negative consequences associated with the undermining of the acquired (delusional) background of meaning.

More recently, Isham et al² conducted a qualitative analysis of the narratives of 15 patients with past or present experiences of grandiose delusions. Although suggesting that serious harm (including social, physical, sexual, emotional and occupational) was occurring to people as a result of the delusions, the narratives examined contained first-person descriptions of the grandiose beliefs as highly meaningful: a meaning-making theme was generated through the analysis, where the delusion seemed to 'provide a sense of purpose, belonging, or self-identity, or to help make sense of unusual or difficult events.' A highly prevalent theme was related to social meanings (i.e. being useful to and a significant part of society), whereby participants felt 'part of a team', respected by others or involved in intimate relationships. Similarly, in their qualitative in-depth analysis of four cases, Gunn and Larkin³⁸ describe the development of delusions as an 'inevitable consequence of a radical alteration in lived experience'. Focusing on what was important to the participants and grounding their interpretation in the data by using interpretative phenomenological analysis, they highlight how all their participants had experienced some perceptual, affective and emotional anomalies demanding explanatory and

sense-making attempts. Although these attempts turn out to be delusional, they nonetheless seem to provide a fitting explanation for the anomalous experiences, as well as potential psychological benefits in terms of enhanced self-efficacy and meaningfulness.

Implications for the clinical encounter

Harry's case highlights the complexities intrinsic to the concept and nature of delusions, which are commonly taken for granted within mainstream psychiatry practice. By appealing exclusively to surface epistemic features, Harry's delusions might appear outwardly almost indistinguishable from fringe conspiracy beliefs. In both cases, they are ill-grounded and we have reasonable contradictory evidence regarding their veracity. Harry (just like many conspiracy theory believers) is not amenable to changing his mind about the fact that he is constantly monitored, that the Queen is a reptile in disguise and that the Earth is flat, among other more systematised convictions. His beliefs are certainly fixed and impervious to counterargument. Do these features make them pathological? By appealing to a pragmatic criterion of harmful dysfunction, we could agree on the fact that Harry's social and occupational functioning is impaired and therefore adequate interventions should be sought – aiming to ameliorate such undesirable state. However, Harry is telling us that he is the happiest man in the world. He reports finding a highly significant meaning for leading his life, something that gives him coherence and purpose. Value judgements necessarily come into play at this point, raising broader and more challenging questions about what makes a good life and where the threshold should be set for something meaningful to become harmful. Although we may not have a clear answer to these questions, we should at least attempt to investigate what the world feels like for Harry. Such phenomenological endeavour might not only open up a space for dialogue, but can also advance our understanding of the nature and constitution of delusional phenomena. Just like the three blind men who came to different conclusions as to the nature of an elephant, looking only at the 'belief' side of delusions might limit our understanding of what makes the delusional experience possible in the first place. This may further aid our attempts to define what makes delusions pathological or when they should be considered part of a disorder.

Taking into account the subjective changes to the sense of self and world often affecting people with delusions can improve our empathic understanding of delusional phenomena; that is, as arising in the context of a more global transformation of the sense of reality and familiarity. Within the clinical encounter, delusions can be at the same time harmful (e.g. causing a dysfunction of some kind) and meaningful. They can have meaning (i.e. make sense) in relation to uncanny changes in the lived world, and they can give meaning (i.e. purpose/significance) in the context of the person's unique life story and framework of values. When a clash of realities creates an impasse within the clinical encounter, clinicians should investigate the presence of anomalous and potentially distressing changes in the subjective experience of the lived world. Clinicians should also acknowledge the relentless sense of perplexity often arising from these experiences, which might trigger a search for explanations and a quest into the meaning of existence. Although empirical research into these issues is at its infancy, the potential role of feelings of meaningfulness in the maintenance of delusions (and their potential subsiding after remission) should be considered throughout the engagement and recovery processes. Further interdisciplinary research is needed to address the question of what constitutes meaningfulness and to explore its relationship with mental illness.

We would like to thank Harry for his participation and contribution to this report. We are also grateful to Lisa Bortolotti for providing helpful comments on an earlier draft of the article.

pmc Formerly Consultant Child Psychiatrist at Sutton Child Guidance Clinic and Clinical Assistant in Psychiatry in the Departments of Obstetrics and Psychotherapy at University College Hospital, London, UK

Gwen (Gwen) Jean Elizabeth Douglas, child psychiatrist and psychoanalyst, who died aged 100 on 22 June 2021, was a pioneer in the treatment of puerperal psychosis. Tom Main, with whom Gwen trained at the Cassel Hospital in London, had previously shown that it was possible to admit seriously ill non-psychotic mothers with their babies to an in-patient unit. Gwen, however, was the first to describe such an approach with psychotic women who, after childbirth, were suffering from schizophrenia or affective disorders. In 1956, having qualified as a psychoanalyst, she published a short but highly influential paper in *The Lancet* on giving psychotherapy to six mothers with puerperal psychosis who had been admitted with their babies to the Neurosis Unit at the West Middlesex Hospital. She concluded that such mothers could be safely looked after with their babies and successfully treated with psychotherapy either alone, or combined with or following physical interventions.¹ She was supported by Main, who wrote of 'the twin dangers of separating mother and child, first and more obvious, to the child and second and as fateful to the mother's confidence in her future capacity as a mother.'² Over subsequent years, treatment on a mother and baby unit gradually came to be accepted as the most effective way to manage post-natal psychotic disorders.

Gwen was born on 4 October 1920 in Papatoetoe (Papatoitoe) on the North Island of New Zealand, the daughter of William (Bill), later Sir William, Jordan, a senior Labour politician and later New Zealand High Commissioner to the UK, and Winifred (née Bycroft). She came with her family to England at 15 and did her medical training at St Andrews University, qualifying in 1944. After qualification she served with the Medical Branch of the Royal New Zealand Air Force. Following the war she married Bill Douglas, a meteorologist, and they moved to Malta, returning to England in 1949 when Gwen trained in psychiatry. She and Bill had a son, Martin.

In 1963 Gwen was appointed to a consultant child psychiatrist post at Sutton Child Guidance Clinic, where she remained till 1986. She later worked as a psychiatrist (together with Betty Tylden and Egle Laufer) in the Obstetric Department of University College Hospital with Professors Nixon and Brandt, investigating the causes of emotional disorders of the puerperium and patients with psychosomatic disorders.

Before retiring as a child psychiatrist, she joined the University College Hospital Psychotherapy Department, and supervised medical students on the student psychotherapy scheme as well as trainee psychiatrists. She retired from

the National Health Service in 1991 and continued to practise privately as a psychoanalyst until the age of 86. She was much loved by colleagues, students and patients, who appreciated her warm, undogmatic and imaginative approach to psychoanalysis, which was influenced by her teachers Charles Rycroft and Donald Winnicott. She spoke with a gentle and confident voice without any trace of her New Zealand origins.

In retirement Gwen was a keen flower painter and gardener, who enjoyed receiving friends in her beautiful garden in Banstead. She was an avid reader and loved going to all the latest art exhibitions in London. After 2007 she spent her final years comfortably and happily at the Mary Feilding Guild in Highgate and more recently at Henford House in Warminster. She was predeceased by her husband, who died in 1987, and her son.

1.1.34 Specialist teams as constituted are unsatisfactory for treating people with personality disorders

Conor Duggan Peter Tyrer

Correspondence

Peter Tyrer (p.tyrer@imperial.ac.uk)

date

2022-04

Abstract

It is now becoming standard practice in most advanced economies to provide specialist services for those with personality disorder. Such services, almost exclusively, provide complex well-structured psychological interventions lasting many months for a small number of those with borderline personality disorder pathology. The evidence suggests that these treatments are effective but they can only be provided for a small number of people. However, in every area the numbers of patients with significant personality disorder far exceeds those that are treated, and most of these have other personality disorders. It is argued that the current service system is not working efficiently and should be replaced by one that provides resources and expertise within community teams with some external advice from specialists but no transfer of responsibility to a designated team.

– Declaration of interest

In 2003 the now well-referenced and praised Department of Health booklet *Personality Disorder: No Longer a Diagnosis of Exclusion* made a number of statements about the development of new services that were being set up across the country at that time. This included: ““Good practice indicates that service provision for personality disorder can most appropriately be provided by means of: the development of a specialist multidisciplinary personality disorder team to target those with significant distress or difficulty who present with complex problems the development of specialist day services in areas with high concentrations of morbidity.’”¹

This advice has been followed for the subsequent 18 years and reinforced by National Institute for Health and Care Excellence (NICE) guidelines in 2009.² We believe it to be false, despite it being made in good faith, and a re-evaluation is needed.

Problems with current practice

Most parts of England now have a service devoted, if not dedicated, to the care of people with personality disorders.³ Although this is probably unique in providing the only national service for personality disorders in the world, it is not working too well. The notion behind these specialist services seems logical. Community mental health teams (CMHTs), at least initially, provide care for the main service-seeking group, those with emotionally unstable personality disorder (EUPD). But they are neither sufficiently skilled nor properly resourced for this task, so the obvious response is to refer them on to a specialist service. Unfortunately, this referral is not always successful, either because the appropriate specialist service is not available (very few offer comprehensive treatments) or it is judged that patients lack the psychological maturity to benefit from such an intervention. Rejections are frequent and this undermines the notion of ‘no longer a diagnosis of exclusion’. There can also be long delays and many bureaucratic hurdles to overcome before patients start treatment even if they are deemed suitable for one of the specialist treatments, mainly mentalisation-based treatment, dialectical behaviour therapy (DBT) or cognitive approaches. The experiences of patients in trying to access these services has promoted anger and also stigma, as many who feel rejected by these services for any reason blame the label of personality disorder and its incompetent adherents for their lack of care.⁴

Readiness for referral

An intervention to anticipate the delay has been suggested in this journal based on a transtheoretical model of change so as to ‘guide how to increase readiness for referral and when to refer’.⁵ This is complicated, including psycho-education about EUPD, personal formulation, crisis planning, motivational interviewing and several other things. But many will fail to negotiate this particular steeplechase of fences. At that point it is frankly ridiculous to expect the CMHT to provide further informed care. This inevitably leads to disenchantment on both sides; patients feel dissatisfied and are increasingly looking for interventions outside the standard systems to satisfy their needs⁴ and CMHTs feel disempowered while at the same time being ‘stuck’ with patients who are reluctant to engage.

The alternative view

A good service for those with personality disorder should be able to provide continuity of care and be able to engage with all those who have personality disorder. Currently, mental health professionals have a fixation with emotionally unstable personality disorder (EUPD) or its DSM equivalent, borderline personality disorder (BPD). This is understandable; it accounts for virtually all published guidelines⁶ and completely neglects the 84% of people with other personality disorders identified in national studies.⁷ There is another reason for paying more attention to the other personality disorders: their long-term outcome is currently less good than that for borderline personality disorder.^{8,9}

Specialist services for EUPD

So why does EUPD get all the attention? It is because it is the quintessential ‘treatment-seeking’ personality disorder (i.e. a type S personality disorder), in contrast to the majority of type R personality disorders, which are treatment rejecting.¹⁰ But treatment seeking should not be the only consideration. When services were being reconfigured to provide for those with personality disorder, a reliance on specialist services was unsurprising as these appeared to be underpinned by research evidence. But evidence is now changing. None of the systematic reviews of psychological treatments for personality disorder show compelling evidence of superiority of one psychological therapy over another or, indeed, when the specialist therapy was compared against good-quality clinical care.

Community mental health teams: a service for all with personality disorders

A good CMHT has: (a) a range of skills that can deal with a wide range of psychopathology, including managing many with comorbid mental illnesses; (b) stability, so that the team will provide continuity of care despite the loss of key individuals; (c) capacity to engage and contain individuals who are treatment resistant – given their experience in providing for those with severe mental illness; and (d) a closer link to general practice than specialist services.

Despite these advantages, nobody can be unaware of the pressures on CMHTs and so any additional service provision requires more training and resources if it is to be successful. In this context, services should be aware that significant funding is coming to community mental health services in the next 2 years (Tim Kendall of NHS England has pointed out that this funding includes a ring-fenced sum of £1.3 million for each 50 000 population group for community mental health and crisis-related services (T. Kendall, personal communication with permission, 2 June 2021)). This is genuinely new money and all should be prepared for this bonanza and ready and able to spend it wisely. This extra funding should enable a CMHT to include training in a simple assessment procedure that will allow it to separate those with significant personality disorder from those with lesser personality difficulties. Fortunately, the simple classification by severity in the new ICD-11 classification¹¹ is suitable for this task and straightforward scales are available to help with diagnosis.^{12,13} Patients with personality disorder who are not treatment seeking currently account for a disproportionate proportion of total costs¹⁴ and to fail to address their extra needs is negligent.

The procedure adopted by each trust could be along the following lines: one or more members of the CMHT are trained in the principles of identification and management of personality disorder on entry to the team each patient has their personality function assessed the trained CMHT members will take over the care-coordinating role for the patients with the more severe disorders when needed, a separate team with expertise in psychological treatments can be called in for advice and guidance, adding elements of the specialist interventions such as DBT but not involving taking over care from the CMHT the specialist team has an oversight role for patients with personality disorder in any part of care; this may often be particularly important when in-patient care is needed relevant information and care plans from the CMHT services will be shared more closely with primary care and crisis resolution teams, and day services when necessary, so that discontinuity in care can be reduced as much as possible greater use is made of primary care services and additional resources such as social prescribing, which has great potential in this group of patients but has been insufficiently embraced in mental health.¹⁵

The advantage of this arrangement is that all personality disorders are recognised, including the Galenic syndromes¹⁶ (closely intertwined mental state and personality disorders, named after Galen, who first postulated the link between personality and disease) such as substance misuse, impulsive disorders and anxiety and avoidant disorders (the general neurotic syndrome). Continuity of care and informed feedback are also more likely when patients are transferred to different parts of the services, and there is also much better transition from secondary to primary care.

This is the way forward, not the further accumulation of specialist teams.

We thank Jo Emmanuel, Tim Kendall and Fatema Ibrahim for advice in the preparation of this article.

1.1.35 The challenges and necessity of situating ‘illness narratives’ in recovery and mental health treatment

Nagina Khan Derek K. Tracy

Correspondence

Nagina Khan (nkhan786can@gmail.com)

date

2022-04

Abstract

In mental health services, recovery constitutes a guiding principle that is endorsed in professional medical guidelines and has become central to mental health policies across the world. However, for many clinicians, it can be a challenge to effectively embed recovery concepts into professionally directed treatment of disease without distortion, and ostensibly away from what matters to those who use the services. We discuss the evolving and multifaceted concept of ‘recovery’, including illness narratives to frame our discussion. We demonstrate how integration between a person-directed management of illness and a professionally directed treatment of disease can converge, resulting in positive outcomes for people with mental illness.

pmc Increasingly, patient-led research has been challenging traditional professional perceptions on the trajectory and outcomes of mental illness. (Of note, 'patient' is the stylistic word choice for this journal; the authors had submitted 'service user' in the draft. We recognise this is an area of discussion and debate). Many people may not fully recover from mental health problems, but can discover how to cope with their condition. Evidence has also highlighted that recovery, and many of the processes involved in it, can happen across a period – in many cases, outside of formal medical environments. In this editorial, we summarise and discuss contemporary aspects of recovery, including the co-concept of 'illness narratives'. We argue that although recovery can be a contested topic with differing views, it is also ubiquitous, and its meanings are not always fully incorporated into truly co-produced models. Models that put patients' narratives at the core could perform as a connecting mechanism that provides a process to take account of 'personalisation', which is likely to create a better fit with individual context, structure and the complex diverse realities of recovery-oriented practice and routinely provided interventions.

Definitions and debate

People outside of the formal health settings understand recovery in terms of their individual, specific and personal perceptions. Accordingly Anthony has shown that illness can hinder a person's perception of a productive life and undermine their process of recovery.¹ Anthony's work remains highly influential (and cited) to definitions of recovery, stressing that 'recovery is what people with disabilities do, recovery is a truly unifying human experience'.¹ He also asserts that recovery, is 'multi-dimensional, defying simplistic measurement'.¹ Other perspectives on recovery have been explored: Slade has divided these into two forms, with clinical recovery being defined as symptom changes viewed by the clinician,² and 'personal recovery' being defined as what the individual narrates and understands in a meaningful way.²

What is strikingly obvious here is that recovery is being presented in a distinct and separated pattern. This separation appears to be divided by the focus and the lens through which it is viewed. It is questionable whether this separation is helpful both clinically and furthering the discourse on recovery itself. The separation pushes apart the idea that 'professionally directed' treatment and 'person-directed' treatment can converge; indeed, the spirit of recovery would challenge the language of this – 'directed' inferring 'being done to a person' and would call for it to be more fitfully replaced by 'perspective'. McWade also reinforces our view that this concept of recovery can be defined in such a way that allows freedom to converge medical expertise and affords patients the autonomy in their individual journey to recovery.³ Patient movements have dominated the concept of recovery since the mid-1970s,⁴ and currently there has been criticism of professionals that look to be trying to 'mainstream' recovery concepts to their advantage.^{5,6}

Research on recovery

There has been a significant amount of research and published work attempting to support each of the individual recovery concepts, but little has been done on the positive outcomes of converging the constructs. Recovery research ranges from personal accounts⁷ to attempts to define, standardise or measure the conceptual framework,^{8,9} alongside histories¹⁰ and empirical studies.^{11,12} Recovery-orientated practice guidelines exist for service provision,^{13–18} including an emerging critique¹⁹ resting on personal recovery,^{9,20–22} recovery-oriented services,^{6,23–29} in addition to provider competencies.^{25,30–36} Despite the accumulation of research produced to support or isolate contested elements of recovery, disagreement and criticism remains over the definitions of recovery and on whether recovery has to be survivor-led or a policy directive.³⁷

Narrative and systematic forms of syntheses and reviews have tested tools^{20,22} to incorporate accepted components of recovery.^{34,38} This, however, has only led to further compound the idea of mainstreaming of recovery.³⁷ Amid this accumulation of criticisms, Braslow has shown that ‘recovery is everywhere’ despite including an array of perspectives.⁵ Since the 1990s, the concept of recovery in mental health domain has affected both the person experiencing mental health difficulties and the clinicians.³⁷ A conceptual framework that acknowledges recovery^{33,36} has been produced by Leamy et al, highlighting five main approaches in their CHIME framework: Connectedness, Hope – optimism, Identity, Meaning – purpose, and Empowerment.³⁸ However, CHIME has not been without its critics. Bird et al carried out a validation study applying thematic analysis of data from CHIME, using focus groups with those with diagnosed schizophrenia, bipolar disorder and depression.³⁶ They demonstrated that the CHIME framework was both valid and appropriate for use, but highlighted areas that were not included, such as ‘a desire for practical support, issues around diagnosis and medication, and scepticism about the concept of recovery’.³⁹ As noted, evaluating recovery is an inherently complex concept,⁴⁰ challenging the essence of creating ‘reliable measures of individual recovery’³⁹ and the construct validity of this. Andresen et al suggest that if the said concept of recovery is entirely individual,⁴¹ contrary to ‘what can it be normed and as might be expected for a concept in which symptom reduction is not paramount’, then ‘correlations with customary clinical outcome measures may possibly be poor and convergent validity low’.⁴²

Embracing diversity

Given all of this diversity of recovery principles, it is perhaps not surprising to find professionals misunderstanding and confused^{40,43} in the operational aspects, emphasised in popular guidelines, discourse, policies and research. Pilgrim aptly suggested that recovery is a polyvalent concept.⁴³ However, this does not translate easily to those who may wish to activate the recovery construct for better patient outcomes and improved service delivery. Quiet so, Braslow has argued that recovery remains an ‘unquestioned overarching principle and popularly known to include a melange of beliefs, values that materialized because of the intellectual and social movements’.⁵

Moving to recovery-orientated services

An anthropological model

To further link back to the discussion on the concept of converging the person-directed management of illness and professionally directed treatment, we recognise, similar to Davidson and Roe, that an anthropological model – one situated upon ‘principles of reciprocity’ that concerns itself more with the integration of healthcare⁴⁰ – could complement and augment professional knowledge.⁴⁴ However, this requires a substantial shift in the clinical lens, incorporating ‘lay types of knowledge’, such as a person’s own understandings of dealing with illness, including social functioning.⁴⁴ Suitably, Davidson and Roe conceptualise that meaningful illness narratives are a gift exchange, providing meaning, emotive steadiness, narration and collective experience.⁴⁰

Illness narratives and professionals' treatment

Biological aspects have often been viewed by patients as both coercive and impersonal,⁴⁵ although we may be seeing some welcomed change with this, and COVID-19 may offer an interesting corollary, with the emphasis of 'long-COVID' care moving toward wellness and self-management of long-term chronic difficulties. Pilgrim has pointed out that the root basis of patients' adverse perceptions can be based on pathology, making clinicians appear as 'chemotherapists with a prescription pad'.⁴⁵

The UK and co-production: the Care Programme Approach as an exemplar

In the UK, the National Institute for Health and Care Excellence explicitly calls for care plans to be jointly drawn up between individuals and their clinician, with shared decision-making and agreed dates to review its progress.⁴⁶ The Care Programme Approach (CPA) necessitates that health and social needs are comprehensively assessed and reviewed with individuals with serious mental illness, with a 'philosophy of recovery and to foster personalised care'.⁴⁷⁻⁴⁹

Despite their imbedding in contemporary British mental healthcare,⁵⁰ there remains a general lack of data exploring actual practice in the community, and even less that is focused on in-patient care.⁵¹ The Healthcare Commission in the UK assessed in-patient performance across 554 wards in 69 National Health Service (NHS) Trusts. About 40% were rated as 'weak' when it came to including patients and carers; astonishingly, half of care plans had no evidence of recording patients' views, and about a third made no mention as to whether there was a carer involved. A further third had input from the patients' community care coordinators only some or none of the time.⁵²

Work by Simpson et al examined the views and experiences of stakeholders involved in community mental healthcare, investigating factors related to the provision of personalised, collaborative, recovery-focused care.⁵³ They found substantial variations among sites for results on therapeutic relationships and participant groups in their study, related to the experiences of care planning and understandings of recovery and personalisation.⁵³ Consequently, carers expressed varying levels of input, and despite risk assessments being part of central clinical concerns, they were rarely discussed with patients.⁵⁴

Patients valued therapeutic relationships with care coordinators and others, and saw these as central to recovery. However, in another study by the same team, the staff, patient and carer interviews revealed gaps between shared aspirations and realities,⁵⁵ and staff accounts of routine collaboration contrasted with patient accounts and care plan reviews. They also found that personalisation was not a common phrase, but care was often delivered in an individualised way.⁵⁵ McWade has argued that this endorses that perspective of failure of co-opting or mainstreaming the 'thing' that is recovery.³

Contact with clinicians and patient engagement

'Illness management' can be understood as an approach to support patients with a diagnosis to engage with clinicians, to reduce patient susceptibility to the disease.⁵⁶ Conversely, 'illness problems' are the principal difficulties that symptoms and disability create in lives, and 'illness behaviour' then consists of initiating treatment (for example, changing diet and activities, resting, engaging in exercise, taking over-the-counter or prescribed medications and deciding when to seek care from professionals).⁵⁷ There is an overdue lack of understanding placed on the notion that there is a pre-existing underlying relationship between the person and their illness. Albeit in separation of formal treatment environments, this occurs in the way individuals perceive their difficulties, the type of help they envisage, and the approach they are willing to engage with for formal treatments; it includes making contact with clinicians and entering into a contract with services for future treatment.

The socialisation of the practitioner

For the purpose of this editorial, a critical discussion cannot be complete without including a focus on clinicians' understandings. Hitherto, psychiatric models have perhaps viewed the concepts of recovery from mental illness in a similar style to how clinicians have viewed physical illnesses.⁵⁸ We propose that Kleinman's illness narratives model has proved influential in this regard, remarking how the practitioner has also been socialised into a distinct collective experience of sickness. It is true that clinicians are trained to capture the essence of illness by using concepts that delineate disease. For instance the use of expressions such as relapse, recurrence, remission and recovery.⁵⁹ In this way, the symptom profile is used to transform the patient's illness (in a form of recasting of illness in accordance with the theories of disorder) into a disease formation.⁵⁷ The absence of an ongoing intervention other than that relationship can be perceived by care managers as a need for premature discharge from services, for fear of creating dependency. However, some who use services desire an ongoing relationship, which commonly matters more than interventions, and this aspect can be missing in some recovery narratives. The construct of so-called 'palliative psychiatric care' is informative in this regard.⁶⁰ Further, moral experience is central to Kleinman's model of illness narratives, incorporating constructs of ideal virtues of the practitioner⁶¹ and so opening up 'illness narratives' to create patient 'storylines', which brings to life inanimate parts of practices, policies and discourses.^{62,63} Hajer suggests that storylines are 'narratives on social reality', which combine elements from many different domains and 'provide actors with a set of symbolic references that suggest a common understanding'.⁶⁴ Albeit critically, Kleinman also envisaged that partnership is vital and is susceptible to change over time, with caregiving perceived as a construct focused more on 'doing good for others in their world' and projecting that 'as earnest and naïve as it sounds, it is what medicine is really about'.⁶⁵

Patient perspectives of 'corporate' recovery/criticism

Despite the common understandings, it should be noted that some patients remain suspicious of the recovery concept because it is potentially intolerant of those who do not change, and so it may remain, in their eyes, a source of oppression used against them.⁶⁶ There is a recurring critique of recovery presented as the 'next best thing',⁶⁷ and a mere form of symbolism, undermining 'authentic alliances'⁶⁸ donning recovery in a sense to reduce effective support.⁶⁹ Service cuts have been associated with the manner in which services and health systems manage future demand for mental healthcare, allied to the economic cutbacks planned for financial savings.^{70,71} Consequently, recovery concepts used in this method risk being used, or at least perceived, as indicative of justification to reduce services or their ability to provide timely input.

Moving forward: making it work

In the majority of English-speaking countries⁴⁰ the importance clinical recovery² and personal recovery are touted in guidelines for key clinicians.⁷²⁻⁷⁶ The significance of tackling personal recovery, in conjunction with more standard concepts of clinical recovery,² is currently endorsed in guidance for all key professions.⁷²⁻⁷⁶ Whether it as a model or framework, a movement or a guiding ethos, recovery is now 'the hegemonic guiding principle of public mental health policy'.⁵ The social sciences have already reworked treating disease as a process of medical micro-encounters,⁷⁷ and to the idea that 'disease problems' can occur within an individual's circumstances of everyday life.⁷⁶ It is evident that researchers, clinicians and services alike may require a more complex approach to personal narratives and construction of meaning if individual recovery is to be more clearly understood.⁷⁸

Psychiatric treatment historically conceptualised primarily based on a disease model could have the potential to impede the long-term treatment and assessment of those with chronic difficulties and illness. Linked to this assertion, Voronka has indicated that narratives can be utilised and shaped as a 'gap-mending' strategy,⁷⁹ not merely because they interfere with professional knowledge, but because they have the power to strengthen the capabilities of individuals to bring forth personal goals and generate a sense of identity,¹⁷ a fusion, a convergence to create a mechanism of acceptability, of both person-directed management of illness and professionally directed treatment of disease, or, in essence, shared understandings of recovery and shared decision-making toward that outcome. Roberts and Hollins have also encouraged that medicine ought to discern that 'disease understandings' are embedded in patients' experiences and their daily lives, and are considerably tied to a person's social history.⁷¹ This necessitates clinicians to move from a tradition

of ‘paternalistic attitudes’ of helping or being the expert, to create meaningful alliances.⁸⁰ Likewise, Lawton et al described an approach to illness experiences that recognises a dynamic interplay between ‘survivor’ and the healthcare system, whereby one affects the other,^{71,77} suggesting that medical encounters merely comprise a relatively insignificant portion of most patients’ lives (although symbolically they may represent more). Accordingly, the medical support to patients’ ‘sense-making’ tends, in reality, to be exhausted by the conditions and encounters met in the extra-medical social world.⁸¹

Recognising and embracing recovery concepts enhances care and the therapeutic experience for professionals and patients. The possible ‘recursivity’ between services and perceptions is relevant to understanding the way in which those with mental health problems might engage with care services.^{73,81} Peer support is increasingly recognised and implemented within NHS services, with roles in the UK typically at band 4/5; indeed, the Health Education England publication ‘Stepping Forward to 2021: The Mental Health Workforce Plan in England’ advocates even greater expansion of this.⁸² Nevertheless, there has equally been a call and need to deliver care in ways that have just not been possible in traditional teams. A potentially very fruitful and positive development in this regard has been the growth of recovery colleges, driven by strong patient engagement and roles, often at odds with, or at blurred boundaries to mainstream NHS services. Accordingly, central to improving outcomes for individuals, services should involve providing services that are ‘person-centred, strengths-based and recovery-focused’.⁷⁴ To enable the interpretation of the recovery approach into practice, there is a necessity to involving illness narratives as a mechanism to personalise treatment and care so that it can be operated and assessed within medical and research environments.^{20,25}

1.1.36 Views on psychotherapy research among members of the Medical Psychotherapy Faculty of the Royal College of Psychiatrists

Marcella Fok Tennyson Lee Jessica Yakeley

Correspondence

Dr Marcella Fok (marcella.fok@nhs.net)

date

2022-04

Abstract

Aims and method

Research drives innovation and improved practice in psychotherapy. We describe views of members of the Faculty of Medical Psychotherapy of the Royal College of Psychiatrists (RCPsych) regarding their knowledge, experience and perspectives on psychotherapy research. We sent questionnaires to the Faculty membership emailing list.

Results

In total, 172 psychiatrists from all levels of training returned fully complete responses. Respondents considered knowledge of psychotherapy research to be important to clinical work. Many have qualifications and experience in research but lack current opportunities for research involvement and would welcome the Faculty doing more to promote psychotherapy research. Perceived obstacles to research involvement included lack of competence, competing demands and wider organisational factors.

Clinical implications

The lack of research opportunities for medical psychotherapists may lead to their underrepresentation in psychotherapy research and a less medically informed research agenda. Providing support at academic, RCPsych and National Health Service organisational levels will allow more clinically relevant research not only in psychotherapy but in other psychiatric disciplines as well.

pmc Research is a cornerstone of psychiatry in all its areas of knowledge, understanding and practice. As a branch of psychiatry, psychotherapy needs research. Although cognitive–behavioural therapy has been considerably researched, the relationship of psychoanalytic psychotherapy to research is complicated. Within psychiatry and among the public, there are common perceptions of psychoanalytic psychotherapy as unscientific and psychotherapists as uninterested in research.

Let us begin by outlining the issue: what is the problem regarding research in psychotherapy? There is evidence that psychoanalytic psychotherapy services within the public sector in the UK have been disproportionately reduced compared with other mental health services.¹ This may be due to a lack of a robust evidence base in psychoanalytically oriented psychotherapy compared with other modalities, such as cognitive–behavioural therapy. However, high-quality research in psychoanalytic psychotherapy can substantially advance our knowledge of the efficacy of treatment of different mental disorders.² Within the psychoanalytic community a lack of understanding and interest in research persists;^{3,4} this is reinforced by a (real and perceived) split in the community between academics, who do research, and clinicians, who see patients. Many of the trials in psychodynamic psychotherapy have lacked sufficient methodological rigour and do not necessarily reflect real-life practice.⁵

Among psychoanalytic psychotherapists, resistance to research is driven by several factors. Research methods (such as manualisation of treatments, randomisation of patients, recording of sessions, administering outcome measures) are often seen as interfering with clinical technique and practice. Practising therapists may have a poor understanding of the research currency of statistics and numbers and end up finding research activity mindless and meaningless. Moreover, research is treated with suspicion, as it may challenge established and cherished theories.⁵

Nevertheless, there are strong reasons for psychotherapists to engage in research. We need first to investigate the efficacy and outcomes of psychotherapy, to ascertain whether change does occur with treatment, and second to investigate the process of therapy, to understand what happens in therapy and how change occurs. We also need to ensure the safety and quality of treatment and to explore patients' experiences of psychotherapy. As for commissioners, patients and the public, their expectation of research engagement and the evidence base for psychotherapy needs to be satisfied. Finally, research is an effective means of interrogating new and existing theories and of communicating with colleagues.

One should bear in mind that psychiatric practice involves at its heart the use of a therapeutic relationship, and research into aspects of this relationship can reap useful and highly applicable rewards.^{6–8} The relative sparsity of research in this area reflects the current dominance of the biomedical paradigm within psychiatry. The predominance of cognitive–behavioural therapy, alongside the biomedical paradigm, has played a part in the neglect of psychotherapy research among psychiatrists.

The Faculty of Medical Psychotherapy of the Royal College of Psychiatrists has a membership consisting of psychiatrists who practise psychotherapy as their main therapy or use its principles in their work, as well as psychiatrists who may not be practising psychotherapy but have an interest in the subject. Among those practising psychotherapy, different modalities of therapy may be used; however, psychoanalytic psychotherapy is the main modality in which the majority of medical psychotherapists have been trained. The Faculty is interested in research and is exploring ways of promoting

psychotherapy research.

In this study, we surveyed our membership, with the aim of describing psychiatrists' views on research in psychotherapy and their experiences in engaging with research.

Method

Design

A web-based survey was designed by the two joint Research Leads (M.F. and T.L.) of the Faculty of Medical Psychotherapy. The Chair and Vice-Chair of the Faculty were consulted in the design of questions and response options. The College Registrar gave approval to the final version of the survey before its distribution to Faculty members. Survey responses were anonymous.

The survey consisted of 26 questions and covered the following areas: general respondent characteristics (member group, current post, work location) views on the importance of psychotherapy research ways of learning about psychotherapy research satisfaction with their own knowledge of psychotherapy research and interest in gaining knowledge research experience opportunities for, and obstacles to involvement in, psychotherapy research views on the Faculty's interest and involvement in research suggestions to the Faculty regarding promoting psychotherapy research suggestions to support trainees in psychotherapy research.

The format of the questions varied (Appendix) and some questions asked for additional free-text responses. The survey was written and hosted on SurveyHero and was sent out via email to the entire Faculty membership (3842 UK members and 827 overseas members). The email contained a brief message introducing the survey and the reason for doing it, and a direct link to the survey webpage. The email was sent in August 2019 by the College Faculty and Committee Manager. A reminder email was sent before closure at the end of September 2019.

Participants

All Faculty members, including psychiatrists at all levels of training and experience, were emailed about the survey.

Analysis

Only fully completed survey responses were included in the analysis. Data were examined numerically and we also identified key themes in the free-text responses.

Results

We emailed 4669 Faculty members about the survey; 501 persons viewed the survey, and 246 responses were received before the closure date, of which 172 were fully completed responses (i.e. all survey questions answered). The participation rate (number responded out of number viewed) was 49.1% and completion rate (number completed out of number participated) was 69.9%. The response rate (number of responses out of number who were emailed about the survey) was 5.2%. The characteristics of the 'completed' respondents are shown in *Table 1*. *Table 1* Characteristics and responses for the 'completed' respondents Total ($n = 172$) Consultant with CCT in medical psychotherapy ($n = 42$) Consultant in other specialty ($n = 60$) Higher trainee in medical psychotherapy or dual training incl. medical psychotherapy ($n = 14$) Core trainee or higher trainee in other specialty ($n = 25$) SAS^a or other ($n = 31$) Medical psychotherapy sessions form part of current post Yes 96 (56%) 34 (81%) 24 (40%) 12 (86%) 15 (60%) 11 (35%) No 76 (44%) 8 (19%) 36 (60%) 2 (14%) 10 (40%) 20 (65%) Work base UK 154 (90%) 41 (50%) 150 (83%) 13 (24%) 26 (84%) Outside UK 18 (10%) 11 (17%) 11 (16%) Do you agree that knowledge of psychotherapy research is important for your work? Respondent characteristics

Of the 172 respondents, 18 (10%) were from outside the UK and the rest were from within the UK; 42 (24%) were consultant psychiatrists with a Certificate of Completion of Training (CCT) in Medical Psychotherapy; 60 (35%) were consultant psychiatrists of other specialties; 14 (8%) were higher trainees in medical psychotherapy (including those in dual training); 25 (15%) were core or higher trainees in other specialties; and 31 (18%) were 'SAS (Specialist and Associate Specialist) or other' psychiatrists. Ninety-six respondents (56%) had medical psychotherapy sessions as part of their current post. In terms of research backgrounds, 82 of the respondents (48%) had some research qualification (i.e. BSc, Masters or Doctorate level degree, or other, or a combination of these); 97 (56%) had published non-psychotherapy research; 50 (29%) had published psychotherapy research; and 44 (26%) had published both types of research.

Views and knowledge of psychotherapy research

When asked ‘Do you agree that knowledge of research is important for your work?’, 168 respondents (97%) answered in the affirmative (‘agree’ or ‘strongly agree’). Respondents were asked to rate their satisfaction with their own level of knowledge in psychotherapy research. Those who had the highest level of satisfaction were consultants in medical psychotherapy (50% were ‘somewhat’ or ‘very satisfied’), followed by SAS or other psychiatrists (48%), consultants in other specialties (37%) and higher trainees in medical psychotherapy (29%). Core and higher trainees in other specialties had the lowest satisfaction rate (16%). Rates of dissatisfaction (i.e. responses ‘somewhat’ or ‘very dissatisfied’) ranked almost in the reverse – highest among core and higher trainees in other specialties (68%), followed by higher trainees in medical psychotherapy (57%), consultants in other specialties (27%), consultants in medical psychotherapy (21%) and SAS or other psychiatrists (19%).

Respondents were asked to report which method(s) they used (from five given options and an option ‘other’) to gain knowledge in psychotherapy research. The most common methods were attending conferences (79% of respondents) and reading journals (78%), followed by discussion with colleagues (69%) and using electronic resources (such as saved Google scholar searches) (53%); 20% endorsed ‘involvement in psychotherapy research activity’ as a way of gaining knowledge; 11% reported ‘other’.

Research experience

Regarding experience in specific research activities, the most common activities were literature review, data collection, and data cleaning or analysis (each reported by 75% of respondents). Also fairly common were writing papers (67%), study design or protocol writing (60%) and recruiting research participants (53%). In total, 38% of respondents had been involved in peer reviewing and 33% in delivering interventions in a trial. Only 3% reported no involvement in any of these research activities.

Opportunities for psychotherapy research

Thirty-nine respondents (23%) reported having current opportunities for involvement in psychotherapy research – these respondents came from all five member groups (12 consultants in other specialties; 12 consultants in medical psychotherapy; 4 core and higher trainees in other specialties; 6 higher trainees in medical psychotherapy; 5 other psychiatrists).

On rating their current opportunities for involvement in psychotherapy research, 71 respondents (41%) were neutral (neither satisfied nor dissatisfied), 45 (26%) were somewhat dissatisfied and 25 (15%) were very dissatisfied. Fewer respondents were somewhat satisfied ($n = 16$; 9%) or very satisfied ($n = 15$; 9%). Trainees reported higher levels of dissatisfaction (i.e. either somewhat or very dissatisfied: 14 (56%) core and higher trainees in other specialties and 9 (64%) higher trainees in medical psychotherapy) than did non-trainee groups (26 (43%) consultants in other specialties, 13 (31%) consultants in medical psychotherapy, 8 (26%) other psychiatrists).

Obstacles to involvement in psychotherapy research

The majority of respondents perceived obstacles to becoming involved in psychotherapy research ($n = 135$; 78%). Additional free-text responses to this question were coded and assessed to identify specific themes. The themes identified are shown in *Table 2* and the following selection of free-text responses. *Table 2* Perceived obstacles to getting more involved in psychotherapy research
Age/retirement
Clinical workload
Lack of contacts or potential collaborators
Lack of funding/infrastructure/research administrative support
Lack of knowledge/competence/confidence
Lack of opportunities
Lack of personal interest
Lack of senior colleague support/mentoring
Lack of time/competing interests or commitments
Not in research post or no allocated time in job plan
Wider organisational factors
Other

Lack of time, competing demands: “‘Dedicated research time has been removed from my job plan. Clinical and managerial pressures now make research very difficult.’ ‘Mainly lack of dedicated time and links with established psy-

chotherapy researchers.”Lack of support and contacts: ““Too little time; no admin support for the scout work; no team or group to support applications; hostile competition from psychology and psychiatry; hopeless stereotypes about medical psychotherapy.’“Support and time. It requires membership of a group. I have not been able to develop these in spite of trying to collaborate with research psychologists.”Lack of opportunities, wider organisational factors: ““Don’t know who to contact/not aware of any current psychotherapy research projects being undertaken within my trust/its associated academic institute.’“There simply is no psychotherapy research as far as I know.’“Not seen as a priority by academics, therefore not encouraged/supported.’“No good research going on – multicentre – in my area of interest that is psychodynamic.’“There just isn’t a lot going on and when I do find some to be involved in it’s hard to get my name on the paper if and when it gets published.”Lack of potential collaborators, lack of senior colleague support: ““The lack of psychotherapy research that I would be interested in in close enough proximity to where I work.’“Limited interest in research among colleagues and trainers.’“The high-flying research department I work in regularly shunned psychotherapy research related proposals I made for seven years.””

Faculty role and activities to promote psychotherapy research

The majority of respondents ($n = 120$, 70%) were unsure whether the Faculty of Medical Psychotherapy was adequately interested and involved in research, 22% ($n = 37$) felt that it was not and 9% ($n = 15$) felt that it was. However, most respondents ($n = 137$, 80%) said they would like the Faculty to do more to promote psychotherapy research. Many ($n = 125$, 73%) said they would be interested in participating in Faculty activities to do with psychotherapy research. Respondents were asked what they would like the Faculty to do; they were offered six options, from which they could select as many as they wished (Table 3). The most popular option was ‘Facilitate networking among members who are interested or involved in research’. Additional free text responses gave further ideas: ““Ask the College to help make links with academics and possible sources of funding.’“Identify research experts.’“Link with other established research bodies.’“Network with other faculties, their newsletters, identify gaps and encourage joint working in projects.’“Networking could extend to mentoring.’“Pair trainees with research-orientated psychotherapists to inculcate a culture of research in next generation of psychotherapists.’“The Faculty could argue for the return of one day per week for research and the completion of the equivalent of an MSc in research.”” Table 3 Interventions the Faculty should deliver to promote psychotherapy research ($n = 172$; multiple selections allowed)

Facilitate networking among members who are interested or involved in research	132 (77%)
Feature articles related to research in the Faculty newsletter or other communication	119 (69%)
Offer conferences on psychotherapy research	118 (69%)
Organise skills workshops or webinars on research methodology	116 (67%)
Compile practical tips and guidance for setting up research projects	115 (67%)
Make psychotherapy research journals more accessible to members (e.g. via RCPsych library services)	104 (60%)
Other	12 (7%)

Trainees and psychotherapy research

When asked what the Faculty could do to specifically support trainees to get involved in psychotherapy research, the most popular response (of the four options offered), among both trainees and non-trainees, was ‘Help link up psychotherapy research supervisors to trainees’ (voted by $n = 148$ (86%) respondents). ‘Offer small grants, or a trainee award or prize for psychotherapy research’ and ‘Place more emphasis on research within the psychotherapy curriculum’ were voted by $n = 108$ (63%) and $n = 90$ (52%) respondents respectively. Again, free-text responses gave further elaborations and ideas, such as the following.

Placing research on the training agenda: ““There should be a better balance of what is asked of us within the curriculum. The more we get space and time to work with research that interests us during our core training, the more we will be able to continue to do it in the future and make an actual difference in research.’“It needs to be valued as a pursuit and encouraged as a part of the career path rather than a defeatist and sometimes elitist attitude precluding most from pursuing it.””Action from trainers and organisations: ““Encourage HEE [Health Education England] to develop more research-oriented training posts.’“Have psychotherapy consultants promoting a research-oriented practice.””Senior-level development opportunities: ““Develop consultants as well as trainees.’“It would be good to establish senior academic positions in medical psychotherapy.””Promoting psychotherapy research: ““Identify a list of research questions that psychotherapy research would be able to answer and publish it and regularly update it so that trainees can be inspired and

if they would like to do research, may consider choosing a topic.’ ‘More emphasis on psychotherapy research across all the curricula not just the psychotherapy curriculum.’” Other comments: “‘Not sure. Depends on the amount of time the trainee has. Pursuing the research agenda may be important but it is not as important as obtaining a thorough and secure grounding in clinical psychotherapy.’”

Discussion

Main findings

In this first ever survey of the membership of the Faculty of Medical Psychotherapy on research, psychiatrists across all levels of training and experience, working within and outside of medical psychotherapy as a specialty, strongly endorsed the importance of knowledge of psychotherapy research in their work. There was a high level of research experience or qualification among the survey respondents – almost half held a research degree, one-third had held a paid research post and 97% had engaged in some kind of research activity.

Given the low response rate to the survey, these findings cannot be taken as representative of the membership of the Faculty in general. Nevertheless, the survey highlights the existence of a group of members within the Faculty who are interested and engaged in research, and gives an indication of how the Faculty can play a part in this area. Despite the high prevalence of research qualifications and experience, only a minority of respondents had current opportunities for involvement in research, and the majority perceived obstacles to engaging in psychotherapy research. This points to an untapped potential and resource for psychotherapy research and begs the question of what one can or should do with it.

Strengths and limitations

Our survey is the first of its kind for the Faculty and addresses an important issue for training and development in medical psychotherapy. The questions were designed to extract relevant background data, views and experiences that can inform the Faculty’s strategy. The entire Faculty membership was surveyed and the low response rate means that the findings cannot be regarded as representative of the Faculty membership at large. The Faculty has a large number of quiescent members and this is also a factor in the low response rate. To put this in context, there were only 269 doctors with medical psychotherapy (or psychotherapy) as their specialty listed on the General Medical Council specialist register in 2019.⁹ This indicates that we had 42/269 (16%) of specialty-listed medical psychotherapists responding in this survey. Many of these doctors may not be working in designated psychotherapy posts or be practising psychotherapy. The number of doctors in postgraduate training in medical psychotherapy in the UK in the same year was 37. This indicates we had 14/37 (38%) of medical psychotherapy trainees responding.

One expects that members who are more research-inclined were more likely to take time to respond to the survey, thus biasing the results towards a more pro-research direction (i.e. viewing research as more important and having greater experience and interest in research) than would be found across the membership in general. Likewise, the views on research opportunities or lack thereof, and desire for more Faculty engagement with research, cannot be generalised across the entire membership of the Faculty. The responses may be subject to some degree of bias due to social desirability, although the free-text responses suggested considerable frankness of expressed views. The choice of interventions that the Faculty could deliver to promote research and support trainees in research were based on a pre-determined list of options and may not have covered all possibilities.

Nevertheless, the survey highlights the presence of a group of research-inclined members in the Faculty and points to ways that these members can be helped to participate more actively in research. Members are keen for the Faculty to facilitate networking. This may mitigate against the sense of isolation and disconnection that individuals may face among local colleagues or within organisations with little interest in psychotherapy research. Networking can take a number of forms – for example connecting experts and supervisors with trainees, linking with other faculties (such as the Faculty of Academic Psychiatry), links with established research and funding bodies. Other ideas for the Faculty to implement include featuring articles on research more prominently in newsletters, organising academic activities (e.g. conferences, skills workshops) on research, offering practical guidance on setting up projects, and better access to psychotherapy research journals (*Box 1* lists useful resources on research). *Box 1* Useful resources related to research Publications

Structural and organisational issues were also highlighted in the survey responses. The real and perceived disinterest and even hostility of academic institutions towards psychotherapy research, sometimes combined with negative preconceptions about medical psychotherapy, especially psychoanalytically oriented psychotherapy, create a culture that does not consider it possible for medical psychotherapists to engage in research. To an extent, this is reflected in certain deficits in research academic development opportunities for medical psychotherapy. In England, the National Institute for Health Research (NIHR) Integrated Academic Training Programme provides academic opportunities for doctors and dentists in specialty training, through the funding of Academic Clinical Fellowship (ACF) and Clinical Lectureship (CL) posts that support trainees to spend 25% (in the case of ACF) or 50% (CL) of their time in research training over 3 or 4 years. In more than a decade of this programme, no single trainee has been awarded such a post within the specialty of medical psychotherapy.

There are top-down as well as bottom-up problems to be addressed. The historical lack of research-active senior medical psychotherapists and the absence of medical psychotherapists within academic institutions means that medical psychotherapy has become a non-existent entity in many research circles. Some argue that research should be more embedded in training in medical psychotherapy, in which the prevailing emphasis is on acquiring clinical psychotherapeutic skill; they believe that knowledge of psychotherapy research, routine use of clinical outcomes, and experience in designing and conducting research should all form part of the curriculum for trainees. Among medical psychotherapy trainees, designated time that is meant for research or special interest (such sessions exist for psychiatry trainees of all specialties) is often used instead for further clinical experience or for personal psychotherapy.

Senior and consultant-level medical psychotherapists in the public sector have faced increasing cuts to sessions and their job plans focus exclusively on clinical service delivery; this approach is short-sighted and deprives medical psychotherapy of possibilities for development. A more beneficial strategy would be to encourage those medical psychotherapists with research experience and interests to pursue projects as part of their job plan, and to provide support where needed to facilitate this. Where a National Health Service (NHS) organisation already has an established partnership with an academic institution, links for psychotherapy research can be set up and formally endorsed by both organisations. Previous research has indicated that, to be willing to participate in research, psychotherapists expected high-quality designs, financial compensation and personal gains.¹⁰ This indicates the importance of support to therapists at both research and career-progression levels to encourage more participation in research.

Conclusions

From the survey, we conclude that there exists a group of members within the Faculty of Medical Psychotherapy who value research and are keen to engage in research activity, and are a resource that ought to be harnessed. Noting the greater level of dissatisfaction with their research involvement among trainees than among consultants, this is a particularly important group to focus resources on. A number of actions recommended by survey respondents are feasible and already being planned, for example establishing research networks, linking trainees with supervisors, conferences and workshops on research, and campaigning for more equitable academic opportunities nationally. Given the role of medical psychotherapists in combining a medical, psychiatric and psychotherapeutic perspective,¹¹ it is critically important that this unique perspective is brought to bear on the psychotherapy research agenda.

We thank Steve Pearce (Chair of the Faculty of Medical Psychotherapy) for advising on the survey design and Adrian James (Registrar of the Royal College of Psychiatrists) for approving the survey.

Survey questions Are you a member of the Medical Psychotherapy Faculty of the RCPsych? If not, this survey is not for you. Are you a: Consultant with CCT in Medical Psychotherapy; Higher Trainee in Medical Psychotherapy (or dual training including medical psychotherapy); Consultant in other specialty (please specify); Core Trainee or Higher Trainee in other specialty (please specify); Other (please specify) Is your work base in the UK? UK; outside of UK. Please specify the geographical region or area What is your current post? Please enter (e.g. consultant in eating disorders) In your current post, do you have any sessions in medical psychotherapy? Please give details if you wish Do you agree that knowledge of psychotherapy research is important for your work? Strongly agree; Agree; Neither agree nor disagree; Disagree; Strongly disagree In which aspect of your work would you most like more knowledge of existent psychotherapy research? How do you gain knowledge of psychotherapy research? (tick all that apply) Reading journals; Using electronic resources (e.g. email alerts, saved scholar searches); Discussion with colleagues; Attending conferences; Involvement in psychotherapy research activity (please specify); Other (please specify) Are you satisfied with your current level of knowledge in psychotherapy research? Very satisfied; Somewhat satisfied; Neither satisfied nor dissatisfied; Somewhat dissatisfied; Very dissatisfied Have you any formal qualifications in research? (please tick all that apply) None; BSc, MSc, PhD or MD equivalent; Other (please specify) Have you ever held a paid research post? Please specify Have you ever been involved in the following kinds of research (not necessarily psychotherapy related)? Qualitative, Quantitative, Neither; Observational, Experimental, Neither; Epidemiological, Outcome, Neither What research activities have you ever been involved in? (please tick all that apply) Literature review; Study design or protocol writing; Recruiting research participants; Delivering intervention in a trial; Data collection, cleaning and/or analysis; Paper writing; Peer reviewing; Other (please specify); None Have you ever published non-psychotherapy research in a peer-reviewed journal? Have you ever published psychotherapy research in a peer-reviewed journal? Currently, do you have any opportunities for involvement in psychotherapy research? Please specify Are you satisfied with your current opportunities for involvement in psychotherapy research? Very satisfied; Somewhat satisfied; Neither satisfied nor dissatisfied; Somewhat dissatisfied; Very dissatisfied Do you perceive obstacles to getting more involved in psychotherapy research? If yes, please specify In your opinion, is the Medical Psychotherapy Faculty adequately interested and involved in research? Yes; No; Unsure. Please give reason for your answer Would you like the Medical Psychotherapy Faculty to do more to promote psychotherapy research? Yes; No; Unsure. Please give reason for your answer. What kinds of things should the Faculty do to promote psychotherapy research? (please tick all that apply) [The list of options appears in *Table 3* of this paper] What can the Faculty do to specifically support trainees to get involved in psychotherapy research? (please tick all that apply) Place more emphasis on research within the psychotherapy curriculum; Link up

psychotherapy research project supervisors to trainees; Offer small grants, or a trainee award or prize for psychotherapy research; Other (please specify)Are you interested in participating in Faculty activities to do with psychotherapy research? Extremely interested; Very interested; Somewhat interested; Not so interested; Not at all interested. Please leave your name and email and say something about your specific interestPlease leave any further comments you have on this subject here

1.1.37 Attitudes toward veganism in eating disorder professionals

Sarah J. Fuller Kimberley M. Hill

Correspondence

Sarah Fuller (sarah.fuller@nhs.net)

date

2022-04

Abstract

Aims and method

Veganism has increased in popularity in the past decade and, despite being a characteristic protected by law, is often viewed negatively by the general population. Little is known about the attitudes of healthcare professionals despite the potential influence on practice and eating disorder patient care. This is one of the first studies to investigate attitudes toward veganism within specialist eating disorder, general mental health and other professionals.

Results

A one-way ANOVA indicated all professionals held positive views toward veganism. General mental health professionals held statistically more positive veganism attitudes than specialist eating disorder and other professionals.

Clinical implications

As one of the first studies to suggest eating disorder professionals are not biased against veganism, it has important clinical practice implications, particularly when exploring motivations for adopting a vegan diet (health, weight loss, environmental or animal welfare concerns) in patients with eating disorders. Implications for further research are provided.

pmc Eating disorders are serious psychiatric conditions characterised by abnormal eating patterns, either through strict or a lack of control of eating, and are driven by the over-evaluation of weight and shape concerns.¹ Research identifies several eating disorder development risk factors,² including, but not limited to, genetics,^{3,4} environmental,³ female adolescence,⁴ biopsychosocial influences⁵ and urbanisation.⁶

Veganism is a philosophy seeking to exclude using animals and animal products in all aspects of life, not just diet.⁷ It is estimated that around 1% of the UK population follow a vegan diet,⁸ reflecting a fourfold increase from 2014 to 2019. In the Western world, the demographics of veganism are predominantly young,⁹ female^{10,11} and living in urban areas.^{10,11} Importantly, veganism is protected by law as a non-religious philosophical belief.¹²

Veganism does not cause eating disorders, but there are similarities between known eating disorder risk factors and the prevalence data for veganism. Research suggests the general population are biased against veganism,^{13,14} but it remains unknown if specialist eating disorder (SED) professionals share these views. SED clinicians may be concerned about the potentially restrictive nature of vegan diets, and therefore may potentially be biased against veganism. Given the legal protection that veganism carries, when exploring the veganism of a patient with an eating disorder, clinicians must act with professionalism, respect, curiosity and a lack of personal bias. This is the first paper to investigate the attitudes of SED, general mental health (GMH) and other professionals toward veganism

Method

Design

This self-reported questionnaire study included the following independent variables: profession (SED, GMH and other professionals), age (18–29, 30–41, 42–54 and 55–67 years) and gender (male, female and other). The dependent variable was attitude toward veganism.

Pilot study

A pilot study involving three participants from SED, GMH and other professional groups indicated no adjustments to study measures.

Measures

Participants completed the General Eating Habits Questionnaire,¹⁵ scored on a 1 (vegan) to 7 (omnivore) Likert scale, and the 20-question Attitudes Towards Veganism Survey (ATvegan),¹⁰ scored on a 1 (negative attitudes) to 7 (positive attitudes) Likert scale, on Qualtrics (version for Windows; www.qualtrics.com). Cronbach's alpha ($\alpha = 0.86$) indicated a good level of internal reliability.¹¹

Participants and recruitment

A power analysis (G*Power for Windows, version 3.1.9.7; <https://www.psychologie.hhu.de/arbeitsgruppen/allgemeine-psychologie-und-arbeitspsychologie/gpower.html>) identified $n = 75$ for each professional group, giving a minimum sample size of 225. Participants were recruited through purposive sampling via professional networks and social media. A total of 430 responses were received and data were cleaned to exclude non-UK residents ($n = 15$), those under 18 or older than 68 years, those not identifying their professional group ($n = 3$) and vegan participants ($n = 20$), as research suggested this could bias responses as vegans have a strong sense of self-identity, which can affect their attitudes on topics ranging from animal welfare to political affiliation, and this could affect any findings of the research.^{13,16} *Table 1* provides key characteristics of the total sample ($n = 392$). *Table 1* Participant demographics Gender, n Profession Age group, year Male Female-Did not say Specialist eating disorder, $n = 11618-29214-30-41733-42-541525-55-68515$ -General mental health, $n = 9018-29418-30-41731142-54515155-6862$ -Other, $n = 18618-29832-30-412655-42-541428-55-68815$ -

Procedure

Full ethical approval was obtained and, following written informed consent, data was collected for 2 weeks during March 2020. Following completion, participants were debriefed, thanked and provided with researcher contact details for further questions. Ethical approval was granted by the University of Northampton's Psychology Ethics Committee (ethics approval donated by student number: 19432991). All adult participants provided written informed consent to participate in this study.

Analysis

Data was analysed using SPSS version 26 for Windows.

Results

An alpha level of 0.05 was used for all statistical tests.

Profession

Total attitude toward veganism scores were calculated indicating generally high mean scores and positive attitudes for all professional groups. This included the GMH ($n = 90$, mean 106.65, s.d. 17.96, range 54–137), SED ($n = 116$, mean 101.49, s.d. 16.13, range 61–136) and other professionals groups ($n = 186$, mean 101.08, s.d. 18.64, range 43–140).

All parametric assumptions were met. A one-way ANOVA was statistically significant, indicating a moderate effect size and a positive main effect of professional group ($F(2, 376) = 3.33$, $P = 0.04$, $p^2 = 0.02$).

Post hoc Bonferroni adjustments¹⁴ indicated mean GMH professionals group scores (mean 106.65 ± 5.72 , s.d. 17.96, $P = 0.04$) were significantly higher and more positive compared with the other professionals group. No significant difference was evident between the SED and GMH or other professionals groups.

Gender

Women ($n = 290$, mean 103.36, s.d. 19.24, range 59–140) had slightly higher mean veganism attitude scores than men ($n = 100$, mean 99.95, s.d. 17.33, range 43–134), but a Mann–Whitney *U*-test conducted on non-parametric data indicated no significant difference between women (median = 104, $n = 279$) and men (median = 101.5, $n = 98$) and attitude toward veganism scores ($U = 14\,777.00$, $z = 1.19$, $P = 0.23$).

Age

Younger participants aged 18–29 years had higher mean and more positive attitudes toward vegan scores ($n = 78$, mean 104.48, s.d. 16.74, range 66–138), compared with ages 30–41 years ($n = 163$, mean 102.17, s.d. 18.56, range 43–137), 42–54 years ($n = 103$, mean 102.81, s.d. 16.30, range 69–140) and 55–68 years ($n = 48$, mean 99.44, s.d. 20.40, range 54–135). However, a one-way ANOVA indicated no significant difference between participants' age and their attitude toward veganism score ($P = 0.50$).

Discussion

This study is one of the first to investigate veganism attitudes within SED, GMH and other professional groups. The aim was to identify whether the potential bias toward veganism found within the general population is prevalent within SED professionals. Findings suggested all three professional groups held positive veganism attitudes, with GMH professionals holding significantly more positive attitudes than SED and other professionals. Despite age and gender influencing veganism attitudes in the general population, no statistically significant age or gender differences were found within these professional groups.

Research has highlighted a level of bias against veganism within Western populations,^{13,17,18} leading to it being viewed as a minority group similar to ethnicity or sexual orientation.¹⁸ Not only are vegans often depicted as going against the status quo of normal dietary culture, but these attitudes are influenced by gender and age, with more prominent negative attitudes often found in older, male generations. As well as investigating whether these biases exist within SED professional populations, it was hypothesised that SED professionals would have a more negative view on veganism than other professionals. This is because SED professionals are aware of how dietary restrictions can negatively affect an individual's physical health and mental health. These general attitudes could be reflected in SED professionals' own veganism attitudes, and SED professionals should be aware of any such biases, as they could affect clinical practice and patient treatment. In 2019, a joint consensus statement from the Royal College of Psychiatrists, the British Dietetic Association and 'BEAT', the national eating disorder charity, was released regarding the importance of working collaboratively with vegan patients with eating disorders.¹⁹ This sought to address concerns raised by some vegan patients that their beliefs were ignored in treatment and that staff could be biased against veganism. In contrast, the current study appears to indicate that SED professionals are not biased toward veganism.

These findings are particularly important because SED professionals may be concerned when patients presenting with eating disorders make any significant dietary change before seeking treatment. Self-imposed dietary restrictions are

common in patients with restrictive eating disorders. These restrictions can be total caloric restriction, but can also involve excluding entire food groups such as carbohydrates or fats, or excluding ingredients in foods such as lactose or gluten. It is not uncommon to see numerous, escalating self-imposed dietary restrictions as a patient's eating disorder progresses. For example, someone who previously ate a diet that included meat could become pescatarian, then vegetarian and finally vegan – with each dietary change becoming more restrictive. There is evidence that there are increased rates of vegetarianism in patients with restrictive eating disorders, such as anorexia nervosa.^{20,21} As veganism requires more dietary restrictions than vegetarianism, researchers suggest that a similar link could be associated with veganism,²² which could raise concerns for SED professionals. Furthermore, SED professionals will be aware of the overlap in the demographics of veganism and factors that make an individual more susceptible to an eating disorder.

To adopt a vegan diet, an individual must avoid all animal products, ingredients or derivatives. Therefore, this requires them to check dietary labels and will result in the exclusion of foods they previously ate. These two behaviours, checking labels and food exclusion based on ingredients, are often seen in patients with restrictive eating disorders regardless of their overall dietary choice. These firm dietary rules veganism provides can be very attractive to patients who are anxious regarding what to eat. Based on the findings of the current study above, SED professionals do not show a bias against veganism. However, as research suggests that the general population perceive multiple barriers to switching to a vegan diet,²³ SED clinicians may therefore be suspicious of the apparent coincidence of such a dietary change during the onset of the eating disorder.

Implications for practice

Findings from this research suggest that SED professionals do not have more negative views on veganism compared with GMH and other professionals. Instead, all groups held positive attitudes toward veganism, with GMH professionals statistically holding the most positive views. This finding may be partly mediated by participant demographics, as GMH professional participants tended to be younger women compared with SED and other professionals. Knowing that SED professionals did not have a negative attitude toward veganism is important because when exploring a patient's veganism, the patient may feel vulnerable having a clinician challenge behaviour that may or may not be associated with their eating disorder. SED professionals can use this research to reassure patients that it is their eating disorder that is being questioned and not their veganism. Taking this dynamic further, it is important for these professionals to be aware of their 'social GRACES'.²⁴ This acronym was developed for clinicians to be aware of the many areas in life where we may have conscious or unconscious bias in clinical work. Using this acronym, there is more than one topic within each 'letter' and the full acronym is 'GRRRAACCEEESSS', encompassing gender, geography, race, religion, age, ability, appearance, class, culture, ethnicity, education, employment, sexuality, sexual orientation and spirituality.²⁴ Clinicians have both an ethical and legal responsibility to their patients not to bring any bias into the treatments they offer, if they themselves have different dietary choices from their patients,^{18,24,25} so there could be a D added to the 'social GRACES' – that of diet and dietary choice.

This research also has a much broader impact as it also reflects that SED professionals are practicing within relevant legal frameworks. As veganism is a protected characteristic within the law, these finds are important.^{12,26} If the main hypothesis of this study had been supported, it would have raised concerns that these professionals' opinions were significantly different. Going forward, our findings highlight the need for all SED clinicians to have an awareness of the nuanced issues veganism can bring for a patient with an eating disorder, as well as an awareness of the legal protection this characteristic holds. Navigating this difficult dynamic may be helped by this research, as it is one of the first studies to consider these issues.

These findings can be generalised to the wider UK SED profession, and will inform daily clinical practice, particularly as veganism is becoming more popular nationally.²⁷ The good response rate and high completion rates suggest that veganism is a topic of interest for professionals. Further international research could help generalise these findings in the wider Western world and globally.

Limitations

Bias was minimised by using reversed questions, valid instruments and measures, but future research in this area should recognise possibilities for bias. Because of the self-reported nature of this research, participants may have shown demand characteristics (participants changing reported behaviours in line with their interpretation of the study) that may have influenced the findings, particularly given the potential implications for SED and GMH professionals. Consequently, participants may have provided what they perceived as the professionally correct answers,^{27,28} or ‘socially desirable’ responses, rather than declaring any strong personal views to the contrary.²⁹

Future research and conclusions

Exploring the sensitive dynamic of veganism and eating disorders would benefit from further research. This includes investigating the extent that vegan clinicians feel that veganism can be used to facilitate dietary restriction in patients with eating disorders. Research targeting vegan SED professionals will provide an unbiased understanding of how veganism may be used to facilitate dietary restriction in patients with eating disorders. Although ethically sensitive, future research could focus on the extent that patients who have recovered from an eating disorder feel that veganism can be used to facilitate dietary restriction in eating disorders. Including SED professionals and patients who have recovered from an eating disorder from a range of demographics, including age, gender and ethnicity, would allow a more culturally diverse interpretation of this topic area.

The current research study was targeted at clinicians who work either in adult, child or adolescent mental health services. These clinicians may have different attitudes toward veganism when they are working with a child or an adult, and future research should consider potential differences here. For example, a 12-year-old girl who is presenting with a restrictive eating disorder and asking to become vegan for animal welfare reasons may evoke concerns from clinicians regarding the authenticity of this dietary change, especially when the nutritional adequacy of the vegan diet can be hard to achieve in this age group because of the nutritional demands of growth and puberty.³⁰ In contrast, an adult patient following a vegan diet because of a family history of heart disease may seem less concerning to SED professionals, and this research did not differentiate between the different motivations a patient may have. Therefore, future research should differentiate within the SED group by their area of speciality – children and young people or adult. Theoretically, an age-informed professional consensus could be developed, potentially demonstrating greater concern for younger patients or those who are following an increasing pattern of dietary restrictions leading to veganism.

In conclusion, veganism is an increasing and legally protected characteristic, but the general population hold negative attitudes toward veganism. Research identifies important similarities between vegan demographics and those at risk of developing an eating disorder. As a patient’s veganism may be challenged as part of their eating disorder treatment, it is important to identify if SED professionals hold the same biases, as this could have important implications for patient care and practice. This is the first study to highlight that SED professionals do not appear to be biased; in contrast, they hold positive views toward veganism, as do GMH and other professionals. Not only does this research suggest that SED professionals are practicing within the law, but it also indicates that they are aware of their social GRACES, and perhaps a ‘D’ for ‘diet’ could be added to this acronym. Further in-depth and more diverse research into professional’s attitudes toward veganism is encouraged.

About the authors

Sarah J. Fuller is an Advanced Specialist Eating Disorders Dietitian with the Bedfordshire & Luton CAMHS Eating Disorders Team, East London NHS Foundation Trust, UK. **Kimberley M. Hill** is an Associate Professor of Psychology with the Faculty of Health, Education and Society, University of Northampton, UK.

Abstract

The concept of *resilience* was applied to the public health field to investigate the way health systems are impacted by health crises, what conditions allow them to mitigate the blow, and how they reorganize once the crisis is over. In 2020, the COVID-19 pandemic caused by the SARS-CoV-2 virus represented a global challenge demanding immediate response to an unprecedented health crisis. Various voices drew attention to the intensity of the crisis in countries with greater inequalities, where the pandemic converged with other social emergencies. We documented the experiences of health personnel who faced the pandemic at the primary care level while simultaneously maintaining the functioning of other areas of medical care. Our results derived from a qualitative study comprising 103 participants from five states of Mexico. We aimed to show through inferential analysis their perspective on what we call “the resilience of local health systems.” We observed three stages of experience during the crisis: (a) Preparation (official guidelines received to organize care, training, and planning of epidemiological surveillance); (b) Adaptation (performance of community-based prevention activities, infrastructure modifications, telehealth); (c) Learning (participatory governance with city councils, business sector, and organized population). The study suggests that the local health systems analyzed benefited from the initiatives of health personnel that in some cases positively exceeded their duties. In terms of the resilience analysis, they were able to handle the impact of the crisis and cope with it. Their transformative capacity came from the strategies implemented to adapt health services by managing institutional resources. Their experience represents a lesson on the strengthening of the essential functions of health systems and shows a way to address successfully the increasingly complex health challenges of the present and future times.

1.1.39 Psychiatric leadership development in postgraduate medical education and training

Alex Till Radhika Sen Helen Crimlisk

Correspondence

Dr Alex Till (alextil54@gmail.com)¹

date

2022-06

Abstract

The value of strong, compassionate medical leadership in the delivery of high-quality care to patients within mental health services is clear. Leadership development, however, is far less well explored. This article is for psychiatric trainees, trainers and mental health organisations. It provides an introduction to the importance of leadership development within postgraduate medical training, the theory that should underpin its delivery, and the opportunities for both informal and formal leadership development within psychiatric training.

Contents

- *Psychiatric leadership development in postgraduate medical education and training*

 - *Informal leadership development*
 - *Formal leadership development*
 - *Discussion*
 - *Conclusions*
 - *Declaration of interest*

pmc Doctors are frequently the head of healthcare teams,¹ with leadership an emergent theme within the skills, knowledge and behaviours required of our future doctors.² Leadership is the most influential factor in shaping organisational culture.³ It must be compassionate to stimulate improvement and innovation,⁴ and is the hallmark of high-quality care.⁵

¹ See pp. XX–XX, this issue.

Leadership can be conceptualised as ‘a process that occurs in a group context, involving the influence of others towards the attainment of a common goal’.⁶ Yet leadership is better conceptualised as a ‘triad’, whereby leadership, management and followership are distinct, but inextricably linked skills, and hereafter are considered as one.^{7,8}

Leadership has been formally recognised as a responsibility for all doctors since 2012,⁹ and is gradually being integrated into both undergraduate¹⁰ and postgraduate medical curricula.¹¹ To help guide trainees’ development within these domains, the Faculty of Medical Leadership and Management (FMLM) have produced standards for medical professionals¹² that clearly outline four key domains for doctors: A doctor’s ability to know and understand themselves and their impact on others. A doctor’s ability to know when to lead and follow, and how to establish and lead teams. A doctor’s ability to understand and positively contribute to the strategic direction and operational delivery of their organisation. A doctor’s ability to understand and positively contribute to the healthcare system.

Despite this initiative, the relevance and importance of leadership development is yet to be fully embraced by the medical profession. It is often still perceived as an ‘optional extra’ within medical training,¹³ and an unpopular, unrewarding and risky ‘add-on’.¹⁴ This lack of external validation, and outdated traditional view of medical professionalism, compromises the development of so-called ‘willing hybrids’, and the integration of leadership and managerialism as a legitimate and essential aspect of medical professionalism.^{15,16}

The argument for strong medical leadership within healthcare organisations is well defined.^{17,18} Mental health services face unprecedented challenges on an almost daily basis. Doctors must be engaged in leadership¹⁹ and with their organisations as a whole.²⁰ They must be capable of understanding and overcoming the volatile, uncertain, complex and ambiguous²¹ nature of providing not only health, but also social care, within an increasingly integrated systems-based approach.

Leadership development, therefore, is crucial, yet far less well explored. There is little robust evidence for the effectiveness of specific leadership development programmes, with a proliferation of diverse interventions throughout medical training and healthcare as a whole.³

It is clear, however, that the systematic integration of basic leadership development for all doctors needs to be embedded throughout postgraduate medical training, supplemented by enhanced and advanced opportunities for aspiring medical leaders, and that trainees themselves need to realise and accept leadership responsibility.

This article is for psychiatric trainees, trainers and mental health organisations. It builds on the already established position highlighting the positive impact of psychiatrists on leadership and management.²² It provides an introduction to the importance of leadership development within postgraduate medical training, the theory that should underpin its delivery, and the opportunities for both informal and formal leadership development available to psychiatric trainees within postgraduate medical training throughout the UK.

Leadership development theory

Healthcare, like many other industries, often falls victim to the ‘great training robbery’.²³ Organisations frequently support and encourage individuals to undertake externally provided leadership development programmes, and yet often fail to provide appropriate conditions on their return for them to contextualise and apply their learning within their clinical environment. Although this can be successful in developing their knowledge, skills and competencies, it effectively sets them up to fail, and leads to the continuation of entrenched and established ways of working.²⁴

If exclusively developed within the ‘classroom’, development will largely remain ‘horizontal’,²⁵ and leaders will fail to learn how to change and adapt to ever-changing circumstances.²³ Alternatively, an ‘*in vivo*’ approach, with the right conditions coordinated throughout a programme, can harness ‘vertical’ leadership development through the delivery of ‘heat experiences’, ‘colliding perspectives’ and ‘elevated sense-making’.²⁶

Heat experiences involve organisations taking calculated risks, and exposing leaders, who themselves must take a risk, to complex uncomfortable first-time challenges. Here, they are forced to grow, not just because they want to, but because there is a chance of failure, people are watching, and results matter. They are ‘the what’ that compels leaders to disrupt and disorient their traditional thinking styles, to discover new and better ways to make sense of the challenges they face. Caution must be excised, however, to get the ‘temperature right’, and control the heat within a safe space, with the right

support, available at the right time, to help the individual stay within that learning ‘sweet spot’. Importantly, there also needs to be an appropriate level of both individual and organisational tolerance of failure.²⁷

Colliding perspectives expand the number of lenses through which a leader can analyse complexity and challenge their existing mental models.²⁸ Individuals are encouraged to view the world through the eyes of different stakeholders, including that of patients, carers and other members of the multidisciplinary team, and by standing in their shoes, learn to identify and manage conflicting paradigms. Ideally combined with peer coaching, partnered with different disciplines, these colliding perspectives provide ‘the who’ that is inclusive and embraces a range of diverse thought.²⁹

Elevated sense-making is the final piece, ‘the how’, that leads to transformational change.³⁰ Not only must structured reflection (through reflective practice groups or action learning sets) be facilitated to allow leaders to reflect on their development over time and integrate their experiences with new found perspectives, but their development should be guided by experienced coaches or mentors.

It is vital that these three conditions are provided within postgraduate medical training, whether through activities embedded informally within the work environment, or formally via a targeted approach within leadership development programmes. Although value can still be extracted from opportunities that do not provide these conditions, leadership talent will remain untapped and dormant within healthcare organisations unless these are met.³¹

Informal leadership development

The common perception of leadership as an optional extra remains pervasive throughout the medical workforce. Combined with a ‘curriculum lag’, whereby there is a delay in implementing and adopting the latest evidence into training, the development of leadership competencies remains somewhat tokenistic.³² The stars are aligning, however, and the importance of leadership development in both undergraduate and postgraduate medical curricula is slowly being realised.³³

The message is clear. Leadership development does not begin or end at any particular stage of training. Leadership is for all doctors, at every stage, and should not be postponed until doctors are formally appointed to a leadership or management position. Leadership is rather a developmental process on a lifelong continuum, with individuals nurtured to help recognise and fulfil leadership roles, especially in the earliest of stages of their careers.³⁴

Everyday leadership experiences are commonplace within psychiatric clinical settings, where decision-making is complex and ethical tensions arise through divergent views, roles and responsibilities within teams.³⁵ Although often undervalued, these present opportune leadership development experiences where, among a range of other activities, leadership can be developed through acute crisis situations, multidisciplinary meetings, mentoring junior colleagues, medical education, clinical governance and quality improvement projects. It is important to recognise, name and make sense of these everyday leadership experiences within training, through supervision, and allow trainees to recognise the value of ‘little l’ leadership within their teams.³⁶

More formal opportunities also exist through representative roles available locally, regionally and nationally, that can all lead on to providing more enhanced leadership experiences and the three primary conditions of vertical leadership development in their own right. Likewise, voluntary and additional professional activities can provide excellent leadership experience. For example, roles available within Royal Colleges, special interest groups, trade unions, healthcare regulators, the General Medical Council, or as a governor for healthcare and affiliated organisations.

Irrespective of the particular opportunity, whether formal or informal, obtaining feedback is critical for gaining insight into the trainees’ own perception of their leadership capabilities, and the perceptions held by others of their behaviours and performance.

Integral tools within psychiatric training for facilitating such structured feedback are the Mini-Peer Assessment Tool and Direct Observation of Non-Clinical Skills (DONCS) workplace-based assessments. These are used across the General Medical Council-approved curricula for both core and specialty psychiatric training within the UK, to assess a trainees performance and allow trainees to demonstrate their leadership capabilities.^{37,38}

Originally founded on The CanMEDS 2005 Physician Competency framework,³⁹ DONCS are applicable to a range of diverse non-clinical skills, and structuring feedback on leadership experiences around the seven domains can at times feel convoluted and ambiguous.

Table 1 has been conceptualised from the evidence base to help suggest key competencies for psychiatric leaders within a DONCS assessment, and aims to support both trainees and trainers attaining and delivering feedback.^{39–42} *Table 1* Your guide to a Leadership and Management DONCS domain DONCS descriptor Medical expert As a medical expert, the psychiatric leader integrates the other six intrinsic roles (as below) to negotiate complexity, uncertainty and ambiguity, while contributing to continuous improvement and maintaining the highest standards of clinical knowledge, person-centred care and professional values. Communicator As communicators, psychiatric leaders will develop trusted interpersonal relationships with and between individuals. They will accurately elicit, synthesise and convey relevant information, in both oral and written form, to develop a shared understanding between stakeholders of the relevant issues, problems and plans at hand. Collaborator As collaborators, psychiatric leaders will work effectively in partnership with patients, carers and extended multidisciplinary teams of expert professionals. This will take place in multiple locations, within and across organisational boundaries, to deliver optimal patient care and prevent, negotiate and resolve interpersonal conflict. Manager As managers, psychiatric leaders will participate in the improvement of healthcare delivery, manage resources appropriately, develop competence in health informatics and contribute to the effectiveness of the team, organisation and system they work within. Health advocate As health advocates, psychiatric leaders will promote diversity and inclusion. They will utilise their expertise and influence to identify and advance the health and well-being of individual patients, communities and populations. Scholar As a scholar, the psychiatric leader pursues continuous personal and professional development. They will critically evaluate information, facilitate and create a safe space for the mentoring and learning of others, and contribute to the creation, dissemination and integration of evidence-based knowledge into practice. Professional As a professional, the psychiatric leader engages with healthcare regulation; maintains the highest standards of personal, professional and ethical behaviour; embraces a compassionate and inclusive approach and is committed to reflective practice. They support the well-being of both themselves and the staff around them.²

Formal leadership development

There are a plethora of leadership development programmes, schemes and other opportunities available throughout the UK. This can be confusing for both trainees and trainers alike, occurring both in and out of training programmes, with a diverse range of requirements, levels of involvement and financial commitment.

Attempting to provide a brief description of these opportunities, *Table 2* outlines a sample of the variety of leadership and management training that is currently available to psychiatric trainees within the UK. It is important to remember, however, that there is an almost constantly evolving stream of new opportunities depending on interests and geography, and that this table is likely to be quickly outdated. *Table 2* Leadership and management training availability to psychiatric trainees (correct as of 2020/21) Eligibility/target Key points Fellowships (12 months) Outside of local education provider National National Medical Directors Clinical Fellow Scheme⁴³, a On completion of the Foundation Programme Funded, out of programme, centrally recruited to national organisations. Chief Residents’ Management and Leadership Programme – Health Education East of England⁵⁷ ST5 and above Funded, centrally recruited, face to face (10-day Judge Business School ‘mini-MBA’), with work-based application and supported leadership role. Postgraduate education Master’s in Medical Leadership (MSc) Various institutions offer ‘step-on, step-off approach’ from PG Cert to PG Dip to MSc (1–3 years)^{58,59} Available to all Predominantly self-funded (£2500–£25 000), sponsorship and bursaries available. Part time, moderate workload, variable online versus face to face. Master’s in Business Administration (MBA) Various institutions, some offer healthcare specialties or NHS endorsement (2–3 years)^{60,61} Available to all Predominantly self-funded (£15 000–£90 000), sponsorship and bursaries available. Part time, heavy workload, variable online versus face to face.^{3,4}

Such formal leadership development could be conceptualised through a tiered approach (*Fig. 1*). Firstly, basic generic professional capabilities are provided in leadership for all doctors via an integrated approach within local training programmes. A second tier then provides enhanced local and regional leadership development offers for future service and divisional leaders. Then finally, at the upper tier, nationally coordinated, advanced programmes and fellowships, are delivered for aspiring organisational- and system-level leaders. *Fig. 1A* tiered approach to leadership development. FMLM, Faculty of Medical Leadership and Management.

Discussion

It is important to note that leadership development does not suit a one-size-fits-all approach, and that the evidence does not suggest that any particular activity should be completed before another.³

Up to 90% of learning occurs informally, through often spontaneous, unstructured activities embedded within the work environment.⁶² As revealed through the developmental journeys of medical, clinical and managerial National Health Service chief executives,⁶³ although formal leadership development can be transformational for some, it is insufficient in isolation.

Leadership development can often be better attributed to engagement with inspirational role models, and through the opportunistic experiences that emerging leaders seized because they could, and because they were motivated to make a difference.

For this very reason, it is vital that we overcome the shortage of role models with protected characteristics. Those in medical leadership positions must reflect the wider workforce and communities we serve.⁶⁴ It is not permissible to

³ NIMDTA, Northern Ireland Medical & Dental Training Agency; NHS, National Health Service; PG Cert, Postgraduate Certificate; MBA, Master of Business Administration; MSc, Master of Science; PG Dip, Postgraduate Diploma.

⁴ Predominantly non-clinical (although some do allow limited ongoing clinical activity), and therefore often require an extension to training via out-of-programme experience approval.

allow ourselves to fall victim to a complex range of social, cultural, political, economic and historical factors, whether unconsciously or otherwise, that marginalise and disempower aspiring leaders from diverse backgrounds.

Equality and diversity should be a top priority for all individuals and organisations. We must counteract the deeply embedded prejudice and discrimination that have become endemic within modern society.⁶⁵ No matter what the characteristic, whether it be gender, sexual orientation, race, religion or any other characteristic that differs from the majority of leaders, these individuals do not easily fit within a structure that is coded towards the 'snowy white peaks of the NHS',⁶⁶ and this must be overcome.

To build this diversity into our psychiatric leadership, and that we need within our mental health services, we must embrace the 'lived experience' of talented leaders regardless of demographic differences, and adopt an inclusive leadership approach.^{67,68} After all, organisations with greater inclusion, rather than merely diversity, are proven to perform better, with greater improvement and innovation, higher levels of morale, and new insights that maximise the potential of employees.^{68,69}

As Vernā Myers puts it 'Diversity is being invited to the party; inclusion is being asked to dance'.⁷⁰

Multiple strategies can be employed to improve diversity and develop an inclusive approach,⁶⁵⁻⁷² but it is no easy task. Fundamentally, it is a cultural change. All doctors, and particularly existing leaders, must engage with these groups, create a psychologically safe space, listen to their stories, confront the hard truths laid bare by their experiences, and challenge the status quo, making diversity and inclusion a personal priority. Allies from non-disadvantaged or less discriminated against groups can confront and have a powerful impact on the behaviour of others. They must not just question what privileges they have been afforded that others might not, but question and reflect on the absence of challenges and barriers that they have not had to overcome but others might. Crucially, they must then act, working within the organisation and system to counteract and mitigate these for others.

Individuals should not feel like 'outsiders'. We should rather recognise an individual's need to belong and proactively seek role models with greater diversity, to make the inclusion of leaders with protected characteristics explicit and visible. This allows those from marginalised groups to identify with the existing leadership, see themselves as leaders and, crucially, feel empowered to seize those opportunistic leadership experiences that are so crucial for their development. In combination, active career sponsorship will be crucial to retain and advance their leadership talent, with mentorship being a powerful mechanism for both the individual and the organisation.^{68,73}

It truly is an inclusive leadership approach that is required. Demographic diversity in isolation, is insufficient. Active role-modelling and the support of key allies in existing leadership positions is essential to provide equitable access to formal and informal leadership development.

Just as we would expect within clinical practice, trainees of all backgrounds must be supported by experienced trainers who expose them to increasingly uncomfortable challenges, yet who provide them with the psychological safety net to take risks, experiment and develop 'on the job'.

Conclusions

Mental health services face unprecedented challenges on an almost daily basis. To survive in this world, and lead quality improvement towards more preventative, holistic and personalised care, doctors must develop a deep understanding of leadership and effectively demonstrate the core values and behaviours expected of medical professionals.

Greater attention must be paid towards medical leadership development and an inclusive approach, whereby all doctors, from every background, are supported to advance. This has never been more important. The view of leadership development being an optional extra within medicine, or a skill set to be developed later in a medical professional's career, is outdated.

No matter which one of the many diverse interventions are pursued, doctors must engage with, and be supported in, both informal and formal leadership development. This is a collective responsibility, and much more must be done to ensure equity of access to leadership development for all, from the earliest of stages in a doctor's career.

1.1.40 Effects of the COVID-19 pandemic on provision of electroconvulsive therapy

Richard Braithwaite Robert Chaplin Vimal Sivasanker

Correspondence

Richard Braithwaite

(richard.braithwaite@nhs.net)

date

2022-06

Abstract

Aims and method

COVID-19 has had a heavy impact on healthcare provision worldwide, including delivery of electroconvulsive therapy (ECT). A survey was completed in the UK and Republic of Ireland in April and July 2020 by 95 and 89 ECT clinics respectively.

Results

In April 2020, 53% of the clinics provided only emergency treatment and 24% had closed. Reasons included unavailability of anaesthetists, infection control measures and staff sickness. Restrictions persisted in July, with disruption to an estimated 437 individuals' treatment and poor outcomes, including clinical deterioration and readmission.

Clinical implications

Risk stratification, longer clinic sessions, improvements in ventilation, regular virus testing, pragmatic staff rostering and availability of personal protective equipment will protect against service disruption in subsequent waves of the pandemic.

pmc Recent editorials in the *BJPsych*¹⁻³ concerning the effects of COVID-19 on psychiatry were written at the outset of the pandemic. It would perhaps have been impossible for their authors to have predicted what has been by far the most devastating effect of the pandemic on psychiatric care: suspension or reduction of normal service provision. This has included minimisation of face-to-face care and, crucially, limited provision of one of the most effective psychiatric treatments, electroconvulsive therapy (ECT).

ECT typically involves aerosol-generating procedures (AGPs), including bag-mask ventilation, suction of secretions and, less commonly, laryngeal mask or endotracheal airway insertion and removal.⁴ It was apparent early on in the pandemic that ECT might pose a risk of viral transmission between patients and healthcare professionals, and that alterations to practice might be needed to ensure safety. However, it quickly became apparent that provision of ECT was rapidly diminishing in most areas and even grinding to a halt in some. Anecdotally, anaesthesia staff had been redeployed in many localities but, although anticipated, significant levels of staff sickness and shielding were yet to be encountered.

We present the findings of a survey conducted at two time points during the pandemic. The aim of the study was to establish the nature, extent and effects of any disruption to ECT services, with a view to establishing how obstacles to full service provision might be overcome in due course.

The survey was conducted by the ECT Accreditation Service (ECTAS), the department of the Royal College of Psychiatrists responsible for the setting and monitoring of clinical standards in the delivery of ECT services across three regions of the UK (England, Wales and Northern Ireland) as well as in the Republic of Ireland. The survey did not cover ECT clinics in Scotland, where standards are set and monitored by the Scottish ECT Accreditation Network.

Method

Each ECTAS member clinic was sent a link to an online survey via the network's email discussion group during two 1-week periods in April and July 2020. The questionnaire was developed following consultation with clinical experts from ECTAS. Reminders were sent to non-responding clinics 2 days before the closing dates. Because this was a retrospective survey of clinicians and did not influence patient care, ethical approval was not required.

In addition to the questions set out in *Table 1*, respondents were asked for the total number of patients at their clinic who had had their treatment affected by the pandemic since 16 March 2020, including those who would otherwise have received ECT but had not. *Table 1* Survey responses from ECT clinics in England, Wales, Northern Ireland and the Republic of Ireland

Questions	Responses, n (%)	April 2020	July 2020
Is your ECT service currently being affected by the COVID-19 pandemic?	Yes	84 (88)	69 (78)
	No	11 (12)	20 (22)
What is the reason?	a	Lack of availability of anaesthetists	49 (52)
	b	Increased PPE/environmental requirement	43 (45)
	c	Required infection control procedures have reduced treatment capacity	48 (54)
	d	Staff sickness/shielding	43 (45)
	e	Staff redeployed	3 (3)
	f	Other	20 (21)
What has been the impact on service provision?	a	No service provided at present	23 (24)
	b	Reduced number of sessions	12 (13)
	c	Service restricted to most urgent/severe cases	50 (53)
	d	Other	14 (15)
What has been the effect on patients who would normally have received ECT prior to the pandemic?	a	Having ECT at a different clinic	16 (17)
	b	Reduced frequency of ECT	20 (21)
	c	Not having any ECT, in-patient, duration of stay potentially increased	47 (49)
	d	Not having any ECT, discharged from hospital	17 (18)
	e	ECT course curtailed	35 (37)
	f	Continuation/maintenance ECT stopped	46 (48)
	g	Clinical condition worsened, probably as a result	18 (19)
	h	Admitted to hospital	3 (3)
	i	Detained in hospital	1 (1)

¹ ECT, electroconvulsive therapy; COVID-19, coronavirus disease 2019; PPE, personal protective equipment.

² Multiple responses were allowed for these questions.

³ These options were not listed in the March 2020 version of the survey.

⁴ 'Other' category included clinic/theatre space or equipment needed by another service, and staff being redeployed to other areas.

⁵

Results

We are aware of 108 ECT clinics in existence in the four regions covered by this study; of those, 98 are members of ECTAS and were sent surveys to complete. In total, 95 clinics (97%) submitted responses to the survey in April 2020 and 89 (91%) in July 2020. Thus, our data cover 89% and 82% of all existing clinics at the two time points respectively.

The main findings are summarised in *Table 1*. Of 95 clinics, 84 (88%) were being adversely affected by the pandemic in April 2020: 50 (53%) were restricting ECT to the most urgent and/or severe cases and 22 (23%) were providing no service at all. By July, of 89 clinics, 69 (78%) were still affected, with 38 (43%) restricting cases and 8 (9%) remaining closed.

Additionally, the 364 patients who had had their treatment affected by the pandemic since 16 March 2020, including those who had had ECT withheld, had risen to 437 by July 2020. One clinic alone had had the treatment of 41 patients affected.

Discussion

Our survey shows that the vast majority of ECT services have been, and continue to be, adversely affected by the COVID-19 pandemic. Obstacles to delivery of ECT have been, and remain, various.

Anaesthetists and operating department practitioners were withdrawn from ECT lists to staff enlarged intensive care units (ICUs), despite most ICUs never having even neared capacity. This affected over half of the clinics at the beginning of the pandemic, with some still experiencing problems by July 2020, when the first peak of COVID-19 infections had long subsided.

Some ECT suites, with no means for adequate ventilation, have been unable to safely host a treatment that potentially involves AGPs. Even those suites that were adequately ventilated or have since been fitted with ventilation systems may continue to operate at reduced patient capacity. Many require patients to fully recover in treatment rooms owing to limited space for safe distancing between patients elsewhere and repurposing of recovery areas for doffing of personal protective equipment (PPE). Even in suites that retain separate recovery areas, the treatment room must be left fallow after any AGP for a set period before cleaning in preparation for the next patient. In some clinics this is as long as 30 min, depending on the frequency of air changes the room.

Treatment rooms require full cleaning between patients, and staff members spend a lot of time donning and doffing PPE. These necessities at best halve patient throughput.⁵ Some ECT services run from suites without adequate ventilation have instead delivered treatments in general hospital operating theatres,⁶ which are subject not only to the restrictions listed above but also necessitate vying for time and facilities with surgical teams. Additionally, poor supply of PPE may have temporarily limited ECT provision in some hospitals.

The resultant loss of productivity has been devastating for many patients. It has led to services variously cancelling all ECT or prioritising only the sickest patients; some clinics have stopped out-patient treatment. Widespread cessation of continuation and maintenance ECT has led to recurrence of severe illness, and delays in initiating acute courses have resulted in worse patient outcomes, particularly in life-threatening illness. Admissions and even formal detentions in hospital have occurred or been lengthened as a consequence.

⁵‘Other’ category included patients being treated at a neighbouring clinic, and list length reduced to allow time for use of PPE and decontamination of facilities between patients.

Recommendations

Looking to the near future, it is imperative that ECT services remain functional even if there is a second wave of COVID-19 infections this winter. Guidance published in September 2020 jointly by four anaesthesia organisations in the UK⁷ takes a pragmatic approach towards COVID-19 risk stratification that might prove helpful in increasing patient turnover. Crucially, it asserts that in-patients who are regularly tested for the virus and are on wards where COVID-19 patients are not being treated should be considered low risk. Previously only a small minority of out-patients who were shielding at home and regularly tested for the virus had been considered low risk. For treatment of low-risk patients, staff need wear only basic PPE (an apron, gloves and a surgical mask, with consideration of eye protection), usual recovery areas can be used and treatment rooms do not require full cleaning between patients.⁷

However, patients in medium- and high-risk groups will continue to present for ECT. Some clinics may require improvements in ventilation to facilitate faster throughput of such patients. It is essential that any shut-down clinics be reopened without delay, following liaison between infection control, anaesthesia and ECT staff. Psychiatric staff must work closely with anaesthesia colleagues to develop pathways enabling out-patients to access ECT, including regular fast-track virus testing.

It would be all too easy, with the benefit of hindsight, to criticise decisions made at the outset of the pandemic to redeploy anaesthetists, en masse, in anticipation of a surge in ICU usage of far greater magnitude than ultimately occurred. But it is important that the same situation does not recur and that staff are pulled from delivering ECT only if ICUs have a genuine need for the personnel and careful consideration of the balance of negative outcomes concludes that such action is unavoidable. PPE must be kept available. Lastly, the need to lengthen or widen ECT lists into afternoon sessions or on more days of the week must be seriously considered by healthcare providers, with job planning and prioritisation of staffing for ECT services made to facilitate this.

We thank Eve Blanchard and Sinead Rogers of the ECT Accreditation Service for organising and collating the results of the survey and Professor George Kirov for his suggestions regarding this paper.

pmc In medical school we used to debate whether we would prefer to be a kind doctor or a clever one. Of course, most of us wanted to be both. But when we were ill ourselves, if we had to choose we were sure we would want a clever doctor to deal with serious conditions and a kind one for the minor things.

There is a related rift in mental health services between psychodynamic work and evidence-based medicine. Certainly, most patients are given one or the other. Corinne Dignan in her article¹ focuses on something more on the psychodynamic side, that we are in danger of forgetting: the feelings and the shared experiences that she neatly calls the person behind the diagnostic labels. In this commentary I focus on this specific suggestion, rather than the general topic of medical humanities.

To clarify, she is not pushing us to become psychotherapists. She sees a beauty in each person, the special moments in each life and the treasured memories that gradually disappear in dementia. She experiences shared memories as special objects that will die unless a person keeps them alive. Indeed, as long as one person keeps them alive, part of the departed person still exists. In some senses they do; the memories exist, and we may sometimes feel that the person does too. This is a point that I’ve not seen so well treated elsewhere. Each experience, or at least an echo of it, continues to exist for as long as someone thinks about it (akin to the tree in the quad²). Dignan’s article serves to warn us not to forget John Eccles’s World 2 (subjective knowledge) as opposed to Worlds 1 and 3 that doctors usually focus on (physical objects and objective knowledge).³

I’m pleased that Dr Dignan is not pushing us all to be poets (I might rebel). Instead, starting from a traditional learning hierarchy of medicine–psychiatry–subspecialty–specific job,⁴ she adds another layer. She proposes that the medical humanities – a vast conglomeration of fields – is a rich hunting ground for broadening experiences. Not only rich, but necessary: I am going slightly beyond her words here, but she seems to believe that exploring the humanities makes us better people, more complete and more able to relate to others.

Dignan’s aims are commendable and her poem is gorgeous. By publishing it, some of the memories she shared with her grandmother will endure for as long as this journal, perhaps in a cloud on a distant planet. Her point deserves to be applauded, explored and amplified.

This commentary started with the question of which kind of doctor serves patients best. We serve patients directly, but also indirectly by serving the systems around them. In the UK, the General Medical Council (GMC) says that a good doctor will ‘make the care of your patient your first concern.’⁵ But not your only concern. ‘Good medical practice’ also includes duties to our own knowledge and skills; to other patients; colleagues; our personal health; the medical profession; and the public. I will comment on a few of these that relate to Dignan’s article.

What's best for our skills?

I'm convinced that everyone becomes usefully dubious of their own intuitions if they regularly spend time with *Thinking, Fast and Slow*.⁶ Kahneman, and many others, have demonstrated that one of the most pervasive of all thinking defects is narrow framing, in other words failing to think broadly enough about a problem.

So for what it's worth, here are some of my favourite thought-broadening activities for psychiatrists, admittedly evidence-light. (a) We could learn from psychologists, many of whom are explicitly trained to become 'scientist practitioners'. It's a lifelong challenge.^{7,8} (b) Some of my best colleagues love long-distance holidays. Who knows which came first? They may have been broad-minded even before the first long-haul trip. (c) In my job, watching two siblings bicker and play can produce a delightful impression of them as parts of the stream of social humanity. It also produces useful objective observations. But are these valuable enough to justify the second child missing school to attend? For the impression, no. But for the observations: perhaps for one session and not subsequently. (d) As Francis Bacon noted in 1597, 'Reading maketh a full man, conference a ready man, and writing an exact man'. Of course, all three parts are relevant to a modern psychiatrist. Reading autobiographies and complex fiction can extend the range of people we empathise with.⁹ And, no doubt, by 'conference' he was referring to respectful participation in a multidisciplinary team.

What's best for us emotionally?

Many doctors need a protective carapace, so they don't become too dispirited by demanding patients. Others need to suppress their enthusiasm for over-engaging with patients. Other doctors (one thinks particularly of researchers) need to give full flow to their meticulous tendencies. Overall, we should try to find a happy, productive, middle course that works for us personally.¹⁰ Part of this might include keeping a personal diary – for ourselves and those who come after us.

Dignan's aspiration is that we should all follow her example, and become more empathic. I hope some of us do. But I'm not optimistic. The classic example is the people travelling to give a lecture on good Samaritans, who step over a sick person, especially if they feel rushed.¹¹ Allow me to give a personal anecdote of my own failure to transfer attitudes between relationships. During my time as a junior psychiatrist I felt sympathy towards a man whose Huntington's disease destroyed the relationships in his family: but I didn't notice the same process happening in my own family at the same time (due to my father's multiple sclerosis).

What's best for healthcare funders?

Dignan advocates that we should spend more time with patients. In my experience, most doctors wish this. But how much time is justified? In many units, a ward assistant will be given the role of making patients feel comfortable and listened to; some of them have a delightful, naturally reassuring manner that hardly relies on personal knowledge. Usually, the history taking is delegated to junior doctors. That system creates good histories, good relationships and good training.

But the more senior doctors need to be quick, more distanced, less emotionally involved. It sounds like a shortcoming, but it isn't: their distance makes a necessary contribution to the thinking of a diverse team. The older psychiatrists typically have a wider social circle and have known vastly more patients: they have all exceeded the Dunbar number of 150 people that we can personally relate to.¹² Even more distance is needed by doctors in poor countries: if they have only 5 or 10 minutes per patient, constant personal involvement will overwhelm them.

What's best for the future of healthcare?

As a field, we need different things: practitioners exploring literally everywhere for insights, with the more distant explorers widely spread out, not following others, to cover the vast, less promising terrain. Even after our explorers have found a promising activity, as Dignan has done, it's fiendishly difficult to prove that it's worthwhile.¹³

We discussed these issues in our continuing professional development (CPD) group recently. One consultant said it was only her impending retirement that made her feel safe enough to say that getting to know the patients was highly undervalued, and actually disapproved of by managers. Another felt it had to be conducted as a 'guerilla activity' because managers saw it as detracting from the necessary work. The group found art and writing activities useful for patients, but there were no takers for creating any form of art themselves.

1.1.43 Friston's free energy principle: new life for psychoanalysis?

Jeremy Holmes

Correspondence

Jeremy Holmes (j.a.holmes@btinternet.com)

date

2022-06

Abstract

The free energy principle (FEP) is a new paradigm that has gain widespread interest in the neuroscience community. Although its principal architect, Karl Friston, is a psychiatrist, it has thus far had little impact within psychiatry. This article introduces readers to the FEP, points out its consilience with Freud's neuroscientific ideas and with psychodynamic practice, and suggests ways in which the FEP can help explain the mechanisms of action of the psychotherapies.

Contents

- *Friston's free energy principle: new life for psychoanalysis?*
 - *Friston's forebears*
 - *Free energy*
 - *Free energy and psychopathology*
 - *Psychotherapeutic implications*
 - *Conclusions*
 - *Declaration of interest*

pmc Today's psychiatrists are pragmatists, on the look-out for what 'works' and sceptical about the grand theories that held sway in the previous century. But ideology cannot be wholly avoided, nor theoretical controversy evaded. Current psychiatry's pantheon includes evidence-based practice, DSM diagnosis and neuroscience. The search for evidence is theory driven. Diagnostic profusion raises questions about the medicalisation of human suffering. Despite extraordinary recent advances in neuroscience, their impact on everyday psychiatric practice has been modest.

The purpose of this article is twofold: first, to introduce readers to an overarching model of brain function associated with the mathematical psychiatrist Karl Friston, the free energy principle (FEP), which has been influential in neuroscience generally, but thus far has caused relatively little stir within psychiatry or clinical psychology. My hope is to redress that. Second, I make the case that FEP can revitalise the psychoanalytic psychotherapies, marginalised by the inexorable rise of cognitive-behavioural therapy (CBT) as the dominant psychological therapy paradigm.

It should be noted that FEP is deliberately described by Friston as a 'principle', akin to the principles of natural selection or gravity. The evidence for its validity is circumstantial rather than direct, and its detailed neuronal mechanisms and clinical implications remain to be fully explored.

Friston's forebears

Friston's project builds on the work of a number of pioneering predecessors and their concepts. These include Erwin Schrödinger, Heinrich Helmholtz, the Claudes – Claude Bernard and Claude Shannon – and Thomas Bayes. We live in an entropic universe. Broken cups don't spontaneously reassemble. Coffee cools once poured. Stars burn out. The exception is life itself. Quantum physicist Schrödinger¹ coined the term 'negentropy' to describe how living matter, Canute-like for its lifetime, reverses this cosmic tide towards disorder and homogeneity.

The key to negentropy is homeostasis. As Bernard famously put it, the condition of a free life is the stability of the interior milieu – whether one is a unicellular amoeba or, like Schrödinger, a Nobel-prize winning primate. Homeostasis, and the more general processes of allostasis,² resist the forces of entropy, physiologically and behaviourally. Inherent in homeostasis are boundaries: cell membranes, the skin, the brain within its skull. Janus-like, homeostasis faces outwards towards the environment and inwards towards the *milieu interieur*. Temperature sensors in the skin tell us it's a hot day; the sympathetic nervous system activates sweat glands, the brain tells us to fling off jumpers, move into the shade, etc., all in the service of resisting being entropically fried. Note that homeostats vary in 'precision' – some are highly sensitive, whereas others tolerate a great range of variation.

Friston had the insight and mathematical sophistication to see that the negentropic homeostatic principle applies not just to the organism as a whole but to the brain itself.^{3,4} The brain's job is to counteract entropy and to maintain internal stability on behalf of the organism whose processes and behaviour it controls and directs; this applies, reflexively, to itself.

The FEP goes back to the ideas of 19th-century polymath Hermann von Helmholtz, updated by artificial intelligence (AI) neuroscientists Geoffrey Hinton and Peter Dayan.⁵ Naively, we tend to think of vision as a camera-like image passively projected onto the visual cortex, or the auditory system as microphone-like, responding indiscriminately to the prevailing phonic universe. In the Helmholtz model the *brain makes its own world*. Our sense organs, external and internal, are constantly bombarded by a vast range of stimuli from an ever-changing environment. To operate with maximum efficiency, the brain selects out the 'meaning' of its sensations, attending only to those that are relevant to its 'affordances'⁶ – its specific ecological niche – and especially to input that is anomalous or novel.

Working in the 1950s at the Bell telephone company laboratory, Claude Shannon saw that this 'meaning' could be quantified – as 'bits' of information. Gregory Bateson, anthropologist and family therapy guru, called these 'differences that make a difference'. White noise is chaotic, entropic and devoid of information. Language, whether spoken, sung or gestured, is structured, ordered, negentropic. The measure of informational energy is 'surprise', i.e. how unexpected a signal is. In the board game Scrabble, the letter 'x' conveys more information than 'e' because it is relatively unusual, applying to a smaller range of words, and so in calculating the score, is 'worth' more. The brain's aim is constantly to reduce informational entropy and maximise meaning.

A crucial building block for the FEP is the concept of the Bayesian brain. The Reverend Thomas Bayes, a late 18th-century clergyman and founder of probability theory, grasped, Doris Day-like, that the future's not ours to see. Yet, to survive and adapt we need to know, moment to moment, 'what is going on' – in ourselves, in the interpersonal world

and in the physical world. On the basis of prior experience, the Bayesian brain⁷ continuously estimates the likelihood of future events. Probabilities are computed by comparing current states of affairs with past occurrences, estimating the extent of correspondence between them, factoring in the likelihood of errors in both memory and perception, and ending with a portion that represents that which cannot be predicted. This is ‘prediction error’, which must, in the service of negentropy, be minimised as far as is possible – prediction error minimisation or PEM.

The brain, ‘top-down’, uses Bayesian probabilities to clarify ‘bottom-up’ input, extero- and interoceptive:⁸ ‘My stomach is complaining, but it’s not surprising – I overdid it on the pudding, so it’s probably not cancer’; ‘I know that tune, I’ve heard it so many times – yes of course, it’s the Beatles’ Yellow Submarine’; ‘Is that a stick or a snake? Come on, no adders in city centres, probably safe to pick it up’.

Free energy

Now to the free energy principle itself. ‘Energy’ equates to information, albeit physically embodied in patterns of neuronal impulses, synaptic transmission (‘fire together, wire together’⁹) and the neurohormonal environment. Prior models of the world, top-down, ‘bind’ incoming bottom-up information. Energy *unbound*, or prediction error, reflects novelty in need of binding – and so forestall the dangers of entropic chaos.

Circumstantial evidence for the FEP is the fact that more neuronal fibres reach the eye downwards from the brain than travel upward towards the visual cortex. Whenever possible, the brain ‘tells’ the eye what it is likely to be seeing. The FEP postulates a hierarchical series of neuronal interactions, starting from the least to the most complex, from the periphery to the central nervous system, from specificity to abstraction, most of which operate below conscious awareness. At the level of the eye itself the retinal receptors are activated: ‘round, two dots and a straight line between’. Top-down, even in a 1-month baby, this will elicit an answering smile (‘face equals security’). Once language arrives, verbal concepts shape perceptions: ‘Oh of course, that’s a face’. At the highest level is mentalising – thinking about thinking: ‘I wonder why bearded faces always make me feel slightly unsettled? Perhaps it’s reminiscent of my scary grandfather’.

The FEP visualises a series of ‘conversations’ in which top-down ‘priors’ ‘bind’ bottom-up input into probabilistically recognisable meanings. Each level can be thought of as a meaning–action boundary. Ascending the hierarchy, the Bayesian process ensures that the most mathematically probable pattern prevails across these statistical boundaries or ‘Markov blankets’.¹⁰ Prediction error is minimised by ‘binding’ bottom-up energy (informational as well as physiological) by top-down generative models based on pre-existing patterns and concepts. Thus is order preserved, entropy eschewed. We know what we like and, mostly, see what we want and expect to see.

But there will always be a discrepancy between our pre-existing models of the world and incoming sensations, an excess of energy that cannot be bound and will have to be passed onto the next level up of the hierarchy. Lockdown excepted, we don’t live huddled in ‘dark rooms’.¹¹ The environment is constantly in flux; we need to explore as much as conserve – to find new sources of food, suitable mates, interest and excitement. Surprise, calibrated by the brain as the discrepancy between expectation and incoming sensation, is a proxy for free energy – and hence entropy. Surprise is both vital to survival but also potentially entropic, disruptive or even life-threatening. This represents the prediction error aforementioned. The brain minimises such surprise/error by whatever means possible.

At this point the role of affect becomes important. Free energy is aversive and can be thought of as representing mental pain. Conversely, ‘binding’ free energy is rewarding and therefore motivating. The role of affect, positive and negative, is to drive the free energy minimising processes. This is another ‘AI’ – active inference.

The idea of active inference captures a number of psychological processes central to psychological health. First, action or agency. Given that incoming stimuli are inherently subject to error and imprecision, the brain increases precision by movement – approaching an ambiguous stimulus source, turning the head to use foveal rather than peripheral vision, switching lights on in order to see better, etc. Second, top-down model revision. Now we know what that vague shape really ‘is’ – a cat, clothes strewn on the floor, etc.: ‘Let’s listen more carefully. Oh, that’s not the Beatles at all, it’s the Beach Boys’. Third, and vitally in the case of social species such as our own, active inference is enhanced by recruiting help or ‘togetherness’: ‘Did you hear something, or was I just imagining it?’; ‘You know about ’70s music – what was that group’s name?’. Friston & Frith call this ‘duets for one’ and have worked out the mathematics of such collaborative Markov blankets.¹² Fourth, if all else fails, by choosing or fashioning environments that conform to the

brain's pre-existing models of the world: 'I can't stand modern music. Let's go over to Classic FM'. This last aspect is captured by the psychoanalytic concept of 'projective identification', in which we shape our interpersonal world, often deleteriously, to conform with expectations: 'You psychiatrists are all the same – never there when I need you'.

Free energy and psychopathology

The FEP has clear implications for those who work in mental ill health, and especially who favour psychological methods of treatment. Consider depression, typically triggered by loss, trauma or multiple setbacks. Adversity is widespread – poverty, inequality, racism – but not all succumb. To understand resilience, we need an illness model that encompasses not just events, but individuals' responses to them. Attachment research shows that those who are securely attached are able to repair the inevitable ruptures to which all are prone, often through the typical sequence of protest, rage, grief and mourning.¹³ As children, securely attached people have had caregivers they could depend on to acknowledge their pain, tolerate protest and help them to move on. Repeated episodes of everyday rupture–repair cycles help build this resilience.

The free energy released by the rupture is bound by the child's knowledge that help is at hand and that their epistemically trusted caregiver will provide a generative model to counteract the free energy associated with ruptures: 'Don't worry love, I'm just going to the loo, I'll be back in a minute'. In the 'still face' paradigm, parents are asked to freeze their facial expression for 1 minute while talking or playing with their child.¹⁴ Securely attached children continue actively to try to re-engage with their caregivers in the confident expectation that they will be 'back soon'. For insecurely attached children, by contrast, rather than rupture–repair, cycles of rupture–despair or rupture–disappear are the norm. Their caregivers have either themselves been overwhelmed by their child's unhappiness and so despairingly abandon attempts to alleviate it; or repress the impact of the child's mental pain and so 'disappear' emotionally. Both leave the child alone to find ways to bind the free energy the rupture evokes. When their caregiver's face freezes they look away, become miserable and regressed, and often resort to self-soothing rituals such as rocking or emotional dissociation.

Such insecurely attached children are primed in later life for depression in response to loss or trauma or, in extreme cases, to developing post-traumatic stress disorder. The ingredients of free energy minimisation needed to maintain psychological equilibrium are for them problematic. Active inference is compromised. They tend to be passive rather than active. They stick with limited and simplistic and inflexible 'top-down' models such as 'It's no use trying to make things better, it never works' or 'Feelings are dangerous, best to keep them buried'. They find it hard to trust people and so can't 'borrow' an intimate other's brain with which to process feelings and build up alternative ways of viewing the world.

Psychotherapeutic implications

The most commonly used therapy for depression, CBT, attempts to address these deficiencies. Therapists encourage patients actively to test their negative 'hypotheses' by looking more closely at their experiences and by exploring alternative top-down models to account for them ('Maybe my boyfriend didn't answer his phone because he'd run out of battery, not because he doesn't love me'). But CBT has its limitations. 'Treatment-resistant depression' is common.¹⁵ People with personality disorders do badly with standard CBT, often refusing to engage or dropping out.¹⁶ The FEP provides explanations for this. From an FEP perspective, one way to minimise free energy is to gravitate towards or engender environments that confirm one's view of the world, however negative. Depression relegates sufferers to emotionally impoverished relationships, stereotyped and simplistic top-down models, and thus becomes a self-fulfilling hypothesis, resistant to psychotherapeutic interventions. In addition, these negative top-down priors are 'inferentially inert', i.e. inaccessible for modification.

A degree of chaos/uncertainty/free energy needs to be tolerated before new generative models can evolve. Homeostatic imprecision needs to be tolerated for a while. The holding and 'negative capability' of the therapist's 'borrowed brain' paves the way for a more complex, nuanced top-down reset. Given that people with personality disorders notoriously find it difficult to trust others, the brevity and defocus on the therapeutic relationship in standard CBT limits the scope for such fundamental change.

Moving from depression to an FEP perspective on trauma, the latter creates an overwhelming influx of free energy for which there are no available top-down models with which to bind it. Thoughts of cruelty, neglect and abuse remain

in the realm of the unthinkable and are therefore ‘defended against’ by repression or dissociation.¹⁷ However, when jointly considered – under a shared Markov blanket – these bottom-up unprocessed experiences can be bound with the therapist’s encouragement and expertise into manageable narratives. However painful, they become less overwhelming, a source of new ways of thinking and psychic reorganisation. As the patient begins to feel that the therapist is safe, reliable, compassionate and empathic, so everyday ruptures – session-endings, holiday breaks and misunderstandings – are repeatedly repaired via model revision (‘Maybe the weekend break does not inevitably mean I’m forgotten’), and the trust this engenders can be generalised into the patient’s everyday life.

We can see here how contemporary psychoanalytic psychotherapy and revitalised Freudian ideas resonate with the FEP. Freud started off his working life as a neurologist. Like Friston, he conceptualised the brain’s aim as reducing psychic energy, typically through action and ‘word representations’ – i.e. transmuting free energy into thinkable thoughts. He saw unbound energy (which he later transmuted into ‘libido’) as potentially disruptive and responsible for the symptoms of psychological illness. Psychoanalysis was designed first to evoke and then to quieten this trauma-related unbound energy. To achieve this, three key psychoanalytic procedures are free association, dream analysis and analysis of transference.

The ‘virtual’ nature of the psychoanalytic relationship brings both top-down and bottom-up components of the FEP process into focus, enabling them to be mentalised rather than enacted. Free association taps into the mind’s normally unvoiced upward-welling stream of consciousness, counteracting the elusiveness of affect seen in the rupture–despair/disappear attachment pattern. This enables the range of top-down responses to be enhanced and aversive free energy minimised. At the top-down level, in a process comparable to the immune system’s lexicon of antigen-activated antibodies, dreaming is the means by which the mind generates a repertoire of narratives with which to bind the free energy which life’s vicissitudes engender. Transference analysis turns the spotlight on the limited varieties of top-down narratives that sufferers use in their dealings with intimate others to minimise free energy. The enigmatic ambiguity of therapists’ persona enables patients to experience, reconsider and extend the top-down assumptions with which they approach the world of intimate others.

Psychoanalysis has tended to self-isolation, sequestered from cross-fertilisation by other disciplines. The Friston–Freud consilience opens up new possibilities. Psychoanalytic and attachment-derived mentalisation-based therapy (MBT) is now established as a highly effective therapy for borderline personality disorder, previously considered untreatable.¹⁸ MBT leads to big reductions in medication use, suicide attempts, hospital admission and unemployment among people with borderline personality disorder, as compared with treatment as usual.

MBT is both practically and conceptually consistent with the FEM. It encourages patients (a) to identify the bottom-up feelings that fuel their self-injurious actions, (b) to pause and think of different ways of handling these, i.e. to tolerate a quantum of free energy with the help of the therapists’ ‘borrowed brain’ and (c) through mutual mentalising (therapist and patient together forming a neurobiological ‘bubble’) to generate more complex and adaptive models of the self and significant others. The result is manageable surprise: confounding sufferers’ negative assumptions about the world, becoming less overwhelmed by unbound affect (fewer ‘melt-downs’) and facilitating greater resilience.

Conclusions

If rehabilitation of the psychoanalytic method in the light of the FEP comes as a pleasant surprise, this is consistent with its principles. As in Mark Twain’s trope, rumours of psychoanalysis’s death have been greatly exaggerated. In place of despair or disappearance, the FEP suggests that repair is possible. FEP-grounded psychoanalytic approaches such as MBT are now known to help those with profound mental distress. They also suggest a scientifically sound account of the interpersonal and neuronal mechanisms by which psychological change comes about.

Jeremy Holmes is a retired psychiatrist and psychoanalytic psychotherapist. He is a Visiting Professor at Exeter University, UK, and author of many articles and books in the field of attachment theory and psychoanalysis, including *The Brain Has a Mind of Its Own: Attachment, Neurobiology, and the New Science of Psychotherapy*, in which the ideas of this article are explored in greater detail.

Abstract**Aims and method**

COVID-19 has forced many educational events to go ‘virtual’. We report on the first online student-run National Psychiatry Summer School (NPSS). Evaluation of the online format and content was undertaken through survey feedback from almost 400 attendees.

Results

The NPSS positively affected attendees’ perceptions of psychiatry as a career choice. The virtual format was positively received, with benefits including breaking down traditional barriers of geography and cost.

Clinical implications

Post-COVID-19, a hybrid future of mixed virtual and face-to-face events is likely. Our work shows the viability of this and unique gains it might offer, and offers experiential learning on challenges encountered for others who wish to trial further virtual conferences.

pmc COVID-19 has presented many changes, including a rapid move to virtual teaching.¹ Online conferences have become the ‘new normal’, providing numerous new challenges and opportunities for medical education.² ‘Choose Psychiatry’ initiatives by the Royal College of Psychiatrists (RCPsych) have also adapted to these changes. The National Psychiatry Summer School (NPSS) was one such event, planned from the outset as a virtual event with RCPsych sponsorship and successfully hosted online over 2 days in July 2020. To our knowledge, it was the first virtual summer school led by medical students with collaboration across devolved nations of the UK.

The NPSS had three primary aims: (a) to promote psychiatry as a career; (b) to help compensate for clinical placements lost during the pandemic; (b) to reduce geographical, financial and time-frame barriers to attendance. The first of these has been a common theme for other initiatives.³ However, the other two reflect innovative attempts to offset losses accrued during the COVID-19 pandemic and tap into novel opportunities from this disruption. Two secondary aims were to explore underrepresented subspecialties within the undergraduate curriculum and to evidence high-quality medical student-led initiatives.

We report the practicalities and learning from hosting this online event, present feedback data on the content and novel format, and offer proposals for the future optimisation of student engagement and recruitment through technology. We also consider the future of advancement of hybrid models and events that will likely combine virtual and face-to-face aspects, much of which is applicable to other online conferences.

Method

Free-text feedback and ratings on a range of questions were collected on both days of the NPSS and a total of 726 feedback forms were completed (383 for day 1 and 343 for day 2), accounting for just over 81% of attendees. Merging the survey data produced a total of 379 responses.

Participants gave informed consent for their anonymised data to be subsequently analysed and disseminated in future research and promotional materials. Ethical approval was not required as the purpose of the study was to evaluate and improve a service. No formal research methodology was used beyond descriptive analysis of the survey data.

Survey data collection

The majority of attendees were based in the UK (347/379); of those specifying a country, 7 were from Wales, 15 from Northern Ireland, 28 from Scotland and 87 from England. International attendees came from (1 from each country unless otherwise stated): Albania, Brunei (2), Canada, Egypt, Hungary, India (2), Ireland (2), Kuwait, Malaysia, Oman, Pakistan (3), Poland, Romania, Saudi Arabia and the United Arab Emirates (3).

In total, 215 attendees were current medical students, 104 were sixth form students, 13 were doctors and 33 were current/post-graduate students in other fields, including biomedical sciences and psychology.

Feedback responses

Attendees were asked to rate (on a scale of 0–10) how likely they were to choose a career in psychiatry/mental health before and after the event. The mean score increased from 5.66 (s.d. = 2.61) to 7.31 (s.d. = 1.95) (*Fig. 1*). They also completed a six-point questionnaire on various aspects of the event (*Table 1*). Feedback was very positive for the event; for example, across the 379 survey responses, over 99% of attendees ‘strongly agreed’ or ‘agreed’ that the presenters appeared enthusiastic about the subject and over 98% of attendees ‘strongly agreed’ or ‘agreed’ that, overall, this event was high quality. *Fig. 1* Attendee likelihood rating (a) before and (b) after event. *Table 1* Subjective attendee ($n = 379$) ratings of the 2020 National Psychiatry Summer School

Statement	Strongly agree	Agree	Neutral	Disagree	Strongly disagree
‘The presenters appeared enthusiastic about the subject’	84.96	14.25	0.53	0.26	0.00
‘Overall, this event was of a high quality’	79.95	18.73	0.53	0.53	0.26
‘The event was well organised’	86.81	12.14	0.53	0.26	0.26
‘This event was successful in promoting psychiatry’	75.99	22.96	0.79	0.00	0.26
‘The event length was adequate’	56.73	33.51	7.92	1.58	0.26
‘There were enough breaks during the day’	38.79	40.63	11.87	7.92	0.79

Free-text survey responses

Formal qualitative methods were not used, but free text was used to identify key themes in feedback from attendees. In total, 180/331 respondents from day 1 and 132/297 from day 2 provided qualitative free-text feedback. Attendees were asked whether there were ‘any other topics you wished we had covered?’. Popular responses included (but were not limited to) ‘Child and adolescent psychiatry’, ‘Perinatal psychiatry’, ‘Addiction psychiatry’, ‘LGBTQ mental health’, ‘Intellectual disability psychiatry’, ‘Psychotherapy’ and ‘Patients with lived experience’. Other responses referred to specific disorders or topics covered on day 2.

Attendees were asked to provide feedback to help improve future events, from which we identified 20 major themes: 10 on the format of the online event (*Table 2*) and 10 on its content (*Table 3*). *Table 2* Major themes regarding the online format of the 2020 National Psychiatry Summer School identified from qualitative data analysis

Format theme	Example quote
Accessibility	‘The fact that it was free and I was able to attend despite being from [...] was very useful.’ (Theme 1)
Medical student hosts	‘I feel that the hosts played a massive part in making the day enjoyable and the way they went about changing it to suit the audience’s needs, like the sixth former talk during lunchtime, would be something I am very thankful for. I am very inspired by the two of them.’ (Theme 2)
Quality	‘The event was incredibly well organised and done so much more professionally and with fewer technical problems than other virtual conferences arranged by larger organisations with more qualified staff.’ (Theme 3)
Organisation	‘I think the day was very well organised, it was truly one of the best events I have attended.’ (Theme 4)
Technology	‘It was amazing that you stuck to time and covered such a breadth of topics with speakers who were confident using the technology and extremely passionate about their subject areas.’ (Theme 5)
Social media use	‘It was great to get a good conversation going on Twitter – almost like networking (but not quite!).’ (Theme 6)
Interactivity	‘Although difficult to do, I think the talks could’ve been more interactive i.e. using the poll/voting tools available on Zoom.’ (Theme 7)
Providing post-event resources	‘Perhaps in future (with the permission of the speaker of course) it would be possible to record sessions so if some people are not able to make it they would be able to watch at a later date.’ (Theme 8)
Target audience	‘Perhaps there could have been different sessions available at different times/in breakout rooms at the end depending what stage you were in that you could choose to attend.’ (Theme 9)
Zoom fatigue	‘I would have wanted would be maybe a couple more breaks, just couldn’t bear to miss any talks yet my eyes are definitely aching after a long day of screen-staring.’ (Theme 10)

Table 3 Major themes on the content of the 2020 National Psychiatry Summer School identified from qualitative data analysis

Content theme	Example
---------------	---------

quoteSpeakers‘Very well delivered webinars, speakers extremely interesting, enthusiastic, and knowledgeable about their subjects.’ (Theme 11)Diversity‘Diverse range of topics, and very glad to see that topics that aren’t addressed enough (Islamophobia, Race, Equality) are being discussed and we can learn how, as medical students, to tackle these in healthcare and in our daily lives.’ (Theme 12)Representation of subspecialties‘I think the timetable has been very well developed to cover a wide variety of interesting topics that are otherwise neglected on many medical school’s psychiatry curriculums’ (Theme 13)Lived experience‘Hearing about people’s real lived experiences of mental health and working within the sector was really inspiring.’ 14Patient simulation‘I enjoyed the actor scenario and use of patient scenarios in the second and third lectures of the day. I always find this useful to put the information being given into the context of the real clinical world.’ (Theme 15)Interest for non-psychiatrists‘I loved it all, and that’s coming from someone not actually pursuing psychiatry as an occupation.’ (Theme 16)Compensation for lost experiences‘Attending this summer school has re-lit the excitement in me about applying to medical school which seemed to have died down a bit in lockdown.’ (Theme 17)Earlier exposure‘At the University of [...], we have psychiatry placements in our final year which were initially supposed to be early next year for me! It was great to get exposure to the speciality through the conference.’ (Theme 18)Choose Psychiatry‘I had slight doubts about choosing psychiatry but no more, this event has only deepened my passion for this career.’ (Theme 19)College engagement‘I hope you offer a summer school like this in future, and all the Royal [medical] colleges should do the same. I will look at signing up to the RCPsych now!’ (Theme 20)

Discussion

Practicalities of running the virtual 2020 NPSS

Psychiatry summer schools are one of the UK’s Choose Psychiatry initiatives and one of many enrichment activities encouraging students to choose psychiatry.⁴ The first UK psychiatry summer school took place in 2009, organised by King’s College London.⁵ These free-of-charge educational experiences have since expanded nationally (hosts have included Liverpool, Wessex and Leeds), ranging from one day to full week programmes.

The 2020 NPSS was not designed to make a profit, and funding for the online platform was provided by the RCPsych. The event was instigated, co-organised and co-hosted by the two medical student authors (P.V and N.N), who were PsychSoc Presidents at their respective universities, Queen’s University Belfast and the University of Manchester, during this period. The programme was organised within approximately 1 month. It featured 18 diverse, eminent and award-winning doctors from a range of UK geographical locations, including RCPsych faculty staff. Thought was given to selecting speakers from subspecialties typically underrepresented on the undergraduate medical curriculum, such as eating disorders and global forensic psychiatry (*Fig. 2*). Speakers were ultimately recruited based on the organisers’ personal professional networks and experience of seeing speakers at previous face-to-face events. No speaker charges were incurred. The decision to use Zoom Video Webinar was made based on the hosts’ previous experience using the platform, which has control functions and security that allow attendees and panellists different privileges (speakers can share slides, sound and video without risk of interruption from the audience and it protects against the new phenomenon of ‘Zoom bombing’). For the NPSS, a 500-participant webinar license (£134.40 for that month) was added onto a pre-existing PsychSoc Zoom Pro meetings account (£14.39 a month). *Fig. 2*National Psychiatry Summer School 2020 programme.

Before the programme’s release the event was advertised on Facebook, Twitter and Instagram using Queen’s University Belfast and Manchester PsychSoc social media accounts. The event was open to all interested, including sixth formers as well as medical students. In total, 480 tickets, all free of charge, were available per day, with no restrictions or limitations in numbers by university or school. In total, 1029 expressed initial ‘interest’ in attending on Facebook, and the Eventbrite event page had 9747 views. Tickets were limited by Zoom platform capacity, and on both occasions all tickets were ‘sold out’ within 12 h. Tickets were released in two batches: the first on 29 June and the second 13 July 2020. The full programme was released on 11 July.

The 2020 NPSS had a total of 434 attendees log in overall on day 1 and 412 attendees on day 2.

The online format: digital advantages and challenges

The 2020 NPSS has demonstrated that moving conferences online creates new challenges to overcome but can provide exciting novel opportunities. Organising a successful online conference can typically be achieved in a shorter time frame than similar in-person events. Once a suitable platform is chosen, there is no need to book a venue, catering, accommodation and so forth, and focus is solely on assembling the best possible programme. In comparison, the annual National Student Psychiatry Conference receives a minimum funding of £1500. Organisers are no longer constrained by geographical barriers (travel reimbursement costs and far greater time commitments) and the speaker pool is therefore much wider, time-zone permitting.

Moving conferences online can increase medical student and sixth form attendance and early career engagement, both nationally and internationally. Attendance at the NPSS overall was higher than at previous in-person National Student Psychiatry Conferences. Virtual forums can hold a greater capacity than a physical space at a much lower cost. The NPSS ‘sold’ 480 tickets. In comparison, previous National Student Psychiatry Conferences have sold approximately 122 tickets (Brighton and Sussex, 2018), 130 (Cardiff, 2019) and 156 (Bristol, 2020); historically, medical students from the host institution form the largest proportion of attendees at these face-to-face events. Cost access barriers to events are also overcome; attendees no longer incur travel expenses and can instead attend from the comfort of their own homes (theme 1 in *Table 2*), and attendance was particularly high for students from all three devolved nations when compared with the aforementioned conferences. The removal of travel costs, alongside the cost of accommodation, tickets and so forth contributes to an overall cost reduction for each attendee, helping to reach prospective doctors and future psychiatrists, especially in hard-to-recruit areas, and students from less advantaged backgrounds.

Attendees valued having medical student hosts and organisers (*Table 2*, theme 2). Prior to COVID-19 restrictions, collaboration between PsychSocs from two different countries was rare; but collaboration pooled perspectives from two institutions and networks, for both advertising and speaker recruitment. Consequently, there was an overall increased awareness of PsychSocs as a whole, and we predict future increase in medical student engagement with their local PsychSocs.

The quality and standard of an in-person event does not appear to have been lost – as reported in feedback (*Table 2*, theme 3). This included appreciation of keeping to programme timings, day structure and excellent organisation (theme 4). The hosts prompted the speakers on their available time and the appropriate number of audience questions, which was greatly valued by the audience, with comments such as ‘The event was incredibly well organised and done so much more professionally and with fewer technical problems than other virtual conferences arranged by larger organisations with more qualified staff’ (theme 3).

There are, however, challenges with online learning. Practice runs increased speaker confidence and minimised technical difficulties on the day, but the schedule was also purposefully designed to allow for some speaker delays and yet remain on time (*Table 2*, theme 5). Even with such precautions we experienced some technical difficulties on the day, including joining an online platform with inadequate internet connection or from a hospital/clinical trust from which access was blocked.

The attendees also appreciated the ‘buzz’ the conference had on Twitter (*Table 2*, theme 6). The NPSS ensured that all the speakers’ Twitter handles were made available to the attendees by displaying them on the screen in breaks.

Audience capacity varies across online platforms and payment schemes. Online free events may attract higher rates of ticket reservation, as attendees face no financial loss in not attending. Some who booked tickets did not attend and, conversely, some wished to attend but were not able to as all tickets had ‘sold out’. Organisers may wish to oversell ticket capacity, but to what extent this should be done is debatable, as there may be a risk of reaching attendee capacity on your platform and leaving some disappointed, particularly if there are some more popular talks from high-profile speakers. Several organisations livestream events across platforms but this may not be suitable for all. Interaction between attendees was limited, as the ‘chat’ function was disabled (*Table 2*, theme 7) because neither organiser had enough time to monitor this while managing other tasks.

We propose that recordings and slides should be made available to attendees following an event, but permission from each speaker must be sought and sensitive information removed (*Table 2*, theme 8). It has been suggested that distributing recordings post-event may reduce live attendance, but the extent of this is unknown. The use of breakout rooms and opportunities they can provide are limitless: perhaps icebreaker games, debates or concurrent workshops,

which can allow for interactivity between attendees (but require a larger organisation committee to manage). Breakout rooms can target specific audiences, for example ‘psychiatry at medical school’ or ‘psychiatry within the foundation programme’ (*Table 2*, theme 9). Overall, we recommend targeting medical student and sixth form students separately to help meet the differing expectations and knowledge of these two groups while maintaining relevance, as shown by Wyke and colleagues.⁶

The length of the day and sessions should be considered: day 2 feedback suggests that sufficient activity-free breaks are welcomed and should be scheduled within the event programme (we had one additional break on the day 2 programme) to prevent ‘Zoom fatigue’ (*Table 2*, theme 10). Overall, attendance reduced throughout the day, but joining remotely provides attendees with flexibility to ‘dip in and out’ of the event, only attending for speakers they wish to hear.

The content: maintaining quality speakers and topics in a ‘saturated marketplace’

Diverse, passionate and knowledgeable speakers are essential to convey the ethos of Choose Psychiatry (*Table 3*, theme 11). Attendees noted and appreciated the importance of the presented topics, including lived experience (theme 14), topics less commonly addressed (such as Islamophobia, race and equality) (theme 12) and subspecialties neglected on many medical schools’ psychiatry curriculums (theme 13). Attendees highlighted appreciation for the two medical student presentations (by P.V and N.N.), which were described as ‘more relatable’ and ‘easier to digest’. Virtual conferences may offer junior colleagues significantly more opportunities to present, and raising the voices of doctors from a variety of clinical standings and locations is equally important. Interactivity throughout the course of the two days included several speakers opting to include audience polls, as well as taking questions from the audience both during and after their talks. In addition, there was patient simulation, where Dr Fernando had invited an actor to play the patient while a medical student took their history (theme 15). Varying the options for student interaction, utilising audience polling, question platforms, chat features and the previously discussed breakout rooms are reported to maximise student engagement online.⁷

Feedback further highlighted the importance of patients’ mental health problems for all healthcare workers, not just prospective psychiatrists (*Table 3*, theme 16). For any medical specialty, it is vital for medical students to consider the mental health of their patients: parity of esteem and valuing mental health equally with physical health were key takeaway messages from the NPSS.

The 2020 NPSS was for some their first experience of psychiatry and/or medical education as a whole, as noted by the unanticipated but welcome large sixth form presence (not seen at past National Student Psychiatry Conferences). Feedback demonstrated how virtual events compensated for lost work experience and provided support for applications to medical school (*Table 3*, theme 17). Further support included providing medical students (a proportion of whom had psychiatry rotations cancelled or reduced because of COVID-19) with an insight into the specialty. Furthermore, the NPSS provided earlier, accessible psychiatry education to medical students who otherwise experience psychiatry rotations later in undergraduate clinical years (theme 18). Virtual psychiatry events may therefore help to mitigate the concerns regarding reduced psychiatry teaching and in turn engender future interest and boost recruitment.⁸

Lastly, the NPSS helped some students to consider pursuing psychiatry as a career (*Table 3*, theme 19), a notion further strengthened by ‘before and after’ ratings (*Fig. 2*). Following the event, there was a clear demand for future similar events and maintaining accessibility. Advertising these opportunities (such as becoming an associate member of the RCPsych) during programme breaks might sustain engagement and long-term recruitment (theme 20).

Conclusions

COVID-19 created a need for online educational learning.² Our survey data showed that the 2020 National Psychiatry Summer School had a positive impact on attendees' perceptions of psychiatry as a career choice, and demonstrated how virtual medical education events can successfully engage large audiences while simultaneously reducing the historical geographical and financial barriers to beyond-curriculum teaching. The survey showed that the virtual format was positively received by our attendees.

The full potential of virtual events has yet to be fully realised, with a continuous evolution of, and learning from, innovative formats. Future work may further inform us of the benefits of virtual medical education events, and more formal qualitative and quantitative methods may be employed.

We believe there may be scope to run events that specifically target, engage and encourage sixth form students from all backgrounds; 'schools only' events offer a strong and fruitful possibility for psychiatry.⁶ Although these virtual events offer a myriad of opportunities, such as increasing access for medical students in the UK's devolved nations, it is important to recognise that they simultaneously reduce the networking opportunities. Post-COVID, the progress we have made with eco-friendly, online alternatives should not be lost, without compromising important aspects of face-to-face meetings that act as a 'social glue' in terms of networking.⁹ Events are most likely to encompass hybrid models and discussion remains on how these can be best utilised within psychiatry, medical education, recruitment and engagement. We must also recognise the risk of only certain groups being able to attend the in-person parts of hybrid events, with other groups 'excluded' from the social element of the events when attending virtually.

We thank Clare Wynn-Mackenzie, Royal College of Psychiatrists Careers Manager, for her support and advice, the Royal College of Psychiatrists for its support.

Abstract

The Royal College of Psychiatrists' Leadership and Management Fellow Scheme aims to develop and support a new cohort of leaders within psychiatry. This article provides an introduction to the scheme, which is accessible to all higher trainees with the support of their host organisation. We explore its development, structure and how it is evolving to provide a strong platform for achieving the College's ambition to benefit patient care by embedding a culture of medical leadership within mental health services.

pmc The Royal College of Psychiatrists' (RCPsych) Leadership and Management Fellow Scheme has been developed by the College's Psychiatric Trainees' Committee (PTC), the Leadership and Management Committee (LMC) and the Centre for Advanced Learning and Conferences (CALC).

It is designed to support the formation of a national network of emerging medical leaders within psychiatry. It builds on the General Medical Council's Generic Professional Capabilities framework¹ and, in accordance with the Faculty of Medical Leadership and Management's leadership and management standards for medical professionals,² it provides an enhanced understanding of medical leadership at an individual, team, organisational and systemic level.

The College has committed to 'provide high quality face-to-face training in leadership and management' that specifically meets the needs of 'psychiatrists making the transition to consultant grade'.³ This scheme, despite the necessity to adapt to an alternative delivery model as a result of the SARS-CoV-2 pandemic, fulfils that commitment. It realises the vision of both the LMC, 'to develop and support psychiatrists as leaders and managers',⁴ and of the PTC, to support trainees in having 'greater autonomy over their careers through in-programme developmental opportunities'.⁵

It is critical that future doctors develop leadership values and behaviours as core attributes, and learn about leadership,

followership and team working.⁶ For this to be successful, however, and for psychiatrists at every level to assume leadership responsibility, trainers and training organisations must ensure that leadership development is given parity with achieving clinical and academic competencies. It is only through this mechanism that we will truly achieve the notion of ‘expert leadership’⁷ within psychiatry.

This paper supplements Till *et al*⁸ which explores the importance of leadership, leadership development theory and opportunities available for psychiatric leadership development.⁸ We focus specifically on the development and structure of the RCPsych Leadership and Management Fellow Scheme as a mechanism to develop emerging medical leaders within psychiatry.

Evidence in practice

The evidence for leadership and leadership development in healthcare is clear.⁹ An engaged medical workforce with capable, high-quality leaders has consistently been demonstrated to be integral to driving improvements and supporting high-quality care.^{10,11}

Complementary to this, there is a growing call at a national level for services funded by the National Health Service (NHS) to strengthen their approach to leadership development and talent management,¹² with future doctors ‘developing an appreciation of leadership at an early stage’.⁶

Leadership development, however, does not suit a ‘one size fits all’ approach. There is little robust evidence for the effectiveness of specific leadership development schemes and difficulty in evaluating their effectiveness.⁹ As a result, multiple leadership development programmes have emerged at a national, regional and local level, with various approaches undertaken to meet the diverse needs of doctors, depending on their stage of training, specialty and location.⁸

Traditionally, leadership development programmes have focused on so-called ‘horizontal’ leadership development, where individuals attend courses run by external providers which focus at an individual level on ‘what leaders need to know’: developing their knowledge, skills and competencies.¹³

Individual interventions alone, however, are insufficient.¹⁴ Developing leadership crucially depends on context, and leadership development must take place in the context in which an individual works. Within healthcare, this should develop organisational allegiance and engagement in the quality and safety agenda of organisations, maintain a systems focus to meet the challenges of increasingly integrated health and social care services, and develop a strong network between tomorrow’s leaders.¹⁵ Furthermore, supported by a recent systemic review,¹⁶ mixed external and internal faculty is crucial, with project work and mentoring increasing the likelihood of good organisational outcomes.

The RCPsych Leadership and Management Fellow Scheme draws lessons from this knowledge, other schemes, and the latest educational leadership theory, to combine a national training programme with a local apprenticeship model, so that fellows not only experience ‘horizontal’ leadership development but are also exposed to ‘vertical’ leadership development.¹³

‘Vertical’ leadership development focuses on ‘how leaders think’, advancing interdependent styles of more complex, systemic and strategic thought.¹³ It relies on three primary conditions: ‘heat experiences’, ‘colliding perspectives’ and ‘elevated sense-making’.¹⁷ These are described further below, with illustrative quotations reflecting how fellows experienced these ways some of the scheme’s fellows have experienced these are reflected in their illustrative quotations below. Fellows consented to anonymised quotes from evaluation data being included in publications.

Heat experiences place fellows in challenging situations where there is a degree of risk. Fellows experience this both in the classroom and through the leadership projects undertaken in their place of work. This is the ‘what’ that disrupts and disorients their traditional thinking to discover new and better ways to make sense of the challenges they face as they assume increasing leadership responsibility: “‘The service development project consolidated our more abstract learning. It helped me get first-hand experience of the challenges faced being a leader, how I might need to develop and adapt my leadership style in different situations, and to become more self-aware and collaborative in my approach to leadership’.”

Colliding perspectives, on the other hand, are the ‘who’. Fellows are exposed to leaders both across the system and within their local organisations, including patient and carer leaders. When combined with the community of learning that they establish with their peers from around the country, fellows are enabled to gather different views and opinions,

challenge their existing mental models¹⁸ and see the world through diverse new perspectives: “‘I valued the opportunity to work with different trainees across the country, hear from eminent leaders about their leadership journeys, and meet individuals within the management hierarchy of the organisation. It allowed us to share experiences and learn from each other, to de-mystify senior leadership roles, and to connect and gain better understanding of those in managerial roles’.”

Elevated sense-making is the final piece, the ‘how’. In combination with their ‘consulting pairs’, where fellows are partnered to coach each other through the scheme, and senior mentoring locally, fellows are afforded the space to reflect and begin integrating their experiences and new perspectives, to advance their action logics¹⁹ and leadership effectiveness: “‘The opportunity to reflect and role-play was very useful and very powerful. It enabled me to see the consequences of my behaviour and how it might affect others. My experience of working with my organisation mentor was also very positive, she really helped me work through fervent leadership dilemmas’.”

Development

The RCPsych Leadership and Management Fellow Scheme was founded through a joint venture between the College’s Psychiatric Trainees Committee, the Leadership and Management Committee and the Specialist Advisor for Workforce. It was first proposed to the Education and Training Committee in February 2017, and although originally modelled on the Royal College of Physicians’ (London) Chief Registrar Scheme, it adopted an alternative model and evolved to embrace a more inclusive approach.

To achieve this, the scheme was modified to be potentially accessible to all higher trainees in psychiatry, including those in less than full time (LTFT) training, without any extension to the duration of their training. It occurred ‘in-programme’, across a 12-month period, averaging 1 day per week, utilising trainees’ protected special interest time. This minimised provider costs, with no requisite for funding fellows’ salaries or clinical backfill.

Medical directors from mental health providers across the UK were highly supportive of the scheme, and in the absence of central funding, were prepared to make a financial investment of £2000 per trainee, with full or partial self-funding (including via the trainee’s study budget) excluded to maximise equity of access and ensure organisational commitment.

With this early adoption, a competitive tendering process was pursued, with the RCPsych Centre for Advanced Learning and Conferences (CALC) being selected above highly competitive offers from multiple business schools and the Faculty of Medical Leadership and Management (FMLM) to deliver the national leadership development training programme.

Recruitment was delegated to host organisations and supported by training-programme directors, with statements required that fellows had been identified and nominated through an open and competitive process, as determined locally.

We welcomed the first cohort of RCPsych Leadership and Management Fellows in September 2019, with an initial intake of 30 fellows from 19 different service providers; over half were female (57%) and from Black and minority ethnic communities (63%).

Structure

The RCPsych Leadership and Management Fellow Scheme is designed to support the formation of a national network of emerging medical leaders within psychiatry and develop their confidence and ability to operate within and lead across a range of mental health organisations and systems to improve patient care.

It combines a bespoke, high-impact leadership development training programme with a local apprenticeship model, where fellows are mentored by senior medical leaders within their organisations and proactively engage in a variety of leadership projects.

National training programme

Building on the College's extensive experience in providing highly regarded leadership and management training, the evidence-based bespoke leadership development training programme is facilitated by the programme faculty, in conjunction with outside expertise where relevant. It is designed to enhance a range of practical knowledge and skills that consider leadership from the perspective of four behavioural domains relating to self, team, organisation and system, as outlined by the FMLM's Leadership and Management Standards for Medical Professionals.² A detailed up-to-date programme is available from the College on request.

Although originally designed for face-to-face learning, the implications of the SARS-CoV-2 pandemic were felt with our first cohort, and we took this as an opportunity to adopt an exciting new digitally focused approach, with the same content delivered virtually.

A central focus of the programme is to develop an underpinning community of learning, as fellows are afforded the space to reflect on their own leadership style, and conditions are established in which collaborative relationships can be optimised as they network with peers, share their experiences and learn collaboratively from best practice across the multiple organisations they represent.

Fellows are additionally uniquely exposed to inspirational national leaders from across the system, with guest speakers, including a number of prominent psychiatric leaders with national roles both within and outside the College, integrated throughout the programme.

Local mentoring and support

Fellows are supported and mentored throughout the scheme by a senior medical leader within their organisation, who commits to a minimum of six mentoring sessions throughout the 12-month duration of the scheme when nominating a fellow. This is a key aspect of the scheme and is essential to the success of the fellow's role.

The expectation is for the mentoring role to be held by the medical director or a nominated deputy of sufficient seniority and, where appropriate, individual project supervision may be delegated to a clinical director.

In conjunction with this, fellows should also have opportunities to shadow at an executive level and with key external health and local authority partners. This aims to generate a deeper understanding of healthcare leadership and management within the wider social, political and economic context.

Leadership projects

A fundamental component of the scheme is the development of fellows as apprentice leaders through their engagement in a variety of leadership projects within their local organisations.

The exact nature of leadership projects is negotiated and managed locally between the fellow and their mentor. Fellows can join existing larger projects or develop their own smaller projects, although it is stipulated that they should be guided to ensure that all projects are of strategic or operational significance to the organisation, ensuring that fellows make a meaningful contribution and organisations gain a return on their investment. Some examples of leadership projects are given in *Box 1*. **Box 1** Examples of leadership projects undertaken by RCPsych Leadership and Management Fellows 2019–2020 Trust-wide leadership and training in quality improvement Quality improvement projects related to high-dose antipsychotic prescribing, reducing restrictive practices under the Mental Health Act, and the co-production of service developments to amplify the patient voice and improve patient experience Trust-wide policy developments related to the management of dual diagnosis, COVID-19, video consultations, physical health management and electrocardiogram (ECG) monitoring Pathway developments related to naloxone prescribing in general hospitals, management of medically unexplained symptoms, attention-deficit hyperactivity disorder (ADHD) in child and adolescent mental health services, and clinical decision units within forensic services

Recognising that projects can evolve, emerge and falter for various reasons, not least a worldwide pandemic, successful completion of the RCPsych Leadership and Management Fellow Scheme is not conditional on the 'success' of a fellow's

project. There is an explicit recognition that learning can occur irrespective of this, and that a fellow's success is rather more meaningfully determined by their engagement with the programme, their reflective practice and their mentor's feedback, with their learning, growth and leadership development assessed throughout the scheme.

Benefits

Boxes 2 and 3 summarise two fellows' experiences of participating in the scheme, with *Box 4* outlining the intended benefits of the RCPsych Leadership and Management Fellow Scheme for individual fellows, the organisations in which they work, and for patient care. *Box 2* Vignette 1: a fellow's experience of the RCPsych Leadership and Management Fellow Scheme 'I feel this fellowship has provided me with the foundations to further acquire the knowledge and skills that are relevant in the context of leading a complex healthcare system. The opportunity to lead a trust-wide project with the support of my mentor allowed me to work collaboratively with multidisciplinary professionals across organisations and think about change management and sustainability in a very different way. Combined with the deeper insight into leadership theories I gained through the national training programme, and the reflective nature of the sessions, which I particularly enjoyed, I now feel more confident in leading service improvement projects and in engaging with diverse stakeholder groups. Furthermore, I found that being part of a national scheme, whilst being supported locally by a senior mentor, helped me build links and network with peers and senior leaders both locally and nationally. This was a unique feature of the scheme and I have no doubt it will help me in my future role as a consultant in the organisation.' *Box 3* Vignette 2: a fellow's experience of the RCPsych Leadership and Management Fellow Scheme 'One of the great advantages of the scheme was the direct support from a senior mentor to get "hands on" in a significant trust-wide project. Like many other trainees, I had previously been involved in small-scale projects, but had never been given responsibility for developing such a complex intervention across multiple community teams. Whilst simultaneously daunting and exciting, I found the direct support of my mentor invaluable in negotiating the complexity of the trust systems, while working collaboratively with a number of colleagues from different backgrounds, including project management, IT and senior managers, in addition to key clinical staff who would be delivering the intervention. Throughout the scheme my mentor was able to help me keep on track with the project and helped me to identify and keep in mind the vision of we wanted to achieve. I now feel much more able to lead change, effectively advocate for improved patient care, and am better prepared for the challenges of starting as a consultant.' *Box 4* Intended benefits of the RCPsych Leadership and Management Fellow Scheme

Benefits for patients and the organisation High-quality care: increase the number of highly skilled medical leaders able to develop and foster collaborative practice and high-quality care Improved services: bring an enthusiastic and fresh perspective with committed time to help improve the safety and quality of your services and help create a culture of continuous improvement Enhanced medical engagement: fellows hold mutually enhancing conversations with trainees, senior leaders and management to boost the performance of the organisation Emerging medical leaders: invest in your local talent and nurture the next cohort of medical leaders within your organisation

Benefits for the individual Heightened self-awareness: gain a deeper understanding of which aspects of yourself enable or constrain your leadership Discover your inner leader: begin or continue the process of discovering and releasing your leadership potential Mentoring, networking and support: learn from senior medical leaders and develop an inspiring network of like-minded peers, including from within the RCPsych Leadership and Management Fellow Scheme Alumni Network, which fellows will be invited to join on completion of the scheme Leadership and management skills: develop your understanding and a widening repertoire of leadership competencies and skills that will help you be a better medical leader and apply for associate fellowship of the Faculty of Medical Leadership and Management Followership skills: gain a greater understanding of the role that followers play in the co-construction of leadership identities Career autonomy: take control of your career and increase your confidence in extending your portfolio and building a local and national profile

Evolution

The RCPsych Leadership and Management Fellow Scheme is an evolutionary process and key to its future development will be feedback from both fellows and mentors, the needs of our healthcare system and the sociocultural needs of the wider society we lead within.

Although the College has a well-established reputation for delivering leadership and management training, this is the first developmental scheme for trainees. It emerged organically, being co-produced by those for whom it was intended. The scheme will continue to be developed on this basis in order to further adapt and respond to the specific needs of higher trainees in psychiatry, provide value to the sponsoring organisations and achieve FMLM accreditation.

We are proud of our first cohort in 2019–2020, who despite the SARS-CoV-2 pandemic all successfully completed the scheme. We are also pleased to have been able to adapt to an exciting new digitally focused approach for 2020–2021, allowing for more regular contact that will be supported by a new online platform to promote networking, shared learning and reflection.

We acknowledge the challenges that the loss of face-to-face learning involves, particularly regarding the development of close and trusting relationships, but believe that a digital approach will be critical for the future. It not only ensures that mental health services are capable of weathering the current storm, but also that leadership capabilities within the psychiatric workforce are still developed and able to rise to future challenges as we deal with the mental health implications of the SARS-CoV-2 pandemic alongside the implementation of the NHS Long Term Plan.²⁰

Reassuringly, however, although we and many others look forward to the return of face-to-face learning, research from the Centre for Creative Leadership²¹ has highlighted similar levels of results for online leadership training, while providing the additional benefits of increased convenience and accessibility.

Combined with increasing confidence and familiarity with digital engagement, we will therefore integrate these opportunities as face-to-face learning returns and embrace a more blended approach. We hope that this increased flexibility will widen access to the scheme for Category 1 less than full time (LTFT) trainees (i.e. those with health reasons or caring responsibilities) and for those living at a greater geographical distance from the College, by reducing face-to-face learning.

Providing additional value, current alumni have been invited to facilitate action learning sets, and to join the programme faculty for future cohorts. They have also established an RCPsych Leadership and Management Fellow Scheme Alumni Network. This will be integrated with the RCPsych Leadership and Management Committee and future cohorts of the RCPsych Leadership and Management Fellow Scheme. It aims to maintain links between fellows as they become future leaders within mental healthcare across the UK, nurture the next generation through near-peer mentoring, promote collaboration across the system, develop shared learning and good practice, and strengthen the connection between mental health services and the College.

The success of this scheme highlights the appetite for strong medical leadership among progressive healthcare organisations throughout the UK, who recognise the importance of advanced leadership development schemes for aspiring organisational and system leaders.

The scheme has also unearthed a wider unmet need for leadership development among specialty doctors, new consultants and other groups; they of course have their own unique challenges that deserve appropriate recognition. Appreciating this, the scheme is diversifying and strengthening its leadership faculty in order to improve its offer, strengthen its resilience and develop greater resources from which to further develop the leadership and management skills of the wider membership.

Conclusions

Leadership and management is for all doctors, for all psychiatrists at every level. It is not just for those with formal roles within organisational hierarchies who hold designated leadership positions. Nor is it about stand-alone heroic individuals: it collectively lives among us as a professional body and we must learn to nurture, support and value one another.

The RCPsych Leadership and Management Fellow Scheme is just one step towards developing leaders in psychiatry. Through the combination of a national training programme with a local apprenticeship model, both formal and informal leadership development is provided, where emerging leaders have a safe space to take risks, experiment and develop ‘on the job’.

It is important to recognise, however, that leadership development does not suit a ‘one size fits all’ approach. Whether through this scheme or another, we each have a responsibility to collectively develop and establish a culture that nurtures leadership talent and ultimately improves the lives of people with mental illness.

We thank Dr Aideen O’Halloran for her initial support of the scheme, alongside Dr Kate Lovett, Dr Ian Hall, Dr Wendy Burn, Ms Karla Pryce and Ms Michelle Braithwaite for helping us reach where we are today. We also thank our inaugural cohort of fellows and mentors for taking a risk and supporting our initial pilot, along with our guest speakers, who have offered their valuable time to nurture the next generation of psychiatric leaders.

Alex Till, MBChB, MRCPsych, MSc, MBA, is a specialty registrar in forensic psychiatry with Health Education England (North West), UK, and was Chair of the Royal College of Psychiatrists’ Psychiatric Trainees Committee in 2018–2019. **Deepa Bagepalli Krishnan**, MBBS, MRCPsych, PGDip, Dip IBLM/BSLM, is a Clinical Assistant Professor in the Faculty of Medicine and Health Sciences, University of Nottingham, UK, and a speciality registrar in general adult psychiatry with Health Education England (East Midlands); she was an RCPsych Leadership and Management Fellow in 2019–2020. **Russell Gibson**, BSc(Hons), MBBCh, MRCPsych, MSc, is a specialty registrar in general adult and old age psychiatry with Health Education England (Peninsula), UK, and was an RCPsych Leadership and Management Fellow in 2019–2020. **Michael Hobkirk**, FRCPSych, MSc, MMedEd, FHEA, is a consultant child psychiatrist and Director of Medical Education with Sussex Partnership NHS Foundation Trust, and former College Lead for Training, Royal College of Psychiatrists, UK. **David Somerfield**, FRCPSych, is Medical Director and a consultant psychiatrist with Devon Partnership NHS Trust, UK. **Helen Crimlisk**, FRCPSych, MSc (Ashridge), FAcadMED, is Deputy Medical Director of Sheffield Health and Social Care NHS Foundation Trust and an Associate Registrar for Leadership and Management, Royal College of Psychiatrists, UK.

Data availability

The data that support the findings of this study are available from the corresponding author, A.T., upon reasonable request.

All authors met the four ICMJE criteria for authorship, being equally involved in the design, drafting and revision of the article.

This research received no specific grant from any funding agency, commercial or not-for-profit sectors.

Declaration of interest

A.T. founded the RCPsych Leadership and Management Fellow Scheme in collaboration with M.H. and D.S., with H.C. assuming oversight following her appointment as Associate Registrar for Leadership and Management. D.B.K. and R.G. were inaugural RCPsych Leadership and Management Fellows in 2019–2020.

1.1.48 Response to Beale

A. 26. FRCPsych

B. 26. FRCPsych

date

2022-06

Contents

- *Response to Beale*
 - *Declaration of interest*

pmc We write to add our personal experience of 30 years of consultant psychiatric practice and of having a son with a long history of serious psychiatric problems to endorse Chloe Beale's powerful indictment of current mental health service failures. Having found our son in his room 2 weeks ago attempting to hang himself, we called 999. The ambulance arrived within a few minutes; he sat for 9 hours in the ambulance outside A&E before being seen by a series of three mental health nurses with questionnaires and was then summarily sent to walk home, still actively suicidal, past a famous 'suicide spot'. We were not informed that he had been discharged. We had rung to ask what was happening and were summarily dismissed by one of the nurses with the cryptic comment that he had been 'signposted to the Road' (apparently a counselling charity). This actually meant he was given some leaflets. Thankfully he had enough wish to live to ring us after a cold walk and we provided such support as we are able, as we have for several years.

He had therefore been put through exactly the process of checklist assessment, meaningless non-intervention of 'weasel words', legalised neglect, and dangerous and unfair self-guarantee of safety that is described by Beale. This useless approach has therefore, of course, made both him and us feel there is no point in contacting the service again, nor of suggesting anyone else do so.

As doctors and psychiatrists, it has always been our training and teaching that the person/patient was our prime concern, but this is clearly no longer the case. Protection of the system from the rightful needs of patients is the current priority in psychiatric services. The amount of energy and time put into that process now is almost unbelievable and extremely damaging, not only to patients and their families. It is an example of the stigmatisation and dismissal of psychiatric problems, even by staff working in the specialism, that is returning psychiatry to the hopeless laughing stock that it had been before the last war and which we and our teachers and colleagues had done so much to try to turn into a valued and respected medical specialism. Only the sort of fundamental re-humanisation and recovery of professional standards of treatment set out by Beale in her last paragraphs can return psychiatry to self-respect and our patients to proper care.

Beale's paper should be required, albeit uncomfortable reading for all involved in psychiatric care ('mental health' are two more weasel words which demean psychiatric illness). Let us hope that Beale's call to arms is heeded for the sake of our patients.

1.1.49 Evensong: how the medical humanities can strengthen a patient-centred approach to both physical and mental health conditions

Corinne Rowena Dignan

Correspondence

Dr Corinne Dignan

(corinne.dignan@wales.nhs.uk)

date

2022-06

Abstract

The medical humanities may offer an antidote to the unconscious depersonalisation of patients into clinical variables and diagnoses at the hands of physicians, cultivating a patient-centred and individual approach to the management of both physical and mental health conditions. The emphasis on the person behind the diagnosis helps physicians to remain motivated and compassionate in the face of increasing social and organisational pressures that threaten this human connection. As a doctor and the relative of a patient with dementia, I reflect on the way in which poetry has helped to translate my experience as a relative into improving my own practice as a doctor. This article includes one of the poems I wrote during my grandmother's illness to aid reflection on the patient perspective I gained during her time in hospital, and also a brief commentary exploring the influence this process has had on the interactions I now have with my patients.

pmc We all have our stories. Our triumphs and our failures, the people we love, the landscapes we create and the goals we pursue; all those days, from the greatest moment to the most mundane, come together to form the fabric of a life.

Presenting complaint

One of the great privileges of a physician is that our patients share their stories with us, and our eyes witness the momentous: the first cry of new life, the last sigh as old age departs it, and countless tears, smiles and occasional bursts of anger that our involvement in these stories inevitably brings. During my time as a doctor, however, I have noticed that by assigning the role of patient to these individuals within our own narrative, we often, however unconsciously, deprive them of their individual story. They become lists of vital signs, blood results and diagnostic difficulties, the faces of medical conditions that leap out of textbooks into the hospital beds in front of us, embodying the frailty and mortality that is truly such a small part of who they really are.

Past medical history

I first became sensitised to this when my grandmother's memory faded with vascular dementia, which followed the stroke she suffered while I was at medical school. Her story was lost to the doctors caring for her on the ward, and the impression that they formed of the truculent and demented old woman who obstinately refused her medication was infinitely removed from the independent, active and astute lady of just a few weeks earlier, the one with a roguish twinkle in her eye who loved to sing, laughed often and always cheated at playing cards. This was compounded by the resistance that we, as her relatives, experienced when attempting to engage with the doctors in our new role as proponents of her story, finding that our attempts at advocacy were rejected as an irrelevant distraction from her medical care.

The condensation of a rich and complex individual into the black and white of a clinical diagnosis does our patients a disservice, but it is a phenomenon that many doctors report in their professional practice. For my grandmother it contributed to delays in her diagnosis, a lack of appropriate stroke rehabilitation, a void of professional support and an inexorable decline into depression, incontinence and pressure ulcers. The strain of increasing service demands without a correlating increase in resources and support stands as an obvious culprit, but the influence of compassion fatigue and the unconscious desire to protect our own sanity and emotions when treatments fail and operations do not go to plan cannot be ignored.

Investigations and management

Reflecting as both a physician and a relative, I realised that I too frequently overlooked the person behind the confused and wandering patients on my ward; I was also too ready to make assumptions about the quality of life of octogenarians, and I recognised the previously unacknowledged dread of the demands of relatives during visiting time while my pager chimed and my list of daily tasks multiplied before my eyes.

To lend some perspective, I started to organise my thoughts and reflections on paper, and soon found that verse provided a structure and rhythm that helped me to understand how I could progress in my own practice and, in my own small way, help families in similar circumstances to my own. The process of writing helped me realise the unique opportunity we have as physicians to gain such an insight into another person's life, and the responsibility of ensuring that we allow patients and their loved ones to tell us a little about the most important things in their lives. Once we understand where a patient has come from, we are in a better position to help them navigate the difficulties they encounter whilst in our care and to ensure that their story can continue in a way that is most congruent with their values. Support from other members of the multidisciplinary team is crucial in providing this holistic care, and the engagement of therapists in rehabilitation, psychologists in support or the chaplain in blessing should not be underestimated.

I wrote this particular poem to give voice to a part of my grandmother's story, highlighting the beautiful things that I remember about her and that I hoped would provide an insight into the person she was and the things that she loved before her illness. To me the process of writing this poem served as a reminder to give all my patients the chance to tell their story, to see past the observation charts and appreciate what truly makes up their lives. Only then can we hope to treat our patients with the compassion and understanding that we hope our own loved ones will experience at the hands of medical professionals; by ensuring that this process starts first with us.**Evensong**I remember the ardent goldfinches:a charm in your camellias,cheeks sanguine as the Eucharist.A joyful celestial choir exuding praise and glory for long sweet days of Litha.All Gods and old Gods exalted in unison.I remember the last slivers of sunlighting shrinking vestiges of the rapeseed harvest.We waded together along faded paths which led to the field where horses rose as

monoliths in the fading gloom. I remember the smell of hot sweet apples; the spoon crushing vaulted pastry roof, sinking to the bubbling nave. Skin still scored and prickling from circlets of thorns, the jealous brambles constraining their inky treasures. You laughed at their bite and spleen. I remember the hoary birch branches, prising the silvery vellum from the resisting trunk. Dancing and unravelling, widdershins around the bole; sinuous snakes entwining our ankles, threatening to topple, threatening to fall. I remember because now you cannot. A ghost mind astray, reneging on its past. Though your smile tells me that something flickers far back in your mind: a fading spark, in the darkness.

2022-06

Abstract

Globally, there has been an emphasis on the importance and value of involving people with lived experience of mental health conditions in service delivery, development and leadership. Such individuals have taken on various roles, from peer support specialists and other specialised professions to leadership in mainstream industries. There are, however, still obstacles to overcome before it is possible to fully include people with lived experience at all levels in the mental health and related sectors. This article discusses the benefits, both to the individual and to the public, of involving persons with lived experience in service delivery, development and leadership.

pmc The World Health Organization (WHO) describes advocacy as ‘an important means of raising awareness on mental health issues and ensuring that mental health is on the national agenda of governments. Advocacy can lead to improvements in policy, legislation and service development’.¹ By this definition, people with lived experience of mental health conditions (hereafter referred to as ‘persons with lived experience’) have increasingly become the driving force behind advocacy and awareness work globally, and have entered the mental health workforce in various capacities of service delivery, from peer-to-peer support work to professional occupations in the field of mental health and human rights.

The all-encompassing objective of lived experience involvement is development and leadership and to create communities in which people with lived experience are able not only to survive but rather thrive with a mental health condition.

Obstacles for lived experience involvement in service delivery, development and leadership

Despite the growing acknowledgement of the value of lived experience, there are still a number of obstacles to overcome before it is possible to fully include people with lived experience at all levels. We are embedded in frameworks of shared values and beliefs – social, cultural and environmental factors that directly and indirectly influence psychopathology.² Our experiences throughout our life journeys largely determine the nature of our perceptions and our attitudes towards notions. Although there is undoubtedly a complex connection between culture and mental illness, negative perceptions and insensitivity result in stigma, discrimination and violations of human rights. The language used to talk about mental health also creates barriers because the way in which we understand, and subsequently express, experiences can be easily misinterpreted and consequently negative assumptions are made about others. It is therefore imperative to obtain clarity in the distinction between terms such as ‘mental health’ and ‘mental illness’.³ People continue to believe that individuals with mental health conditions are violent, mad, lazy, possessed by demons⁴ and incapable of positively contributing to society and the economy. Negative stereotypes and inaccurate portrayals such as these affect help-seeking behaviour and result in an unwillingness of those suffering to seek support from loved ones. People ought to be cognisant that when they perpetrate and share negative stereotypes, it has an impact on the entire recovery process and it affects not only those who struggle with mental illness but also those working in the mental health field. The fact is that negative perceptions lead to prejudice at home, in the workplace, within local communities and within our healthcare systems.³

Apart from these attitudinal barriers, social determinants of mental illness,⁵ including poor education, unemployment and poverty, further hinder opportunities for people with lived experience to develop leadership potential, pursue their passion for mental health work and follow a career in mental health advocacy and service delivery. Specifically, poor education along with a lack of access to adequate information are contributing factors that result in low mental health

and human rights literacy among the more disadvantaged people with lived experience who are subjected to social and economic inequalities.⁵

Lived experience in development and leadership

Lived experience advocates who have pursued a passion to improve mental healthcare and services have been using their own experiences and recovery journeys as a means to highlight the gaps, not only within the mental healthcare system but also within other societal systems outside of the healthcare sector. Lived experience advocates have, of course, also challenged the status quo and taken a stand on a human rights perspective as the foundation of change, transformation and systems strengthening. Building on this, there is growing recognition of the value of persons with lived experience as agents of change through contributing their unique expertise, in-depth knowledge of navigating systems, first-hand experience of segregation and discrimination, and their ability to provide high-level and practical solutions. This recognition places persons with lived experience as experts by experience and leaders of development and change, through their influence on policy and practice.

At a global level, there is evidence that mental health guidelines, strategies and policies have notably become more consistent in including lived experience perspectives and recognising those experiences as integral to service development, implementation, monitoring and evaluation. Engagement with persons with lived experience is critical to identify the flaws in the system – what others may perceive as a complex breakdown in the system may often be repaired with simple, practical, cost-effective and innovative solutions proposed by the users of that particular system or service.

The Global Mental Health Peer Network (GMHPN), an international lived experience organisation, was established to enhance the voices of persons with lived experience across the world and has a specific focus on leadership development. That focus derived from the recognition of the obstacles (described above) that ultimately deny countries the expertise and value that people with lived experience are able to contribute to improving the accessibility and quality of mental healthcare and services at the local level. The GMHPN's executive structure is designed to develop new global lived experience leadership and create a sophisticated platform for diverse lived experience voices to be at the forefront of change. Empowerment as a critical element in leadership development is built into the GMHPN structure. Lived experience leaders are appointed to the GMHPN Executive Committee as representatives of their respective country or region, and ultimately serve in an advisory capacity, contribute to the development of strategies to achieve common advocacy goals and ultimately influence policy and practice.

The benefits of people with lived experience in leadership positions is evident from the following statements (all statements in this article appear with the permission of those named). “‘Since I have been appointed as the Deputy Representative for the African Region on the GMHPN Regional Executive Committee, it has given me the courage to think big. It has made me a person with a mission, to bring some meaningful changes on how people perceive mental health, not only in my country Zimbabwe but in Africa. This has given me a chance to dream big about how people with psychosocial disabilities throughout the world should live – with dignity and stigma-free.’ (Angelica Mkorongo, Zimbabwe) ‘Learning from shared experiences from other GMHPN members has largely widened my horizon to see what can be achieved through lived experience advocacy. Gatherings of such courageous individuals with high calibre from diverse geographical and cultural settings for the common cause of lived experience advocacy is really eye-opening. This has greatly impacted my understanding of mental health being a global issue. I can definitely certify that my engagement as Country Executive Committee representative for Ethiopia is the greatest empowering, uplifting, and inspiring experience I ever had in my journey as global mental health advocate and as a person with lived experience.’ (Eleni Misganaw, Ethiopia) ‘My position as regional representative for Africa on the GMHPN Regional Executive Committee means a lot for me as a person, and for persons living with mental health conditions in my country. It is validating of our experiences and an opportunity for me to join other global voices to make mental health matter. It is also a wonderful global opportunity to de-stigmatize mental illness and advocate for better inclusion policies with regard to persons with lived experiences, especially in a region like mine where mental illness is generally considered taboo, due to witchcraft or spiritual attacks.’ (Marie Abanga, Cameroon) ‘My role in the GMHPN on the Regional Executive Committee enables me to empower individuals with lived experiences, bring forth issues such as local laws and civil society support, and bring together the larger issues of universal rights concerning mental health, such as basic income and housing, employment rights and peer and ally support networks. This position allows me to gain insight and mobilize resources to address challenges unique to the cultural understanding of mental health in South East Asia, allowing a culturally relevant solution-focussed approach.’ (Anjali Singla, India) ‘My role on the GMHPN Regional

Executive Committee is a vitalizing booster to what sometimes feel like a rocky up-cliff journey, and an active propeller to encourage lived experiences to be part of the strategy in building mentally healthy workplaces. It is crucial to share best practices within and across regions so we do it together, and in a way that respects local cultures and thoughts.’ (Enoch Li, China)”

Lived experience in service delivery

Persons with lived experience have not only been users of services but many have become service providers themselves – something that would never have been imagined just a few decades ago. However, in our experience, even today it is still unimaginable in some countries that someone with a mental health condition can in fact be meaningfully employed, let alone employed within the mental healthcare workforce.

Several GMHPN Executive Committee members (with lived experience) from across the world are service providers in various capacities – some of these members kindly provided insights into their work and shared the benefits of being a person with lived experience who is providing a mental healthcare service.

Virtual support group facilitator: Sandra Ferreira (South Africa)

“I facilitate online mental health support groups during the COVID-19 pandemic. The virtual platform has provided participants from across the world the opportunity to voice their experiences during the pandemic and discuss the impact on their mental health. One of the most interesting observations that I have drawn from this experience was that many of the participants were actively involved in advocacy and awareness work in their respective countries. This is not uncommon as our struggles often lead to the need to better the road for those that may follow, aligned with a need to be relevant, to be valued and to make a difference. Essentially, giving us a purpose. In its purest form, this virtual support group has been a space to “unmask”, to breathe easy, and to be free – not only during current struggles of dealing with the pandemic and the restrictions it has imposed on our daily lives but also to just be yourself without judgment. The greatest benefit from providing a support service is the validation that through helping others, we are helping ourselves become better human beings, more knowledgeable advocates, and most importantly, more empathetic supporters of humankind.”

Founder of an online peer support platform (CARA Unmask): Bernard Ang (Singapore)

“Reflecting back on my journey with depression, I wish I could have opened up about my mental health issues to someone who listened and understood. My experiences led to me founding CARA Unmask (caraunmask.com), an online peer support platform that encourages people to reach out earlier rather than later, to have a chat about their mental health. We recognize the direct benefits that come from wanting to share valuable lived experiences, which creates purpose, cultivates a sense of gratitude, facilitates personal growth and simply paying it forward. Peer support is evidence-based and proven to work effectively, side-by-side with clinical support for a sustainable long-term recovery outcome.”

Peer support specialist: Syd Gravel (Canada)

“It was worrisome at first – that first peer meeting. Knowing how complex and confusing things had been for me being mentally injured by a traumatic incident at work. Now, the psychologist was asking me if I would be willing to meet others who were also injured in similar situations. The goal was to see how we could help each other by sharing our experiences so that we would realize that we were not alone. I was not even sure I knew how to help myself let alone someone else. I wondered how this conversation could even start – how was this meeting going to help me? How could sharing my situation help someone else? That was 32 years ago and since that evening of our first peer support meeting, I have never looked back, as we created a bond that never waned. We are in touch with each other, to this day. I am now a full-time consultant on trauma management and peer support development for First Responder agencies and author to several books on the subject. Amazing isn’t it, how when life throw us lemons, we can learn to make lemonade.”

Social worker: Thandiwe Mkandawire (Zimbabwe)

“During my training as a clinical social worker, my therapist once said to me “We all become therapists because we all have psychological pain we are trying to heal, to find our true selves and in doing this work, not only do we help others, we also help ourselves”. The healing of the mind, as is any form of healing, is painful and difficult as it takes honesty, vulnerability, courage and bravery to face your emotions and engage in the necessary war of fighting the rhetoric in your mind. Working in the field of mental health and listening to service users and carers share their stories and their truths in support groups, at awareness campaigns or clinic days at the hospitals, fighting through self-stigma and societal stigma and discrimination, allowed me to realize that experiences are as unique as the person, a person’s truth cannot be classified as greater or lesser than the next person’s. My experience is my truth and it needs to be shared’.”

Advanced lived experience practitioner: Mark Sanderson (UK)

“I have worked in mental health services since 2016. I started as a volunteer on an inpatient ward, where I had been a previous inpatient. After 6 months of volunteering, I was employed into a paid peer support role. Within my first year I won a runner up prize for innovation, which boosted my confidence. I continued to grow in the role and was constantly given opportunities to contribute to service development and presented at various conferences and training sessions. I am currently pursuing a Master’s degree in Mental Health Recovery and Social Inclusion. I continued to advance in my career and obtained a non-peer position, which involved supporting the discharge process of service users from the ward into the community. Alongside this role I worked with the senior management team to develop a senior peer support position within the inpatient setting and simultaneously was working with another manager to develop a senior peer support position for the community. In around four and a half years I have worked my way from a volunteer to an Advanced Lived Experience Practitioner and have found my studies to play an essential role in my development. Moving forward I aim to continue developing in lived experience roles within the NHS.”

Psychiatrist: Raluca Mirela (Romania)

“Working in child and adolescent psychiatry as a person with lived experience and as a former victim of psychological and physical child abuse was often more of an emotional curse than a benefit, because I deeply empathise with the children for whom I felt responsible. My frustrations resulted from working with families that were not used to a bio-psychosocial approach – and they often asked me why I am talking so much about their child, because they just wanted the medical certificate (in order to apply for disability aid). They were not familiar with taking children to other specialists like neurologists, paediatricians, or to psychotherapy, and mostly refused to do so by justifying that they do not have money or time (even if they receive a paid medical leave to take their children to the doctor). Despite the emotional burden, working with compliant families and seeing the improvement in their child’s health (mentally and emotionally) gives me enormous joy and a motivational boost.”

Discussion

Global recognition of the importance of the role of persons with lived experience in mental healthcare has gained momentum, with academics, clinicians, researchers and mental health organisations placing emphasis on improving the status quo through peer support systems and improved service delivery.

Caution, however, must be exercised in our approach and we must take into account the implications of the diverse experiences of individuals in their mental health recovery processes and recognise that ‘many people with lived experience lack the confidence or ability to articulate their views, particularly if they contradict the status quo and especially when speaking to people who hold similar roles to those who have taken choices away from us’.⁶

Nevertheless, there is no denying that there is potential for leadership development of persons with lived experience in mainstream industries. Mental healthcare organisations ought to take the lead in driving initiatives by wisely employing the insights of persons with lived experience. Strategies for peer support-based service delivery is encouraged because having the support of a peer who has been exposed to similar experiences has a way of allowing for meaningful

conversation in a safe environment. The conventional hierarchy of clinician and client or patient does not apply in peer support systems, as the focus is placed on peer relationships and the development of trust among peers. The challenge, however, lies in ensuring that the discipline of lived experience in mental healthcare does not become too codified or regulated, as it will lose its real purpose and lose what is the most important reason for someone's existence.⁷

It is likely that people who enter the field of mental healthcare do so because of their desire to help others and often also because of their personal experience of mental health conditions. In principle, having lived experience and having knowledge of service delivery and its corresponding processes provides them with an 'advantage' of being in a better position to step into another's shoes and be truly empathetic to their clients' or patients' needs and vulnerabilities. In most cases people choose to become therapists to make a difference in someone else's life, to be appreciated for making a difference in society and to help others who have struggled with similar painful experiences as they did.⁸

Given the above, by empowering persons with lived experience by means of education and by developing and maintaining leadership roles there will undoubtedly be a positive move towards improvement in mental health recovery. Therefore, stakeholders are encouraged to further explore the value of peer support as well as the personal experiences of clinicians for improved mental health recovery and improved quality of service delivery. Lastly, all stakeholders must ensure that they take into consideration the inputs and recommendations of persons with meaningful and authentic lived experience and implement them in their strategies and policies.

1.1.51 Adverse childhood experiences and adult self-harm in a female forensic population

Rachel Holden Imogen Stables Penelope Brown Maria Fotiadou

Correspondence

Dr Rachel Holden

(rachel.holden@kcl.ac.uk)¹

date

2022-06

Abstract

¹ Joint first authors.

Aims and method

This study aimed to investigate the prevalence of adverse childhood experiences (ACEs) among patients in a female forensic psychiatric in-patient medium-secure unit, and to analyse the link between ACEs, adulthood self-harm and associated comorbidities and risk factors. The study used a cross-sectional design, with data gathered from the anonymised electronic health records of patients.

Results

It was found that there was a high prevalence of both ACEs and self-harm among this patient group, and that there was a relationship between the two; those with more ACEs were more likely to have self-harmed during adulthood. Of the individual ACE categories, it was also demonstrated that emotional abuse had a significant association with adulthood self-harm.

Clinical implications

In medium-secure settings for women, implementation of trauma-informed care will be beneficial because of the high number of those with mental disorders who have experienced adversity during their childhood.

pmc Adverse childhood experiences (ACEs) are stressful or traumatic life events that occur before 18 years of age.^{1,2} Having a history of ACEs is not uncommon: in a national household survey of adults residing in England, 47% of participants reported at least one ACE.³ Research on ACEs has demonstrated links between ACEs and self-harm.⁴ In a female prison population, all types of childhood abuse and neglect were more prevalent in those who self-harmed compared with those who did not, with significant associations between adulthood self-harm and both childhood emotional and sexual abuse.⁵ ACEs have a cumulative effect on health outcomes, with higher numbers of ACEs predicting more adverse health outcomes.⁶

This study occurred on Spring Ward, the female ward of River House Medium Secure Unit (MSU) in South London and Maudsley NHS Foundation Trust. Since opening in April 2008, the ward has offered a multidisciplinary biopsychosocial approach to support women toward recovery and reintegration into the community.⁷ In 2017, following the success of implementing the Healing Trauma programme (a gender-specific intervention for trauma victims),⁸ a trauma-informed care approach was introduced. Implementation involved team consultation, presentation and a training session on Stephanie Covington's Becoming Trauma-Informed Programme.⁹

This study was conducted as part of a service evaluation to determine the prevalence of ACEs in a female MSU cohort and to explore the relationship between ACEs and adulthood self-harm. Links between ACEs and adulthood self-harming behaviours, violence and comorbidities (such as personality disorder) will be explored, which will enable us to better understand the present and future needs of patients.

Aims

Our first aim was to establish the prevalence of ACEs in patients in a female MSU, using a structured ACE questionnaire. Second, we aimed to establish the prevalence of adulthood self-harm, personality disorder, alcohol and drug misuse, and history of violence among female in-patients in the MSU. And finally, we aimed to explore the relationship between ACEs and adulthood self-harm.

Method

Design and procedure

The main study utilised a cross-sectional design, using medical records. The researchers conducted a thorough review of each patient's electronic medical records. Using previously recorded information, the amount of ACEs were calculated by the researcher, based upon the trauma history recorded in the patients records.

Participants

All patients who were admitted to or were receiving continuing treatment on the ward between April 2008 and July 2019 were considered eligible for participation in this study. Criteria for admission to the ward include being over 18 years of age, committing an offence or having a significant history of violence. All patients are sectioned under the Mental Health Act 1983 (MHA) throughout their admission. The ward can accommodate 15 patients. Because of the relapsing and remitting nature of the mental disorders of many patients, several patients had multiple admissions during the study period; for these patients, data was gathered from medical records documented during their most recent admission.

Initially, 68 participants were included in the sample. Two participants were excluded from the analysis because of insufficient information in their medical records regarding their childhood, taking the final sample to 66 participants. Demographic and clinical information included age on admission, ethnicity, primary diagnosis, MHA section, personality disorder, alcohol and drug misuse, and violence history. Ethnicity was recorded into subsections: White British, Black British, Black African, Black Caribbean, Asian and other. Primary diagnosis was recorded into three categories, according to the ICD-10: schizophrenia spectrum disorders (codes F20–F29), mood [affective] disorders (codes F30–F39) and personality disorders (codes F60–F69).¹⁰ MHA sections of all patients were recorded into categories: forensic (section 37, sections 37 and 41, sections 47 and 49, and sections 48 and 49) and civil (section 3).¹¹

Data collection and analysis

Exposure to adverse experiences up to 18 years of age was assessed for each participant, following a thorough review of their medical notes; ACE history was summarised by a ten-item version of the Adverse Childhood Experiences Questionnaire.¹² The ACE questionnaire consists of ten binary (yes/no) questions that assess exposure to emotional, physical and sexual abuse; emotional and physical neglect; and household dysfunction, including domestic violence, substance use and incarceration. Participants' self-harm history since 18 years of age was obtained via medical records, along with comorbid personality disorder, alcohol and drug misuse, and history of violence. Self-harm was coded as a binary variable, with the presence of self-harm being recorded if there was any mention of self-harm or suicide attempt in adulthood mentioned in the medical records. ACEs were extracted from records of patients' trauma history recorded in psychological and psychiatric reports contained in their medical records. Personality disorder presence was defined as a previous diagnosis of any type of personality disorder. Alcohol and drug misuse were defined as any positive history of problematic use of alcohol or drugs. History of violence was defined as any violence history before the event leading to admission. Each of these variables were recorded as dichotomous (yes/no) variables.

Data was analysed with the Statistical Package for Social Sciences (IBM SPSS, version 25 for Mac).

Ethical approval

Ethical approval was granted by the Research, Outcomes and Service Evaluation Committee, a branch of the Behavioural and Developmental Psychiatry Clinical Academic Group of South London and Maudsley NHS Foundation Trust. The ethical approval included the use of anonymised medical records. This was a service development project using historic clinical records and as such the study was exempt from a need to provide informed consent.

Results

Patients were aged between 18 and 72 years at admission (*Table 1*). The sample was primarily Black and minority ethnic, and most patients had a primary diagnosis of schizophrenia, schizotypal and delusional disorders (ICD-10 codes F20–F29).¹⁰ The majority of the sample had a history of drug misuse. Over a third of the sample had a history of alcohol misuse, and over a quarter had a comorbid personality disorder diagnosis. *Table 1* Demographic and clinical characteristics of the patient sample

Characteristic	Cases (N = 66)	n (%)
Age at admission (years), mean (s.d.)	38.40	(±11.37)
Age categories (years)		
<25	10	(15.2)
25–34	13	(19.7)
35–44	26	(39.3)
45–54	12	(18.2)
55	5	(7.6)
Ethnicity, n (%)		
White British	20	(30.3)
Black British	13	(19.7)
Black African	13	(19.7)
Black Caribbean	10	(15.2)
Asian	2	(3.0)
Other	8	(12.1)
Primary diagnosis, n (%)		
F20–F29, Schizophrenia, schizotypal and delusional disorders	57	(86.4)
F30–F39, Mood [affective] disorders	4	(6.1)
F60–F69, Disorders of adult personality and behaviour	5	(7.6)
Comorbid personality disorder, n (%)	20	(30.3)
Alcohol misuse, n (%)	25	(37.9)
Drug misuse, n (%)	34	(51.5)

Number and prevalence of ACEs

In the total sample, the mean number of ACEs was 2.89 (±2.35) (*Table 2*), with ACE number showing a positively skewed distribution. Within the sample, most individuals (n = 54, 81.9%) had experienced at least one ACE during childhood; of the total sample, 28.8% had experienced two to three ACEs and 37.9% had experienced four or more ACEs. Among the ACE categories, emotional and physical abuse were the most common, and the rarest ACE was incarceration of household members (*Table 2*). *Table 2* Main study prevalence of number of ACEs and each category of ACE

Cases, N = 66	Number of ACEs, mean (s.d.)	Number of ACEs, n (%)

Incarceration of household member	2	(3.0) ²

² Within the sample, two was the most common amount of ACEs (56% of the sample experienced two or more ACEs) and emotional and physical abuse were the most common ACE categories. ACE, adverse childhood experience.

Number of ACEs and adulthood self-harm

Adulthood self-harm in the sample was analysed. It was determined that over half of the sample had self-harmed during adulthood ($n = 36, 54.5\%$). Because of the positive skewed nature of the number of ACEs, we ran a Spearman's correlation to assess the relationship between number of ACEs and adulthood self-harm on the total sample of 66 patients. There was a statistically significant positive correlation between number of ACEs and adulthood self-harm ($r_s(64) = 0.45, P < 0.001$). Following this, binary logistic regression was performed to ascertain the effect of increasing number of ACEs on the likelihood of adulthood self-harm. The binary logistic regression model was statistically significant ($\chi^2(1) = 15.11, P < 0.005$). The model explained 27.4% (Nagelkerke R^2) of the variance in adulthood self-harm, and correctly classified 75.7% of cases (specificity 83.3%, sensitivity 69.4%). For every one-point increase in number of ACEs, individuals were 1.62 times more likely to self-harm as adults.

ACE categories and adulthood self-harm

We conducted an analysis to determine whether there was any association between individual ACE categories and adulthood self-harm. The total sample who had self-harmed during adulthood was analysed to determine the prevalence of each type of ACE within this category. In those who had self-harmed during adulthood, emotional abuse was the most common ACE ($n = 22, 33.3\%$), followed by physical abuse ($n = 19, 28.8\%$), emotional neglect ($n = 19, 28.8\%$) and physical neglect ($n = 17, 25.8\%$). Estimates of the odds ratio for each of the ten ACEs ranged from 1.38 (95% CI 0.47–3.99) for sexual abuse to 8.05 (95% CI 2.07–31.39) for physical neglect. However, statistically significant associations with adulthood self-harm were only seen for emotional abuse, physical abuse, emotional neglect and physical neglect. These relationships were then further explored by Pearson's χ^2 -tests and Fisher's exact tests, which confirmed that four categories of ACE had a statistically significant association with adulthood self-harm: emotional abuse ($\chi^2(1) = 13.37, P < 0.001$), physical abuse ($\chi^2(1) = 4.62, P = 0.032$), emotional neglect ($\chi^2(1) = 5.94, P = 0.015$) and physical neglect ($P = 0.001$, Fisher's exact test, two-sided).

Multivariate binary logistic regression was conducted to determine whether emotional abuse, physical abuse, emotional neglect and physical neglect maintained their statistically significant association with adulthood self-harm when all four categories were accounted for. In this model, 31.2% (Nagelkerke R^2) of the variation in adulthood self-harm was explained by these four ACE categories. This model correctly classified 71.2% of cases (specificity 80.0%, sensitivity 63.9%). When accounting for emotional abuse, physical abuse, emotional neglect and physical neglect, only emotional abuse maintained a statistically significant relationship with adulthood self-harm ($P = 0.034$), showing that being emotionally abused increased the likelihood of adulthood self-harm by 7.36 times (Table 3). Table 3 Multivariate binary logistic regression to analyse the association between emotional abuse, physical abuse, emotional neglect and physical neglect, and adulthood self-harm

Variables	Bs.e.	Waldd.f.	Significance	Exp(B)	95% CI for Exp(B)	Lower	Upper	Step 1

3

This multivariate binary logistic regression model included all adverse childhood experience categories that were individually significantly associated with adulthood self-harm. It was run to determine whether statistical significance was maintained when all the categories were accounted for; only emotional abuse remained significantly associated with adulthood self-harm.

Discussion

This study was the first to analyse the prevalence of ACEs, adulthood self-harm and their relationship in a female MSU population in the UK. Multivariate binary logistic regression revealed a statistically significant association between an increasing number of ACEs and increased likelihood of adulthood-self harm. Emotional abuse was shown to have a statistically significant association with adulthood self-harm.

We found a high prevalence of ACE exposure in this female MSU cohort, with over 80% of individuals experiencing at least one ACE and 56% experiencing more than two ACEs. The prevalence of ACE exposure among this female MSU group was higher than the 47% prevalence in the general adult population of the UK.³

Within this population, there was a high prevalence of adulthood self-harm. Adulthood self-harm in our sample was reported by 54.5%, similar to the rates reported by Ribeiro et al¹³ (whose MSU population overlapped with ours), who found that 46.7% had a documented history of self-harm before MSU admission. Baker et al¹⁴ interviewed female patients in a medium-secure setting and discussed their experiences of self-harm; an overarching theme discussed was that of ‘the traumatised individual’, suggesting that individuals linking their traumatic experiences to self-harming behaviour is not uncommon. The high prevalence of ACEs amongst the female MSU population indicates that a trauma-informed approach to care in MSU settings for women is crucial. Application of ‘universal trauma precautions’ is necessary, to ensure that all who have been exposed to ACEs receive care that is not only growth-promoting, but also less likely to cause re-traumatisation than standard care.¹⁵

We found a statistically significant correlation between an increasing number of ACEs and the likelihood of adulthood self-harm. This is similar to research by Cleare et al,¹⁶ showing that those with a history of repeat self-harm were significantly more likely to report exposure to multiple ACEs. Moreover, our finding of a statistically significant relationship between emotional abuse and adulthood self-harm supports the research by Howard et al,⁵ who found a statistically significant association between emotional abuse and self-harm in a sample of female prisoners.

It was advantageous to focus on those admitted to a single female MSU over the past 11 years, as there is limited data regarding this population. Use of electronic medical records to obtain data meant minimal information was missing and there was low attrition. In this niche population, we achieved a good sample size; only around 12% of the 3500 MSU beds in the UK are occupied by women.¹⁷

The ACE questionnaire is limited as it provides no information regarding the severity, degree, duration, timing or quality of each ACE component, which may differ significantly from person to person. Furthermore, data collected about self-harm behaviours could have been improved by using the Inventory of Statements about Self-Injury questionnaire,¹⁸ examining the type, frequency, severity and reasons for the behaviour. Further research could focus on collecting more in-depth childhood histories from patients, or using self-harm measures that capture frequency and severity.

Limited research is also available in forensic psychiatric settings, specifically MSUs, and nationwide research into ACEs and self-harm within these units could be beneficial. Furthermore, the neurodevelopmental and psychological mechanisms by which ACEs and self-harm are linked need exploration.

Abstract

The topic of patients recording healthcare consultations has been previously debated in the literature, but little consideration has been given to the risks and benefits of such recordings in the context of mental health assessments and treatment. This issue is of growing importance given the increasing use of technology in healthcare and the recent increase in online healthcare services, largely accelerated by the COVID-19 pandemic. We discuss the clinical, ethical and legal considerations relevant to audio or visual recordings of mental health consultations by patients, with reference to existing UK guidance and the inclusion of a patient's perspective.

pmc .. _sec1:

Why do patients record healthcare consultations?

Recording consultations is increasingly accessible for patients as smartphones and electronic devices with recording capabilities have become ubiquitous in modern society. The integration of these devices into healthcare has been accelerated by the COVID-19 pandemic, which prompted a global upsurge in the use of telemedicine.¹ Many digital platforms that are used for online consultations, including Zoom and Microsoft Teams, have in-built recording functions.

Several reasons have been suggested for why patients record healthcare consultations. These include enhancing their understanding of healthcare information, replaying clinical encounters, sharing these with others and for therapeutic purposes.² Some patients hold digital copies of consultations to evidence the care received and to support any future complaints or litigation;² this may particularly be the case if patients have had prior negative healthcare experiences or lost trust in healthcare providers. For some patients, digital recordings provide a sense of ownership over their health information.²

Advice from professional bodies

The General Medical Council (GMC) recommends that doctors make arrangements, wherever practical, to support patients in understanding and retaining health information; such support is described to include accommodating a patient's wish to record relevant conversations.³ They clearly state that doctors must obtain patients' consent to conduct visual or audio recordings of them.⁴ However, the GMC currently does not provide formal guidance on the management of other circumstances in which patients record healthcare interactions. For example, should clinicians encourage patients to record them for reasons other than understanding and retaining information?

The Medical Defence Union (MDU), Medical Protection Society (MPS) and British Medical Association (BMA) advise that patients do not require the doctor's permission to record their healthcare consultations.⁵⁻⁷ This is because information disclosed during a consultation is confidential to the patient, not the doctor, and a recording is therefore not a breach of confidentiality in itself. Similarly, where recordings are made entirely for personal reasons, they are unlikely to engage the Data Protection Act. The MPS further advises that a doctor's duty of care should prevail over any reluctance to engage in filming by patients.⁶

Although patients can record healthcare consultations, it is less clear how the recorded material can be utilised. The MPS declares that, since 'the content of the recording is confidential to the patient, not the doctor' this means that 'the patient can do what they wish with it'.⁶ However, the BMA advises that healthcare staff can request the removal of recorded materials posted online;⁷ furthermore, refusal of this request could result in litigation owing to misuse of the professional's private information. Depending on the nature of the posting, it could potentially violate the Protection from Harassment Act 1997, the Malicious Communications Act 1988 or the Communications Act 2003.⁷

Interestingly, none of the above organisations specifically refer to the mental health or mental capacity of the patient making the recording, despite the unique considerations this brings.

The Mental Health Act

The Mental Health Act Code of Practice applies to patients detained under the Mental Health Act 1983. It states that ‘when patients are admitted, staff should assess the risk and appropriateness of patients having access to mobile phones and other electronic devices and this should be detailed in the patient’s care plan’.⁸ It does not directly comment on the use of devices for recording healthcare encounters; nonetheless, it seems reasonable to apply the principles of the above statement to this situation. The terms ‘risk’ and ‘appropriateness’ suggest that professionals should consider the safety of healthcare consultations being recorded, and the suitability of the context, content and intended use(s) of any recording. These factors will vary according to individual patients and situations, demonstrating the need for a person-centred approach. If valid clinical reasons exist for denying access to electronic devices under the Mental Health Act, professionals should consider whether these extend to the recording of consultations. In the same way that clinicians note restrictions on access to personal items, they should document any reasons for preventing a patient from recording healthcare interactions. This is important for medico-legal purposes and to alert other professionals of identified risks.

Clinical benefits of patients recording mental health consultations

The recording of healthcare consultations could help patients to remember vital information, such as self-help strategies, medication advice and suicide safety plans. This is particularly useful in psychiatry, given that concentration and attention are impaired in various mental disorders. If the patient is acutely agitated or distressed during the consultation, this could further limit their recall of conversations. Viewing the healthcare encounter when feeling more relaxed could improve a patient’s adherence to medical recommendations. This could also empower patients and make them feel more involved in their care by allowing greater time for information processing.

Recordings make it easier for patients, especially those with poor recall, to inform family members about their health. This could further involve families in decision-making processes in the interests of providing holistic care. The previous recording of healthcare consultations could additionally aid decision-making processes for patients who lack mental capacity. For example, they could demonstrate a person’s previously expressed wishes and values, which the team could refer to when determining the patient’s best interests. This could therefore promote autonomy as an ethical principle for patients with mental illness.

Recorded consultations also potentially offer more accurate, detailed and undisputable accounts of healthcare interactions than those that are formally documented, especially for lengthy clinical encounters where clinicians must summarise vast amounts of information.⁶ Consultations recorded over time may help patients to chart their progress and response to care.

Risks of patients recording mental health consultations

Despite the above benefits, there are several risks of recording consultations. First, this could potentially restrict the quality and quantity of information gathered throughout doctor–patient interactions. Patients may be less likely to disclose sensitive information, particularly if they intend to share the recording with others. This could influence their diagnosis and treatment, while also indirectly affecting the risks to the patient and to others. For example, a patient may withhold details of thoughts to harm family members if they are sharing the recording with these persons, limiting the validity of clinical risk assessment. Similarly, the doctor may less freely ask probing questions that expose a patient’s vulnerability if they are aware of the recording being widely distributed. For these reasons, clinicians should discuss with patients which aspects of healthcare consultations they wish to record, the purpose(s) of the recording and whether this could affect their engagement or ability to provide honest information. Ideally, patients and clinicians should reach a mutually agreeable decision and work together to mitigate any potential impact on psychiatric assessment.

Some patients may lack the mental capacity to decide whether they wish to record healthcare consultations and how to use the recorded information. In such circumstances, patients could act without understanding the benefits and risks associated with their intended use(s) of the recording. This could result in harm to the patient and/or them making a decision that they later regret when they regain mental capacity. For example, a patient with mania may report reckless spending and display disinhibited behaviour during their consultation, but impulsively decide to record this and post the content online. The patient may be incapable of understanding and appraising the consequences of doing

this, including heightening their risk of financial abuse and vulnerability. Furthermore, they may not recognise that they are demonstrating symptoms of mental illness, and this lack of insight could result in the unintended sharing of confidential health information. In this situation, the person would seemingly lack the mental capacity to record their healthcare encounter; consequently, the healthcare professional would have a professional and legal duty to act in their best interests. Healthcare professionals must remember that mental capacity is assumed until proven otherwise, and unwise decisions do not equate to the loss of mental capacity.⁹

Clinicians should be mindful of the content of healthcare consultations and patients' reactions to this. Discussing sensitive topics such as suicidal thoughts, self-harm and abuse can evoke strong emotions and distress. Any intense negative emotions encountered by the patient could be re-experienced on viewing recorded consultations; in the absence of appropriate support, this could trigger acute distress and heighten the individual's risk to themselves in that present moment. Clinicians should advise patients accordingly of these risks and agree an appropriate safety plan to address them.

Social media sites are increasingly popular in modern society and some patients may post their recorded consultations on such platforms. This could result in both positive and negative comments from the public and their health information being shared beyond the original intended audience. Sharing of clips with partial information may also be misleading without providing a fuller picture of the relevant context. Clinicians should consider discussing these risks and benefits with patients, including how public reactions to private health information could affect their mental state.

Risks to other patients and persons

Healthcare professionals must protect the safety, dignity and privacy of all patients. A common concern is that healthcare recordings may include the voice, image or details of other patients in the vicinity of the recording. This could potentially breach their privacy rights under Article 8 of the European Convention on Human Rights.^{7,10} The increased use of single bedrooms in mental health units lessens this risk; however, in-patient mental health wards are often louder than other environments and professionals should consider whether other patients are visible or audible in the background. In such circumstances, it seems best practice that the patient is offered an alternative environment for the consultation to be recorded in. If this is not feasible, the recording may need to be prevented to preserve the confidentiality and privacy of other patients. The proximity of colleagues to the recording should also be considered to protect their privacy and to avoid indirectly compromising patient confidentiality, such as by capturing a colleague's discussions relating to others.

The content of healthcare conversations can include details of third parties whose confidentiality should be protected.¹¹ For this reason, when patients request access to their medical records, content relating to external persons is usually omitted before granting access.¹¹ A similar process should apply to recorded consultations, with the doctor ensuring that the recorded material does not breach the confidentiality of others.

Further ethical and legal considerations

Owing to the nature of mental illness, some patients lack the mental capacity to make decisions regarding their care. For example, approximately 40–60% of psychiatric in-patients have been estimated to lack capacity regarding treatment decisions.^{12,13} This means that recorded consultations may not accurately reflect a patient's desires and opinions, especially if these change throughout the course of the person's illness or if treatment is being provided against their wishes (under the principles of the Mental Capacity Act or the Mental Health Act). These factors should be considered when interpreting prior recordings made by patients.

Covert recording

Studies have estimated that 26–40% of healthcare recordings by patients are made covertly.¹⁴ Reasons for this behaviour include distrust in the healthcare system, lack of knowledge regarding policies for ‘open’ recording and fear of recordings being prevented by clinicians.^{14–16} Covert recordings have been used in disciplinary proceedings by the GMC,^{5,17} although the BMA highlights that most recordings support the actions of doctors.⁷ To reduce covert methods, some authors have suggested that clinicians should encourage patients to visibly record their healthcare interactions.^{14,15} This could build trust, encourage shared decision-making and promote an open and honest culture within organisations. This also provides an opportunity for patients and clinicians to work together to maximise the benefits and reduce the risks of any recording, while ensuring that important non-verbal interactions are captured in any media. The practice of clinicians encouraging healthcare recordings likely requires organisational support and a clear organisational framework to support and govern this activity.

Recordings made by carers or relatives

For some patients, their carers or relatives may attend their healthcare appointments and record consultations on their behalf. All patients who have mental capacity can refuse the recording of their health information by others, but for those without mental capacity, clinicians must consider whether any recording is in the person’s best interests. This is particularly relevant in child and adolescent mental health settings, where parents are commonly involved in their children’s healthcare. In the UK, children aged 13 years and above are typically deemed to have the mental capacity to access personal health records and accept or refuse parental access to these; however, there is no strict age threshold, and some children achieve mental capacity earlier than others.^{18,19} Children with the relevant mental capacity should be permitted to record their consultations and to give or deny their parents permission to do so. The healthcare professional must also consider any safeguarding concerns or relationship dynamics that could influence third party recordings and their clinical assessment. For example, children could less freely report difficulties at home if their parents are filming healthcare encounters. For patients with neurodegenerative conditions or chronic mental illness, early discussions about their healthcare preferences and other’s involvement in their care could aid decision-making about recording consultations if and when mental capacity is reduced in the future. A potential benefit of recording healthcare appointments by parents or carers is that this can provide an easily accessible record and evidence of access to care when attending multiagency meetings with education and social care agencies, especially when neglect is a concern.

Patient perspective

The following gives a patient’s (N.R.’s) view on the subject. “Having spent considerable time in psychiatric and therapeutic appointments as a patient, I was initially shocked when learning of the lack of clear national guidance regarding patients’ recording of appointments in mental health settings. This lack of guidance leaves the patient vulnerable to breaches in confidentiality, potentially in cases where mental capacity is lost for the patient, and they inadvertently disclose potentially embarrassing information in public forums. We must consider the potential humiliation that service users could feel when errors occur with the use of such recordings. At the same time, recordings could provide a sense of security to patients and give them greater confidence in their care.”

“Ideally, there would be an independent method or platform that manages and stores recordings of healthcare consultations. This way, they could be used for the benefit of patient care and/or for medico-legal purposes, while protecting patients from some of the risks.”

Summary

Clinical services must adapt to accommodate evolving patient preferences and work collaboratively with patients to ensure that health information is appropriately and safely stored and shared with others. The recording of healthcare consultations offers several benefits to patients; however, it may also sometimes risk their privacy, safety and dignity or that of others. We recommend the establishment of clear national guidelines regarding the recording of mental health consultations. These guidelines are needed to protect both patients and professionals and are urgently required, given the increasing use of teleconsultations in mental healthcare. Such guidelines would need to acknowledge the broad range of settings and circumstances in which consultations can be recorded, including in-patient wards, home visits, community settings and online. Particular consideration needs to be given to specialist groups such as children and adolescents, patients with intellectual disabilities and persons with cognitive impairment. Furthermore, the views of numerous stakeholders must be considered, including patients, carers, multidisciplinary team members, and legal and ethical experts.

Abstract

Aims and Methods

To examine whether national initiatives have led to improvements in the physical health of people with psychosis. Secondary analysis of a national audit of services for people with psychosis. Proportions of patients in ‘good health’ according to seven measures, and one composite measure derived from national standards, were compared between multiple rounds of data collection.

Results

The proportion of patients in overall ‘good health’ under the care of ‘Early Intervention in Psychosis’ teams increased from 2014–2019, particularly for measures of smoking, alcohol and substance use. There was no overall change in the proportion of patients in overall ‘good health’ under the care of ‘Community Mental Health Teams’ from 2011–2017. However, there were improvements in alcohol use, blood glucose and lipid levels.

Clinical implications

There have been modest improvements in the health of people with psychosis over the last nine years. Continuing efforts are required to translate these improvements into reductions in premature mortality.

pmc Concerns have repeatedly been raised regarding premature mortality among people with schizophrenia and other psychotic disorders.^{1–6} People who experience psychosis die on average 10–20 years earlier than the general population.^{7,8}

Factors contributing to this inequality may include economic disadvantage, health risk behaviours and difficulties accessing and adhering to medical treatments.^{9–11} These frequently translate to poor physical health, and psychotic disorders are strongly associated with unfavourable outcomes for a range of physical health measures: smoking status, weight, serum glucose levels, blood pressure and serum lipids.^{12,13} These issues can be compounded by metabolic side-effects of antipsychotic medication,^{14–17} and an increased risk of cardiovascular disease is widely accepted as the primary mediator of reduced life expectancy.^{4,18–20}

National initiatives

In 2014, the National Institute for Health and Care Excellence (NICE) produced recommendations to guide screening and intervention for common physical health problems experienced by people with psychosis.²¹ The same year, NHS England announced a new Commissioning for Quality and Innovation (CQUIN) framework, providing financial incentives for physical health screening and interventions within secondary mental health services.²² The ‘Positive Cardiometabolic Health Resource’ was published, with support from the Royal Colleges of Psychiatrists, Physicians, Nursing and General Practice, establishing a user-friendly manual for clinicians providing care to patients with severe mental illness.²³

Since these initiatives were implemented, there is some evidence that the quality of physical healthcare delivered to patients with psychosis has improved.²⁴ However, there are ongoing concerns that this has not translated to an improvement in patients’ health. A recent study found that cardiometabolic risk factors were already pronounced in those presenting to services with a first episode of psychotic illness, and that physical health deteriorated during the first year of treatment.²⁵

In light of these apparent contradictions, we aimed to investigate whether physical health has improved among people with psychotic disorders. We conducted a secondary analysis of data gathered over the past 9 years, during national audits of services for people with psychosis.

Method

All data for this study were collected during two audit rounds conducted as part of the National Clinical Audit of Psychosis (NCAP) by the Royal College of Psychiatrists.²⁶ Both examined services providing care to people with psychotic disorders in England. A ‘core’ audit generated data on people under the care of community mental health teams (CMHTs), with three rounds of data collection in 2011, 2013 and 2017. A ‘spotlight’ audit collected additional data on the quality of care received by people with first-episode psychosis (FEP) who received care from early intervention for psychosis (EIP) teams. Three rounds of the spotlight audit were conducted in 2014, 2018 and 2019. All National Health Service (NHS) Provider Trusts in England with CMHTs and EIP teams that provided care to patients with psychotic disorders were invited to take part in these respective audits.

For both audits, all participating organisations were asked to provide an anonymised list of eligible patients who fulfilled inclusion criteria during a 12-month ‘sampling window’ before the point of data collection. From each list, 100 patients were randomly selected for inclusion in the audit. For the CMHT audit, patients were eligible for inclusion if they had an active period of care with a participating CMHT, were aged 18 years and had an established diagnosis of schizophrenia or schizoaffective disorder (ICD-10 codes F20/F25) recorded during the 12-month sampling period. Patients were excluded if they had received in-patient care or care from an EIP team during this period. For the EIP audit, patients were eligible for inclusion if they had an active period of care with a participating EIP team, were aged 14 years and had a diagnosed ‘first episode’ of any psychotic disorder (ICD-10 codes F20-F29) recorded during the 12-month sampling

period. For the purposes of this study, we excluded any patients whose host organisation did not participate in all three rounds of the respective audit.

For both audits, staff from each organisation were asked to conduct a retrospective review of case notes from the sampling window, and extract data to complete an online data collection tool. The tool included questions on physical health measures, quantifying patients' smoking status, alcohol use, blood pressure, body mass index (BMI), serum glucose, serum lipids and whether they were known to use illicit substances. The data collection tools for both audits were based on NICE guidance for management of psychotic disorders.²¹ They were developed in collaboration with patients and providers of psychiatric services, and carer representatives with lived experience of supporting patients with psychotic disorders. The tool was piloted by six volunteer trusts before the main audit, to ensure that the process was understandable and acceptable.

During the development of this project, the National Research Ethics Service and the Ethics and Confidentiality Committee of the National Information Governance Board advised that formal ethical approval and individual participants' informed consent were not required because this was a secondary analysis of audit data and patient-identifiable data were not being collected. The authors assert that all procedures contributing to this work comply with the ethical standards of the relevant national and institutional committees on human experimentation and with the Helsinki Declaration of 1975, as revised in 2008.

Exposure, outcome measures and covariates

The primary outcome measures for this study were whether patients were considered to be in 'good health', according to for seven discrete physical health measures and one composite measure. The seven measures of good health were smoking status (not currently smoking, e.g. non-smoker or ex-smoker), alcohol use (no recorded 'harmful or hazardous' alcohol use), illicit substance use (no recorded illicit substance use), blood pressure (normotensive, i.e. <140/90 mmHg), BMI (within normal range, i.e. 18.5–24.9), serum glucose (within normal range, i.e. fasting blood glucose <5.5 mmol/L and/or random plasma glucose <11.1 mmol/L and/or hemoglobin A1C <42 mmol/mol) and serum lipids (within normal range, i.e. total serum cholesterol <5.1 mmol/L and/or high-density lipoprotein >1 mmol/L and/or non-high-density lipoprotein <4.1 mmol/L). The definition of good health for each measure was based on the standards implemented by the national Mental Health Commissioning for Quality and Innovation analysis.²² To be considered in good health for the composite measure, patients had to fulfil the criteria for good health for all of the seven discrete measures.

In addition, patients' age and gender were recorded, to provide demographic information about the overall sample for each audit.

Statistical methods

We used SPSS (version 26 for Windows)²⁷ to analyse the study data. For each round of the audits, the proportion of patients with good health were calculated for each of the physical health measures and the composite measure. The variation in these proportions between each round of the two audits was then examined with binomial logistic regression.

Variation in demographic characteristics (age and gender) were compared between the CMHT and EIP audits, using *t*- and ²-tests, respectively.

For many patients, data were not recorded for some of the physical health measures (presumably because it was not available in the clinical records, possibly because of patients refusing to undergo investigation or provide information).²⁸ Missing values were not included in the analysis.

Results

For the CMHT audit, 57 NHS Provider Trusts submitted data for all three rounds. Data from 16 752 sets of case notes were analysed (4618 from the first round in 2011, 4785 from the second round in 2013 and 7349 from the third round in 2017). For the EIP audit, 54 NHS Provider Trusts submitted data for all three rounds. Data from 20 611 sets of case notes were analysed (2158 from the first round in 2014, 8768 from the second round in 2018 and 9685 from the third round in 2019).

Table 1 summarises the demographic characteristics (age and gender) for the total samples of the CMHT audit and EIP audit, respectively. Across the three rounds, patients in the CMHT audit were significantly older than those in the EIP audit, with mean ages of 47.11 years and 29.66 years, respectively ($t(37\ 361) = 156.94, P < 0.001$). In the CMHT audit, 65.6% of the total sample were men, compared with 64.2% in the EIP audit, which was not a statistically significant difference. *Table 1* Demographic characteristics of people with psychosis in the CMHT and EIP audits

	CMHT audit	EIP audit
Age, mean (s.d.)	47.11 (± 12.02)	29.66 (± 9.47)
Difference in age between audits was statistically significant as determined by <i>t</i> -test:	$t(37\ 361) = 156.94, P < 0.001$	
Gender, <i>n</i> (%)	Male 10 989 (65.6)	13 232 (64.2)
	Female 5763 (34.4)	7379 (35.8)
Difference in gender between audits was not statistically significant as determined by χ^2 -test:	$\chi^2 = 1.23, P = 0.267^1$	

Table 2 summarises the proportion of CMHT patients in good health according to each of our outcome measures (including the composite measure), and the variation in these proportions over time across the three rounds of the CMHT audit. There were variable amounts of missing data for each of the seven outcome measures, meaning that the composite measure could only be used for 31.3% (5243/16 752) of CMHT patients. *Table 2* Proportion of people with psychosis with good health outcomes at each round of the community mental health team audit

	2011	Audit 2013	Audit 2017	<i>n</i> / <i>N</i> / <i>n</i> / <i>N</i> %/%	Odds ratio (95% CI), <i>P</i> -value	Odds ratio (95% CI), <i>P</i> -value	Odds ratio (95% CI), <i>P</i> -value

Body mass index	502/1202	571/2587	992/4537	22.8/22.8/22.1	Reference	0.96 (0.84–1.10), 0.572	0.95 (0.84–1.07), 0.406
Blood pressure	1900/2593	2191/2946	3642/4855	73.3/73.7/75.0	Reference	1.06 (0.94–1.19), 0.371	1.10 (0.98–1.22), 0.107
Blood glucose levels	1449/2297	1502/2690	3393/4332	63.1/55.8/78.3	Reference	0.74 (0.66–0.83), <0.001	2.12 (1.89–2.36), <0.001
Blood lipids	924/2186	1143/3002	2350/4152	42.3/35.6/56.6	Reference	1.00 (0.89–1.12), 0.998	1.78 (1.60–1.98), <0.001
Composite measure	33/100	434/1372	76/286	3.3/31.2/2.7	Reference	0.74 (0.46–1.22), 0.294	0.80 (0.53–1.21), 0.348

There was some evidence of improvement in health. CMHT patients in the third round were significantly more likely than those in the first round to be in good health according to measures of alcohol use (odds ratio 1.48, 95% CI 1.31–1.67, $P = 0.001$), blood glucose levels (odds ratio 2.12, 95% CI 1.89–2.36, $P < 0.001$) and blood lipids (odds ratio 1.78, 95% CI 1.60–1.98, $P < 0.001$).

However, CMHT patients in the third round were less likely to be in good health for the illicit substance use measure (odds ratio 0.76, 95% CI 0.68–0.85, $P < 0.001$), i.e. a higher proportion of CMHT patients were using illicit substances in 2017 compared with 2011. The proportion of CMHT patients in overall good health according to the composite measure was consistently low across all three rounds of the audit, and decreased from 3.3% in 2011 to 2.7% in 2017, although this was not statistically significant.

Table 3 summarises the proportion of EIP patients in good health according to each of our outcome measures (and the composite measure), and the variation in these proportions over time across the three rounds of the EIP audit. Similarly, there were variable amounts of missing data for each of the seven outcome measures, meaning that the

This audit also showed improvements in some of the measures of health over time: notably, those relating to smoking (odds ratio 1.22, 95% CI 1.11–1.35, $P < 0.001$), alcohol use (odds ratio 1.43, 95% CI 1.23–1.68, $P < 0.001$) and illicit substance use (odds ratio 1.86, 95% CI 1.68–2.07, $P < 0.001$). Furthermore, the proportion of EIP patients with overall good health was significantly higher in the third round compared with the first (odds ratio 4.65, 95% CI 3.32–6.52, $P < 0.001$), although this remained the minority (10.3%). Also, EIP patients in 2019 were significantly less likely than those in 2014 to be in good health for the BMI measure (odds ratio 0.69, 95% CI 0.60–0.79, $P < 0.001$).

Discussion

This study corroborates previous findings that the physical health of people with psychosis remains poor, despite an improvement in physical health screening and intervention following national initiatives implemented in England since 2014.²⁴

Both CMHT and EIP audits showed improvements in health according to some of these measures, and deteriorations in others. The proportion of patients in overall good health according to a composite measure was low across all rounds of both audits, but did improve significantly post-2014 for those patients receiving care from EIP services.

Unhealthy weight remains a particular area of concern, with large proportions of patients in poor health according to BMI across all rounds of both audits, and a significant deterioration over time in the EIP audit. This supports existing evidence that weight management is challenging for patients with psychotic disorders.^{29,30}

We did find some evidence of a modest improvement in rates of smoking amongst patients under the care of EIP services post-2014. This contradicts recent studies where results have been more pessimistic,^{25,31} but would be in line with previous research suggesting a change in the epidemiology of smoking, with a gradual reduction in smoking in younger age groups.³² This improvement over time was not reflected in the CMHT audit, where patients were on average significantly older.

There was also a marked reduction post-2014 in the proportion of patients under the care of EIP services who were using illicit substances. This contrasted with the CMHT audit where the proportion increased slightly over time.

Strengths and limitations

Data were obtained from large, heterogenous samples over a 9-year period: all NHS Trusts in England with CMHT and EIP services that provided care to patients with psychotic disorders were invited to participate in the respective audits. These data therefore represent a variety of different settings, and we would expect that results would be generalisable to similar patient groups across the country. The primary outcome measures we used to assess physical health are universally recognised as clinically important, and the thresholds for good health were based on national standards that have been widely used elsewhere.^{33–35}

However, this study does have important limitations. First, this is an observational study and we do not know what caused the changes we observed. Although they may reflect changes in services during this period, other changes in society are affecting population health,³⁶ and these could be responsible for some or all the differences we detected.

The EIP and CMHT audits were conducted at different times, both before and after the CQUIN framework was implemented, and used different selection criteria. Differences in the physical health of patients between the two are therefore likely to reflect the differing clinical and socioeconomic demographic characteristics of the patients in each audit, as well as different processes of care. We were able to examine changes in physical health over time within each audit, by comparing different rounds. However, as each service provided a random sample of eligible patients at each round, subsequent rounds of the same audit did not necessarily include the same cohort, and so we are unable to make inferences about changes in health at the level of individual patients even within the same audit.

For both the EIP and CMHT audits, we were able to examine physical health measures before and after the introduction of the Commissioning for Quality and Innovation programme.²² Although the introduction of the programme was associated with a marked increase in the proportion of patients who were offered interventions for their physical health,²⁴ we found only limited evidence that this resulted in changes to the health of people under the care of CMHTs.

These data were produced from retrospective case note audits at each round, and are therefore dependant on accurate reporting and documentation of events at the time of occurrence. Clinicians working in CMHTs and EIP services may not have had full access to records held by primary care, where some physical health screening may have occurred.

Also, there were variable amounts of missing data for each primary outcome measure, meaning that the composite measure could only be used for a relatively small proportion of the overall sample. However, the proportion of missing data did generally improve over subsequent rounds of each audit, possibly reflecting the previously noted incentivised improvements in screening rates and recording.²⁴

Implications

We found some evidence that overall health improved for patients with psychotic disorders under the care of EIP services between 2014 and 2019. However, we did not find evidence of a similar improvement for patients under the care of CMHTs between 2011 and 2017.

This may reflect differences in the model of care implemented by EIP services. Typically, these services advocate a more 'intensive' programme of intervention, with a focus on relatively smaller case-loads, proactive engagement and an increased frequency of contact.³⁵⁻³⁹ Although this approach is primarily intended to address psychiatric symptoms, multiple sources have suggested additional benefits for patients' overall health, including increased levels of screening for physical health problems.⁴⁰ EIP services may, therefore, have been better placed to implement changes resulting from the national initiatives rolled out in 2014.

However, the difference may also be because of differences in demographic and clinical characteristics between patients in the CMHT audit and the EIP audit. Patients in the EIP audit were younger on average, and were also likely to have had a shorter duration of psychiatric symptoms (as this audit specifically examined patients with a diagnosed 'first episode' of a psychotic disorder). These patients may have been more accepting of interventions intended to improve their physical health and, therefore, have seen greater improvements – even if CMHTs and EIP services had implemented identical changes since 2014.

It may even be the case that people in younger age groups have become more 'health conscious' in recent years regardless of any intervention, as suggested by some epidemiological studies.³² However, this seems unlikely in these cohorts in light of previous findings that patients on EIP case-loads already had pronounced cardiovascular risk factors, even at the point of first presentation.²⁵

Both audits identified some isolated areas of improvement in specific measures. Interestingly, these differed between the patients in the CMHT audit, where there were improvements related to alcohol use, serum glucose level and lipids, and the EIP audit, where there were improvements in alcohol use, smoking and illicit substance use. Again, these changes may relate to demographic differences in the patients under the care of these respective services. Older patients may be more receptive to those that they perceive as reducing their risk of major cardiovascular events, such as reduction in serum glucose and lipids.

However, these varying improvements may also be because of differences in the treatment approaches adopted by CMHTs and EIP services. These findings merit further research to identify the factors explaining these variations, as well as the improvement in overall good health seen among those treated by EIP services. There may be elements

where each service outperforms the other; for example, access to staff with training in physical health interventions, or improved links with primary care. Cohort or case-control studies could be used within CMHTs and EIP services to examine what interventions are associated with favourable physical health outcomes at an individual patient level. Qualitative studies to explore the perspectives of patients with psychosis may also identify effective strategies for improving patients' physical health. It may also be of interest to include other services, such as assertive outreach teams, in future studies.

The fact that the EIP audit showed an improvement in rates of illicit substance use over time, but the CMHT audit showed the opposite, is an intriguing finding and of unclear significance. It does not seem to reflect the current understanding of the changing epidemiology of illicit substance use,⁴¹ and suggests that EIP services have been able to implement effective measures to support people in abstaining from illicit substances.

Interestingly, the one measure where both CMHTs and EIP services improved over time was alcohol use. Many drug and alcohol services in the UK are now provided by third-sector organisations rather than NHS mental health teams.^{42,43} The fact that both CMHTs and EIP services were able to effect improvement suggests that effective liaison with external organisations may be a key strategy for improvement, rather than attempting to deliver more services with internal infrastructure, which may already be overstretched.

Both audits showed specific areas where standards of physical health worsened over time. The findings related to patients' weight are particularly concerning: the proportion of patients with a healthy BMI fell significantly across the three rounds of the EIP audit, and was universally low in the CMHT audit. Weight gain is a well-recognised and particular troubling side-effect of many antipsychotic medications.¹⁷ Given the implications of obesity for subjective well-being, medication adherence and therapeutic outcomes in the context of treatment for psychosis, and associated diabetes and cardiovascular risk and likelihood of premature mortality,⁴⁴⁻⁴⁶ improving interventions in this area needs to remain a focus for researchers. To date, studies of current weight management programmes for people with psychosis have produced mixed results.⁴⁷⁻⁴⁹

In addition to these findings, it is also important to note that the majority of patients did not have adequate information recorded for all seven of the physical health measures recommended by nationally agreed standards. Only around half of patients in the EIP audit, and a third of those in the CMHT audit, had usable data recorded for all seven measures. The reasons for this are unclear from this project, and may reflect barriers to physical health screening, such as refusal, lack of provision or inadequate documentation. Clearly, accurate monitoring is required, and will be the focus of quality improvement activities before future rounds of the national audits.

In conclusion, we found limited evidence that overall health improved for patients with psychotic disorders under the care of CMHTs, following the enactment of national initiatives in 2014, although there was some evidence of improvement in specific areas. There was more substantial evidence of improvements for those patients under the care of EIP services. This may be a result of differences in CMHT and EIP services' abilities to implement effective changes in policy and procedures, or demographic and clinical differences in their respective patients. However, these findings merit further research into the processes underlying the improvements in health, to improve the standard of care for people with psychosis.

The authors would like to thank all members of the NCAP team at the Royal College of Psychiatrists, for their support with this study.

Data availability

All authors had access to the full study data-set. The data-set is held by the NCAP team at the College Centre for Quality Improvement, Royal College of Psychiatrists, and could be made available on request.

M.J.C. formulated the presented research question, designed the study and supervised the work. R.W. and S.N. performed the statistical analysis. R.W. drafted the manuscript and designed the figures. B.T., E.W., A.Q., V.G., P.F. and J.S. were involved in gathering and processing the NCAP data, and commented on drafts of the manuscript.

R.W. is supported by a UK National Institute for Health Research (NIHR) Academic Clinical Fellowship (ACF-2017-21-006). The NCAP is commissioned by the Healthcare Quality Improvement Partnership (HQIP) as part of the National Clinical Audit and Patient Outcome Programme (NCAPOP), which is funded by NHS England and the Welsh Government. The views expressed are those of the authors and not necessarily those of the NHS, the NIHR, the Royal College of Psychiatrists or the Department of Health. The funders had no role in the design or conduct of the study; collection, management, analysis or interpretation of the data; preparation, review or approval of the manuscript; or decision to submit the manuscript for publication.

Declaration of interest

None.

pmc ‘Nature is the future’ reads the design on Elli’s sweatshirt, and yet there is nothing natural about Elli or what lies ahead for her. Elli is an android robot, designed to closely resemble a certain 10-year-old girl, who lives with her ‘Papa’ – a man whose real daughter went missing 10 years earlier. Papa keeps Elli in his home as a daughter and sexual companion, and together they reminisce on times when she was alive. So goes the premise of *The Trouble with Being Born*, directed by emerging Austrian filmmaker Sandra Wollner.

Controversial for obvious reasons, the film was withdrawn from the 2020 Melbourne International Film Festival when two forensic psychologists publicly expressed their opposition to its inclusion in the programme. They cited concerns about the film’s alleged normalisation of sexual interest in children and its possible exploitation by paedophilic audiences, reigniting a national debate about film censorship. Certainly, the film is ethically challenging and difficult to watch at times, but it has much to offer artistically and psychologically.

The Trouble with Being Born is a masterful study of trauma, grief, memory, loneliness and the nature of human (and non-human) relationships. Breathtaking in its complexity and vision, the film explores its disturbing subject matter in a detached (perhaps dissociative) formalistic style, reminiscent of Michael Haneke, Wollner’s older compatriot. Far from endorsing the perverse relationship between father/adult and daughter/child, the film is a techno-dystopian parable, warning its audience of the egregious consequences of humanity’s attempts to technologically circumvent and transcend the terrible but ordinary vicissitudes of life.

The story pivots when Elli gets lost in the forest surrounding her house and is discovered by a man who gifts her to his elderly mother, Mrs Schikowa. Elli is re-programmed to be Emil – a likeness of Schikowa’s brother, who died 60 years earlier. Triggered by reminders of his previous life as Elli, Emil’s identity and memory become entangled with Elli’s and he becomes increasingly unpredictable, leading us to the film’s tragic climax.

Elli and Emil are two ghosts in a machine who haunt the people they left behind, and their unnatural resurrection leads to unnatural consequences. Both Papa and Schikowa are trapped in their grief and guilt – Papa will not confront his loss and keeps himself frozen in the moment of his daughter’s disappearance and Schikowa foolishly revisits and attempts to repair her childhood experiences with Emil. Despite its futurism, *The Trouble with Being Born* bears a sense of the archetypal in its exploration of primal anxieties around death, incest and aloneness.

The storytelling in this film is not straightforward and the audience is not left with an answer to the existential question implied by the film’s title. Yet the crafted confusion of past and present, and the moral morass we are offered in this film, are signs of Wollner’s penetrating insight into the disorder and ambiguity of human nature and experience.

- *Michael King, MD, PhD, FRCP, FRCGP, FRCPsych*

pmc Formerly Professor of Psychiatry, University College London, and Director of the Division of Psychiatry, University College London, UK

Professor Michael King, who died on 10 September 2021 aged 71, made numerous important contributions in primary care psychiatry, including risk prediction and the evaluation of complex interventions for mental disorders. However, his research interests went much further than this. Always curious and with an insatiable intellectual appetite, he was an academic polymath, often drawing on approaches from other fields and applying them to psychiatric research. He was particularly fascinated by subjects that were difficult to study, such as improving mental health at the end of life for people with cancer, the role of spiritual beliefs in mental well-being, and the mental health and stigma experienced by people from sexual minorities. Michael was a brilliant methodologist and a prolific researcher, producing almost 800 peer-reviewed publications, attracting over £45 million in grant income and supervising 30 PhD students over the course of his career. He was also tremendously generous and effective in supporting the development of junior clinical and non-clinical academics, many of whom are leaders in their fields today.

Michael believed that visibility was key in addressing homophobia in society and, as an out gay man, he was also a courageous advocate for the rights of LGBT people, drawing on the scientific evidence to make his case. In the 1990s he was instrumental in changing how the cause of death was recorded for victims of AIDS, to mitigate the associated stigma without compromising the collection of accurate statistics. His research into male victims of sexual violence influenced the current legal definition of male rape. He was often called as an expert witness in cases of child custody involving lesbian and gay parents. He also gave expert evidence to the Church of England Synod on same-sex marriage and the ordination of LGBT ministers. In 2001, with Annie Bartlett, he co-founded the Royal College of Psychiatrists' LGBT special interest group (now the Rainbow SIG). Michael contributed hugely to the work of this group, presenting at numerous conferences and providing wise counsel to the College on relevant, often contentious, matters of policy. He was able to remain calm, even when seriously provoked, always presenting his arguments in an empathic, open and assured way. At the time of his death, he remained the foremost expert in LGB mental health in the UK and an international leader in this area. He also weathered a number of attacks on his reputation as a consequence of his courage in speaking up for sexual minorities. Although he was not someone who sought accolades or prizes, he was honoured to be invited to give the prestigious Beattie Smith lecture at the University of Melbourne in 2017, in recognition of his immense contribution to this field.

Michael was one of two brothers born in Christchurch, New Zealand on 10 February 1950, to Bruce, a farmer, and Patricia King. He completed his medical studies at the University of Auckland in 1976 before moving to the UK to train in family practice. In 1981 he began his training in psychiatry at the Maudsley Hospital, remaining firmly

invested not just in psychiatry but in medicine and primary care throughout his career. He was awarded Membership and Fellowship of the medical Royal Colleges of all three specialties. He trained in psychiatric epidemiology at the General Practice Research Unit of the Institute of Psychiatry and gained both an MD (University of Auckland 1986) and PhD (University of London 1989) prior to his appointment as senior lecturer in the Department of Academic Psychiatry at the Royal Free Hospital School of Medicine in London. He became the Head of Department in 1995 while he was still only a Reader and, under his energetic and inspiring leadership, the Department rapidly expanded. Later, when the Medical School became part of University College London (UCL), he became Director of the UCL Division of Psychiatry, a role he retained until 2014.

As an adult, Michael learnt Spanish, French and German and developed a number of long-standing international collaborations, particularly in South America, Europe, India and Australasia. He was also an excellent clinician, setting up the psychosexual service at Camden and Islington NHS Foundation Trust for which he was the consultant psychiatrist for 30 years.

Michael met his life partner, Professor Irwin Nazareth, in 1984 at the Gay Medical Association. They celebrated their civil partnership in 2006 and married in 2017. In 2019 he contracted a rare non-tuberculous mycobacterium (NTM) infection, later found to be connected to the extremely rare lung condition pleuroparenchymal fibroelastosis, from which he died. As was typical of his approach to life, finding that no patient support group existed, he established one, NTM Patient Care UK (www.ntmpatientcare.uk). Michael is survived by Irwin, two nieces and a nephew. He is very much missed by his family and by his many friends and colleagues across the world.

pmc Nice White Parents is a podcast series about an ordinary middle school in New York.¹ It charts how, over the school's 50-year history, White parents have consistently, and almost always unwittingly, exercised their enormous unsaid power in the public education system to directly and indirectly hamper the school's mission of providing a progressive and integrated education to children of all racial and socioeconomic backgrounds.

One of the most striking messages from the series is how White parents have been able to game all aspects of the education system and hoard resources for their own children. The White parents covered in the series had more time, influence and resources, and were therefore much better equipped to navigate the system and advocate for their children than Black and minority ethnic parents in the same city. Although the White parents were making seemingly justifiable and rational decisions, the collective impact of their decisions has been to perpetuate long-standing racial inequalities that go back several decades.

Listening to this podcast series, it was hard not to draw parallels with what I see as a clinician in the UK's National Health Service (NHS). Some scenarios that I encounter regularly bear an uncanny resemblance to it, such as parents ferociously seeking referrals to multiple agencies and specialists to get diagnoses for their children by lobbying multiple doctors and seeking second opinions. Other scenarios are less directly analogous, but nonetheless relate to power dynamics and individuals' ability to navigate a complex system – wealthy professionals seeking NHS referrals on the basis of private medical reports, and individuals demanding specific investigations or treatments on the basis of informal conversations with medical family members or friends.

The nature of a publicly funded system, whether it is health or education or any other sector, is that every decision needs to be seen through two lenses – at the individual and the population levels. The traditional medical paradigm, and more specifically recent movements such as patient-centred care, encourage us to favour the individual lens. The danger of this, as we are seeing very powerfully in 2021 with the COVID-19 pandemic, is that it ignores the vulnerable, the less powerful and the voices that cannot shout as loud. Resources are inevitably finite and so each decision we take about one individual or one family can have very real and profound repercussions for many others.

Of course, not all White patients are manipulative, and not all manipulation is by White patients. But as the podcast series points out, nobody talks about White parents, and likewise in medicine, we rarely talk about White patients. Just like the ‘nice White parents’ in New York, my White patients are not acting maliciously and they are not fundamentally against the NHS values of compassion and equality. The problem is rather that they are rarely cognisant of their power and, more importantly, the system simply works better for those who can game it.

As we seek to achieve greater equity in healthcare, is it time we talked more about White patients?

Abstract

Objectives

The growing rate of retraction of scientific publications has attracted much attention within the academic community, but there is little knowledge about the nature of such retractions in schizophrenia-related research. This study aimed to analyze the characteristics of retractions of schizophrenia-related publications.

Materials and methods

The Web of Science was searched for eligible studies. A bibliometric analysis was conducted to describe the characteristics of the retractions using R software and Excel 2019. Content analysis was conducted to examine the essential components of retraction notices.

Results

A total of 36 retracted publications with 415 citations were identified from 1997 to 2021, of which, 83.3% occurred in the last decade. The overall retraction rate was 0.19%, with most of them (29; 80.56%) from the United Kingdom. The retractions were published in 33 journals, and the 2020 IFs ranged between 0.17 and 49.96 (Median = 3.93). The retractions involved 21 research areas, particularly in Psychiatry (19; 52.78%), Neurosciences and Neurology (10; 27.78%), and Psychology (7; 19.44%). Data issues (17; 42.22%), administrative errors of the publishers (5; 13.89%), and study design (4; 11.11%) were the top three reasons for retractions.

Conclusion

This study provides an insight into retractions of schizophrenia-related publications. Institutional governance should be further strengthened to improve the scrutiny of publications, prevent continuing citations, and erroneous propagation after retraction.

pmc .. _S1:

Introduction

Retraction of peer-reviewed scientific publications is becoming more common. The growing rate of retractions with the increasing scientific publications in recent years has attracted much attention. Numerous reasons for retractions include concerns about data quality, and research misconduct, such as redundant publication, plagiarism, copyright infringement, unethical research, and peer review manipulation (1). The main objectives of retraction are to ensure research integrity rather than to punish authors, and to alert the academic community that these publications' findings are not credible and should not be cited (2, 3). In the process of creating innovations, research outputs play a vital role as an important medium for information communication and presentation of findings. The filtering of these publications deserves attention, as the risk of disseminating inaccurate information and results of poor-quality research increases with the rapid expansion of ongoing research (4). For instance, to date, 196 articles related to COVID-19 have been retracted due to various reasons (5). If research articles are fraudulent, they could lead to catastrophic consequences on human health. In 1998, Dr. Andrew Wakefield and his colleagues unethically conducted research on children and concluded that there was a link between measles, mumps, rubella (MMR) vaccine and autism; consequently, thousands of parents refused MMR vaccines for their children which caused an outbreak of fatal measles (6). This misinformation continued to spread for at least 12 years, which had an immeasurable health impact on families with children with autism and also resulted in a huge financial cost to verify the accuracy of this finding (6). Another paper that was retracted from *The Lancet* due to doubtful data authenticity (7), claimed that hydroxychloroquine was ineffective in treating COVID-19 and even caused arrhythmias, which provoked a strong reaction in the scientific community and the public (8).

The retraction rate of scientific publications across many fields has been increasing in recent years. One study found a retraction rate of 0.38 per 10,000 publications in all fields in 1985, 2.03 in 2000, and 5.95 in 2014 (9), while another study found an average rate of 2.5 per 10,000 between 2013 and 2016 in all fields (10). A recent report found that the

retraction rate has increased 10 times in veterinary medicine and animal health publications during the period between 1993 and 2019 (11). The trends of retractions varied by publication year (9) and research field (12, 13). The most common reason for retraction is academic misconduct, such as fraud or suspected fraud, duplicate publications, and plagiarism (13, 14).

Previous studies have reviewed the retracted literature in different specialties of medical fields, such as nursing and midwifery (15), neurosurgery (16), hematology (13), and anesthesiology (1). However, few studies have focused on the mental health literature (17). Schizophrenia is a severe mental disorder characterized by disturbances in perceived reality and behavior, such as persistent delusions, hallucinations, disorganized thinking, negative symptoms, and cognitive impairment (18–20). Approximately 1 in 300 people are affected worldwide, and its global disease burden has increased 11.4% from 1990 to 2019 (21, 22). Beyond the disease itself, relevant stigma and violations of human rights associated with schizophrenia can have a significant impact on the individual's family, work, and social function (23–25). Additionally, schizophrenia patients have a shorter life expectancy when compared to the general population (18). Due to these features, schizophrenia is one of the most important areas of research in psychiatry and medicine.

A bibliometric analysis showed that the research on schizophrenia has been increasing in recent years, involving a wide range of research areas, including Psychiatry (69.8%), Neurosciences (20.7%), Clinical Neurology (12.4%), Pharmacology and Pharmacy (9.6%), and Genetics/Hereditry (3.4%) (26). Schizophrenia related research has mainly focused on epidemiology, etiology, and treatment aspects, but the findings remained variable and at times controversial (18). Ensuring academic rigor is important for the medical advancement in schizophrenia and other fields of medicine. False research results could mislead the academic community or drive researchers in wrong directions, leading to much wasted research resources and negative impact on patient care and recovery (27, 28). Timely retraction is an important measure to prevent erroneous findings from being propagated. However, the nature of retractions in schizophrenia-related publications is unknown.

Bibliometric analysis has been widely used to examine the research trends in a specific field. Compared with traditional descriptive reviews of the literature, it is based on two components: one is the performance analysis that can provide the general characteristics of relevant publications, such as the number of publications, publication years, authors, institutions, countries, and journals; the other is science mapping, which examines and visualizes the relationships between research constituents such as co-citation analysis, bibliographic coupling, co-word and co-authorship analyses. In recent years, bibliometric analysis has been used to explore the characteristics of retractions in academic fields such as rehabilitation (29) and oncology (12). However, to the best of our knowledge, no bibliometric analysis on schizophrenia-related publication retractions has been published. As such, we performed a bibliometric analysis and content analysis of the characteristics of retracted publications on this topic, including publication years, sources, research areas, citations, and reasons for retractions.

Materials and methods

The retracted publications on schizophrenia-related studies were searched from the Web of Science Core Collection in the database of the Web of Science (WoS). The search term was “TI/AB = *Schizophrenia OR Schizophrenias OR Schizoaffective OR Schizophreniform OR Psychosis OR Psychotic OR Schizophrenic Disorders OR Disorder, Schizophrenic OR Disorders, Schizophrenic OR Schizophrenic Disorder OR Schizophrenic Disorders OR Dementia Praecox OR Schizoaffective disorder OR Psychotic Disorders.*” The article type was limited into “*Retracted Publications and Retractions.*” A comprehensive screening procedure was conducted manually to avoid false positive or negative results.

The R software and Excel 2019 were used to summarize the characteristics of retractions, including the published year, countries, journals, and research areas. The Journal Impact Factor (IF) in 2020 was used for impact analysis of the journals. Given the rapid growth of journal impact factors, a 5-year IF was used to describe the impact of journals, as it is more stable compared to Immediacy IF. Furthermore, an IF without journal self-citation was used to reduce the potential inflation of IF because self-citation of journals could result in a higher IF value (30). In addition, content analysis was used to examine the reasons for retraction by reviewing the retraction notices. To analyze the transparency of retraction notices, this study included the following four essential components as previously recommended (3): initiators, cause, whether there was consensus between editors and authors on the retraction decisions, and whether retractions were related to the post-publication review (such as comments on PubPeer).

Results

A total of 19,176 publications on schizophrenia-related publications were searched in WoS from its inception to the search date (20/03/2022). Forty retractions were found after limiting the study types, four articles were discarded due to irrelevant topics or duplications in the process of data cleaning. Thirty-six publications from 1997 to 2021 were finally included in this study; of all the retractions, 83.3% ($N = 30$) occurred in the last decade. The overall retraction rate was 0.19%, and the years of retraction were between 2002 and 2021. The distribution of publication year, retraction year and annual citations are presented in *Figure 1*. The delay between publication and retraction time (year) ranged from 0 to 10 years with an average of 1.89 years (standard deviation = 2.22 years). The total citations of the 36 retracted publications were 415, with the most citations arising from a single publication (151) (31). The citations of the 36 retractions during the recent ten years accounted for 49.9% (207) of the total citations. *Figure 2* presents the distribution of research areas of the retracted publications. The top three included Psychiatry (19, 52.78%), Neurosciences and Neurology (10, 27.78%), and Psychology (7, 19.44%).

The retracted publications were from 15 countries or regions. *Table 1* shows the top five countries where the publications originated, including the United Kingdom (29; 80.56%), the United States (8; 22.22%), China (8; 22.22%), Canada (7; 19.44%), and Germany (7; 19.44%). *Table 2* shows that the 36 retractions were published in 33 different journals. The IFs of the journals (in 2020) ranged between 0.17 and 49.96, with a median of 3.93. The Journal of Developmental and Behavioral Pediatrics ($IF = 2.22$), Journal of ECT ($IF = 3.63$), and Psychiatry and Clinical Neurosciences ($IF = 5.12$) each retracted two publications, respectively. A total of 17 journals (47.2%) were related to Psychology and Psychiatry.

Countries/regions with retractions of schizophrenia-related studies.

IF, impact factor; “–”, not reported in Web of Science.

Supplementary Table 1 shows the characteristics of the retractions. All the 36 retraction notices reported the reasons for the retraction. In sum, nine (25.0%) retraction notices did not report who were the initiators, 24 (66.7%) did not report whether there was consensus between editors and authors on the retraction decisions, and 28 (77.8%) did not report whether retractions were related to the post-publication review. *Table 3* lists the reasons for retraction as indicated by relevant journals, which include eight categories: data issues (17; 42.22%), administrative errors of the publisher (5; 13.89%), copyright (3; 8.33%), plagiarism (2; 5.56%), redundant publications (2; 5.56%), study design issues (4; 11.11%), ethical issues (1; 2.78%), and others (1, 2.78%). Based on the classification of reasons for paper retraction outlined by the Committee on Publication Ethics (COPE) (2), 11 (30.56%) out of the 36 retracted publications were due to honest errors, including occasional errors made in the original database or experimental data (7; 19.44%) and improper data manipulation (4; 11.11%).

Reasons for retracted publications on schizophrenia-related studies.

Reason	Type	N	%
Data issues (17, 47.22%)	Honest error (Data error)	11	30.56
	Misconduct (Suspicious fabrication)	2	5.56
	Invalid data	3	8.33
	Unreplicable results	1	2.78
	No original data	1	2.78
Administrative errors of publisher	–	5	13.89

Plagiarism	–	2	5.56
Redundant publication	–	2	5.56
Ethic issue	No ethical approval	1	2.78
Others	No permission to publish by the author	1	2.78

Discussion

This is the first bibliometric study on retractions of schizophrenia-related publications. We identified 36 retractions among 19,176 publications on schizophrenia-related studies. The overall retraction rate was relatively lower (0.19%) compared with other fields such as neurosurgery (7.3%) (16). Three-quarters of retractions occurred during the past decade (2011–2021), a trend similar to the retractions in the obstetrics literature where 76% of retractions occurred in the recent decade (2009–2019) (27). This is likely to be related to the overall growing number of academic publications, which may lead to increased academic errors. Additionally, publishers have promoted the awareness of scrutiny of publications (29). Academic misconduct has become a priority in the review procedure for many journals. Currently, many guidelines to standardize the process of retractions are available; of them, the most authoritative guidelines were issued by the COPE (2). The number of retractions has grown since the COPE guidelines were published in 2009 (29). Our analysis revealed that the average gap between publication and retraction time was 1.89 years, which is shorter than the retractions in other fields such as nursing and midwifery (2.3 years) (15) and life science research (3.8 years) (9). A longer delay in retraction may be associated with a more negative academic impact. The erroneous research findings may mislead other researchers, resulting in a waste of time, effort, and resources, and may even harm research participants (27). The high citations of retracted publications suggest that these retractions continued to have a certain impact on the schizophrenia research field as some were still cited even after retraction. Thus, a prompt retraction process is needed and clear signs and labels, such as attaching a clear watermark to the retraction (32), may be helpful in preventing further citations of retracted publications.

The retracted publications identified in this study involved 21 research areas; however, it should be noted that one retracted article may involve more than one research area. More than half of the retractions were classified in the field of Psychiatry (52.78%). The retractions also involved some experiment-based research areas such as Neurosciences, Neurology, Pharmacology, Pharmacy, and Behavioral Sciences. A previous study (29) found that publications based on basic experiments were more likely to be retracted for academic misconduct. Certain countries such as the United Kingdom, United States, China, Canada, and Germany were associated with the most retractions. However, these countries also contributed to the most publications in schizophrenia-related research; the United States contributed the most publications, followed by the United Kingdom, Germany, China, and Canada (26). Most retractions were published in journals related to Psychology/Psychiatry, such as the American Journal of Psychiatry, British Journal of Psychiatry, and Schizophrenia Bulletin. Given the small number of retractions per journal, we could not examine the correlation between the number of retractions and the impact factor of the journals involved. Previous studies on the relationship between retraction rate and journal impact factor found mixed results including positive (33), negative (15), and also non-significant associations (13).

This study analyzed all the retraction notices comprehensively to understand the degree of transparency of retractions. Incomplete information regarding the retraction notices will prevent any assessment of their historical and academic significance, while inadequate information can mislead or distort the readers and provide a biased view (34). Thus, promoting the transparency of the retraction notices is vital to maintain the scientific integrity by acting as a warning or

discontinuation measure (35). Although the COPE released a guideline to formalize retraction notices, there has been little or no change to improve the transparency (3). In our study, although the reasons for schizophrenia-related retractions were reported, the other three essential components (e.g., initiators, whether there is consensus between editors and authors on the retraction decision, and whether retractions are related to the post-publication review) were mostly lacking. Possible reasons may include stigma (e.g., fear of reputational damage or legal responsibility), inconsistent requirements regarding the retraction notices between journals (34) and difficulties in implementation. Thus, reform in reporting retractions can encourage authors and publishers to explain the issues clearly and standardize the information provided among journals.

Overall, 86% of retractions of schizophrenia-related studies were attributed to author-related reasons. The most common reason was data issues, of which 64.7% were honest errors. For example, one paper published in *Nature* (111 citations) entitled “Microglia-dependent synapse loss in type I interferon-mediated lupus” was retracted due to the non-replicable results in the follow-up experiments (36). Another highly-cited paper entitled “Expression of Oct-6, a POUIII domain transcription factor, in schizophrenia” suggested that Oct-6 may be a marker of the neuropathology associated with schizophrenia (37). The data was suspected of being fraudulent; thus, the authenticity of this finding was in doubt. Other studies were retracted due to incomplete data (38), lack of original data (39), or errors in data processing that led to biased conclusions (40). These findings highlight the importance of data accuracy, integrity, and data double-checking.

In contrast, 13.89% of the retractions were due to journal or publisher reasons, such as administrative errors, suggesting publishers should enhance their measures to avoid such errors (16). Three retractions were due to inconsistencies between the contents or research methods and the original study design (41–43). For example, Ninomiya et al. (41) examined the long-term efficacy and safety of blonanserin for first-episode schizophrenia, which was retracted as subjects did not satisfy the inclusion criteria. Incorrect or inappropriate research results could mislead researchers, the public, or even entrepreneurs, resulting in wasted research funds, selection of ineffective drug treatments, and unethical profit-making (4, 44). A study may be invalid or potentially harmful if it does not align with the content of the original study registration. All clinical trials need to be registered before implementation, such as in the International Clinical Trials Registry Platform (ICTRP) supported by the World Health Organization (45). The aim is to ensure adequate knowledge about the research, increase research transparency, and strengthen the validity and value of the scientific evidence base (45).

The lack of ethical governance is another reason for retractions. One paper from the *American Journal of Gastroenterology* with 151 citations was retracted 10 years after publication; one of the reasons was having no local ethics committee approval (31). Thus, authors, editors and publishers should strengthen the consideration and review of all submitted research information including appropriate ethical approvals. The range and frequency of retraction reasons varied between different academic fields. For example, in both dentistry and obstetrics, redundant publications, and plagiarism were the most common reasons (27, 46), while in the field of pharmacy, falsification, or data manipulation were the most frequent (47), which are in contrast to our findings in schizophrenia-related research. The development and application of Plagiarism Detection software, such as iThenticate and Turnitin (16, 46), may contribute considerably to preventing plagiarism issues. Previous studies have proposed the notion of a “publish or perish” culture to explain the research misconduct issues (1, 9, 48). Quantity and quality of publications are associated with academic ranking, promotion and reputation; further monetary incentives in research commonly occur in some institutions/countries (49). Personality traits combined with highly competitive pressures appear to drive some researchers to falsify or fabricate data (1). Moreover, one study in China found that the majority of survey respondents considered that the current academic assessment system contributes heavily to academic misconduct and needs to be reformed to create a healthy academic environment (50). This supports the importance of developing appropriate academic assessment criteria for researchers. We suggest that the publication of good-quality research is a collaborative effort between organizations, publishers, journals and authors to ensure transparency in reporting, prevent research misconduct and disclose any research limitations.

There are several limitations to this study. First, following relevant guidelines of bibliometric analysis (51) and previous studies (52–54), the WoS was used in the literature search. However, the possibility that some studies may be missed could not be excluded. Second, some retraction notices were conservative in stating the reasons for retraction and the information was limited. For instance, where the study results were not reproducible, it was unclear whether this was due to research misconduct or honest errors. Thus, the retraction notices should be standardized to improve transparency. Third, not all academic misconduct could be uncovered by publishers or readers, therefore retraction rates may well be

underestimated.

Conclusion

This study provides an insight into retractions of schizophrenia-related research. The distribution of the retractions varied across countries, journals, and research areas. The number of annual retractions has risen over the past decade with the implementation of existing retraction guidelines, and honest errors account for most retractions. Transparency in reporting retraction notices should be implemented. Researchers should employ measures to ensure the authenticity of their research data. Institutional governance needs to improve the scrutiny of publications and prevent continuing citations and erroneous propagation after retraction.

1.1.58 Have You Seen the NEWS Today? - a QI Project

Harleen Kaur Birgi*Presenting author.

date

2022-06

Abstract**Aims**

The main focus of this QIP was to improve the documentation of NEWS (National early warning scores) and subsequent escalation as appropriate in an Old Age Psychiatric Ward setting. This would in turn lead to improved Physical health outcomes, especially in the COVID-19 pandemic.

Methods

The NEWS chart is based on a simple aggregate scoring system in which a score is allocated to physiological measurements, when patients present to, or are being monitored in hospital. This will ensure that patients who are deteriorating, or at risk of deteriorating, will have a timely initial assessment. This should supplement clinical judgement in assessing the patient's condition.

Early detection and escalation of deteriorating NEWS leads to improved patient outcomes and referral to the appropriate specialties, for subsequent management.

The initial phase of the QIP comprised of retrospective data collection surrounding the recognition and documentation of NEWS on an 18-bedded Old age Psychiatric ward. This period spanned the 2nd wave of the pandemic, from November- December.

Potential interventions were implemented in the form of raising NEWS awareness by educating nursing staff via teaching sessions, displaying posters all over the ward and nursing station. Team also reviewed all NEWS charts everyday during ward management rounds which served as a daily reminder for the staff measuring the observations.

NEWS of & greater than 3 was defined as the threshold for escalation.

Following change implementation, data were collected to capture the progress made over a month.

Results

Analysis of data pre and post- interventions displayed a significant improvement in escalation of unwell patients from 26% to 60%.

Conclusion

Improved outcomes and early detection of potentially deteriorating patients, leading to early transfer of patients to an Acute Medical setting and better overall management.

Raised awareness and understanding of physical health management in Mental Health nurses.

The QIP was presented at the Trust QI Forum meeting and was met by an overwhelmingly positive response. In order to enhance NEWS recording an electronic format is now being adapted. There is also a consideration around providing regular NEWS teaching sessions to all inpatient staff across the trust.

1.1.59 A Quality Improvement Project (QI) on Screening for Rapid Eye Movement Sleep Behaviour Disorder (RBD) in Patients Referred to Trafford Memory Assessment and Treatment Service (MATS), Part of Greater Manchester Mental Health Trust (GMMH)

Rachel Moir Ruth Pye-Jones Amit Sindhi Boben Benjamin*Presenting author.

date

2022-06

Abstract

Aims

Lewy Body Dementia (LBD) is predicted to be under-diagnosed in the general population. RBD is one of the four core clinical criteria for the diagnosis of LBD. Longitudinal studies of RBD show strong association with LBD, so there is potential for early identification of LBD and subsequent management. We aimed to screen 100% of patients referred to Trafford MATS for RBD.

Methods

We performed three Plan-Do-Study-Act (PDSA) cycles; in the first cycle we introduced a validated RBD screening question, from the DIAMOND-Lewy study, to the initial memory assessment proforma. This asked ‘Have you ever been told that you “act out your dreams” while sleeping (punched or flailed arms in the air, shouted or screamed)?’

In the second PDSA cycle, we delivered a RBD and LBD educational package to the specialist memory nurses who undertake the initial assessments. In the third PDSA cycle reminders were sent to the team to use the new assessment proforma.

We collated data from patients who had undergone an initial memory assessment between 06/04/21-22/06/21 from the trusts electronic database.

Results

Initial baseline data showed that 0% of initial assessments screened for RBD; at the end of PDSA one this was 100% and 75% at the end of PDSA two. This increased to 100% at the end of the last PDSA cycle. The main reason for non-completion of the screening question was use of the old proforma.

4/152 patients screened positive; patients were diagnosed with Alzheimer’s disease, delirium, vascular dementia and mixed Alzheimer’s disease and vascular dementia, respectively.

Conclusion

The introduction of a RBD screening question into the MATS initial assessment proforma improved screening for RBD. We think the variation in screening compliance rates was likely due to practitioners using old assessment proformas, hence sending reminders of the new proforma.

A limitation of the project was that some patients did not have a bed partner, which makes identification of the disorder more difficult.

Since the completion of the project, we have circulated a news bulletin through the Dementia United charity to raise awareness of our QI project nationally and also discussed the project with the Lewy Body society. Whilst our project has not yet identified a patient with LBD, we feel that introducing this screening question is a very easy and reproducible change to implement and RBD should be screened for in all memory patients.

1.1.60 Developing Inpatient Management Strategies for Behavioural and Psychological Symptoms of Dementia (DIMS-BPSD)

Jennifer Parker Ryan Beazley Stephen De Souza*Presenting author.

date

2022-06

Abstract

Aims

This project details the development of a Quality Improvement Project aiming to review and improve the management of behavioural and psychological symptoms of dementia (BPSD) on an old age psychiatry ward. BPSD refers to a constellation of non-cognitive symptoms and signs which arise in people with dementia, including disturbed perception, thought content, mood or behaviour. Examples include agitation, depression, apathy, repetitive questioning, psychosis, aggression, sleep problems, and socially inappropriate behaviours. BPSD arise in 5/6 of people with dementia over the course of their illness and are associated with a deterioration in cognition and progression in dementia plus secondary harms such as falls and hospitalisation. Pyrland Two ward is a mixed gender specialised organic old age psychiatry inpatient unit serving the county of Somerset. Most patients have a diagnosis of dementia, are being cared for using either MHA or MCA legislation and exhibit one or more BPSD. There was no structured or formalised approach to the management of BPSD at inception.

Methods

A point-in-time audit was conducted to produce baseline measurements of BPSD management on the ward, measured against NICE criteria. Plan-Do-Study-Act (PDSA) methodology was employed to incorporate incremental quality improvement interventions such as a ward-round checklist and staff education.

Results

Baseline: (n = 14) 4/14 formally diagnosed with BPSD. 6/14 were prescribed antipsychotic medications, of which 1/6 fully met NICE standards. 2/14 had structured assessment tools used. Results following introduction of improvement methods: (n = 8) 8/8 formally diagnosed with BPSD. 7/8 were prescribed antipsychotic medications, of which 4/7 fully met NICE standards. 7/8 had structured assessment tools used.

Conclusion

It was possible to see modest improvements in the ward-based management of BPSD using quality improvement methodology, including more favourable psychotropic prescribing. However, total patient numbers are small and further interventions, such as more PDSA cycles, may add value and encourage sustainability.

1.1.61 Training Non-Medical Staff for SARS-CoV-2 Swab Collection on a Psychiatric Old Age Ward

Joanna Legg Sophie Ouabbou Susan Hay*Presenting author.

date

2022-06

Abstract**Aims**

In the second half of 2020 patients admitted to Highgate Mental Health Centre had to isolate in their rooms until a negative SARS-CoV-2 test result was obtained. This was stressful for both patients, who were unwell in their mental state, and staff. Swabs for PCR testing were only being collected by junior doctors which meant that out of hours, this responsibility would fall exclusively upon the duty doctor. There were often significant delays to obtain a sample. We decided to train non-medical staff on an old age ward so that the responsibility of collecting samples could be shared with nurses and healthcare assistants.

Methods

In November 2020 we held one training session with several members of staff from our ward. In the following days we did one to one training sessions with the members of staff who, due to their shifts, were not available for the original training session. We excluded admissions that happened prior to SARS-CoV-2 being mandatory, those where the patient refused to be swabbed, and those patients who were transferred from another institution already with a pre-admission swab.

Results

There were 37 admissions, of which we included 30 based on the exclusion criteria. 17 admissions occurred prior to training and 13 after the training sessions. Prior to training, it took 1.059 days to obtain a sample and it took 0.846 days after the training sessions.

Conclusion

Providing a training session to enable nurses and healthcare assistants to take samples for SARS-CoV-2 testing reduced the amount of time between admission and obtaining a swab sample. We therefore shortened the first step of the process that leads to obtaining a negative result and enable a patient to come out of isolation.

1.1.62 Improving Access and Confidence in Learning Lessons From Serious Incidents: A Quality Improvement Project Aimed at Junior Doctors

Cornelia Beyers Eleanor Parkinson Rajendra Harsh Sameer Nardeosingh Dolapo Oseji Alice Packham Nick Conway Renarta Rowe Ruth Scally Joshua Rochelle-Bates Onaiza Awais Farhaana Surti*Presenting author.

date

2022-06

Abstract

Aims

Birmingham and Solihull Mental Health Foundation Trust (BSMHFT) previously developed some methods of learning lessons following serious incidents. However, despite various systems available, frontline junior doctors were not regularly exposed to important learning opportunities. This potentially resulted in doctors not being aware of learning from serious incidents, and not feeling embedded within the organisation, with potential effects on their training experience. As we identified an unmet need within the Trust in learning lessons from serious incidents amongst junior doctors, we aimed to improve access and confidence in learning from serious incidents by starting a Quality Improvement project on this theme.

Methods

The current approach involved a comprehensive quarterly bulletin circulated by email to staff. An initial survey confirmed that this was not very effective in delivering learning lessons information to junior doctors.

Using a QI driver diagram, we identified potential areas for change. Selected change ideas were sequentially trialled including shortened email bulletins, supervision templates and remote learning lessons sessions. Initial PDSAs highlighted difficulties with communication via email, with many trainees failing to read/engage with this format.

Results

The use of remote interactive learning sessions yielded positive results, with improvement in the confidence in learning from Serious incidents. We therefore continued to refine this method to wider groups.

During the COVID-19 pandemic we experienced multiple setbacks and created a timeline to support team morale, maintain team energy, visualise progress and motivate the team. We therefore managed to persevere and strengthened the group by recruiting members to the team and complete the project.

Conclusion

The team have been able to create a sustainable, effective and interactive short teaching session which has shown to be effective in engaging trainees in this vital area and help us meet our aim. This format further has the potential to be refined and implemented locally and nationally.

1.1.63 Safety of Delivering Eating Disorders Day Treatment Programme on the Virtual Platform in (COVID-19) Pandemic

Adaora Obiekezie Claudia Friel Mohammad Tayeem Pathan*Presenting author.

date

2022-06

Abstract

Aims

Intensive treatment for eating disorders include day treatment programme and specialist inpatient. COVID-19 pandemic led to lockdown in the UK on the 23rd March 2020. Adult Eating Disorders Day Treatment Programme in Surrey started delivering their care on the virtual platform from that date. It offered a combination of ‘virtual’ only and ‘blended’ care (virtual and in person) for more than a year. This service evaluation examined the safety of delivering intensive eating disorders treatment on the virtual platform.

Methods

Data from March 2020 to March 2021 were retrospectively collected from Electronic patient record. Two clinicians collected the data on age, referral origin, accommodation, employment status, diagnosis (subtype), length of illness, comorbid mental and physical health diagnosis, duration of day care treatment, medication, admission weight and BMI, discharge weight and BMI, changes in bloods and ECG, acute hospital admission, risk-to-self events, admissions to Specialist Eating Disorders Unit and reasons for discharge.

Results

Data indicated that 21 patients were admitted in day treatment programme over 1 year period. 10 patients had solely virtual treatment and 11 patients had blended day treatment programme. 11 patients had anorexia nervosa restrictive subtype, 5 patients had Anorexia Binge purge subtype and 5 patients had Anorexia Nervosa, Unspecified.

Average length of illness was 4.49 years. Mean age for the group was 24.7 years and most patients lived with family (n 18) and were unemployed (n 11). More than 2/3rd (76%) patients had comorbid mental health diagnosis and 48% (n 10) had comorbid physical health diagnosis.

Average length of admission was 5.26 months. Mean BMI on admission was 15.3 (Range 12–19) and mean BMI on discharge was 16.9 (Range 13.65–22).

Safety and outcome data indicated that there were no serious incidents recorded in that time period. 1 (5%) patients required admission to acute hospital as their physical health deteriorated. 8 (38%) patients required specialist inpatient admission as the day care did not affect any changes to their eating behaviours, and 4 (19%) patients had events indicating self harm episodes(19%).

Conclusion

Our service evaluation data indicated that it is relatively safe to deliver day treatment programme on the virtual platform. Weekly face to face physical health monitoring (weight, BP, Pulse, temperature) and regular physical health investigations (Blood tests and ECG) were integral part of managing risks to health. On the other hand, delivering day treatment programme on the virtual platform has enabled the day treatment programme to prevent any significant outbreak of COVID-19 in a vulnerable group of patients and allowed them to receive uninterrupted support during pandemic.

1.1.64 Timeliness and Quality of Response to Referrals Received by a Psychiatry Liaison Service for Older Adults During a Pandemic

Nirja Beehuspoteea Robyn-Jenia Wilcha Amelia Edwards Agnes Mbazira*Presenting author.

date

2022-06

Abstract

Aims

To improve timeliness of response and provide a committed plan to referrals received by the liaison service for older adults in Croydon University Hospital. Background: A quality improvement project in 2019 aimed to evaluate effectiveness of the liaison referral pathway. A questionnaire distributed to ward staff revealed some comments regarding 'non-committal advice' given by the liaison team.

Methods

Data were collected from 44 referrals received by the liaison team in June 2021. Variables included referral date, reason for referral, date of first assessment, plan documented in the notes, date and details of committed plan of action.

Multi-disciplinary team (MDT) discussion identified that more committed advice could be provided by the following, which were implemented at the start of September 2021. Huddle at the start of each day to triage and allocate referrals to appropriate members of MDT. Prompt discussions with senior members of the team following assessment to discuss diagnosis and management. Team teaching sessions were organised once a week, in the form of case-based discussions and role play, to improve communication skills, confidence and history-taking. Data were then collected from 48 referrals received in September and October 2021.

Results

Of the 44 patients in June, average time taken from point of referral to assessment was 1.27 days and to providing a concrete plan 1.80 days.

Of the 48 patients between end of September and October, average time to assessment was 1.31 days and to providing a concrete plan 1.88 days.

In June, 75% of patients were seen on same day or within one day and 50% had a concrete plan within one day.

In September/October, 65% of patients were seen on same day or within one day and 52% had a concrete plan within one day.

Conclusion

These results highlight that assessments by older adult liaison service require detailed collateral history, investigations and MDT discussions.

While ‘obtain collateral history’ may not seem as committed a plan as prescribing medication, it remains an important part of old age psychiatry.

Given the rapid turnover of patients and increased pressures during the pandemic, it is the responsibility of the liaison team to communicate effectively with the wards and offer a timeline for completion of plan.

Following above changes, another questionnaire has been sent to request feedback on effectiveness of the liaison team.

pmc This second edition book reviews significant changes to the Mental Capacity Act (MCA) and readily accomplishes its aim to help clinicians in their daily practice. It is a short book of seven chapters and 120 pages and is written in an engaging style, being expertly presented with the use of sub-headings and crafted case studies, and avoiding large tracts of boring text.

Although all chapters are pertinent, the chapters on assessment of capacity and best interests stand out. Sage advice and clarity in breaking down the constituents of the capacity assessment elucidate the intricacies of assessing capacity that can be taken for granted at times in the hurly burly of clinical work. The best interests chapter updates the reader on the plethora of Court of Protection case law that has emerged and how the person's wishes have become central to the process.

An overview of Deprivation of Liberty Safeguards (DOLS) describes how issues with their use nationally provoked their reform and the subsequent development of Liberty Protection Safeguards (LPS), due to take the place of DOLS in autumn 2020. The chapter reviewing LPS provides a great starting point for understanding their practical use, although we await the associated Code of Practice to further flesh this out. Helpful chapters specifically address MCA use in the acute hospital (cleverly based on one sequential case study looking at realistic scenarios) and social care settings. My favourite chapter was the final one, which considers clinical ambiguities in the assessment of capacity which can often be clinically vexing, e.g. patient ambivalence, fluctuating capacity, unusual values/belief systems, self-harm, and consent and refusal of treatment.

This is a book for the jobbing clinician of all specialties, not just mental health. It provides a succinct yet comprehensive review that all healthcare professionals can benefit from. For students – both medical and nursing – this should be a required text. My only suggested improvement would have been to include a section on how the reader can access online MCA resources to help them keep abreast of developments. I hope the learned authors of this book continue to provide future editions as MCA case law evolves, including the inevitable future emergent case law, à la DOLS, from the introduction of LPS.

pmc *Nutt Uncut* is a profile of psychopharmacology and healthcare policy development as much as an autobiography of Professor David Nutt. Regarding his desire to inform the public about the risks of psychoactive substances (legal and illegal), he has had the courage of his convictions to persevere with work in the field and to provide answers founded on research evidence.

Early in Nutt's career, anti-vivisection activists bombed his workplace and he was 'put under the protection of the anti-terrorism police'. In 2009, he was sacked as chair of the UK's Advisory Council on the Misuse of Drugs, a statutory public body. The affair attracted widespread media attention. Nutt also described how the Cabinet Office deleted a chapter on the harm caused by alcohol from an independent report that it had commissioned and to which he had contributed. The Cabinet Office had taken advice from the drinks industry, a striking conflict of interest. Political, economic and vote-driven prejudices could supplant the best scientific evidence in policy-making. Nutt has encountered many other hurdles in his work. When planning to investigate the therapeutic effects of magic mushrooms (psilocybin) on depression, challenges included gaining research ethics committee approval, then obtaining the illegal drugs legally.

Politicians' substance misuse mantra seems to be 'once illegal, always illegal'. No drug has been removed from those listed as controlled substances in the Misuse of Drugs Act 1971, despite more recent research on relative harms. The Psychoactive Substances Act 2016, which Nutt designated 'the most repressive piece of legislation in the UK for 400 years', likewise marginalised risks. Misinformed international drug policy can also have untoward consequences: when the United Nations allowed police forces to seize the precursor of ecstasy, it resulted in black market trading of more hazardous alternatives.

Nutt's book achieves his goals, to 'put into the public domain, in non-specialist terms, the truth about psychiatric disorders and their treatments' and to counter 'extreme and unfounded claims' about drugs. It is also an absorbing read for clinicians who want to brush up on their psychopharmacology and to appreciate better the convoluted paths of government health policy decision-making.

1.2 2021

1.2.1 The effects of COVID-19 on self-harm in UK prisons

Thomas Hewson Russell Green Andrew Shepherd Jake Hard Jennifer Shaw

Correspondence

Dr Thomas Hewson

(tomhewson@doctors.org.uk)

date

2020-7-16

Abstract

Self-harm is a major international public health concern and is especially prevalent among prisoners. In this editorial, we explore recent trends in prisoner self-harm during the coronavirus lockdown, and consider strategies for improving the prevention and management of self-harm in prisons as we emerge from the pandemic.

Contents

- *The effects of COVID-19 on self-harm in UK prisons*
 - *Declaration of interest*
 - * *Supplementary material*

The frequency and severity of self-harm have been increasing within UK prisons over recent years, with rates far exceeding those observed in the general population.¹ We postulated that the coronavirus pandemic could adversely affect the mental health of prisoners and further increase rates of self-harm, given the rapid changes and reductions to prison regimes and the negative psychological effects of quarantine.² However, internal reports from Safer Custody Units in 31 prisons where healthcare is provided by CareUK (R. Green, personal communication, 2020) have revealed fewer implementations of ACCT (assessment, care in custody and teamwork) processes since lockdown; these processes initiate care plans for prisoners at risk of self-harm or suicide. Across the 31 prisons, there were 1079 ACCTs implemented in February 2020, compared with 828 in April 2020, a relative reduction of just under 25%. Furthermore, a closer analysis of eight of these prisons revealed overall reductions in recorded incidents of self-harm, decreasing by a third from 324 in February 2020 to 214 in April 2020. There are many possible reasons for these apparent reductions, with important lessons to be learned.

The accurate recording and maintenance of ACCT processes is a legal requirement stipulated in Prison Service Instructions,³ supporting the reliability of the above figures. However, minor acts of self-harm may be more likely to be missed or unrecorded during the pandemic owing to potentially reduced face-to-face contact with prisoners and staffing issues. There have been national reports of fewer Accident & Emergency attendances for various health problems,⁴ raising the possibility that prisoners have similarly been less likely to seek healthcare interventions for self-harm throughout the lockdown. A reduction in ACCTs is also not synonymous with reductions in self-harming behaviour, as multiple factors, including staff discretion, affect ACCT implementation; furthermore, Humber et al found that ACCTs were more likely to be opened following identification of risk factors for self-harm or suicide, rather than following an act of self-harming behaviour.⁵ The data are, however, mirrored by internal reports of recent reductions in prison violence and referrals to mental health teams, as well as fewer calls to see prisoners already known to mental health services (R. Green, personal communication, 2020). These data may not be representative of all prisons, owing to individual differences between establishments, but those included encompassed all security levels and prisoners of varying age, gender and sentence type.

Assuming that self-harm rates have dropped, why might that be and what can we learn for future self-harm risk management? First, although numerous negative psychological consequences are associated with confinement and social isolation,² spending increased time in cells has probably reduced prisoners' exposure to negative and intimidating behaviours, such as bullying, threats and violence from other inmates. This could increase their overall sense of safety and security. Previously, prisoners may have resorted to self-harm to express their safety concerns, occasionally using this behaviour as a last-resort measure to seek transfer to segregation or another prison.⁶ Furthermore, conflicts with other inmates can cause significant emotional distress, and the most frequently cited reason for self-harm is emotional dysregulation.⁷ Prisoners may be less likely to experience such tensions in the context of reduced peer contact.

Anecdotally, drug use has recently decreased within prisons, probably owing to suspension of prison visits and enhanced difficulties in trafficking illicit substances into custodial settings. There are multiple links between drug use and self-harm, although it is difficult to establish causality.⁸ For example, prisoners may harm themselves while intoxicated because they have less conscious control of their actions, or while withdrawing because of unpleasant physical symptoms. Substance misuse is linked to the aetiology, perpetuation and relapse of various mental disorders, including psychosis, which are associated with increased rates of self-harm and violence. Stress, anxiety and depression may be induced by problems such as accumulation of debt, extortion and violence arising from drug use.⁸ Prisoners may self-harm to communicate distress about these difficulties or to seek escape from them.

The anticipated negative influence of coronavirus on prisoners' mental health may have encouraged a more pro-active approach among all staff to identify and support prisoners at risk of mental distress. This could have resulted in timely interventions before symptoms escalated to involve self-harm or require high-level input, potentially explaining the apparent decreased number of ACCTs and referrals to mental health teams. Although there have been staffing

shortages due to COVID-19, staff who are present may have more time for one-to-one conversation with prisoners, owing to fewer violent incidents and group activities requiring their attention. Staff morale may also be higher owing to greater public recognition of ‘key workers’, which could improve the quality of their interactions with inmates. Furthermore, prisoners may feel more valued, having witnessed various measures being implemented to protect their health. Increased societal cohesion has been observed during prior public health crises, with less differentiation between societal groups and more focus on ‘coming together’ and responding collectively to tackle emergent issues;⁹ anecdotally, this same cohesion has been observed within prisons. Prisoners may also feel better connected to wider society owing to increased communication about external affairs throughout the pandemic. Feeling part of a group is associated with increased self-esteem; particularly among young people, self-harm can be used to achieve a sense of belonging when this is felt to be lacking.⁷

The pandemic has created more of a ‘level playing field’ within prisons, as many of the previously extended rewards for good behaviour are no longer feasible for reasons of infection control, whereas others, such as telephone access, have been made more widely available to increase support for all prisoners during the crisis. This is likely to have reduced feelings of injustice and inequity among prisoners, which can sometimes fuel mental distress and make institutional adjustment more difficult. It could be argued that increasing access to such privileges helps to improve mental well-being; furthermore, it may increase prisoners’ sense of self-worth, an important factor related to self-harm, as those who previously enjoyed fewer rewards may have felt inferior to fellow inmates.

Although prison visits are temporarily suspended, approximately half of English and Welsh prisons have provided secure phone handsets to risk-assessed prisoners,¹⁰ and some have been trialling virtual family conversations through video platforms; therefore, contact with family and friends may have actually increased for some prisoners, albeit through electronic methods. Such contact can provide much-needed emotional support and act as a protective factor against suicide and self-harm. Increased communication may also alleviate concerns about loved ones and make prisoners feel better connected to outside society. However, the effects of this may vary, and prisoners at the greatest risk of suicide and self-harm, particularly those with serious mental health problems, are more likely to be alienated from support networks; contact with family and friends may be unchanged for these individuals.

Interestingly, suicide rates among the general population have initially dropped during the immediate aftermath of prior national disasters.¹¹ This has been attributed to evolving social connectedness and a renewed sense of vigour and purpose, which may shift a person’s focus to surviving. Worryingly, this has previously often represented a ‘honeymoon period’, with subsequent increases in suicidality among the general population;¹¹ the same may occur with rates of prisoner self-harm. Although there are several possible reasons self-harm may have recently decreased in prisons, there are also multiple mechanisms by which COVID-19 could have profound negative effects on prisoners’ mental health. It is likely that prisons will maintain current reverse cohorting and shielding measures for some time; this is essential to protect against ‘explosive outbreaks’ of the virus, but it further heightens the need for vigilant monitoring of mental well-being, given that prolonged quarantine is associated with poorer psychological outcomes.² Reasons for engaging in self-harm vary widely between prisoners, and changes to prison regimes will likely affect different prisoners differently, depending on individual coping styles, personalities and the presence of pre-existing mental health problems. Prisons must be mindful of these differences and potential future challenges to pre-emptively plan strategies for preventing and treating any future increase in suicidal and self-harming behaviours. Potential difficulties could arise if social distancing measures are eased more quickly in wider society, as this dissonance could reduce prisoners’ sense of ‘social connectedness’ with outside communities and worsen feelings of isolation. Where possible, prisons should coordinate their pandemic responses with external society, ensuring clear communication to prisoners throughout the process.

Multiple measures already exist within prisons to prevent and effectively manage self-harm; examples include ACCT processes, mental health screening and support services, peer support schemes such as ‘Listeners’, and various initiatives for promoting staff understanding of self-harm and positive prisoner–staff relationships.^{12,13} Assuming that the recent reductions in recorded incidents of self-harm and initiations of ACCT processes equate with actual reductions in self-harm in prisons, we must consider what can be learned from the pandemic to improve prisoner safety post COVID-19. The data highlight a need for mental health to be addressed in the prison as a ‘social whole’, with an enhanced focus on preventive social measures to reduce self-harm and creating therapeutic environments; the importance of a whole-prison approach, and of environmental stressors, has been identified previously.^{12,13} A recent rapid evidence assessment identified a lack of research on protective factors for self-harm in prisons;¹³ consequently, researchers, prison staff and inmates need to work together to identify factors helping to reduce self-harm in recent months and how these could be

sustained in the future. For example, prisons could consider continuing increased provision of certain ‘privileges’, such as telephone and video communications with external support networks, and must continue implementing strategies to reduce bullying, violence and substance misuse. The increased forms of communication available to prisoners and methods for facilitating in-cell activities should also continue post COVID-19. Importantly, staff must remain alert to any potential future deteriorations in mental health and increases in self-harm throughout the pandemic, ensuring that the negative psychological effects of quarantine are reduced wherever possible, while protection from coronavirus is maintained.

1.2.2 Model for ethical triaging of electroconvulsive therapy patients during the COVID-19 pandemic

Abstract

Electroconvulsive therapy (ECT) is an essential treatment for severe mental illnesses such as depression with suicidality and catatonia. However, its availability is being threatened by resource limitations and infection concerns due to the COVID-19 pandemic. This may necessitate the triage of patients for ECT but there is no established ethical framework to prioritise patients. We offer an application of an ethical framework for use of scarce medical resources in the ECT setting.

Electroconvulsive therapy (ECT) is the most effective acute treatment for severe depression.¹ It is also effective in reducing psychotic symptoms in treatment-resistant schizophrenia and in treating mania and catatonia. The National Institute for Health and Care Excellence (NICE) treatment guidelines for ECT² and the Royal College of Psychiatrists' position statement on ECT³ state that ECT should be a first-line treatment where rapid response is required because of high suicide risk, poor oral intake or other conditions where the patient's physical health is at risk. These guidelines also state that valid informed consent should be obtained without pressure or coercion, in the context of significant stigma, discrimination and controversy associated with the treatment.² A substitute decision maker should be available to patients lacking capacity to give consent, as there is increasing evidence that patients lacking capacity have equivalent⁴ to superior responses⁵ to ECT compared with capacitous patients. Despite its impressive effectiveness and broad spectrum of effect, ECT has experienced at least 20 years of decreasing in-patient use in the USA. In 2017 a study reported that only 1 in 10 US hospitals offered ECT and only 1.5% of severely depressed in-patients received ECT,⁶ the most effective treatment for severe depression. These trends are also evident in the UK and Ireland.⁷ Furthermore, the use of ECT is controversial and has its detractors and some consider it unacceptable in modern psychiatry.⁸

With the COVID-19 pandemic, ECT challenges have compounded from a problem of getting patients to accept ECT to an additional challenge of struggling to continue providing ECT for existing patients. Already scarce ECT resources have been further reduced by lack of personal protective equipment (PPE), restriction of anaesthesia and limited institutional support.⁹ The International Society of ECT and Neurostimulation (ISEN) has published a position statement on ECT during COVID-19 which includes classifying cases into elective, urgent/essential and emergency and suggests triaging patients to reduce demand for ECT.¹⁰ This recommendation to triage patients is a relatively novel situation for many ECT practitioners, who are more accustomed to a 'first come, first served' situation in routine ECT practice. We suggest a useful ethical model that can be used in conjunction with existing ethical frameworks to assist ECT practitioners to take a consistent approach to triaging patients for ECT, rather than relying on individual institutional norms

or clinician intuition.

General medical ethics applied to ECT

A commonly accepted framework for medical ethics uses the ‘Georgetown principles’ of beneficence, non-maleficence, autonomy and justice. Ottosson & Fink¹¹ suggest the following ECT-specific considerations for each principle.

Beneficence

The highest priority for ECT should be patients who would gain the most potential benefit from the treatment (e.g. those with psychoses and involuntarily committed or with depression with high suicidality), have the potential for fast response (e.g. catatonia) and have the highest risk to life or long-term disability.

Non-maleficence

Given that mortality with ECT is lower than overall mortality associated with general anaesthesia,¹² and lower than if the patient had not received ECT,¹³ the main side-effect of concern is cognitive impairment. However, the cognitive impairment is often transient, lasting for a shorter period than the therapeutic effect of ECT and can be minimised using empirically derived dosing of ECT.¹⁴

Autonomy

ECT ideally should be administered with the patient’s consent. However, no patient should be denied ECT just because they lack capacity to consent to treatment. Ottosson & Fink make a distinction between weak paternalism in the patient’s best interests and authoritarianism that discounts the patient’s autonomy. Prescribing ECT with a substitute decision-making process or in patient’s best interests is increasingly supported by recent evidence of equivalent to superior outcomes in patients lacking capacity to consent to ECT.⁵

Justice

There are three broad forms of distributive justice: egalitarian (equal access), libertarian (the right to social and economic liberty) and utilitarian (maximise public utility). During a time of limited resources, Emanuel *et al*¹⁵ argue that a utilitarian approach is the most appropriate, i.e. emphasising population outcomes by triaging patients who are most likely to respond and derive the most benefit from ECT with the least risk of harm to the patients and the ECT team. This could even mean pausing ECT for a patient with low utilitarian potential in order to start ECT for a patient with high utilitarian value.

For the purposes of this discussion, the context is that of a predominantly public or taxpayer-funded healthcare system rather than one that is predominantly insurance or self-funded. The former system is more likely to face the problems of scarce resources requiring healthcare rationing¹⁶ and the libertarian aspects of justice may be less dominant.

What has changed for ECT during COVID-19?

Beyond decreased ECT availability, there are at least five other factors to take into account when considering ECT during COVID-19: disruption of routine care delivery during the crisis, leading to increased risk of harm to patients' health; increased risk of patients getting COVID-19 owing to lack of ECT (e.g. delayed discharge from hospital while their illness resolves more slowly and higher vulnerability to COVID-19 among severely mentally ill patients⁹); increased risk of patients getting COVID-19 while attending for ECT (e.g. repeated out-patient appointments for ECT, requiring patients to travel more frequently); increased risk to the team delivering ECT, due to the higher risk of infection from patients receiving general anaesthesia and potential aerosolisation of patients' respiratory material; utilisation of highly skilled staff during a time of scarcity, in particular the services of anaesthetists, who could otherwise be redeployed running intensive treatment units (ITUs).

How should we ethically triage ECT patients during COVID-19?

Emanuel et al¹⁵ provide a four-point framework to guide rationing of scarce healthcare resources during COVID-19: (a) maximise benefits; (b) treat people equally; (c) promote and reward instrumental value; and (d) give priority to the worst off.

Maximising benefits is achieved by prioritising limited resources for saving the most lives and with maximal improvement in patients' lives after treatment. Treating people equally refers to not letting a patient's financial resources or status affect treatment allocation. Promoting and rewarding instrumental value is giving priority to those who can save or have saved others. Lastly, giving priority to the worst off could be interpreted as giving priority to the sickest or to younger people, who would have lived the shortest lives if untreated. *Table 1* lists Emanuel et al's principles, with a column added describing how they could be applied to an ECT setting. *Table 1* Ethical values to guide rationing of scarce healthcare resources in the COVID-19 pandemic, adapted for electroconvulsive therapy (ECT)

Ethical values and guiding principles	Application to COVID-19 pandemic	Specific ECT applications
Maximise benefits	Save the most lives	Receives the highest priority
Treat people equally	First come, first served	Used for selecting among patients with similar prognosis
Promote and reward instrumental value (benefit to others)	Prioritise in-patients with severe psychotic depression, lethal catatonia, neuroleptic malignant syndrome, manic delirium	Prioritise patients with severe psychotic depression, lethal catatonia, neuroleptic malignant syndrome, manic delirium
Give priority to the worst off	Sickest first	Used when it aligns with maximising benefits
	Youngest first	Used when it aligns with maximising benefits such as preventing spread of the virus ¹

Deprioritise patients with predictors of poorer outcome to ECT (e.g. personality disorder, depression that is more chronic or treatment resistant, without suicidality or dangerousness)

Deprioritise patients with high medical risk during ECT

Deprioritise patients who must expose themselves to greater risk of COVID-19 infection to access ECT (e.g. living far from the ECT facility)

Give higher-dose ECT and avoid milder ECT modalities, to minimise number of sessions and patient and staff risk of exposure to COVID-19

Save the most life-years – maximise prognosis

Receives the highest priority

Treat people equally

First come, first served

Should not be used

Use random allocation to prioritise patients with similar prognosis

Random selection

Used for selecting among patients with similar prognosis

Promote and reward instrumental value (benefit to others)

Retrospective – priority to those who have made relevant contributions

Gives priority to research participants and healthcare workers when other factors, such as maximising benefits, are equal

Prioritise patients who are healthcare workers or work in essential services

Deprioritise patients who pose a higher risk of infecting the ECT team, to conserve ECT resources

Prospective – priority to those who are likely to make relevant contributions

Gives priority to healthcare workers

Give priority to the worst off

Sickest first

Used when it aligns with maximising benefits

Prioritise younger pre-morbidly well patients with acute onset of an ECT-responsive psychiatric disorder

Youngest first

Used when it aligns with maximising benefits such as preventing spread of the virus¹

¹

Based on Emanuel et al's four-point framework.¹³

Applying these principles to clinical scenarios

Applying Emanuel et al's principles and the ECT-specific considerations outlined above, a high-priority patient might be a young healthcare worker in your healthcare institution with no psychiatric history and admitted for an acute onset of psychotic depression, catatonic symptoms and a serious suicide attempt, whose family is supportive of ECT. Two clinical scenarios are presented for further discussion.

Scenario 1

A 33-year-old labourer with a long history of well-controlled schizophrenia is brought to the psychiatric emergency room with symptoms suggestive of acute onset of stuporous catatonia (mutism, negativism, posturing) and poor oral intake for 2 weeks. His BMI is 16, he is clinically dehydrated and his blood pressure is borderline hypotensive. Although he has no clear symptoms of COVID-19, he lives in a large accommodation facility with dozens of people who have tested positive for COVID-19. The facility already follows recommended infection control procedures and screening, instituted several weeks before this presentation.

This is a challenging clinical scenario where there is a psychiatric emergency (catatonia with poor oral intake) that is highly responsive to ECT, but in a patient with a primary psychiatric condition (schizophrenia) that may not be indicated for ECT as a first-line treatment and moderate to high risk of having COVID-19. Using the proposed ethical framework below, the patient's youth and catatonia would satisfy the principles of 'maximising benefits' and 'giving priority to the worst off', but it would be contrary to the principle of 'promoting and rewarding instrumental value', as treating the patient would expose the ECT team and other patients to a significant risk of getting COVID-19, especially if the ECT unit is not fully prepared to deal with suspected or positive COVID-19 patients.

As with many ethical scenarios, the initial approach to resolution would be a medical solution. If the patient's catatonia responds to high-dose benzodiazepines (e.g. lorazepam), then there would be no need to consider the use of ECT. If benzodiazepine treatment failed, a negative result on polymerase chain reaction testing for COVID-19, the lack of other patients requiring ECT and the availability of specialised treatment facilities (e.g. negative-pressure rooms) might mitigate the risk of infection of ECT team members and allow ECT to proceed in an ethical fashion.

Scenario 2

Another challenging scenario is that of a 67-year-old woman who is admitted to a psychiatric ward for the in-patient treatment of major depressive disorder with acute suicidality. She also has a history of borderline personality disorder, comorbid generalised anxiety disorder and panic disorder and has not previously experienced much response to full courses of psychotherapy and adequate pharmacotherapy. She consented to a course of ECT and had already received five sessions before a fellow ward patient was diagnosed with COVID-19. The entire ward is quarantined as a result. The patient is keen to continue her ECT course as she has not yet felt any improvement and other treatment options have been relatively ineffective.

This scenario has a patient with both positive (depression, older age) and negative (history of personality disorder and anxiety) predictors for ECT response,¹⁷ no response to the first five ECT treatments and a significant risk of having presymptomatic COVID-19. The principle of 'maximizing benefits' is less clear here, as her prognosis of responding to ECT is mixed, and the principle of 'promoting and rewarding instrumental value' would discourage continued ECT, at least until she is cleared of COVID-19. The other two ethical principles, of 'treating people equally' and 'giving priority to the worst off', may be useful to help clarify the ethical position. The former might suggest that other patients in the same ward who are also receiving ECT with similar prognosis would have an equivalent claim for ECT and the

The Authors own the copyrights to the individual articles.

patient's request for continued ECT should not give her higher priority. The latter would further refine this point by considering the severity of the woman's psychiatric diagnosis and perhaps giving sicker patients priority to ECT (e.g. a patient with severe psychotic depression, who is also highly likely to respond to ECT).

What is the road forward for ethical triaging for ECT during COVID-19?

Where treatment resources are limited, fair allocation of resources requires careful consideration of all relevant ethical issues in the context of the local resources and situation. The ideal solution is to ensure adequate ECT resources, so that both high- and low-priority patients can receive high-quality ECT. This requires deliberate short- and long-term planning and negotiation for scarce resources within healthcare systems, the exploration of new ECT resources (e.g. advanced practice nurses for both anaesthesia and ECT delivery,¹⁸ dedicated ECT suites to avoid competition with surgical needs) and adequate PPE for ECT staff and patients. The current COVID-19 crisis has placed significant strain on healthcare resources for many months, and at the height of the pandemic many non-emergency non-COVID services were suspended to divert resources to deal with the COVID-19 emergency. This has resulted in a significant backlog of untreated patients, with consequent increased pressure on already scarce resources. Furthermore, as healthcare systems reorient themselves to provide routine care and begin to deal with the backlog, there remains a need to maintain social distancing and scrupulous hygiene, for instance deep cleaning operating theatres and equipment between each patient, which will reduce efficiency and capacity. For all these reasons, these pressing ethical dilemmas about how to prioritise patients must be addressed to ensure that patients with non-COVID disorders continue to have their healthcare needs met fairly and equitably in a fully accountable way. These efforts should be a priority even after the COVID-19 situation eventually resolves. Given the SARS outbreak in 2003¹⁹ and the current COVID-19 outbreak,⁹ which both caught most of the world largely unprepared, there is a strong ethical imperative to prepare for the future third coronavirus outbreak or, indeed, second or third waves of COVID-19 either locally or globally.

1.2.3 Does COVID-19 pose a challenge to the diagnoses of anxiety and depression? A psychologist's view

Lucy Johnstone

Correspondence

Lucy Johnstone

(LucyJohnstone16@blueyonder.co.uk)

date

2020-9-03

Abstract

The COVID-19 pandemic has led to predictions of a widespread mental health crisis. However, this makes little sense when fear and anxiety are so understandable in context. The individualisation and medicalisation of normal human reactions disconnects us from our feelings and from the appropriate solutions, in relation to the pandemic and more generally. We have an opportunity to challenge this pervasive way of thinking, and thus be in a position to create a fairer society that is better for everyone's emotional well-being.

- * *Supplementary material*

The COVID-19 pandemic is one of a series of interlinked global emergencies that will affect everyone on the planet.¹ But it is important to challenge the idea that, as numerous headlines are telling us, we are now facing a 'pandemic of mental health disorders'.² We are apparently due for 'an epidemic of clinical depression'.³ The Mental Health Foundation found that six out of ten people were anxious about the crisis and at risk of 'persistent and severe mental health problems'.⁴ We are exhorted to learn the lessons from China and prepare for 'a public mental health crisis'.⁵

Yet if ever there was an example of our reactions being appropriate in the circumstances, this is it. It has never been more obvious that the thoughts, feelings and behaviours we call 'mental illness' are defined in relation to social norms. Suddenly, being too scared to leave the house for fear of contracting a fatal disease, and spending most of the day washing our hands and wiping down doorknobs, are not signs of 'OCD' but of a responsible citizen. Arguably, the 'abnormal' people are now the four in ten of us whose anxiety levels have not increased. Who can say how we ought to be feeling at such a time?

Never was there a clearer illustration of the fact that judgements about who is 'mentally ill' are social not medical ones. So, where do we draw the line between 'normal' and 'abnormal'? Can such a line even be drawn? As Miranda Spencer notes in her analysis of US media responses, the messages to the public are deeply confusing: "'Becoming more anxious in response to COVID 19 would be normal if you are mentally healthy and a sign of illness if you're not, although apparently some normal people might experience so much anxiety that they, too, could now be seen as mentally ill. And [...] everyone is now to practice behaviors that in the past would be a sign that they had OCD, but now are considered reasonable... unless one goes "too far"'.⁶"

These contradictions are not new, although the pandemic has thrown them into sharp relief. They lie at the heart of

psychiatric thinking. In this article, I will discuss the implications for the diagnoses of ‘anxiety’ and ‘depression’ and by extension for all psychiatric diagnoses. I will argue that the pandemic gives us a chance to challenge, rather than reinforce, the narrative of ‘mental health/illness.’

The truth behind the headlines

First, it is worth looking behind the dramatic headlines to see whether people are in fact more distressed than before. Interestingly, this is not the general picture. A UK survey of over 74 000 people has shown that, despite an initial decline in happiness before the lockdown, well-being rose during the first 3 weeks of April 2020 and anxiety levels fell for people both with and without psychiatric diagnoses.⁷ Where increased distress has been identified, an initial survey suggests that this is occurring for very obvious reasons.⁸ Those with children at home, a pre-existing health condition, exposure to the virus, high estimates of personal risk and facing loss of income were more likely to be feeling anxious and low in mood.

As with every crisis, the impact is far greater on those who are already more vulnerable, whether through physical illness and disability, having an abusive partner, bringing up children without support or living in poverty. COVID-19 and its consequences are not hitting us all equally. In ordinary language, people with more to be exhausted, depressed and anxious about are feeling more exhausted, depressed and anxious. However, the general picture is, in the words of Shevlin et al, of a population that is ‘largely resilient.’⁸

It is also worth noting that people with a psychiatric history are not necessarily those in most distress. This is not to deny that some people are suffering greatly, especially if they suddenly find that their usual services are unavailable.⁹ But equally, it is untrue and even patronising to assume that everyone in this group will fail to cope. In fact, some have described managing better than usual, as they draw on talents for survival that the officially ‘normal’ population may lack. One person tweeted: ‘For those of us who already live with trauma or the significant impact of mental health on our daily life we are perhaps more prepared/less complaining about self isolation, surviving on low income, restrictions in movements and facing cuts in our health/social care services’. Psychiatric survivors have set up an impressive list of peer networks and resources in response to the pandemic,¹⁰ including a set of ‘lived wisdom’ strategies drawn from ‘hard won expertise learned through traversing challenging life experiences’.¹¹

‘Most of us are managing our feelings reasonably well in these difficult circumstances’ is not such an eye-catching headline, but it appears to be a more accurate one. It is also consistent with research, which shows that, although crises and disasters are painful, the vast majority, including front-line staff, will cope without needing specialist mental health support.¹²

Who is promoting the narrative – and why?

How and why is the ‘mental health pandemic’ narrative being promoted when it is contradicted by the evidence and the reality on the ground? Part of the answer may lie in the high-profile public health campaigns in schools, the media and so on, which urge us all to ‘talk about mental health’ – this mysterious, indefinable but apparently fragile state of mind – more or less constantly. We are encouraged to use the ubiquitous term ‘mental health’ as a synonym for ‘how we all feel’ in relation to any state of mind short of complete contentment. We then become legitimate targets for mass professional and technical monitoring and intervention, focused not on the real-life situations that evoke our reactions, but on the newly defined ‘mental health problems’ themselves. Moreover, while it is still generally believed that only a minority of us is ‘mentally ill’, the new discourse reminds us that ‘we all have mental health’. This apparently innocuous, indeed nonsensical, phrase draws us all into the realm of surveillance and potential ‘treatment’. The trend is as much of a global epidemic as the coronavirus, and just as hard to counter. But the idea that we are facing two simultaneous pandemics – a physical health one and, by a tragic coincidence, a ‘mental health’ one too – simply makes no sense at all.

To give a relatively benign example of how this plays out in practice, Public Health England has promoted a commendable message of ‘It is normal to feel anxious in a crisis’ and has suggested a range of common-sense strategies and supports. However, the campaign headline urges us to ‘look after our mental health’.¹³ The phrase immediately pulls us back into an individualising, subtly pathologising narrative that evokes not collective resilience and resourcefulness, but anxiety about how easily we might become unable to cope.

A more concerning example comes from an article in *The Lancet Psychiatry*.¹⁴ It sets the scene by predicting an increase in ‘anxiety, depression, self-harm, and suicide’, along with warnings that quarantine and isolation also raise the risk for substance misuse, gambling and so on. This is used to justify a call to fund a major international research programme of ‘paramount importance’ and ‘urgent need’. Demonstrating a bizarre disconnect between the very real social ills that are likely to result from the pandemic (‘the potential fallout of an economic downturn [...] increasing unemployment, financial insecurity and poverty’, etc.) and the suggested remedies, the article lays out a vision of monitoring the entire population for ‘causal mechanisms associated with poor mental health’. Those who lack the required ‘digital resources’ to permit this unprecedented intrusion into their personal lives through ‘digital phenotyping [...] to ascertain early warning signs for mental ill-health’ will be pursued through telephone calls. Even if people manage to avoid exhibiting the digital markers of unacceptable levels of (say) loneliness, they will still come under pressure to adopt ‘a mentally healthy life’ supported by ‘mechanised interventions’, once such a concept has been ‘mapped out’ in one of the many putative research studies. Expert-defined and delivered training in ‘elicit[ing] community support’, exhibiting ‘altruism and prosocial behaviour’ and other desirable qualities that have been systematically eroded by austerity and a neoliberal agenda over the past 40 or so years will then be available.

In fact, people have been spontaneously forming self-help communities across the country without waiting for an app to instruct them or being required to complete a rating scale about their ‘mental health’ afterwards. This article represents a terrifying combination of opportunism and empire-building. Not a single new research study is needed to confirm that being poor, jobless, isolated, ill and bereaved makes people unhappy, or to work out the appropriate remedies.

Reframing the problem, reclaiming the discourse

There is emerging evidence for long-term neurological effects in some COVID-19 patients, and this certainly needs funding and research; but these are not ‘mental health’ problems, although often conflated with them. One of the reasons it is important to counter these dire predictions is to stem an unnecessary rush to ‘treatments’, both psychiatric and psychological. Psychiatric drugs benefit some people, but with nearly a quarter of us already being prescribed them,¹⁵ we do not need to increase the well-documented risks of dependence and withdrawal. Equally, we know that formal psychological interventions are unnecessary for most, and can actually be harmful if implemented too early.¹² In fact, the media experts have nothing specialist to recommend; with or without a psychiatric history, we are advised to keep up social connections, exercise, maintain a routine, not watch too much news and distract ourselves from gloomy thoughts.⁶

If we are not facing an outbreak of ‘anxiety disorders’ and ‘clinical depression’, but human reactions to difficult circumstances, it is time to reclaim some of the territory increasingly occupied by the ‘mental health’ discourse, and translate it back into ordinary language. Deconstructing ‘I have depression’ into ‘I feel miserable and hopeless’ makes it obvious that the first response should not necessarily be to prescribe a pill (although that might have a role) but to look for reasons for those feelings. Similarly, the statement ‘I’m worried and scared’ invites us to ask, in line with the well-known survivor slogan, not ‘What is wrong with you?’ but ‘What has happened to you?’ In the context of a pandemic, the answers are not too hard to find and the solutions are obvious, if not always easily available. In the current jargon, popular in both psychology and psychiatry, we need a formulation – a shift from ‘patient with illness’ to ‘person with problem’.¹⁶ The pandemic poses a particularly stark challenge to these diagnostic assumptions which, like an ever-mutating virus, have infected not just our mental health system but our whole society; and the Global Mental Health Movement (<https://www.mhinnovation.net/organisations/movement-global-mental-health-mgmh>) is transmitting it even further. As soon as we start assuming the existence of an entity called ‘depression’ or ‘anxiety’ – whether a medical or a psychological one – that people *have*, in the same way that they might ‘have’ a tumour, a broken leg or a viral infection, we are in trouble. As colleagues and I have argued in a recent outline of a conceptual alternative to the diagnostic model, these very real and painful experiences are better seen as what we *do* – in other words, as meaningful patterns of responses to threats.¹⁷

This applies beyond ‘anxiety disorders’ and ‘clinical depression’. Diagnostic categories are described as unscientific even by the professionals who draw them up.¹⁸ A large body of evidence (see, for example, [acestoohigh.com/research/](https://www.acestoohigh.com/research/)) tells us that the various forms of distress diagnosed as ‘psychosis’, ‘bipolar disorder’, ‘personality disorder’ and so on are causally related to experiences of trauma, abuse, neglect, loss, poverty, unemployment, discrimination and inequality. The hostile voices that some people hear often echo the words of real-life abusers. People who have been hurt and rejected may be angry and distrustful. In other words, when placed in context, these very real and agonising

experiences are also understandable responses to adversities. While it may take time for the personal story to become clear, a formulation-based approach assumes that ‘at some level, it all makes sense’.¹⁹

Collective trauma needs a collective response

If we allow psychiatric diagnoses to individualise and depoliticise our responses, we will simply revert to a way of life that, even before COVID-19, was leading many people to self-harm, despair and suicide. Instead, we need the courage to stay connected with our feelings, and the feelings of those around us, not file them away in boxes marked ‘anxiety disorders and depression’. People who have lost their jobs are likely to feel desperate, but we don’t have to describe this as ‘clinical depression’ and prescribe drugs for it. Those with backgrounds of severe trauma may find that their worst memories are being triggered, but we don’t have to describe this as a relapse of their ‘borderline personality disorder’.²⁰ The economic recession that will follow the pandemic may lead to as many suicides as austerity measures did, but we don’t have to say that ‘mental illness’ caused these deaths.

The COVID-19 pandemic is an opportunity to implement what we already know about universal human needs for social contact, financial security and sufficient material resources, protection from trauma, abuse and neglect, especially in early years, decent healthcare, and a sense of purpose and belonging. As an editorial in *The Lancet* puts it, COVID-19 is ‘overturning core values, norms, and rules that sit at the heart of long-standing market-oriented political agendas’ and presenting us with the need for ‘re-making the social contract’.²¹ It is giving us an opportunity to reduce income inequality.²² In other words, as urged by Psychologists for Social Change, we need to ‘Build back better’ so that ‘participation, community, trust and connection might be valued over status, individualism, and competition.’²³ We already know that these measures will do more to reduce fear and misery than any number of psychological or psychiatric interventions.

Psychologists use the term ‘trauma’ to describe difficult events that overwhelm our usual ways of coping. In ‘collective trauma’, there is a challenge to the lifestyle, values and identity of a whole society.²⁴ In the case of COVID-19, the crisis extends beyond national borders and, like the climate change crisis to which it is linked, raises profound questions for our whole way of life. Community action around common purposes is healing for all of us. Journalist Johann Hari, who has described his own escape from the ‘mental illness’ identity, prefers the term emotional health, not mental health. In his words: ‘This is a collective crisis and giving people exclusively individual solutions is not going to work’.²⁵ As he says, many people were already ‘in quarantine’, marginalised from society; we already had a rise in distress linked to ‘junk values’; and ‘depression and anxiety are not malfunctions. They are signals’. The real ‘antidepressants’ are financial security, human connection and having a sense of value and purpose. The real crisis is one of meaning.

The more we can challenge the ‘mental health’ narrative, the clearer our current dilemmas and future directions will become. It is not a pandemic of ‘mental health’ problems that we need to fear, but a pandemic of ‘mental health’ thinking.

1.2.4 Does coronavirus pose a challenge to the diagnoses of anxiety and depression? A view from psychiatry

Lynne M. Drummond

Lynne M. Drummond

(lynnemd@sgul.ac.uk)

date

2020-9-03

Abstract

Some authors have suggested that the emergence of the novel coronavirus, SARS-CoV-2, and the subsequent pandemic has meant that the constructs of pathological anxiety and depression are meaningless owing to widespread anxiety and depressive symptoms. This paper examines what is required to make a diagnosis of a depressive or anxiety disorder and how this may differ from fleeting symptomatology in response to specific situations or stimuli. All people experience the emotions of both anxiety and depression, but far fewer have a persistent anxiety or depressive syndrome which interferes with their quality of life and functioning. The pandemic and its issues are then discussed, and existing studies examining the reactions of people living through the pandemic are presented. Finally, the paper examines possible ways to cope at times of increased stress and how we can try to protect ourselves from long-term mental health sequelae of chronic stress.

One of the challenges of conducting studies to examine the prevalence and frequency of anxiety and depression is that these terms describe symptoms rather than a diagnosis. Everyone has experienced these as symptoms at some point in their lives. Diagnoses are made on the basis of a recognised cluster of symptoms associated with anxiety and depression. One of the difficulties is that these terms are also used in general parlance to describe short-lived emotional changes which can occur as an emotional reaction to a stimulus or event, rather than a full-blown syndrome that affects the individual's quality of life. Indeed, if we as a species did not experience anxiety responses in threatening situations, we would undoubtedly have become extinct as we walked over cliff edges, faced up to dangerous carnivores, or generally partook in dangerous and risky behaviour. Levels of anxiety and depression also vary between individuals without necessarily being pathological. For example, we will all know some members of our social circle who are thrill-seekers and attracted to danger, whereas others are much more risk averse. Similarly, some people seem to be happy and philosophical at all times, whereas others are more pessimistic and prone to feel low and miserable at the slightest upset. Overall, therefore, population studies are fraught with difficulties in accommodating this area of potential self-reporting bias. For a diagnosis of anxiety disorder or depression to be made, an individual should be experiencing a range of symptoms associated with the anxiety and depression, and the symptoms should be apparent for a period of time (not just hours or minutes but weeks or months) and sufficiently severe that they interfere with the person's ability to function fully in their home, work, social or private leisure settings. The consistency of the emotional symptoms is inherent in diagnostic instruments such as the ICD,¹ and widely different prevalence figures may be obtained in self-report questionnaires unless the same criteria are applied.

In medical and psychological parlance, stress is a physical, mental or emotional factor that causes bodily or mental tension. Stresses can be external (from the environment, psychological factors or social situations) or internal (e.g. illness). Stress, both recent and in childhood, is known to affect mental well-being. The coping ability of the individual affects whether or not stress results in deterioration of mental well-being.² Different individuals subjected to similar trauma and stress do not all react in the same way; whereas some will experience lasting symptoms, other will seem to have hardly any lasting sequelae.

Population studies examining the prevalence of anxiety and depression have demonstrated that these are among the most common conditions in diverse societies. The World Health Organization (WHO) estimated that in 2015 the prevalence of depression was 4.4% globally; however, this figure varied with gender, with women having a prevalence of 5.1% and men 3.6%. Depression also increased with age in adulthood, peaking in both genders at age 55–74 years, and varied among different countries. The lowest rate of 2.6% was found in men in the Western Pacific region, and the highest rate of 5.9% in women in the African region. These rates of depression were found to have increased by 18.4% since 2005.³ For anxiety, the prevalence was estimated to be 3.6%. As with depression, anxiety disorders are more common among females than males (4.6% compared with 2.6% at the global level). Again, anxiety disorders were found to have increased since 2005 by 14.6%. As depression and anxiety are often comorbid disorders, it is not accurate to combine these two figures.³

A recent large study in the UK examined adults for a range of physical and mental disorders (BioBank UK). A questionnaire asking about mental disorders found that 21.2% had received a diagnosis of depression at some time in their lives and 14% had been diagnosed with anxiety. The sample who answered the questionnaire were not representative of the whole population, as the participants were aged 45–82 years, with 53% aged 65 or over, 57% were female and 45% had a degree (compared with census data in which 23% had a degree).⁴

History of SARS-CoV-2

On 31 December 2019, the WHO was informed of an outbreak of pneumonia of unknown cause in Wuhan City, in Hubei Province, China. It was then announced on 12 January 2020 that a novel coronavirus had been identified in samples from infected individuals. This virus was referred to as SARS-CoV-2 and the associated illness as COVID-19. China acted by completely closing down Wuhan and Hubei Province, but this was not before the virus seemed to have travelled widely globally. In the UK, people arriving from Wuhan or those believed to have been in contact with SARS-CoV-2 were quarantined, but transmission within the UK and people affected by the virus who had not been abroad was first documented on 28 February 2020. The WHO declared a pandemic on 11 March. On 15 March, following observations of a larger outbreak in northern Italy, the UK government asked people to work from home if possible, avoid unnecessary travel and avoid contact with others. Anyone with symptoms suggestive of SARS-CoV-2 was asked to self-isolate, and those over the age of 70 years, pregnant women and people with underlying conditions were asked to self-isolate for at least 7 weeks. However, on 20 March, the four governments of the UK shut all schools, restaurants, pubs, indoor entertainment venues, non-food or non-essential shops, and banned people from meeting anyone they did not live with. People were prohibited from leaving their homes except for one period of exercise per day and to obtain essential food supplies or attend to medical needs. At all times, people were asked to stay at least 2 metres away from those they did not live with (social distancing). On 13 May 2020, some adjustments to the requirements were made in England only, with people being allowed to exercise as much as they wished and to drive to an area to exercise; everyone who could not work from home was urged to return provided they could remain at least 2 metres apart, and plans were made for children to return to school in June. The devolved governments of Wales, Scotland and Northern Ireland maintained their 'stay at home' policies. On 14 May 2020, the WHO reported 4 248 389 cases of COVID-19 globally and a worldwide death toll of 292 046.⁵ In the UK, as of 09:00 h on 23 May, over 35 000 people had died having tested positive for the virus,^{6,7} although other sources state that the number of actual deaths of people with symptoms suggesting COVID-19 was much as 55% higher than this number.⁸ Other countries worldwide have had varying numbers of cases and deaths, and widely differing responses to the pandemic.

Studies of anxiety and depression symptoms since the arrival of SARS-CoV-2

Given that we are facing an unknown and unseen threat to our health and survival, it is unsurprising that there have been increased numbers of people complaining of symptoms of stress, anxiety and depression. A population survey of 1210 respondents from 194 cities in China found that 28.8% of respondents reported moderate to severe symptoms of anxiety, 16.5% reported moderate to severe depressive symptoms and 8.1% reported moderate to severe levels of stress. Almost 85% were spending 20–24 h each day at home, and over 75% were worried about family members contracting COVID-19. Women, students and those who reported poorer general health were more likely to report distress.⁹ Among healthcare workers in China (over 60% from Wuhan), a much higher proportion reported psychological symptoms, with over 70% suffering from distress, more than half having symptoms of depression, and over 44% having symptoms of anxiety. Unsurprisingly, those working on the front line were more likely to report symptoms, as were those working within Hubei Province.¹⁰ In a Spanish population survey, 18.7% of the sample had depressive symptoms, 21.6% anxiety symptoms and 15.8% post-traumatic stress disorder symptoms. Fewer symptoms were found among older people, those who were economically stable and those who felt they had adequate information about the pandemic. A greater number of symptoms were found in women and those who had symptoms consistent with the virus, and those who had a close relative with symptoms were more likely to report distress. Reported loneliness was also predictive of more psychological symptoms.¹¹ A Turkish study using the Hospital Anxiety and Depression Scale¹² and the Health Anxiety Inventory Health Anxiety¹³ found that almost 24% were above the cut-off to suspect depression, and more than 45% were above the threshold for anxiety. Being a woman, living in an urban area and having a history of psychiatric disorder were found to be risk factors for anxiety, and being female and living in an urban area were risk factors for depression. Women with chronic physical disease and a psychiatric history were at greater risk of health anxiety.¹⁴

Discussion

Overall, it can be seen that anxiety and depression are normal emotions existing within the population and experienced to a greater or lesser extent by all people over time. The SARS-CoV-2 pandemic has led to great changes in our way of life, as well as a real fear that we and our loved ones may contract a potentially life-threatening disease. In addition, front-line workers, including healthcare workers, are under increasing stress and heavier workload. It is therefore not surprising that there is an increase in the symptoms of anxiety and depression in the general population, particularly in people working in front-line healthcare. In addition, many people have been indoors with restrictions on physical activity and an inability to visit friends and family. This is even more poignant and damaging as many are not able to be with loved ones at the end of their life and are unable to attend funerals.

The National Health Service has issued guidance for the population to look after their mental health. This includes setting a structure to the day whether or not you are working, making time to speak to friends and family using remote methods, and looking after diet and exercise, as well as restricting the amount of new reporting an individual is watching if this is leading to distress.¹⁵ Preventive measures such as these may help to reduce some of the symptoms. Indeed, structuring the day and including a balance of activities which give a sense of mastery as well as those that give pleasure can be helpful in combating depressive symptoms.¹⁶ Ensuring a good balanced healthy diet and adequate hydration, and avoiding smoking, alcohol and drugs are also useful in reducing anxiety and depressive symptoms.^{16,17} Working on sleep hygiene and trying to get a good sleep at night using tried and tested methods can also be useful.¹⁷ Exercise is also important and known to be beneficial to our mental state¹⁸. Extreme isolation such as that recommended in the UK for those aged over 70 years and those with severe pre-existing medical conditions may have a detrimental effect not only on physical health and the ability to withstand infection but also on mental health.

Conclusion

Overall, it can be seen that anxiety and depression are ubiquitous human emotions which occur in response to certain situations and stimuli. These symptoms are usually reversible once the situation changes. However, continued stress at this time may result in longer-term anxiety and depressive syndromes. There are some practical steps we can take to try to limit the effects of the current situation on our own mental health as well as that of our loved ones and our patients.

1.2.5 Is COVID-19 changing psychiatry?

David M. Foreman

Correspondence

David M. Foreman

date

2020-9-03

Abstract

Two articles on the potential impact of the current coronavirus pandemic on psychiatry reveal agreement on many points, but opposing positions on the methodology, philosophy and politics of psychiatry's response. This points to the need for psychiatry to audit its approach to evidence when agility is required.

Contents

- *Is COVID-19 changing psychiatry?*
 - *Declaration of interest*

All disasters stress-test the societies they impinge upon. The current coronavirus pandemic is no exception. In this issue of *BJPsych Bulletin*, two authors^{1,2} consider the impact the virus might have.

Perhaps surprisingly, there is much agreement. Neither finds dire forecasts of an imminent psychiatric epidemic convincing, although both recognise that there are risks, for some more than others. Both are concerned that the understandable worries associated with COVID-19 may be excessively medicalised and recommend interventions that will limit this. They also implicitly agree that diagnosis is central to psychiatry's identity and validity, focusing on how diagnostic procedures should respond to a change in our average level of fear, though from opposing positions.

Behind the disagreement lies a clash of methodology as well as philosophy and politics. Like the mills of God, orthodox research into diagnostic validity and reliability both improves diagnosis and clarifies its flaws painstakingly but glacially, through peer-reviewed publication and replication. In contrast, networks of critical professionals and patients can both flag difficulties and propose persuasive solutions, using conferences and social media to promote them rapidly as 'grey literature', for incorporation into reports from stakeholder organisations. Crises demand rapid responses, and the rapidly rising tide of concern about the quality of academic literature on COVID-19 suggests that our current approach to evidence lacks agility when that is needed. We hope that these articles spark a conversation about how psychiatry should audit its response to the pandemic, so it can learn and improve.

1.2.6 COVID-19, medical education and the impact on the future psychiatric workforce

Flora Greig¹

Correspondence

Dr Flora Greig (flora.greig2@nhs.net)

date

2020-10-21

Abstract

Since the start of the COVID-19 pandemic the UK's National Health Service (NHS) has been transformed to meet the acute healthcare needs of infected patients. This has significantly affected medical education, both undergraduate and postgraduate, with potential long-term implications for psychiatric recruitment. This article discusses these ramifications, and the opportunities available to mitigate them as well as to enhance the profile of psychiatry.

 - *Opportunities to mitigate the potential impact of COVID-19 on recruitment into psychiatry*
 - *Conclusions*
 - *Supplementary material*

When it became clear that the first two cases of SARS-CoV-2 infection reported in the UK in January 2020¹ represented an emerging pandemic, the National Health Service (NHS) completely reconfigured its services. To meet the needs of patients diagnosed with COVID-19, elective treatments were cancelled, face-to-face appointments moved online and huge numbers of healthcare workers were redeployed. While mass transfers of staff to front-line roles were facilitated, movements of other healthcare workers were delayed or cancelled: 20 000 junior doctors due to rotate training placements on 1 April 2020 were informed by Health Education England that, except in exceptional circumstances, their

rotations were cancelled.² At the same time, medical students throughout the country faced widespread disruption of their studies.³ Both these events have resulted in a significant number of undergraduate and postgraduate medical trainees missing out on psychiatry placements, with potentially significant consequences for future recruitment into the specialty. These have not gone unnoticed.⁴

The recruitment crisis in psychiatry and its wider workforce implications

Concerns about recruitment into psychiatry are not new. A review of medical student career choices over 40 years demonstrated that the number choosing to specialise in psychiatry has remained constant – at 4–5% – despite the increasing mental health needs of the population.⁵ Surveys of career choices of foundation doctors show a similarly fixed number applying for core psychiatry training.⁶ A recent estimate suggests that, if the projected increase in Certificate of Completion of Training (CCT) holders is accurate (based on numbers applying to training), by 2033 there will be a per capita reduction in psychiatrists of around 11%.⁷

A number of reasons for this crisis have been suggested. These include stigma towards the profession, perceived lack of a scientific basis to diagnosis and treatment, and erosion of the role of the psychiatrist within mental health teams.⁸ Poor teaching and clinical experience at medical school have also been implicated.⁹ In contrast, experience of psychiatry during foundation training has been found to have a positive influence in choosing the specialty.^{10,11} During medical school, the length, quality of teaching and types of patient interaction have been identified as important.¹²

Knowledge of the push and pull factors for the specialty has led to the development of a number of initiatives to promote recruitment. University-based enrichment activities^{13,14} such as Psych Socs,¹⁵ special study modules (SSMs) and summer schools have emerged to support and encourage medical students with an interest in the field. Nationally, the Royal College of Psychiatrists (RCPsych) has developed the Psych Star Scheme and student Associate role, to enable enthusiastic medical students to further their interest in the field.¹⁶ Following graduation, ‘flexible pay premia’ encourage applications for hard-to-fill posts,¹⁷ including psychiatry. In parallel, the RCPsych’s Choose Psychiatry campaign promotes psychiatry to medical students and foundation doctors through the use of videos, social media and podcasts.¹⁸

All of these complement the recent expansion in the number of psychiatry posts within the UK Foundation Programme. This was a direct response to concerns regarding recruitment into psychiatry and was recommended in the 2014 Broadening Foundation Programme report.¹⁹ It is recognised that the structure of the NHS and provision of healthcare need to change to meet the challenges of treating a population that is older, with increasing numbers of chronic health conditions. It emphasised the need for the Foundation Programme to provide broad-based training for junior doctors, giving them adequate experience and education in community and mental healthcare.¹⁹ Key for psychiatry was the recommendation that 22.5% of Foundation Year 1 (FY1) doctors and 22.5% Foundation Year 2 doctors (FY2) should have a post in psychiatry.¹⁹ Alongside the hope that this would boost recruitment into the specialty, it also represented an acknowledgement that there are numerous skills, including communication, empathetic understanding and multidisciplinary learning, acquired within a psychiatric placement, that are valuable whatever specialty the post holder ends up practising in.²⁰

Despite this increase, many foundation doctors still have limited clinical experience of psychiatry. To address this the RCPsych, alongside the UK Foundation Programme, has developed Psychiatry Foundation Fellowships.²¹ These offer access to additional education and supervision resources to support doctors with an interest in the field during their foundation years through to specialty application. Academic Foundation Posts in psychiatry offer opportunities for trainees interested in research, directly challenging the negative assumptions regarding the lack of scientific basis to the field.⁸ Additionally, pilot Longitudinal Integrated Foundation Training (LIFT) posts in psychiatry are being developed, following the success of these in general practice.²²

A recent announcement by the RCPsych suggests that these initiatives are working. In England, fill rates for core psychiatry training have increased for the third year running, with almost 100% of places filled for August 2020.²³

The impact of COVID-19 on medical education

On 12 March 2020, all doctors in the UK were informed that they would need to respond ‘rapidly and professionally’ to the challenge of COVID-19 and might be required to work in areas outside their usual practice.²⁴ Although it was initially suggested that foundation doctors currently in mental health placements would not be redeployed,² different local arrangements meant that some were moved from psychiatry to front-line roles.²⁵ This was followed by the cancellation of all medical training rotations in April, May, June and July.^{2,26}

There are approximately 15 000 foundation doctors in the UK,²⁷ and thanks to the changes to the Foundation Programme, a significant number now undertake a post in psychiatry across their 2-year foundation training. One-third of these were due to start on 1 April 2020 but did not. If undertaking a high-quality psychiatry post during foundation training increases the likelihood that a trainee will apply to the specialty,²⁰ this is likely to have a negative impact on the recruitment cycles for 2021 and 2022.

Undergraduate medical education has also faced significant upheaval. In the early weeks of March 2020, universities across the UK suspended face-to-face teaching and other educational activities. For medical students this meant the widespread cancellation of their clinical and elective placements,³ and a move to online education. While final year medical students were being fast-tracked through pre-registration to support the front line,²⁸ students in other years missed out on vital educational experiences.²⁹ The impact of these changes is already emerging.³⁰ A recent survey of final year medical students found that over a third had their final year objective structured clinical examinations (OSCEs) cancelled and almost half had assistantships cancelled, with significant effects on self-reported ratings of preparedness to start as FY1 doctors.³⁰

For psychiatry recruitment, the effects could be profound. Psychiatry placements often take place in the penultimate year of medical school. These students will now move into their final year, where the focus is on preparing for practice, with little time in the curriculum to make up for missed clinical placements. Given the uncertainty regarding the status of clinical placements during a second wave of the pandemic, it is highly likely that further year groups will similarly miss out on vital face-to-face psychiatry experience. In addition, the impact of the cancellation of the SSMs, elective placements and other enrichment activities, known to be key to fostering positive attitudes to a career in the specialty,^{13–15} is perhaps more concerning. These activities are available throughout medical school. The legacy of these losses therefore, means that the after-effects of the pandemic on psychiatric recruitment could be felt for years.

The impact of COVID-19 on mental health

The potential impact on recruitment is particularly concerning given the postulated effects of the COVID-19 pandemic on the population’s mental health.³¹ There is already evidence of psychological sequelae in those who were infected with SARS-Cov-2.³² More broadly, the impact of the public health measures, including shielding, social distancing and quarantine, is starting to emerge; a recent national survey demonstrated an increase in mental health problems across all age groups in April 2020.³³ In the longer term, the consequences of the predicted economic recession³⁴ will further increase psychiatric morbidity. These effects will be against a back-drop of a pre-pandemic predicted increase in mental healthcare needs within the population³⁵ and ongoing workforce supply difficulties.³⁶

Opportunities to mitigate the potential impact of COVID-19 on recruitment into psychiatry

What can be done and what are the opportunities? Over the coming months, there will hopefully be some time to consider what we can do to mitigate any negative impact the acute response to COVID-19 has on recruitment into psychiatry. There are a number of dimensions to this.

Foundation trainee rotations have now resumed. In addition to the recommendations for these placements made by the RCPsych,³⁷ trainers should take the opportunity to highlight some of the positive effects the NHS response to the pandemic has had on the delivery of mental healthcare, for example the cross-specialty collaborations demonstrated by initiatives such as the CoroNerve,³⁸ the potential for telehealth, or new research avenues such as the role of the immune system in emerging psychiatric symptoms.³² These clearly demonstrate how central psychiatry is to the health and scientific communities’ response to COVID-19, helping challenge many of the negative views of the specialty.

For those doctors who missed out on their chance to undertake a psychiatry foundation post, there are other opportunities for their potential enthusiasm to be encouraged. Existing initiatives for foundation doctors should be strengthened,³⁹ with targeted invites to those doctors affected by the cancellation of rotations, if possible. For FY1 doctors there remains the opportunity to undertake taster days in psychiatry as FY2s. These are usually limited, but given the flexibility foundation doctors demonstrated to facilitate the NHS's acute COVID-19 response, supporting them to make up for lost clinical experience by extending these seems reasonable.

Foundation doctors are increasingly not applying directly to specialty training, instead undertaking F3 and F4 years.⁶ The expansion of clinical fellowships in psychiatry – which offer full access to supervision and the other educational opportunities that core trainees receive – may offer alternative opportunities for those who missed out first time round.⁴⁰

The Medical Schools Council has outlined the need for clinical placements to restart,⁴¹ with priority given to those closer to graduation. Further cohorts of medical students are therefore likely to be affected by the loss of clinical experience in psychiatry. In recent years, virtual work experience programmes have been developed to support school-age students considering a career in medicine.⁴² Universities should consider learning lessons from these, to create virtual psychiatry placements, with an emphasis on patient interaction and high-quality clinical teaching. This could complement the number of psychiatric summer and autumn schools that have already moved online.⁴³

Although developing imaginative alternatives to face-to-face clinical placements is important, it is essential that this does not become the default. Positive attributes of undergraduate psychiatry education include time on placement, working directly with the multidisciplinary team and the influence of role models from within the psychiatric team.⁴⁴ It is hard to see how these can be achieved remotely. The continued facilitation of face-to-face psychiatry experience for medical students should therefore remain a priority.

It has been suggested that time for enrichment activities such as SSMs should be redirected towards core clinical placement activity.⁴¹ It is vital that undergraduate psychiatry departments are involved in these discussions. Not only are enrichment activities in psychiatry important for recruitment, they help fight stigma towards the specialty and the patient population. These should be viewed not as optional extras, but as essential to creating a generation of doctors who view mental illness in parity with physical illness.

One of the positive outcomes of the COVID-19 pandemic has been the speed and readiness with which medical education departments have adapted to the use of online learning. The Medical Schools Council is recommending the use of a number of online platforms to support undergraduate education.⁴⁵ It is vital that psychiatric education is embedded throughout these. The potential for moving SSMs and other psychiatric enrichment activities online should also be fully explored. The use of webinars has greatly expanded as a result of the pandemic, with the RCPsych producing a number that are freely available, and grand rounds and journal clubs now frequently take this form. Delivering psychiatric education this way offers great scope to widen the potential audience, with the main barrier being the lack of awareness among potential attendees. At a national level these resources should be highlighted within the Choose Psychiatry campaign. More locally, promotion of online educational material should be embedded within induction for medical students and via local postgraduate education departments.

The expansion of simulation for psychiatry is another area of potential.⁴⁶ These courses should be re-offered to those who missed out on their clinical placements, as well as expanded to supplement loss of clinical experience of future students. Although much postgraduate education remains online, face-to-face foundation simulation programmes continue. A number of providers have already developed psychiatric simulation courses for foundation doctors, but frequently these are available only to trainees undertaking a psychiatry post. The skills of managing risk, communication, human factors and de-escalation, inherent in these courses, are key outcomes of the Foundation Programme Curriculum⁴⁷ and could easily be incorporated into existing programmes. Through their inclusion alongside other 'core' subjects, psychiatric simulation courses would reduce stigma as well as encourage some to consider a future career in the specialty.

Conclusions

Developing a set of strengthened undergraduate and postgraduate psychiatric educational resources can only benefit future recruitment into the specialty. But as autumn continues, we are now facing the second wave of COVID-19 cases. Although the redeployments of healthcare workers and cancellations of placements were necessary first time round, it is essential that we reflect on their impact. Understanding the effects of the acute management of the COVID-19 pandemic on psychiatric recruitment is vital to inform decisions regarding future suspensions of medical student attachments and movements of trainee doctors. These must try to balance the acute requirements of COVID-19 patients with the need to ensure that there is an adequate psychiatric workforce to address not only the current, but also future mental health repercussions of the pandemic.

Flora Greig is a general adult and old age psychiatry registrar at South London and Maudsley NHS Foundation Trust, Croydon University Hospital, London, UK.

1.2.7 Running a journal club in 2020: reflections and challenges

Isabel Mark Motaz Sonbol Cyrus Abbasian

date

2020-11-13

Abstract

The online environment brings both challenges and opportunities. The skills learned in journal clubs remain highly relevant where the ability to critique rapidly generated information and apply evidence to patient care is vital. Creativity and flexibility are needed to ensure that learners' needs are met and efforts are made to involve those who may not be naturally drawn to online environments. This article explores how journal clubs have been approached in the past, both in person and more recently online, considers techniques for maintaining engagement in online teaching and proposes new approaches for future journal clubs.

The Royal College of Psychiatrist's curriculum for core trainees requires the development of critical appraisal knowledge, skills and habits for practising evidence-based medicine (EBM).¹ Since 1999, critical appraisal skills have been assessed in MRCPsych written examinations.² It is accepted that attending a journal club offers trainees a key opportunity to learn and practise critical appraisal skills. Attending and presenting at a journal club are recommended for all trainees, being a workplace-based assessment (WPBA) for core trainees within their curriculum and required for annual review of competency progression (ARCP).¹ Monitoring of attendance and reinforcement of its importance are likely to vary within UK deaneries and internationally.

Journal clubs of the past

Doctors assembling to review current literature has been recorded as far back as 1875.³ However, recent difficulties in engaging doctors in journal clubs have been discussed.² In 2009, Agell wrote of a 'journal club syndrome,' in which he reported an observed correlation between reported 'mishaps' preventing trainees from engaging in the learning process and the timing of their scheduled presentations.⁴ This somewhat cynical view highlights the long-standing anxieties and struggles with engagement that trainees might face.

In 2008, Deenadayalan et al recommended establishing an overarching goal for a journal club which is reviewed and agreed by participants, recording and expecting attendance, establishing sustainable leadership with access to a statistical expert as needed and providing incentives such as food.⁵ Other aspects, such as article choice, are also specified. In psychiatry, Swift built on these strategies, highlighting the importance of structure, clear aims, a social aspect for the group and discussing selection of the facilitator (with critical appraisal and teaching skills but also able to provide enthusiasm and approachability for more junior colleagues).^{2,6} Moving away from the traditional format by introducing 'evidence-based journal clubs' has been suggested.^{2,7} Such sessions would address a specific clinical problem by referring to available literature.

Journal clubs online: what we know so far

Although the COVID-19 pandemic resulted in a rapid move to online learning, journal clubs have existed in the virtual world for some time. These can take the form either of synchronous learning, when a teacher is present at the same time as students, or of asynchronous learning, when a teacher directs study but is not present when the learning takes place.

Many asynchronous options for journal review have been developed, supporting the face-to-face meetings. MacLaren et al have discussed the internet possibilities, using social media platforms such as Facebook, Twitter handles and Mentimeter as a means to widen potential journal club participation and support learning.⁸ Other e-sources are available for accessing mental health information, an example being the Mental Elf, which has used blogs, social media and gamification to incentivise users.⁹

There has been a recent surge of asynchronous Twitter journal clubs,¹⁰⁻¹³ in which participants contribute via tweets over a specified time period (typically between 1 h and 1 week), providing free participation, open journal access, time efficiency and a diverse international forum for discussion. Instructions for those wishing to set up an asynchronous journal club can involve a number of steps, including incorporating other social media platforms and considering the most convenient time for its target audience, to make their establishment accessible to all.¹⁴ Plante et al note that content may be unregulated and that some might struggle to learn from reviewing past discussions, and suggest that Wiki Journal Club (a website that allows collaboration in writing summaries, critical analysis and reviews of chosen papers, similar to Wikipedia) overcomes these barriers by providing editorial and professional moderation, easily referenced and referred to.¹⁵ MacRae et al found a significant improvement in critical appraisal skills among participants of their surgical journal club, compared with a control group, but acknowledged that those involved in a Twitter journal club are likely to be more motivated than the general surgeon population.¹⁰

Synchronous online journal clubs have had less exploration. Among Lin & Sherbino's suggested steps for setting up an online journal club is the added possibility of 'live' video panel discussions using technology such as Google 'Hangouts on Air' and YouTube.¹⁶ More recently, the *BJPsych* has collaborated with university psychiatric societies to help successfully launch live virtual journal clubs, with student presentation followed by expert-panel discussion.¹⁷ A

similar approach has been followed with dental trainees, highlighting the benefits of accessibility, ease of interaction and effective learning.¹⁸

Although additional online options may increase the potential for journal club participation, they are unlikely to suit all trainees. Twitter is the most popular form of social media communication among healthcare professionals,¹⁹ but the exact prevalence of use among doctors, or more specifically trainees, is to our knowledge not reported. If medical education becomes dependent on social media platforms, the risk is that some will be alienated or simply not reached.

Techniques for maintaining engagement with online learning

Difficulties in engaging learners online are a recognised challenge for educators; traditional face-to-face teaching methods cannot simply be adopted in the online environment.²⁰ Additional considerations are needed (*Box 1*). Box 1 Instructor considerations for maximising engagement in online learning Consider three domains: cognitive, affective and managerial²¹ Existing face-to-face options cannot simply be replicated online; a new approach is needed²⁰ Initial resistance is to be expected and learners may need additional support at the outset²⁴ Clinical scenarios improve perceived relevance/authenticity²⁴ Consider the diversity of the group and individual learner needs and preferences^{25,26}

Coppola et al proposed that the online instructor's role has three domains: cognitive, affective and managerial, achieving a balance between imparting information effectively, communicating approachability, enthusiasm and intimacy, and being an effective organiser and administrator.²¹ A recent Best Evidence in Medical Education (BEME) review describes techniques used by educators to maximise student engagement online, necessitated by COVID-19.²² These include the need for effective organisation and structure, and varied options for student interaction, such as using online chat features, polling, hand-raising and breakout rooms.²² Warren et al argue the need for flexibility in this process, incorporating different learning modalities, considering technical resources and support.²³ Engagement can still be delayed unless a learner is willing to change habits and thus suspend their disbelief in a new approach, with additional support and time needed for them to do so.²⁴

Online learning is often more effective when activities are 'authentic', using complex clinical scenarios and tasks to increase the perceived level of relevance for the learner.²⁴ In the current climate, using cases or studies involving COVID-19 specifically might assist with this.

One must consider all students rather than just the most vocal or communicative.²⁵ Haggis proposes that teachers address student diversity by shifting their approach away from the struggling learners towards a more dynamic stance, considering the overall student–teacher interactive process.²⁵ Problematic areas need to be addressed, including acceptance of the wide range of students' experience, motives, interaction and communication preferences. The instructor could consider using diverse examples when setting problems/tasks and fostering social relationships within the group, while still respecting the student's own responsibility for driving their learning and seeking help.²⁶ Forcing some students to contribute, when not part of a shared collaborative process, could endanger their autonomy and motivation.²⁷

Recent learning following COVID-19 restrictions

In 2020, since the COVID-19 pandemic, psychiatry training has depended on online technology to replace all face-to-face journal club meetings. Within months, our use of platforms such as Zoom and Microsoft Teams became the 'new normal' and the only option for teaching and networking. Although some participants were already familiar with the array of online options, many may not have been and could still be struggling to keep up.

Within South West London and St George's Mental Health NHS Trust, we have continued to run a weekly journal club using the virtual platform of Microsoft Teams, supported by a WhatsApp group to offer further discussion as needed. Efforts were made to boost the effectiveness of the journal club by recruiting additional higher trainees to support the sessions, increasing the level of support offered to the lead presenter and making particular efforts during journal club meetings to encourage all to contribute. Although the numbers in the virtual room have been noticeably higher than those in face-to-face meetings before March 2020 – up to two or three times as many – engagement levels have been difficult to measure, with many of those present in the virtual room not taking an active part. In the absence of visual cues, with most turning off their screen camera and not using the 'chat' function, we struggle to assess who is actively

engaging in the group and who finds it useful. Several trainees have commented on missing the social aspect of the group.

As it has become unclear how long COVID-19 restrictions will continue, morale has declined. The initial high level of discussion has not been maintained; not all trainees have appeared confident to engage, either by speaking openly, using the written chat/Q&A function or through the WhatsApp group. This experience is, of course, likely to vary between different hospitals, trusts and deaneries, depending on the confidence of trainees, as well as the ethos and culture of the organisation.

Reflections and feedback from trainees are continuously sought and contribute to future planning (*Box 2*), but we are aware that those most disengaged from the process are less likely to communicate their needs. *Box 2* Lessons learned from recent experience Assessing and maintaining engagement in online forums is a challenge Uncertainty about the future can be unsettling and disempowering for some trainees Trainees feel a loss of the social aspect of journal clubs Learning and training opportunities have been threatened by clinical workload, technological limitations and noisy surroundings Facilitator encouragement, support and continuity are critical Trainees appear to appreciate a flexible approach, such as presenting articles in pairs, structuring their session in varied ways and focusing on different aspects of the paper. Some are interested in statistical methods and details, whereas others prefer to focus on how the research relates to previous and future research or how they can make use of the data in their practice

Journal clubs of the future

Journal clubs continue to be a valued part of psychiatry training, offering a key opportunity to learn and practise critical appraisal skills, presenting skills, critical thinking and structured discussion. There is no current alternative within the RCPsych curriculum that offers these opportunities, and journal club remains a WPBA for core trainees.¹ The current pandemic reminds us how critical evidence-based medicine is to our practice, with a flurry of new research on COVID-19, and the need to recognise how new research should be integrated into practice. The transition to online journal clubs now requires a new set of organiser and administrator skills, which is a challenge in some departments. Even before 2020, journal clubs were struggling with participant engagement.^{2,6} Online journal clubs might be embraced by those with research or education focus; but there is a high risk that others could feel excluded. Others might be starting to get online fatigue.

Considering techniques for effective engagement in online teaching can enhance our ability to facilitate journal clubs.^{20–23} The use of clinical problems and specific tasks, similar to the previously introduced evidence-based journal clubs, may provide additional relevance and authenticity for learners.^{6,7,24} Considering the diverse range of learner needs and preferences is advised.²⁵ The online platform potentially supports educators in managing diversity by improving accessibility, in particular for those shielding or working on a different clinical site. Publicising and encouraging the use of additional asynchronous learning resources^{8,9} such as Twitter journal clubs to support sessions¹⁴ is worthwhile.

When running future synchronous online journal clubs, instructors need to transform their approach, not only in offering appropriate guidance and knowledge, but also in helping to establish an approachable atmosphere, optimising the potential for discussion and collaboration.²² Trainee uncertainty about the future and feelings of social loss need to be acknowledged, as does the consideration of variability in resources and skills, with limited availability of functioning computers for some. Trainees have fed back that they appreciate additional guidance on presentation style, paper choice and additional resources. They have expressed a preference for flexibility, not defining the style of presentation and allowing the option of multiple communication forms (speaking in person, typing in the written ‘chat’, as well as using WhatsApp and other social media platforms). A challenge of measuring active participation remains, as the administrative resources required to record contributions might not be feasible within all training programmes. Forcing contribution could endanger trainee autonomy,²⁶ although it should be recognised that it is an expected and important part of the trainee curriculum.¹

This article can only be the start of a more complex discussion and re-evaluation of the function, purpose and delivery of online journal clubs and the part they play in the psychiatry curriculum, as well as considering the level of support provided to trainees and by whom. Collaboration and discussion between professional educators in neighbouring training programmes will help explore and expand the wider networking potential of journal clubs.

We thank the core trainees at South West London and St George's Mental Health NHS Trust whose opinions and views contributed to the conclusions of this article.

Abstract

The COVID-19 pandemic has brought untold tragedies. However, one outcome has been the dramatically rapid replacement of face-to-face consultations and other meetings, including clinical multidisciplinary team meetings, with telephone calls or videoconferencing. By and large this form of remote consultation has received a warm welcome from both patients and clinicians. To date, human, technological and institutional barriers may have held back the integration of such approaches in routine clinical practice, particularly in the UK. As we move into the post-pandemic phase, it is vital that academic, educational and clinical leadership builds on this positive legacy of the COVID crisis. Telepsychiatry may be but one component of 'digital psychiatry' but its seismic evolution in the pandemic offers a possible opportunity to embrace and develop 'digital psychiatry' as a whole.

The COVID-19 outbreak has posed an unprecedented challenge to healthcare systems and to society as a whole, with millions infected globally and tens of thousands of deaths in the UK alone. Stay-at-home and lockdown guidance was instituted to ensure that the National Health Service (NHS) had the capacity to deal with a possible surge in COVID-19-related presentations, not least as NHS staff were equally affected by quarantine and sickness challenges. Remote consultations, or ‘telemedicine’, hitherto a somewhat niche offering in the NHS led primarily by technology enthusiasts, saw an explosive growth, with the New York Times reporting: ‘Telemedicine arrives in the U.K.: “10 years of change in one week”’.¹

The urgent need to deliver patient care effectively and safely in the pandemic was supported by new NHS guidance² that facilitated a rapid rollout of remote consultations in most areas of psychiatric practice.

This occurred despite the pre-existing cautionary digital guidance from the Royal College of Psychiatrists echoing the General Medical Council (GMC) in its advice that ‘standards expected of doctors [...] apply equally to digital and conventional consultation settings’ and that doctors must give ‘consideration to the potential limitations of the medium used’.³ In particular, for psychiatrists, perhaps more than any medical specialties, there have been long-standing concerns of loss, potentially harmfully so, of the ability to pick up by distance the subtle interpersonal cues of the mental state examination.

‘Telepsychiatry’ is not new. Defined as the provision of psychiatric services remotely through various technological communication platforms,⁴ technology-based mental healthcare has been in operation for several decades. Samaritans, the well-known telephone helpline service, started its operations in 1953. However, a more important contemporary phrase is ‘digital psychiatry’, which moves beyond just the digital delivery of a consultation to the provision of an on-demand, highly personalised, confidential and secure care made available through an easy-to-use, intuitive interface. However, digital psychiatry is much more than that. Rethinking conventional psychiatry, heavily reliant on the written and printed word to store medical information, often distributed by traditional methods such as by post, to move to a world where digital tools can record, analyse and make intelligent interpretations of data will require a clinical, administrative and intellectual evolution.

The NHS Long Term Plan outlines its vision of every patient (in England) being able to access digital services – at least at the primary care level – by 2024, putatively saving 30 million patient trips and over £1 billion/year in costs.⁵ However, the possibility of delivering a socially distanced but safe and effective service has provided a fresh fillip for the adoption of digital health in both primary and secondary healthcare. Will the relatively enthusiastic adoption of virtual assessments provide a template for the wider rollout of new technologies in clinical practice beyond the pandemic?

If such promise is to be realised, remote consultations, digital self-help, electronic patient record systems, triaging using artificial intelligence (AI) and a range of other digital tools will need to be scaled up sustainably, paying attention to patient preference, patient safety and clinical outcomes, including the concept of precision psychiatry. This article outlines the key factors that need urgent consideration to ensure the integration of digital solutions in routine clinical practice.

Is digital psychiatry safe, effective and acceptable to patients and clinicians?

The justifiable clinical concern of coronavirus infection during the pandemic has shifted the fulcrum of safety significantly away from face-to-face consultations. The use of telemedicine in post-disaster situations is well-established.⁶

Systematic reviews demonstrate substantial evidence to support the effectiveness of remote psychiatry.^{7,8} Most of the evidence has emerged from the need to overcome accessibility barriers to psychiatric care, for example in areas isolated owing to disasters such as hurricane Katrina or to their geographical location, such as rural Canada and Australia. Studies looking at the effectiveness of remote clinical work are mainly head-to-head and non-inferiority studies demonstrating equivalence with face-to-face interactions. These show effectiveness comparable with face-to-face assessments in terms of patient engagement, validity/reliability of assessments, and clinical outcomes.^{9,10}

Rapidly emerging evidence shows that telepsychiatry is being successfully utilised globally, in the wake of the COVID-19 pandemic. Yellowlees et al¹¹ reported the process, challenges and lessons learned from a rapid conversion of a direct psychiatric clinic to a virtual one within the space of 3 working days in Northern California. Rosic et al¹² provided an interesting patient and provider perspective on the transition to a virtual clinic following the onset of the pandemic in Canada. Sharma et al¹³ have discussed a similar transition in a child and adolescent setting in Seattle. Duan & Zhu¹⁴ have described the development of mobile phone and social media-based platforms to provide psychological care in China. These examples demonstrate the point that COVID-19 has propelled the global psychiatric community into a new era with the use of technology in delivery of psychiatric care.

Remote access has been noted to be effective for treating a variety of conditions, such as depression, anxiety, post-traumatic stress disorder (PTSD) and psychosis. It has been particularly useful for individuals who face specific difficulties attending out-patient appointments, such as some with psychosis and social anxieties, and social difficulties such as housing instability.

In child and adolescent psychiatry, we have evidence for the effectiveness of digital psychiatry for the psychiatric assessment and management of attention-deficit hyperactivity disorder and early psychosis, as well as delivery of therapy for obsessive-compulsive disorder and tic disorder.¹⁵ Hantke et al¹⁶ demonstrated the effectiveness of remote working in a variety of older person's settings, such as nursing home, community and hospital settings for individuals with cognitive, functional and sensory impairment. Such interventions have also been associated with reduced transfers to hospital and benefits for patients with limited mobility.

Benefits have been shown in criminal justice and other forensic settings, where safety concerns about physical movement of high-risk patients can be mitigated through remote assessments and remote expert testimony.¹⁷ Remote psychiatry has also been demonstrated to have a positive impact on the assessment and management of individuals with intellectual disabilities, with some data showing no loss in therapeutic engagement compared with face-to-face assessments and even some evidence for improved engagement among children with severe anxiety and autism.¹⁸ In addiction psychiatry, remote treatment of opioid use disorder produced similar outcomes as face-to-face treatment in both general¹⁹ and obstetric settings.²⁰

Interestingly, healthcare providers were more likely than patients to express concerns regarding adverse effects of remote assessments on therapeutic alliance.⁷ Although there is considerable evidence for remote therapy,²¹ Norwood et al²² found that working alliances were inferior compared with face-to-face work, even though symptom reduction was equivalent.

However, the (few) studies on the topic tend to report overall high levels of satisfaction with digital consultations,²³ including for children and adolescents.^{15,24}

Bashshur et al²⁵ identified telemedicine as a cost-effective solution for triage, consultation, prescribing medications, provider-to-provider discussions, appointment scheduling and reminders. Furthermore, the study also found that remote interventions in primary care were at least as effective as traditional care.

Given these effectiveness and experience data and the evidence that telepsychiatry is cost-effective compared with face-to-face treatment, one must question the historical factors limiting adopting technological solutions in the value-driven public NHS.

Potential barriers to implementing digital psychiatry

The potential barriers to digital working fall into three broad categories – regulatory concerns, technological hurdles and human factors.

NHS practice is influenced by several bodies, including the GMC, the medical Royal Colleges and medical defence unions, clinical guidance from the National Institute for Health and Care Excellence (NICE), and local and national commissioning protocols involving a host of stakeholders, such as clinical commissioning groups, NHS trusts and so forth. None preclude digital working, and indeed all generally support the principles. However, their nature, number and potentially conflicting messaging can make them inherently resistant to swift changes, even for interventions with proven clinical benefit and cost-effectiveness.

There is a wide variation in the technological maturities among mental health providers across the country. Technological and security concerns include clinical governance issues, safeguarding, legal liability, confidentiality and secure storage of digital information, with worries about reliability of technology and variation in bandwidth across the country.

Human factors can be a potent barrier, with clinician anxieties centring on: building rapport in a digital interview; being ‘recorded’, with potential consequences for personal liability; and perhaps most powerfully, the lack of personal incentives to change. The densely populated nature of the UK may make some accessibility problems seem less relevant. The edict of *primum non nocere* – first do no harm – is so embedded in medics’ psyche that it perhaps makes clinicians inherently cautious about change. This is likely only exacerbated by many doctors’ adverse perceptions of restrictive, stifling information governance rules and regulations.

For patients and carers, lack of access to technology on account of financial, technological, physical or cognitive factors may be a barrier. Global evidence, however, demonstrates that patients show a clear preference to having alternatives in addition to face-to-face assessments.

The COVID-19 crisis demonstrated that all these barriers can be rapidly overcome. NHSX provided timely and much needed guidance and assurance on the use of a variety of methods to enable and support working.³ Despite inevitable hiccups, internet and technology solutions worked in a manner perhaps not attainable had the pandemic occurred say even 5 years ago. Clinician and patient experiences have surely buried the ‘unacceptable’ argument.

Digital psychiatry: the future

Recent experiences have exemplified the differences between older-fashioned ‘telepsychiatry’ and the innovations possible with ‘digital psychiatry’. Doing ‘the same’ but via video calls is limited progress, though perhaps the initial leap made by most clinicians. A variety of platforms have been made available with new features such as: a waiting room (simulating clinics); multiple participants (to enable multidisciplinary team working); a screen sharing feature to show written information (to aid explanations and education during the clinical interview); and inbuilt capability to email or message the patient, carer or other colleagues and to save these communications directly in the electronic clinical records. Recent developments have also shown clinician benefits beyond ‘just’ the flexibility of working from home, including examples of offering more flexibility in hours of work and timings of clinics, such as evening and weekend working (no longer needing office buildings to be kept open). Asynchronous meetings are allowing staff to read, comment on and contribute to documents outside of the ‘standard meeting’ time, as well as message and add written comments as meetings progress.

Simultaneously, there have been some anecdotal concerns about ‘sharing’ one’s home environment with others, whether colleagues or patients, alongside some sense of fatigue at engaging many participants online without full human engagement. The range of competing platforms is potentially confusing and we are still learning to navigate these, and when and how to use the novel technologies within.

But while we attempt to master the etiquette of how and when to speak across large meetings, digital solutions have also emerged to support home-based care for our patients. From the surge in the use of digital apps for mental health and well-being to the rise in digital prescribing, digital dictation and even digital therapies as people adapted to the lockdown world, technology has felt more palpable for both clinicians and patients. Innovations such as AVATAR therapy for

auditory hallucinations in chronic schizophrenia or individualised risk stratification using AI machine learning to ‘read’ patient records that are currently being piloted seem that much closer to routine practice.

Although the outcomes for patients receiving digital psychiatric care do not seem to be inferior to in-person care, we need better data about the subgroups of patients for whom this might not hold true. For example, early evidence suggests caution for individuals with cognitive impairment, at high-risk, with significant concomitant physical health needs and so forth. National data-sets from agencies such as NHS Digital or the Care Quality Commission may help inform this.

The legal, ethical and regulatory framework relating to remote consultations also needs clarification. Both patients and clinicians need to feel safe participating, and key issues include consent, capacity, confidentiality, need for chaperones, safeguarding for vulnerable patients, escalation arrangements, security of data and indemnity for clinicians. Early and successful resolution of these issues will avoid the stifling of innovation and will enable a more rapid adoption of wider digital enhancers to patient care.

The theme of integration is key to the NHS Long Term Plan and features prominently in the new community mental health framework.²⁶ Digital psychiatry in its broadest sense offers a unique opportunity to realise this integration, albeit virtually, of primary care, social care, third-sector partners, the criminal justice system and other stakeholders working with patients and clinicians to improve clinical outcomes. From virtual meetings to seamless patient-owned records, the possibilities are limitless.

A central feature of UK health policy and service delivery is its focus on person-centred care and this is particularly true for psychiatric practice and training.² Co-production has largely been absent in the evolution of digital psychiatry and it is vital that patients and carers have a central role in further rollout of this new technology. Current guidance issued for the pandemic will need to be updated on the basis of emerging evidence on indications and pathways and it will also need to take into account patient and professional feedback.

Workforce implications will need to be carefully considered. Roles and responsibilities for clinicians working remotely need to be clearly defined. Current arrangements enable the enforcement of national regulatory jurisdictions, and this might be challenged by some forms of virtual working. For example, licensure arrangements across several states in the USA have been relaxed to allow licensed clinicians to work remotely from outside normal state boundaries. This may be particularly relevant for countries such as the UK, where there has been a traditional reliance on international healthcare workers to provide an adequate clinical service: both an opportunity and challenge in working with clinicians outside of traditional workforce bases emerge.

Finally, the workforce will need appropriate training to deliver remote consultations safely and effectively. Currently, in the UK there are no curricula-specific training requirements, either at core or higher specialty level, for psychiatry trainees to demonstrate competence in digital skills that may be considered essential to good clinical practice, e.g. managing digitally enabled consultations, extracting clinically meaningful data from electronic patient records or prescribing evidence-based digital apps. Examinations may be moving online, as is the case with MRCPsych examinations beginning later this year, but embedding digital literacy in the training and assessment framework will require a significant shift in culture and practice.

Conclusions

The COVID-19 pandemic has given the NHS permission to rapidly review its ways of working to embrace technological advances. These offer the potential of flexible home-based consultations for clinicians and patients; the opportunity to connect multiple agencies more quickly to deliver a person-centred care plan; accessibility to communities who might otherwise not be reached; a window into the personal and home life of our patients; and all this potentially with a smaller carbon footprint and lower costs.

However, if we are to fully tap into the potential gains of digital psychiatry, we must realise how much more than this is on offer: an integrated use of technology in mental healthcare, supported by multidisciplinary, diverse teams of technologists, designers, health and care professionals and those with lived experience. It is about agile methodologies, user research, behaviour-change science, data science and social science blending together in organisations with less hierarchical power play and a more pragmatic and courageous approach to risk, as has been the case during this pandemic.

Our aspiration for digital psychiatry should reflect the expectations of the internet age – on-demand entertainment on a mobile digital device, real-time customer logistics so that one knows where a parcel is and the name of the driver, universal standardisation of our experience through ‘operating systems’ that allow fine-grained personalisation. We have much more to achieve than remote consultations, and certainly far more than doing video calls. And it is truly ‘digital’ platforms – ubiquitous computing through standardised operating frameworks on highly personalised and network-connected mobile devices – that have allowed us to achieve the adoptions we have in a matter of months.

We propose that what we have described as the barriers to adopting digital psychiatry are solved through harnessing the values, culture, practice and technological capabilities of the internet age.

Although the growth of digital psychiatry in the NHS may have been more of an evolution than a revolution, with the right leadership, training, research on digital innovations, and the necessary clinical, ethical and legal guidance we can dispel the digital darkness and usher in a new era of integrated, personalised and accessible psychiatric care. We call on the Royal College of Psychiatrists to set up a task force to develop national guidance to ensure that the Big Bang effect of COVID-19 on digitisation of clinical practice and training is sustained and amplified in the future.

1.2.10 Introducing the new culture section of *BJPsych Bulletin*

David Foreman

Correspondence

Dr David Foreman

(david_foreman@doctors.net.uk)

date

2021-02

Abstract

This editorial launches the new culture section in the journal. Without any unchallengeable definition of ‘culture’, potential contributors may consider submissions under four headings: the arts and humanities relating to practice; regulatory culture; becoming a cultured practitioner; and psychiatry’s cultural context. A new article type, ‘Cultural reflections’, has been created, and submissions may reflect any appropriate methodology, including those from the arts. Peer review (from methodologies outside psychiatry if appropriate) will assure quality. Our objectives are to establish *BJPsych Bulletin* as the ‘journal of record’ for cultural studies relevant to psychiatric service delivery and demonstrate equivalent quality between them and scientific studies.

Contents

 - * *The arts and humanities concerning psychiatric practice*
 - * *Regulatory culture*
 - * *The cultured practitioner*
 - * *Culture and society*
 - *Quality assurance*
 - *Submitting articles*
 - *Our hope for the future*

The ‘mission statement’ of *BJPsych Bulletin* appears at the top of its Instructions for authors. It reads, ‘*BJPsych Bulletin* prioritises research, opinion and informed reflection on the state of psychiatry, management of psychiatric services, and education and training in psychiatry’.

We try to provide what psychiatrists need to practise well. With our daily professional lives governed by scientific evidence and policy delivery, the utility of audits, guidance reviews, clinical recommendations and service-related research is obvious. However, we believe that psychiatrists also need excellent cultural understanding and culturally informed practice to deliver what our patients need from us. We have therefore created a new Cultural Section, with

an associated article type, 'Cultural reflections', to allow submission of articles that do not fit the currently available Journal frameworks.

What do we mean by culture?

Like baldness or serious professional misconduct, culture is something we have little trouble recognising but great difficulty defining. Jahoda observed that the definitions of culture commonly used in psychological science are mutually incompatible, not amenable to empirical testing and suggests that we define it by usage rather than semantically.¹ As editors of the journal, if someone wishes to submit something they consider 'cultural', we recommend that they think in terms of four headings: the arts and humanities concerning practice; regulatory culture; the cultured practitioner; and the cultural context within which psychiatry operates.

The arts and humanities concerning psychiatric practice

The arts and humanities are what we usually think of when 'culture' is discussed. However, while a vibrant psychiatric literature on these topics continues, a historical perspective suggests that mutual engagement and understanding between these worlds has declined. The famous painting of Pinel unchaining the inmates of the Salpêtrière, painted in 1895, illustrates not a consequence of the French Revolution but the benefits of an empirical psychiatry based on observation that prioritises patient benefit without presuming prior theory.^{2,3} This active, empirical approach still characterises psychiatry.⁴ Nevertheless, psychiatrists are now represented as theorists, more interested in investigation than benefiting our patients,⁵ and sometimes entirely indifferent to them.

As the humanities' awareness and understanding of psychiatrists has diminished, so has our involvement with them. The conjunction of psychiatric, surrealist and philosophical thought between the 1920s and 1960s contributed to the development of both postmodernist thinking and antipsychiatry.⁶ Yet, even the memory of those connections now seems lost to us, and we are invited to consider them as if they are alien to our tradition and we had never responded.^{7,8}

To encourage a rapprochement and interchange that takes into account the progress made since the middle of last century, we will seek to publish not only cultural thinking by psychiatrists but also work by practitioners of other methodologies. It is often forgotten that the visual arts, music, poetry and literature are also methods for exploring the world, especially our subjectivities. For psychiatry, the subjectivity of our patients is part of our core business, and we are no longer so restricted by the limits of paper and physical printing. We therefore do not necessarily require that a submission to the culture section is in the form of a conventional academic paper, provided that it addresses a cultural issue that has an impact on psychiatric practice and meets our quality standards.

Regulatory culture

The arts and humanities are often seen as a counterpoise to excessive regulation. However, there is also regulatory culture, which operates to deliver the intentions of a regulatory regime when circumstances are indeterminate and discretion is essential.⁹ It can be thought of as the set of explicit or implicit attitudes and intentions expressed through norms, routine policy and everyday practice. It has become an explicit part of financial regulation, and firms are reviewed to ensure that their management structures deliver it.¹⁰ Within the National Health Service (NHS), regulatory culture is much more variably instituted¹¹ and an audit model may not capture many of its necessary components.¹² We therefore wish to publish articles relevant to improving the regulatory culture of psychiatric care, as the level of variation found suggests an ongoing and urgent need.

The cultured practitioner

The mission of *BJPsych Bulletin* focuses on topics that affect what we do in our daily practice. The norms and values that our culture instils do precisely this. For example, social constructs such as masculinity and societal power gradients predict the balance between a response style of decisiveness versus accommodation.¹³ The concept of specifying moral principles in practical, situational terms is well-established in biomedical ethics.¹⁴ The same is needed for cultural influences, as professional practice cannot be detached from its cultural environment.¹⁵ Patient (service user) groups have begun developing this from an antipsychiatry perspective.¹⁶ We believe that practitioners need explicit accounts of how psychiatrists should express our discipline's best culture in daily practice. We will seek articles that relate the practice of psychiatrists to aspects of culture, applied to the benefit of their patients.

Culture and society

Psychiatrists are taught their discipline as applied science. However, it is also one of society's institutions, tasked with performing an essential role. The Parthenon can be described entirely in engineering and aesthetic terms, but those perspectives do not explain how the Parthenon functioned. We also need to know that it was a Greek temple to Athena, the tutelary goddess of ancient Athens. To properly understand what our discipline delivers, and why, we need to be aware of how it is situated in our culture, how it maintains itself and the drivers that shape the services it delivers. Science is but one of these, and funding not only limits policy but also follows it. We are therefore interested in publishing articles that will let us map psychiatry's 'cultural geography', for example patterns of influence with other institutions, such as the law and politics, cultural drivers of research or service prioritisation, or the role of the relationship between psychiatrists and patients in shaping our clinical culture. We believe that having a clearer account of these will enable our profession to develop and deliver more effective services.

Quality assurance

Cultural commentary from many perspectives is becoming increasingly widely distributed (e.g. [medium.com](https://www.medium.com); [quillette.com](https://www.quillette.com)) and, without expertise, quality can only be judged on its language and plausibility. Even 'fact-checking' may fail when, as often occurs in cultural scholarship, accuracy lies in the awareness of multiple interpretations, rather than allegiance to one. *BJPsych Bulletin* has two great strengths as a forum for cultural research and scholarship in psychiatry. Being open access, it has a potential reach similar to that of the online commentaries just mentioned. However, it also has a mature peer-review system. This combination gives it the potential to become the cultural 'journal of record' for our profession, as peer review will be applied to all the section's submissions, and articles and correspondence can be published from outside the profession. As we have seen above, at present, our cultural memory may be too short. Given the section's intended scope, psychiatrists will not be in a position to judge the quality of all potential submissions. Therefore, we plan to create a panel of reviewers covering the full range of methodologies, including the arts, to ensure that all articles will be evaluated by a respected peer in the field, as well as receiving a psychiatric review.

Submitting articles

Articles should be submitted as 'Cultural reflections'. Since the section is new, as the Culture Editor I will be pleased to discuss possible submissions at an early stage with potential authors. The purpose of such discussions is to ensure that the submission is in a form that meets the goals of the section and is suitable for forwarding for peer review.

Our hope for the future

I have argued above that psychiatry needs to engage with culture to deliver best practice. I hope that the new section will support this by helping to establish cultural studies of all kinds as being of practical value to service delivery and demonstrating that the evidential quality of these studies is comparable with the best of scientific research.

David Foreman is an affiliate senior lecturer in the Institute of Psychiatry, Psychology & Neuroscience, King's College London, UK. He is a member of the editorial board of *BJPsych Bulletin* and the editor of the new culture section.

1.2.11 Patterns and motivations for method choices in suicidal thoughts and behaviour: qualitative content analysis of a large online survey

Abstract

Background

Choice of suicide method can strongly influence the outcome of suicidal behaviour, and is an important aspect of the process and planning involved in a suicide attempt. Yet, the reasons why individuals consider, choose or discard particular methods are not well understood.

Aims

This is the first study to explore method choices among people with a history of suicidal behaviour and individuals who have experienced, but not enacted, suicidal thoughts.

Method

Via an online survey, we gathered open-ended data about choice of methods in relation to suicidal thoughts and behaviours, including reasons for and against specific means of harm.

Results

A total of 712 respondents had attempted suicide, and a further 686 experienced suicidal thoughts (but not acted on them). Self-poisoning was the most commonly contemplated and used method of suicide, but most respondents had considered multiple methods. Method choices when contemplating suicide included a broader range of means than those used in actual attempts, and more unusual methods, particularly if perceived to be lethal, 'easy', quick, accessible and/or painless. Methods used in suicide attempts were, above all, described as having been accessible at the time, and were more commonly said to have been chosen impulsively. Key deterrents against the use of specific methods were the presence of and impact on other people, especially loved ones, and fears of injury and survival.

Conclusions

Exploration of method choices can offer novel insights into the transition from suicidal ideation to behaviour. Results underscore the need for preventative measures to restrict access to means and delay impulsive behaviour.

Background

Suicide is a leading cause of death worldwide.¹ In England, the 2014 Adult Psychiatric Morbidity Survey found that a fifth of adults (20.6%) reported thoughts of taking their own life at some point, and one person in 15 (6.7%) has made a suicide attempt.² Choice of method is one of the most important determinants of whether suicidal behaviour is fatal, and a key aspect of the process and planning involved in a suicide attempt. Indeed, earlier studies have shown that gathering information and access to means of suicide are known indicators of high suicidal intent and risk.^{3,4} Yet, previous literature has mostly focused on prevalence of methods, and associations with gender, age and mental disorder.⁵ How or why individuals consider, choose or discard particular methods are not well understood.

Epidemiological studies have shown that different methods, and combinations of methods, vary not only in relation to lethality, but also in the extent to which they predict subsequent suicidal behaviour and ‘method switching’.^{6–10} Their wider impact can also vary, not least by virtue of the exposure and potential clustering/‘contagion’ effects associated with more public, unusual and ‘newsworthy’ methods.¹¹ Indeed, avoiding ‘excessive detail of the method [...] to prevent simulative acts’ remains to date the only official regulation for the reporting of suicide in the UK.¹²

This clearly points to the importance of better understanding the cultural and cognitive availability of different methods of suicide. Previous studies in this emerging field have identified these as key drivers in people’s method choices, but have explored their significance in relation to a relatively narrow range of methods and with generally small study samples.⁵ Furthermore, earlier literature has tended to focus on fatal and non-fatal suicidal behaviour, overlooking its immediate, and generally less understood, precursor: suicidal ideation. Understanding the psychological processes preceding a suicide attempt is crucial for the potential to intervene, as is knowing what prevents the majority of individuals in distress from acting on thoughts of suicide, at a particular moment and/or over time.

The stability, or otherwise, of method choices also warrants further attention. A recent systematic review found that a third of individuals (33.3%) switch methods between successive episodes of self-harm, and almost half (42.11%) between an episode of self-harm and suicide.¹³ Based on prevalence of methods, there appears to be no discernible or predictable pattern to such means switching.^{9,13} Exploration of meanings, motivations and mechanisms may, however, offer valuable new insights. For example, a study in Austria showed that, despite method switching between episodes of self-harm being common, choice of means in the time immediately preceding a suicide attempt is often stable, and focused on a single method.⁸

Aims

The present study aimed to investigate, for the first time, first-person accounts of the factors deterring and prompting consideration and/or use of specific methods of suicide among people with a history of suicidal behaviour and those who have experienced, but not enacted, suicidal thoughts. Dominant models of suicidal behaviour point to this as an important distinction, with potential for novel insights into the transition from suicidal ideation to behaviour.^{14,15} Given the disproportionate risk of suicide in men in the UK,¹⁶ gender differences in method choices were also explored, in relation to both suicidal ideation and behaviour.

Method

Online survey

Data were gathered as part of a wider study of method and location choices in relation to suicidal thoughts and attempts in the UK (QUEST, Qualitative Understanding of Experiencing Suicidal Thoughts^{17,18}). A national online survey inviting people to share their experiences of suicidality was advertised through suicide prevention organisations such as Samaritans UK, online forums, social media and special interest groups. Study posters and leaflets were also placed on university bulletin boards, at local branch offices of relevant charities, in the National Suicide Prevention Alliance newsletter and were mailed out to supporters of the charity Campaign Against Living Miserably (CALM).

The 16-item anonymous survey asked participants if they had ever experienced suicidal thoughts and, if applicable, to describe in an open-text format whether this involved a specific method or methods, and why. Those who reported prior

suicidal behaviour were then asked the same question in relation to their suicide attempt/s. All questions were optional, and no word limit, prompting or structure were imposed on open-ended responses. This also meant that multiple methods and/or reasons for (or against) using different means of suicide could be provided. Further information was gathered about the specific location or locations of suicidal thoughts and behaviours; about suggestions for preventative measures at different locations; and sociodemographic details (see Supplementary Appendix available at <https://doi.org/10.1192/bjo.2021.15> for a copy of the full survey).

Links to further information about the study and to support services for those experiencing suicidal thoughts were available both at the beginning and the end of the survey. All participants gave informed consent to participate in this study, and all research materials and procedures were reviewed and approved by the Psychology Department Research Ethics Committee at Middlesex University (reference: ST019-2015).

Statistical analysis

Open-ended survey responses were coded through a multi-stepped approach. Suicide methods were classified using the intentional self-harm (X60–X84) codes of ICD-10.¹⁹ Reasons for engaging in specific methods were analysed inductively for content,²⁰ and an additional coding category was created to capture deterring factors, where reported. Three coders (D.F.St-H., H.M., N.E.-G.) coded 10% of the data, with substantial interrater reliability (Kraemer's kappa 0.774) (see Supplementary Appendix for a full description of the coding protocol and details of interrater reliability in relation to individual code categories).

Survey data are presented as frequencies or percentages, as appropriate. Variations in method choices were analysed using chi-square tests (for categorical variables) and *t*- and Mann–Whitney *U*-tests (for continuous variables). All statistical analyses were performed at a 5% level of significance.

Results

We analysed the responses of 1398 people (Table 1). Of these, 68.5% identified as females, 29.5% as males, and 2.0% as transgender/gender fluid. Participants had a median age of 32 years (range 16–73), and around a third were aged between 18 and 30 years old (37.7%). The majority of the participants described themselves as White (92.8%), heterosexual (74.7%), and non-religious (53.0%).

Table 1 Self-reported characteristics of the participants

Characteristic	n	(%)

All participants reported prior thoughts of suicide. Of these, 686 respondents (49.1%) had experienced suicidal ideation but not engaged in suicidal behaviour; 712 (50.9%) reported having engaged in at least one suicide attempt. The latter subsample included a higher proportion of women, but did not differ significantly from the former in relation to the other sociodemographic characteristics captured (*Table 1*).

Self-reported method choices: suicidal thoughts

When asked about previous thoughts of suicide, all but a small minority of respondents reported having considered a specific method, or methods ($n = 1279$, 91.5%). For most ($n = 799$, 57.2%), multiple methods had been contemplated (median 2; maximum 10), at different times or over time. On average, respondents with a prior history of suicidal behaviour reported having considered more suicide methods than those who had never attempted suicide (mean 2.17 (s.d. = 1.48) v. 1.84 (s.d. = 1.3), $P < 0.001$), with no significant difference between male and female respondents.

Overall, self-poisoning was the most frequently contemplated method of suicide (809/1398, 57.9%), including when only one method was considered (220/480, 45.8%). Approximately a quarter of the participants had experienced thoughts of suicide by hanging (381, 27.3%) or jumping from a high place (330, 23.6%) and fewer had considered self-harm by a sharp object (275, 19.7%), train (208, 14.9%) or other vehicle collision (208, 14.9%; all other methods were mentioned by under 10% of the participants).

There were some significant differences in the suicide methods contemplated by those who had and had not engaged in suicidal behaviour. The latter were more likely to cite relatively unusual methods such as crashing a vehicle (thoughts only versus behaviour: 85/686 (12.4%) v. 41/712 (5.8%); $\chi^2 = 18.74$; $P < 0.001$) and handgun discharge (thoughts only versus behaviour: 36/686 (5.2%) v. 21/712 (2.9%); $\chi^2 = 4.72$; $P = 0.030$), whereas those with a history of suicidal behaviour were more likely to report thoughts of suicide by hanging, strangulation or suffocation (behaviour versus thoughts only: 229/712 (32.2%) v. 153/686 (22.3%); $\chi^2 = 17.10$; $P < 0.001$), self-poisoning (behaviour versus thoughts only: 489/712 (68.7%) v. 320/686 (46.6%) $\chi^2 = 69.56$; $P < 0.001$) and self-harm by a sharp object (behaviour versus thoughts only: 159/712 (22.3%) v. 116/686 (16.9%); $\chi^2 = 6.50$; $P = 0.011$).

Self-poisoning and self-cutting were more commonly reported by female respondents, compared with males (self-poisoning, females versus males: 606/896 (67.6%) v. 151/386 (39.1%); $\chi^2 = 90.7$, $P < 0.001$; self-cutting, females versus males: 193 (21.5%) v. 60 (15.5%); $\chi^2 = 6.1$, $P = 0.013$). In contrast, male respondents were more likely to have considered death by hanging, strangulation and suffocation (males versus females: 131 (33.9%) v. 221 (24.7%); $\chi^2 = 11.65$; $P = 0.001$) and, but less frequently, by gasses and vapours (males versus females: 27 (7.0%) v. 31 (3.5%); $\chi^2 = 7.81$; $P = 0.005$), or handgun discharge (males versus females: 30 (7.8%) v. 24 (2.7%); $\chi^2 = 17.35$; $P < 0.001$).

Suicidal behaviour and method choice ‘switching’

Fewer, and often different, methods choices were described in relation to actual suicide attempts (median number of methods reported in relation to suicidal behaviour 1; maximum 7). Self-poisoning was again the most commonly reported method in this context (555/712, 77.9%), particularly among female respondents who had attempted suicide (females versus males: 426/506 (84.2%) v. 104/171 (60.8%); $\chi^2 = 41.1$, $P < 0.0001$). This was followed by self-harm by sharp object (118/712, 16.6%), hanging (103/712, 14.5%; males versus females: 37 (21.6%) v. 64 (12.6%); $\chi^2 = 8.1$, $P = 0.004$), and jumping from a high place (60/712, 8.4%).

A small proportion of those who had considered self-poisoning when contemplating suicide (47/602, 7.8%) reported having adopted a different method or methods when engaging in suicidal behaviour. Relatively less common methods, such as jumping/falling from a height, drowning or vehicle collision, were reported considerably more frequently in relation to thoughts than actual suicidal behaviour.

Among respondents who had made one or more suicide attempts, the vast majority who had considered jumping/falling from a height (137/197, 69.5%), or in front of a train (96/116, 82.8%) or other vehicle (54/86, 62.8%), had not then attempted suicide by these specific methods. This was also observed in relation to suicide by gasses and vapours (24/33, 72.7%), chemicals and noxious substances (28/45, 62.2%), drowning (52/77, 67.5%), crashing of a motor vehicle (38/48, 79.2%), and less frequently reported methods such as handgun discharge (17/22, 77.3%), and smoke, fire

and flames (7/10, 70%). A smaller, but considerable, proportion of those who had contemplated suicide by hanging (143/246, 58.1%), sharp object (91/209, 43.5%) or poisoning by alcohol (29/84, 34.5%) had also then used different methods when attempting suicide.

Motivations for and against method choices

Self-reported reasons for considering one or more methods of suicide were varied and often multiple. In describing their motivations for contemplating or attempting suicide by a specific method or methods, most respondents focused on more than one factor, particularly when discussing suicidal thoughts (815/1238, 65.8%, maximum 11; 359/679, 52.9% mentioned more than one reason in relation to suicide attempts, maximum 8).

There were some interesting differences in the reasons given for considering a specific method when contemplating suicide, as opposed to engaging in suicidal behaviour (*Fig. 1*). *Fig. 1* Self-reported motivations for method choices in relation to suicidal thoughts ($n = 1398$) and suicide attempts ($n = 712$).

Effectiveness, accessibility, ease and speed of a suicide method were the most commonly cited reasons for contemplating suicide by a specific method, alongside the wish to minimise pain and violence. Almost 70% of participants who stated one main reason for contemplating suicide by specific means cited one of these factors (287/423, 67.8%). However, when respondents commented on their motivations for attempting suicide by a given method, accessibility became the single most recurrent concern (reasons for suicidal behaviour versus ideation (all participants): 316/712 (44.4%) v. 319/1398 (22.8%), $^2 = 104.3$, $P < 0.0001$), and impulsivity a more frequently cited reason (behaviour versus ideation: 86/712 (12.1%) v. 85/1398 (6.1%), $^2 = 22.8$, $P < 0.0001$), particularly among women (females versus males: 70/506 (13.8%) v. 12/171 (7%), $^2 = 5.6$, $P = 0.018$).

Accessibility was the most commonly reported reason for attempting suicide by a specific method even when excluding motivations for self-poisoning (the most common method of suicidal behaviour in the participants), and in relation to each method individually (alongside method ease and/or effectiveness for attempts by chemicals and noxious substances, other gasses and vapours, and handgun discharge). The only exceptions were attempts by jumping or lying in front of a vehicle (including trains), for which method effectiveness was the most frequently cited reason (13/45, 28.9%), and smoke, fire and flames (for which, however, only three participants provided data).

When discussing suicidal behaviour, ease of method remained among the more frequently cited reasons for choosing a specific method, but speed, effectiveness and the desire to minimise pain and violence were less commonly mentioned than in relation to suicidal thoughts (speed, behaviour versus ideation: 62/712 (8.7%) v. 272/1398 (19.5%), $^2 = 39.4$, $P < 0.0001$; effectiveness, behaviour versus ideation: 86/712 (12.1%) v. 364/1398 (26.0%), $^2 = 54.8$, $P < 0.0001$; minimising pain and violence, behaviour versus ideation: 99/712 (13.9%) v. 300/1398 (21.5%), $^2 = 17.6$, $P < 0.0001$).

Among those who had engaged in suicidal behaviour, effectiveness appeared to be a marginally (but significantly) greater concern for males (males versus females: 29/171 (17.0%) v. 54/506 (10.7%), $^2 = 4.7$, $P = 0.03$) and reducing pain and violence for females (females versus males: 82/506 (16.2%) v. 14/171 (8.2%), $^2 = 6.8$, $P = 0.009$). In total, 10% of respondents reported having used a specific method of suicide following exposure to that method (via family and friends as well as media reports). Less common reasons, in relation to both suicidal thoughts and behaviour, included a desire for privacy and to avoid interruption, to minimise the impact on loved ones and other bystanders, or to maximise pain.

Some of the differences in the decision-making around suicidal thoughts versus behaviour were reflected in the motivations for contemplating a specific method in those who had engaged in suicidal behaviour and those who had not. In particular, accessibility of method was more frequently mentioned by those with a history of suicidal behaviour (behaviour versus thoughts only: 180/712 (25.3%) v. 139/686 (20.3%), $^2 = 5.0$, $P = 0.025$), alongside perceived lethality (behaviour versus thoughts only: 205/712 (28.8%) v. 159/686 (23.2%), $^2 = 5.7$, $P = 0.017$) and, less often, a wish to maximise pain (behaviour versus thoughts only: 32/712 (4.5%) v. 9/686 (1.3%), $^2 = 12.41$, $P < 0.0001$). Respondents who had never acted on suicidal thoughts were instead more likely to mention wanting to minimise the impact on others (thoughts only versus behaviour: 116/686 (16.9%) v. 83/712 (11.7%), $^2 = 7.9$, $P = 0.005$), including and especially family and friends (thoughts only versus behaviour: 63/686 (9.2%) v. 43/712 (6.0%), $^2 = 4.9$, $P = 0.026$), and, in smaller numbers, to be in an isolated location where one's attempt and body would not be discovered (thoughts only versus behaviour: 21/686 (3.1%) v. 10/712 (1.4%), $^2 = 4.4$, $P = 0.035$).

Concern about the impact on others was also a key theme in the responses of participants who mentioned motivations for not using specific methods (57 respondents discussed discarding a particular method of suicide for this reason), alongside fears around survival (potentially with injuries, $n = 58$), and of not 'getting it right' ($n = 51$). Further deterring factors included concerns over the violent/painful nature of a method ($n = 35$), its 'messiness' ($n = 11$) or slowness ($n = 7$), lack of access ($n = 19$) or privacy ($n = 5$), and the discarding of a method having used it previously ($n = 4$) or researched it ($n = 9$).

Discussion

Main findings and interpretation

Although specific methods, and composite methods, have been associated with a higher risk of death and subsequent suicidal behaviour, epidemiological analyses of repeat hospital admissions for self-harm have concluded that 'method of self-harm is fluctuating and unpredictable'.⁹ The results of this exploratory study of first-person accounts suggest that, although indeed changing and complex, method choices are reasoned, personally and culturally meaningful, and a crucial element of the processes and planning involved in attempting (or desisting from) suicide. With very few exceptions, individuals who had contemplated suicide had considered a specific mean (or, more often, means) of taking their own life, even when they had never then engaged in suicidal behaviour. Almost 90% described a particular reason, or set of reasons, for considering or discarding such method/s.

To date, method choices have primarily been investigated in relation to completed suicide and suicide attempts.^{5,21,22} This is the first study to explore patterns and motivations for method choices in relation also to suicidal ideation, which is a surprising gap in knowledge given that 10–20% of individuals experiences lifetime suicidal ideation.^{2,23} Suicidal thoughts are a known risk factor and immediate precursor of suicidal behaviour, and key to understanding the transition from 'suicidal ideation to action'.^{14,15} In relation specifically to methods choices, suicidal thoughts provide some important insights into the acceptability and cognitive availability of different means of suicide. In other words, they can help us understand which methods are cognitively available to individuals in crisis (in a given sociocultural context), and what makes them more or less 'attractive' to them.

In this study, self-poisoning was the most commonly contemplated method of suicide. However, most respondents had considered multiple methods of suicide, particularly those who had also engaged in suicidal behaviour. These included a fairly wide range of potential methods and, especially among individuals who had never attempted suicide, relatively uncommon means such as jumping or lying in front of a moving object, drowning, handgun discharge and crashing of a motor vehicle. In England and Wales, self-harm involving a moving object, drowning or fall and fracture accounts, all together, for 12% of all suicides,²⁴ and only 1% of hospital presentations for self-harm.¹⁰ Firearm use, although a common suicide method in countries with less stringent gun control such as the USA,²⁵ is even rarer in the UK, accounting for less than 2% of all suicides²⁶ and 0.03% of self-harm hospital presentations.¹⁰ Although these are only a small proportion of completed suicides and hospital presentations for self-harm, such methods tend to be disproportionately reported in the media,¹¹ which may reflect and account for their over-representation and over-availability in people's suicidal thoughts (in the UK, most suicides are hanging¹⁶ whereas most hospital presentations for self-harm involve self-poisoning¹⁰). Almost 10% of the participants explicitly identified exposure to a given method as a primary motivation for considering it as a means of suicide. Even more common reasons were perceived method ease, accessibility, speed and effectiveness, alongside the desire to minimise pain and violence.

However, the range of methods described in relation to actual suicidal behaviour was narrower, as were respondents' motivations for using such methods. Over three quarters of respondents attempted suicide by self-poisoning, with many switching to this method having also considered more violent or unusual means. For almost half of the participants, choice of attempt method was primarily dictated by accessibility, and ease of method and the minimisation of pain were more common concerns than perceived speed or likelihood of death. An exception was jumping/lying in front of a vehicle, for which method effectiveness was the most frequently cited reason (see also Marzano et al¹⁸).

In relation to all methods, lethality appeared to be a greater concern for male than female respondents, and impulsivity less common, as also reported elsewhere.^{27,28} Together with the increased use of methods other than self-poisoning,²⁹ this might contribute to the disproportionate risk of suicide in men.

Of note are also some of the differences between respondents who had contemplated but never engaged in suicidal behaviour, and those who had previously attempted suicide. The former were more likely to mention wanting to minimise the impact on others, especially family and friends, and, in smaller numbers, to be in an isolated location where one's attempt and body would not be discovered. This points to the presence and impact on bystanders and loved ones as important 'dissuaders' in relation to suicide. Indeed, these were also among the most frequent reasons for not attempting suicide by a specific method. Other common deterrents were fears of surviving with injuries and of 'not getting it right'.

Interestingly, impulsivity was not a more common theme in those who had attempted suicide *per se*, but was cited more frequently in relation to suicidal behaviour than ideation. This finding lends support to the idea that individuals who attempt suicide may not have significantly elevated trait impulsiveness, compared with 'ideators'; however, they may have higher impulsiveness when in a negative state.³⁰

Strengths and limitations

We analysed rich descriptions of people's choice of methods in relation to suicidal thoughts as well as behaviours, with strong interrater reliability, and no prompting, structure or limit to the answers that could be provided. This exploratory, inductive approach is rare with samples as large as the current study's, and allows for appropriately powered statistical analyses, as well as more nuanced, in-depth analyses of particular groups or methods, including the different images, myths and cultural scripts that exists around – and against – specific means of suicide (as presented elsewhere in relation to railway suicide¹⁸).

However, findings were based on a self-selected, predominantly female sample, and may not necessarily be representative of all individuals who consider, attempt or indeed die by suicide, within the UK and more widely. National and cultural variations in suicide method choices suggest the need for replication with broader and more diverse samples,²⁵ in a wider range of community and clinical settings.

Given the exploratory nature of this study, we did not gather systematic information about potentially important factors such as prior psychiatric and family history, nor about the sequence or temporality of suicidal thoughts and behaviour. This limits the conclusions that may be drawn in relation to method switching, escalation and substitution, and prevented us from making inferences about age differences in method choice. Further, longitudinal studies could usefully investigate how the frequency, intensity and intent of suicidal thoughts and behaviour may affect method choices in different groups and communities. A more structured approach to gathering information about deterring factors could also offer important insights into how best to prevent, and 'dissuade' from, specific means of suicide, in different contexts and locations.

Implications

Previous research has concluded that 'people's risks or needs [cannot be] based simply on the method of harm',⁹ or the potential lethality of that method. The results of this study also suggest that the methods people consider when contemplating suicide are often not the ones that are then enacted in a suicide attempt, nor are they necessarily chosen for the same reasons. Nonetheless, exploring method choices is far from a fruitless activity, and can usefully inform preventative initiatives.

Consistent with earlier literature, our findings suggest that cognitive and physical availability are key drivers in the choice and prevalence of suicide methods. The former appears to be particularly relevant in the context of people's suicidal thoughts, with methods perceived to be 'easy' and lethal featuring highly in individuals' so called 'ideation menu'.³¹ The latter (i.e. the accessibility of a given method), becomes especially important in the context of a suicide attempt, and impulsivity relatively more common. This clearly underscores the need for preventative measures that restrict access to means and delay impulsive behaviour, such as the erection of barriers at high-risk locations and reduced pack sizes of paracetamol.³² Avoiding depictions and descriptions of suicide methods in the media may help limit the cognitive availability of specific means, particularly for methods portrayed as lethal, easy, quick and painless. This may be especially important in the reporting of celebrity suicides. A recent meta-analysis found that when the suicide method used by a celebrity was reported, there was an associated 30% increase in deaths by the same method.³³

In clinical settings, exploring the decision-making around specific methods may help challenge unhelpful myths and misconceptions, identify areas of ambivalence and hope, and develop appropriate safety and treatment plans. At public-health level, factors known to attract individuals and subgroups to lethal means of suicide may be challenged via targeted communication and media strategies, and common ‘dissuaders’ reinforced. However, the risk and unintended consequences of different approaches to means and ‘myth-restriction’ need careful thought and evaluation, whether in the context of means-restriction counselling³⁴ or as part of wider public health approaches. Further research is needed in this area, but the risks and ethics of how and where research findings are disseminated and ‘translated’ need careful attention to avoid reinforcing the acceptability and availability of (lethal) means of self-harm.

We are greatly indebted to the hundreds of people who generously shared their time, stories and experiences with us. This programme of research was commissioned by Samaritans and funded by Network Rail on behalf of the rail industry. We are grateful to the Project Stakeholder Group for their support throughout the research, particularly Ian Stevens, Rachel Watters and Caroline Kingston (Network Rail), Kim Tuley (British Transport Police), Michael Woods (RSSB), Gary Cooper (ATOC (Association of Train Operating Companies) and National Task Force) and Susie Beevor (ATOC), Stephanie Aston, Ola Rzepczynska and Lorna Fraser (Samaritans). The late Mark Smith, MBE, Head of Suicide Prevention and Mental Health at British Transport Police, played a key role in supporting this research, and several other suicide prevention initiatives. His dedicated and intelligent approach to suicide prevention has helped save many lives, and inspired countless others. Thanks are also due to Professor Keith Hawton, Fiona Malpass, Ian Noonan and Professor Damien Ridge, who provided invaluable advice and support at several stages of the project. Additional thanks are due to the National Suicide Prevention Alliance (NSPA), Rethink and CALM (Campaign Against Living Miserably) for their assistance with participant recruitment, and Andy Bardill, Kate Herd and Kirsty Tither of Redloop (Middlesex University) for help with the study website and recruitment materials.

Abstract

Aims and method

Asylum seekers are required to narrate past experiences to the UK Home Office, doctors, lawyers and psychologists as part of their claims for international protection. The Home Office often cites perceived inconsistencies in asylum interviews as grounds for refusal of their claims. A number of processes affect asylum seekers' abilities to narrate past experiences fully to the professionals interviewing them. The dilemmas around disclosure that asylum seekers face have received little attention to date. This work aims to explore the perspectives of UK-based medico-legal report-writing doctors, lawyers and psychologists whose work involves eliciting narratives from asylum seekers on the processes that affect asylum seekers' abilities to disclose sensitive personal information in interview settings. Eighteen professionals participated in semi-structured interviews in individual or focus group settings to discuss, from their perspectives of extensive collective professional experience, the narrative dilemmas experienced by asylum seekers with whom they have worked.

Results

Professionals identified a number of processes that made disclosure of personal information difficult for asylum seekers. These included asylum seekers' lack of trust towards the professionals conducting the interview, unclear ideas around pertinence of information for interviewers, feelings of fear, shame and guilt related to suspicions around collusions between UK and their country-of-origin's authorities, sexual trauma and, occasionally, their own involvement or collusion in crimes against others.

Clinical implications

Recommendations are made on how to improve the interview environment to encourage disclosure. These have important implications for future research and policy initiatives.

The UK, as a signatory to the 1951 United Nations Convention and Protocol Relating to the Status of Refugees, has an obligation to consider applications from individuals fleeing persecution in their countries of origin.¹ The UK Home Office assesses applications through initial and substantive interviews with asylum seekers, who are expected to narrate their past experiences to demonstrate their reasons for seeking asylum. The United Nations High Commissioner for Refugees defines an asylum seeker as ‘someone whose request for sanctuary has yet to be processed’.² A refugee is defined as ‘someone who is unable or unwilling to return to their country of origin owing to a well-founded fear of being persecuted for reasons of race, religion, nationality, membership of a particular social group or political opinion’ according to the 1951 Refugee Convention.¹ In the year ending June 2018, the UK Home Office received 27 044 applications for international protection and granted 14 308 of them.³ The Home Office sometimes rejects asylum claims based on perceived inconsistencies in asylum seekers’ accounts of their past experiences.⁴ Asylum seekers may have to narrate these experiences to other professionals, including asylum tribunal judges (when rejected asylum claims are subject to appeal), medico-legal report-writing doctors and psychologists (for forensic reports to provide medical evidence in regards to the person’s asylum claim), legal professionals (for witness statements), and psychologists and other therapists (for the treatment of mental health problems).

Asylum seekers’ abilities to disclose information about their past experiences may be affected by various psychological and cultural factors, particularly where there is a history of trauma. Studies on resettled refugees indicate that asylum seekers who have sustained multiple traumas in the past often report high levels of post-traumatic stress disorder (PTSD) and depression.^{5,6} It is well documented that asylum seekers who have had many traumatic experiences will avoid disclosing such memories.⁷ Research suggests that external factors such as the interview room setting and the behaviour of Home Office officials can serve as triggers for traumatic memories.⁸ Currently, little is known about the range of dilemmas faced by asylum seekers when making decisions about the content of their narrated accounts, such as omitting or altering information, sometimes on the instructions of or under the influence of other people.⁹ Professionals working with asylum seekers offer a unique vantage point to guide an exploratory study of these dilemmas, as they are able refer to their extensive professional experience with a variety of asylum seekers. A small sample of individuals with refugee status were interviewed separately about dilemmas they experienced when narrating their past experiences to professionals. This constitutes a complementary study which is currently being prepared for submission.

Method

Participants

Eighteen professionals were recruited from fourteen different organisations that provide clinical and legal support to asylum seekers in England. The research study was advertised through direct email outreach requesting interviews with individuals whose work involves eliciting accounts from asylum seekers. Organisations were identified using chain sampling based on existing professional connections. Current and former Home Office decision makers were also invited to participate, but no individuals accepted the opportunity to do so.

Written informed consent was obtained from all participants. All procedures contributing to this work comply with the ethical standards of the relevant national and institutional committees on human experimentation and with the Helsinki Declaration of 1975, as revised in 2008. All procedures were approved by the University College London ethics committee (reference 8133/003).

Data collection

Data were collected between July and December 2017 through face-to-face interviews, conducted either individually or as focus group interviews. Three professionally homogenous groups of doctors or lawyers were interviewed using a focus group discussion format. *Table 1* shows the distribution of professionals. Focus group discussions were chosen as an appropriate method of data collection for a feasibility study because of their inherent 'dynamic quality of group interaction'.¹⁰ Three therapists were interviewed individually owing to practical constraints. *Table 1* Characteristics of study participants

P18	Therapist	Psychotherapist and director of NGO	Male	25

Semi-structured interviews involving open-ended questions were conducted. The authors of this paper designed the interview schedule collaboratively, with input from a small team of psychologists and lawyers with critical insights into the effects of credibility concerns inherent to the UK's asylum adjudication on asylum narratives. The interviews were structured to encourage professionals to reflect on how asylum seekers they worked with experienced the process of narrating past experiences.

Questions included the following. (a) Have you experienced situations where your clients' narratives evolved or changed over time? (b) In what ways have these narratives changed? (c) What do you think is the impact of the location in which asylum seekers are talking to professionals such as yourselves, and/or the presence of an interpreter, on the type of

narrative that they are able to share?(d)Are there any causes that you might be able to attribute to late disclosure of additional or changed information, based on your experiences?(e)Do you think it's difficult for all asylum seekers to talk about what's happened to them in their past, or more for certain asylum seekers compared to others?

Data analysis

Interviews were recorded and transcribed verbatim. A thematic analysis approach was used to identify patterns of experiences of different professionals and across the interviews.¹¹ The data-set was double-coded by one author (P.A.) who collected the data and another (M.V.W.) who was not familiar with the content of the interviews prior to coding. The entire data-set was coded descriptively, and key themes were identified that were evident across the data-set. Two research questions drove decisions about the 'keyness' of a theme.¹¹

The authors collaboratively interpreted codes and themes in the data. A third author (Y.W.) input the data into NVivo version 10. The research team were cognisant of the theoretical framing that drove the interview schedules and their own analytical skillset that informed the coding. Following Braun and Clarke's reflexive thematic analysis approach, the research team focused on 'reflexive and thoughtful engagement with their data'.¹² (a)What are the dilemmas faced by asylum seekers when narrating their past experiences to different professionals, as understood by professionals who work with them?(b)What factors may inhibit an open discussion of the past experiences that asylum seekers are required to narrate in their claim?

The richness of the data is demonstrated in the Results section through the use of quotes from the data-set that illustrate the key themes in the data.

Results

The four main themes of processes influencing asylum seekers' narratives that emerged from the interviews are reported here. These are: (a)omission of information as a narrative dilemma;(b)alteration of information as a narrative dilemma;(c)embellishment of information as a narrative dilemma;(d)influence of trauma on disclosure.

The term 'narrative dilemmas' refers to the dilemmas experienced by asylum seekers when narrating their past experiences to professionals interviewed for this research. Other issues that emerged from the data included the effects of individual identity and interview environment on disclosure. These are addressed in the Discussion section.

Omission of information as a narrative dilemma

The majority of participants revealed that they had worked with asylum seekers who had omitted a piece of information at least once during their claim for asylum. A medico-legal report-writing doctor presented the example of an asylum seeker who had been imprisoned in a police station and jail, and refused to divulge details of her experiences in the police station. In his opinion: "“This wasn't that she didn't remember. She clearly did. It was much more of a conscious choice of choosing not to re-engage with something that she knew she would find distressing. And there was a sort of moral component to it that she felt she didn't want to be defined by what had happened' (P2, psychiatrist, male).”

Participants described situations in which asylum seekers they worked with did not volunteer information. These included when the information was of a sensitive nature such as sexual trauma, if they were unclear about the pertinence of a piece of information for the interviewer, or when they were asked a direct question in one interview but not in another.

Participants expressed the collective view that asylum seekers who had perpetrated acts of betrayal or violence often did not disclose these experiences in the first interview or meeting with a professional. This was also the case for experiences of sexual violence (particularly for men). Participants attributed this to feelings of guilt, shame and stigma, as well as lack of trust in the professional. Participants reflected that that asylum seekers sometimes omitted information owing to fear of repercussions from people who exercised control over them, such as human traffickers or state authorities in their countries of origin whom they sometimes suspected of colluding with UK state authorities. According to participants,

asylum seekers they worked with may doubt the confidential nature of interviews with UK professionals and as a result omit information.

Alteration of information as a narrative dilemma

Participants shared a common experience that the asylum narratives they heard from their clients were altered over time. This often included delayed disclosure of some aspects of asylum seekers' past experiences. Information disclosed later would replace information that had been omitted as mentioned above or fabricated for reasons discussed below. Participants were of the opinion that asylum seekers sometimes disclosed more new information in the setting of an increasingly trusting relationship with the interviewer over time, on advice of a friend or family member, in response to changing levels of stigma in the community or in situations of external pressure such as being under oath in court.

Participants shared a variety of changed narratives that they had observed in their professional experience, from minor details such as changes of dates to the disclosure of new significant traumatic events such as rape. Examples reported included asylum seekers who said they escaped their country of origin in a specific month and then later changed it to another because they could recall the season but not the dates. In addition, they recounted incidents where some asylum seekers claimed that they entered the country later than they had, based on advice from friends to conceal the number of years spent undocumented before claiming asylum for fear that their claims would be refused on that basis.

A doctor interviewed an asylum seeker who, according to previous interview records, had allegedly been trafficked directly to the UK. However, she later disclosed that she had, in fact, been trafficked to a different country and had subsequently escaped and paid a smuggler to enter the UK. She had fabricated that part of her claim based on the advice of a friend.

A lawyer reported that he had seen many asylum seekers who had downplayed their membership of anti-government groups, based on unfounded warnings from others that asylum claims from members of such proscribed organisations were likely to be refused.

A male asylum seeker who had divulged information about a rape to the doctor preparing his medico-legal report called the doctor years later to have his account of this significant event redacted. He denied having ever mentioned it and wanted his statement altered, despite the doctor's records clearly documenting his previous account of the rape. The doctor attributed this to a wish to take control of the recollection of a past experience in which control had been taken away from him.

It was the common experience of participants that survivors of human trafficking had been given information by their traffickers, such as names of locations they had crossed in order to reach the UK, and that they had believed this information and repeated it in their interviews. Some survivors of trafficking had been specifically instructed to tell a fabricated story and complied because of threats, or owing to the power they perceived their trafficker to have over them. For example, several participants gave examples of traffickers who subjected individuals to 'juju' rituals exploiting their spiritual beliefs,¹³ in order that the individual would feel 'bound' to the trafficker and compelled to comply with their demands for fear of (often life-threatening) reprisals against themselves or loved ones. "I certainly have seen a number of victims of trafficking who are told that if they don't cooperate – for example, if they don't cooperate with the full story, which the trafficker has given them – then the trafficker will do the same thing to their younger sister as they did to them' (P2, psychiatrist, male)."

A medico-legal report-writing doctor had worked with an asylum seeker who drastically changed her narratives. He thought this was because the asylum seeker's abuser was present at the first interview, had acted as an interpreter for her and had controlled what was told to the doctor.

A further medico-legal report-writing doctor who visited asylum seekers in detention recalled receiving a phone call from an asylum seeker the day after the examination. The doctor reported that this asylum seeker had shared her decision to disclose new information that she had previously withheld about the sexual violence she had endured, after seeking the advice of a friend. Participant 6 explained: "With the minor details or changes in dates, and things, I would say that's memory. With more significant, kind of, omissions, I guess, I would say it's normally trust." (P6, psychologist, female)"Participants were of the opinion that sometimes the asylum seekers they worked with lied to

protect the lives of others. Others who identified with their abusers may have wanted to protect the abusers and change their narratives accordingly.

Embellishment of information as a narrative dilemma

A medico-legal report-writing doctor had seen a survivor of a ‘blood feud’ who had embellished his past experiences by fabricating that he was an only child. Whereas in the survivor’s view this ‘would make my story stronger’, according to the doctor, it had the opposite effect when it was uncovered. Similarly, a lawyer shared his experience of what he viewed to be a recent trend: “‘We see a lot of these [nationality redacted] boys, they come from a background of very limited education, shepherds, and then have an experience of living in a conflict zone, domestic violence, their father’s been murdered in front of them, and then maybe they’ve decided to add on a torture story because somebody’s told them that won’t get you asylum and you need to have been tortured [to get asylum]. Maybe they have been and maybe they haven’t, but a whole lot of other bad stuff has happened to them.’ (P7, lawyer, male)”

Psychologist participants explained that often when asylum seekers embellished their symptoms, there were likely clinical explanations for their behaviour, for example, the individual attempting to get help for their unmet needs. “‘The things she was presenting with were not consistent with any formal diagnosis ... however, she desperately wanted to get her needs met but it was almost as though she’d heard other people had done it so therefore she put that into the pot to be sure that I would recognize that she needed help. That’s how I interpreted it, actually’ (P13, doctor, female).”

Influence of trauma on disclosure

Participants reported that in some situations they interpreted the silence of an asylum seeker as indicative of the most severe parts of their traumatic history. Participants thought this inability to verbalise such experiences highlighted the effects of sustained periods of intimidation and subordination on survivors of trafficking and/or servitude and torture, such as the inability to develop an identity or narrative of their own. Sexual trauma, linked to feelings of embarrassment, shame and humiliation, was cited as one of the most difficult experiences for asylum seekers to disclose. Participants attributed this to fears of social stigma and resultant social exclusion. Participants reflected on their interactions with asylum seekers who they thought did not self-identify as victims of abuse, and expressed the opinion that the skewed self-perception of some asylum seekers affected how they presented certain experiences to their interviewers. This was particularly the case with victims of childhood abuse, according to participants, who may not have understood their experiences as constituting abuse and had fragmented memories of their past. Childhood trauma was explained as having particularly prolonged and longstanding effects on individuals, influencing their ability to disclose such events, and seen as potentially leading to intensified symptoms of PTSD. Re-experiencing phenomena and avoidant behaviours are core symptoms of PTSD.¹⁴ All participants spoke about the ‘fragmentation’ of memories that can occur in PTSD, which can lead to ‘gaps’ in the individual’s narrated history, which in turn can lead to ‘inconsistent’ accounts.¹⁵

Participants across all interviews also spoke about their assessments of the effects of dissociation on the asylum seekers’ ability to disclose a full and complete history. Some shared experiences where individuals had appeared to them to lose awareness of their surroundings and their sense of self, inevitably resulting in a lack of clarity or coherence in the narrative. Participants also analysed individuals’ desire to avoid thinking about the traumatic memories as manifesting itself by avoiding talking about the traumatic event, and avoiding external reminders of the traumatic event, which complicated disclosure. For example, a participant shared her experience that clients often use vague expressions and euphemisms when talking about traumatic experiences instead of clearly disclosing a description of the sexual experiences. “‘People use vague terms as part of their PTSD defence and avoidance, about “them” or “that man”, “those people” or “the work”’ (P15, psychologist, female).”

All professionals detailed a myriad of body language indicators of distress, including restlessness, reddening eyes, crying, movement of jaw muscles, hyperventilation and body clutching, as well as other PTSD symptoms described above. Participants continually underlined the importance of non-verbal cues in their professional roles in order to provide corroborating evidence for any clinical conclusions and noted that non-audible features of clients’ accounts were mostly absent from transcripts of Home Office interviews.

The focus group discussions produced consensus over the majority of issues reported this section. There was a minor point of contention in the second focus group discussion with medico-legal report writing doctors regarding the balance between their roles as impartial witnesses and their urge to express their sympathy for the asylum seekers they work with.

Discussion

This exploratory research investigated the processes involved in asylum narratives that changed over time from the perspectives of professionals who work with them. This study revealed the unique vantage points of doctors, lawyers and psychologists with years of collective experience working with asylum seekers from different countries with different types of asylum claims, in professional relationships ranging from singular interviews to long-term therapeutic work.

One of the key findings of this research is that, according to participants in this study, asylum seekers may sometimes select what information to disclose based on their perceptions of its pertinence to the particular interview or interviewer. This is particularly significant given that asylum seekers are interviewed by a range of different professionals and suggests that they make decisions about what information to share with each professional. Most participants conveyed that the time available to build a rapport with the asylum seekers they interviewed was directly related to the level of disclosure they subsequently received from the asylum seekers, owing to the development of a trusting relationship. The different professional standpoints and the difference in time available to participants, such as the length of the interview, the number of appointments, and the duration of the professional relationship, affected the type of information disclosed to them. The findings suggest that any expectation that asylum seekers make full disclosures of their past experiences is unrealistic because disclosure is a prolonged process which often cannot be achieved in a singular interview. Similarly, expectations around the accuracy of detail in a narrative, or consistency over time, are incompatible with the processes of human memory, particularly in individuals suffering from PTSD. Participants mentioned additional factors that contributed to narrative dilemmas experienced by the asylum seekers they worked with, which were in line with previous studies on the influence of the interview environment, including physical features of the room, the gender of the interviewer and the role of interpreters, as well as interviewer expectations of emotional congruence from asylum seekers.^{9,16-21} However, as our study focused on professionals' perceptions of the decision-making processes that drove some asylum seekers' disclosures, we chose to focus on types of dilemmas and their relationship with asylum seekers' traumatic past experiences.

This is a small sample study, whose results cannot be generalised. Furthermore, interviews did not follow an identical format, owing to adjustments made to accommodate individual participants' time constraints, which may have affected the content of the interviews. As this study adopted Braun and Clarke's reflexive thematic analysis method,¹² a collaborative approach was taken that focused away from coding consistency and towards a nuanced reading of interview data.

A limitation of this study was that majority of the participants were white British; future research in this area should endeavour to recruit a more diverse sample, which would additionally allow another layer of analysis, i.e. of the relationship between professionals' ethnicity and asylum seekers' disclosures.

Overall, our findings demonstrate that it is potentially unrealistic to expect that asylum seekers will be able to disclose their past experiences in a complete manner to professionals, particularly in a single interview. It also highlights that there are a number of dilemmas that can affect asylum seekers' decisions around disclosure to professionals interviewing them, which are closely connected to their past traumatic experiences, present strong emotions about stigma and repercussions, and ongoing difficulties navigating the asylum process in the UK.

The scarcity of clear and accessible information about the procedures of asylum adjudication in the UK¹¹ renders asylum seekers susceptible to unhelpful advice from well-meaning friends or instructions from controllers, as conveyed by participants who reported incidents where asylum seekers had altered or fabricated elements of their narratives as a result of advice from friends or instructions from controllers. This demonstrates the need to interrogate what appears to be a 'choice' on the part of the asylum seeker to disclose or not disclose information, when in fact this may be a distressing dilemma arising out of trauma, fear and the control exercised by others such as traffickers, or due to misinformation or misunderstanding about what is 'best' for their asylum case.

Participants considered that the experiences of asylum seekers who had been survivors of trafficking or modern slavery,

sexual trauma, captivity in detention or prison, torture, and childhood traumas negatively affected their ability to discuss their past experiences openly. Such experiences were thought to render such individuals intimidated, devoid of power, mistrustful and suspicious. Our findings also suggest that details of traumatic events were sometimes not revealed to participants, and that on occasion traumatic events were revealed gradually over the course of a trusting professional relationship or following the perceived safety of successfully being granted leave to remain in the UK. These changes were seen by the professionals as a means by which asylum seekers exercised control over which aspects of their narrative they would share, and by doing so tried to regain some of the control that had been taken away from them when they had been subjected to abuse and torture in the past. Psychologists, psychiatrists and psychotherapeutic workers who had a professional understanding of the psychological needs of asylum seekers conveyed the importance of paying attention to the coherence between symptoms and the content of narratives to identify whether presentation of symptoms was a result of traumatic experiences or a misguided way of eliciting the help the individual felt they needed.

It is important to note that all participants spoke about the effects of fragmented trauma memories, which were said to lead to gaps in oral histories, leading to dislocated narratives and inconsistent accounts. These inconsistencies are sometimes cited as a reason for refusal in letters from the Home Office.⁴ Notably, a hostile asylum system and its 'culture of disbelief' was cited as a further source of trauma for some asylum seekers, who experienced anxieties as they anticipated being disbelieved or discredited; this supports recent literature on the effects of immigration detention.^{22,23}

Our findings have a number of practical implications for professionals who interview asylum seekers, and for policy makers and researchers. (a)The participants involved in this study conveyed that professionals conducting interviews can take measures to understand the process of disclosure in its complexity with the aim of making the interview environment conducive to gaining asylum seekers' trust and making them feel relaxed enough to disclose their full history. Participants recounted that certain individuals looked upon the notion of confidentiality with suspicion, or found it difficult to disclose sensitive personal information in front of professionals or interpreters from their own country and preferred instead to speak with foreign professionals. These are important factors to be considered when setting up an interview that requires disclosure of sensitive personal information. Participants' recommendations include considering in advance and where possible adjusting features of the interview setting to suit the specific needs of clients, such as lighting and noise levels, as well as the gender of the interviewer or interpreter; increasing interviewer awareness of PTSD symptomatology; and incorporating non-verbal information shared by the client, such as signs of distress or symptoms of PTSD, into interview notes.(b)Participants conveyed that professionals working with asylum seekers should treat them as individuals rather than a category of people and engage with their individual needs and dilemmas in a non-judgemental manner. Participants in our study explained that they perceived it as their task to understand and clarify the content of narratives and the reasons for any inconsistencies, in order to place the narratives in the context of the individual's asylum claim. This is indicative of a broader structural issue relating to the asylum interview, which, by requiring an individual to produce a narrative that is continuously consistent, places more emphasis on synthesising often traumatic histories into a coherent format, rather than addressing the health and welfare needs relating to these traumas.(c)We also recommend that future research focuses specifically on the experiences and opinions of asylum seekers and seeks their perspective on the issues that influenced any changes in their accounts over time.

We thank the individuals who agreed to share their experiences with us. We also thank Dr Stuart Turner, Professor Jonathan Smith and Dr Nick Midgely for their guidance.

1.2.13 Encouraging recruitment into psychiatry: practical initiatives

Neel Halder Zoé Mulliez

date

2021-02

Abstract

This article highlights key findings from a recent Royal College of Psychiatrists project showing that many UK medical schools are embracing the dual challenge of raising students' interest in psychiatry and ensuring that all doctors can support patients with mental illness. It focuses on two novel approaches to boosting recruitment into psychiatry: I'm a Medic Get Me Out of Here, an online outreach activity enabling schoolchildren to ask questions of health professionals in real time; and a living library, which creates a safe space for dialogue where topics are discussed openly between human books (professionals) and readers (undergraduate students) to challenge stereotypes. It is recommended that sharing these and other examples of good practice will help all medical schools encourage recruitment in psychiatry more widely.

Showing initiative – encouraging students to choose psychiatry

Over the past two years, the Royal College of Psychiatrists (RCPsych) has gathered and analysed information from medical schools and students to produce practical guidance on how to enhance the undergraduate experience of psychiatry. After hearing many positive examples of activities and initiatives, as well as finding out what students found less appealing, they identified four key action areas for medical schools: excellence in teaching; high-quality psychiatry placements; leadership from psychiatrists; and psychiatry-based enrichment activities.

Excellence in teaching

To start with, the focus should be on students' experiences of psychiatry teaching in the classroom or lecture setting. Many students fed back that they would like psychiatry content to be more prominent earlier and throughout the course. Not only would this reflect how psychiatry is an integral part of medicine (rather than just an add-on), but it would allow students to explore at an earlier stage their potential interest in helping patients recover from episodes of mental illness.

A widely held view was that learning in 'real-life' contexts should be further promoted, through simulation teaching, learning videos, case-based discussions, testimonies from people with lived experience as patients or carers, and lectures involving a panel of psychiatrists working in a range of subspecialties. The 'living library' initiative outlined later in this article is an example of this.

Students also highlighted the importance of accentuating how psychiatry is unique in its integration of science with a whole-person approach, and the role it has in driving the most exciting medical advances to transform treatments and foster overall health and well-being globally.

High-quality placements

Providing high-quality psychiatry placements is an intuitively sensible way to increase the number of students interested in it as a career. Of the 792 students who participated in our survey, 52.2% said they were more inclined to choose psychiatry after their placement.

But what does a good placement look like? *Fig. 1* illustrates a few components of medical students' experiences of psychiatry placements. *Fig. 1* Students' experiences of placements in psychiatry. A total of 792 students throughout the UK completed the survey. Note: it is rare to find undergraduate settings providing opportunities for undergraduates to offer talking therapy to patients under supervision, as students may not have received enough training to be able to

deliver this. Source: unpublished survey run by the Royal College of Psychiatrists between 15 October 2018 and 7 January 2019.

While there is no singular ‘best’ model for placements, students did report aspects that were more positive.

They particularly enjoyed the variety of experiences provided by psychiatric placements, in contrast to other specialties. Appeal also lies in the ability to talk to patients, more so than in other placements, and learn their history in greater detail. Some medical schools have set up longitudinal placements to provide the opportunity to follow patients during several weeks and observe the longer-term benefits of psychiatric interventions.

Introducing medical students to patients and clinicians in extreme environments such as prisons or secure hospitals arguably has a larger impact on improving attitudes to psychiatry. Archer et al¹ showed that a single-day visit to Broadmoor Hospital, a high-security psychiatric hospital in Berkshire, was effective in changing the attitudes of medical students towards forensic psychiatry, with 75% of participants stating that their attitude towards psychiatry had improved.

There is a common stereotype of psychiatrists working alone with patients. To combat this, students need to meet all members of the multidisciplinary mental health team. This will ensure that they understand how extensively professionals from a range of disciplines work together to treat patients’ needs holistically.

Students need to understand how psychiatric care fits into the healthcare system and see for themselves the high level of need. One way to do this would be for psychiatric placements to be better combined or coordinated with placements in other specialties and *vice versa*. The students would be able to (a) witness the interactions between general practitioners (GPs), doctors from other specialties and psychiatrists, (b) understand the benefits of integrated psychiatric care and (c) gain further skills in psychiatry, which will be helpful whatever specialty they end up choosing.

How can medical schools help students make the most of their placements? Some students said that they would like to feel better prepared before starting their placements in psychiatry. Budd et al² had previously suggested that this is important, particularly addressing their potential fears and negative perceptions of the specialty. The RCPsych’s Choose Psychiatry guidance for medical schools includes suggestions of what inductions might cover based on feedback from students, including: basic guidance on the type of symptoms to expect from patients with different illnesses and how they should respond; a briefing on procedural issues involved in working in psychiatric settings, including health and safety; and information on how a placement in psychiatry might affect their own emotions and mental health (www.rcpsych.ac.uk/become-a-psychiatrist/choose-psychiatry).

Medical students also said that they need reassurance about getting adequate mental health and well-being support. Some medical schools have set up Balint groups to provide a safe space for students to discuss their emotional reactions to their patients’ experiences. These should be supported and further expanded where possible.

Leadership from psychiatrists

Everyone can remember someone who inspired their career choices. Medical students highlighted the importance of talking to inspiring consultant psychiatrists and trainees during their time at medical school. Some suggested that medical schools could create a ‘bank’ or database of psychiatry mentors.

To raise the profile of psychiatrists in undergraduate education, the RCPsych encourages medical schools to reflect on whether their senior leadership teams are composed of a multispecialty and diverse group of individuals, including psychiatrists, so that students can see them in leadership roles.

Psychiatrists’ progressive and thoughtful leadership could play an integral role in driving the strategic direction of medical schools. The RCPsych advises medical schools to ensure that psychiatric education is designed and led by psychiatrists with both clinical and educational expertise, and that students are presented with up-to-date research in psychiatry throughout the medical curriculum.

Enrichment activities

How can you help immerse students in psychiatry? Many medical schools have implemented enrichment activities to enhance students' exposure to and experience of psychiatry, which are highly valued by the medical students we talked to.

Psychiatry societies ('PsychSocs') are student-led university societies set up to raise the profile of mental healthcare among medical students and to promote careers in psychiatry. Several next steps are recommended both locally and nationally to take advantage of PsychSocs to improve recruitment into psychiatry – including fostering enthusiastic mentoring by local psychiatrists via 'buddy schemes' and continuing to share ideas and learning across the country, as explained by Pandian et al³ earlier in 2020.

The Psychiatry Early Experience Programme (PEEP) provides medical students with the opportunity to shadow core trainees in psychiatry. This initiative was developed by South London and Maudsley NHS Foundation Trust and King's College London Medical School. Given the success of the scheme, students asked for improved availability and access to such schemes.

Special study modules (SSMs) or student-selected components (SSCs) in a psychiatry-related subject are short courses and/or projects in subjects that students can select according to their personal interests. They offer opportunities to learn in innovative ways and have been recommended by the General Medical Council.

Career enrichment courses (often referred as summer, autumn or winter schools) offer an intensive programme of lectures, seminars, debates and networking opportunities to students who are considering a career in psychiatry.

Psychotherapy schemes give medical students the unique opportunity to deliver psychotherapy to one patient for an extended period. Yakeley et al⁴ highlighted that projects that involve medical students offering psychodynamic therapy (under the close supervision of staff) have contributed to an increase in the number of students choosing psychiatry as a career.

Extra-curricular initiatives to give students further opportunities to spend time with people with mental illness are also being developed across the country. The Time for Dementia initiative is an example of collaborative work that has had a demonstrable impact on students' understanding of people with dementia.

Other schemes offered by the RCPsych that can be promoted to medical students include the Psych Star scheme, Student Associate membership, and Divisional and Faculty prizes.

Case studies: two novel approaches to increase students' interest in psychiatry

The RCPsych project highlighted that students who were in the early stages of their medical course were more likely than peers later in the course to feel uninformed about psychiatry. Some students in the later years of study also felt that there was a lack of information on mental health and psychiatry and wanted to be better informed.

A key recommendation made by students was to raise awareness of psychiatry at an earlier stage in their medical course and at secondary-school level. The following case studies provide examples of how this recommendation could be implemented.

A 'living library'

Greater Manchester Mental Health NHS Foundation Trust decided to use an innovative approach based on the 'living library' concept, where experienced clinicians working in their respective fields ('the books') were available 'on loan' to students ('the readers'). This was implemented to improve the student experience, enrich students' learning, provide them with an insight into other professions, encourage the sharing of institutional knowledge and develop interprofessional learning.

The concept is designed to build a positive framework for conversations that can challenge stereotypes and prejudices through dialogue. It is based on the idea of interprofessional learning (defined as 'when professionals learn with, from

and about each other’) that has been identified as an innovative strategy that can help bolster the medical workforce.⁵ Literature reviews suggest that learning with, from and about other healthcare students has the potential to improve communication between professionals and, ultimately, care for patients.⁶

Figure 2 depicts the book covers that were designed and displayed for students to help decide which ‘book’ they wanted to borrow. *Fig. 2* Living library book covers, designed by Lorna Dawson, Greater Manchester Mental Health NHS Foundation Trust.

In total, 25 living-library cards were made available to students on placement within the trust.

After signing up to the library and reviewing potential book choices, all readers were given a library card and were invited to reserve one of the books at a slot during the morning. There were six slots available throughout the day and readers would have around 20 min with each of their books. In theory, each reader could have conversations with six of the nine books.

In total, 22 readers booked places on the event, 13 of whom attended. *Figure 3* shows which disciplines were the most popular and *Fig. 4* describes what attracted the readers to them. *Figures 5* and *6* show the impact of the initiative on readers’ views about both professions and the benefits of interprofessional practice. *Fig. 3* Responses of students ($n = 13$) to the question: ‘Which living book(s) did you read?’. *Fig. 4* Responses of students ($n = 13$) to the question: ‘What attracted you to the living book(s) you selected?’. *Fig. 5* Responses of students ($n = 13$) to the question: ‘Do you feel that your experience at the living library changed your views about another profession?’. *Fig. 6* Responses of students ($n = 13$) to the question ‘Has the living library changed your views about the benefits of interprofessional practice?’.

After the event, 9 (69%) of the 13 respondents rated their overall experience of the living library as ‘Excellent’ and 4 (31%) as ‘Good’; 100% of respondents would recommend living books to others; 11 readers (85%) strongly agreed that the living library was a good way to challenge prejudices and encourage interprofessional learning, with the other 2 (15%) also agreeing with this.

I’m a Medic Get Me Out of Here

I’m a Medic, Get Me Out of Here (shortened to I’m a Medic) is an online, student-led outreach programme, funded by Health Education England and designed to provide equality of opportunity for all school students to engage with the National Health Service (NHS) workforce. The aim is to help inform schoolchildren about a particular career and let them explore whether that career could be for them. The idea is based on research showing that young people start to develop their career aspirations early in secondary school, if not earlier.^{7,8} Findings from a survey with over 20 000 children showed that parents (and parents’ friends), the TV and media were most likely to influence children’s career aspirations. Less than 1% of children had heard about the jobs through people coming to their school.⁷

I’m a Medic was trialled in psychiatry for the first time in 2019. With supervision from teachers, schoolchildren had secure access via a website to healthcare professionals, who answered questions in real time during a 30-min lesson. An online moderator was available for each chat. Pupils could also post a question to be answered at a later stage.

Three healthcare workers took part as individuals: a consultant psychiatrist (N.H.), a mental health nurse and an NHS mental health trust’s head of human resources, responsible for managing and advising a wider team. Four healthcare teams based in various locations across England took part as a group: an arts therapy team, an early intervention team, a home treatment team and a psychiatry ward team.

Students were mainly in year 8 (generally 11.5–13 years old) from schools across England. A total of 47 classes from 20 schools participated in 40 live chats. Over 1000 students logged in, with approximately 85% participating in live chats, asking questions or leaving comments. Students could vote for who they felt they most engaged with and who answered their questions to their satisfaction. *Figure 7* depicts the words most often used by students in these conversations. *Fig. 7* Frequent words used by schoolchildren in live online chats in the I’m a Medic, Get Me out of Here programme. The size of the word represents its popularity.

Students often asked what led healthcare workers to choose their jobs. They would, for instance, ask questions such as ‘What encouraged you to take this job?’ or ‘What inspired you to start what you’ve done?’.

They also asked healthcare workers about their qualifications and the qualifications they would need to attain certain roles in the sector. These were mostly focused on GCSE qualifications, as opposed to A-Levels.

When discussing mental illnesses, students focused heavily on more commonly known illnesses such as depression and anxiety, including how to discuss or treat them.⁹

During focus groups, students fed back that they particularly enjoyed the ability to interact directly with healthcare workers, in real time and in a ‘conversational’ way. Being able to vote also contributed to the engaging nature of the experience.

Additionally, interacting online provided some distinct advantages that face-to-face interactions might not provide. The first one is the ability for children in remote areas to interact with professionals who may not have visited the schools in person. Second, students often appreciated the opportunity to ask questions anonymously without being judged by their peers: “‘It was better because you’re not actually speaking to them. It’s, like, all the questions that you ask online you might feel embarrassed to ask them to their face. Then they just find out, because it’s easier to type it than to actually say it.’ I said some stuff that I would not have said in real life, online. So, it’s just easier to, like, speak anonymously.’”

This benefit was also highlighted by their teachers: “‘Some of the quieter girls and boys definitely asked a few questions that flagged them up on my radar.’”

Data also suggest that the personal and direct nature of the experience helped achieved the desired impact: “‘I think [I connected most with] Neel because of the job that I wanted to be, and he, kind of, helped me, because I’m bad at science, he helped me how to get through it and what qualifications I need. So, that, kind of, helped.’”⁹

Fifty responses were collected through a post-survey questionnaire. 82% of the children ($n = 41$) agreed/strongly agreed that they had learnt more about ‘what it’s like to work in healthcare’ and felt that they knew more about what they would need to study to get their ideal job; 66% ($n = 33$) agreed that they might get a job working in healthcare, and 60% ($n = 30$) said that they would enjoy working in healthcare. This is an increase from the pre-survey, with responses to those questions being 43% and 45%, respectively.⁹

Conclusions and future plans

The findings and recommendations detailed in the RCPsych Choose Psychiatry guidance for medical schools and the two case studies included in this article would help lay the foundations for developing a strong medical workforce, comprising both psychiatrists and doctors working in all specialties able to give people with mental illness the best possible care.

The RCPsych project highlighted that students’ consideration of both the importance of mental healthcare in medicine and psychiatry as a career were largely determined by: the integration of psychiatry courses into the curriculum as widely and as early as possible, the high quality of placements in psychiatry, the students’ ability to be in contact with inspiring psychiatry leaders and the availability of enrichment activities to enhance students’ exposure to, and experience of, psychiatry.

Opening up the living library to medical students in the early years of studying could also help increase the number of students choosing to enrol in psychiatry enrichment activities – such as psychiatry modules or psychiatry societies – which in turn will hopefully drive up numbers choosing psychiatry as a career.

We know that schools may have limited resources for careers advice. I’m a Medic is a time-efficient and gratifying initiative that can reach many students without them needing to be taken out of school or disrupting the timetable.

The next step will be to produce a practical booklet to support PsychSocs with their activities. It will include the ideas given above and many others that may not have been considered or shared otherwise, following a consistent framework. The booklet would be particularly helpful to PsychSocs around the UK, but could also be used by foundation doctors and other trainees.

N.H. will contact all UK PsychSocs for contributions but welcomes any authors (from undergraduates to consultants) who wish to contribute. Feedback for this project is also welcome. Please contact the corresponding author.

Meanwhile, the RCPsych is creating an online hub showcasing case studies of psychiatry extra-curricular activities at medical schools across the UK. The case studies will be represented visually on a map of the UK, and users will be able to click to reveal more information about an initiative which will explain how the activity works and may highlight its impact on students' interest in psychiatry and/or mental healthcare more generally.

Medical schools are also encouraged to use the Gatsby Wellcome Neuroscience Project run by RCPsych to integrate the latest research on neuroscience into their curriculum.

Examples of good practice of how students are being inspired to learn about better mental healthcare have been compiled into a practical guidance published on the RCPsych website as part of the Choose Psychiatry campaign.¹⁰

Abstract

The Scaling-up Health-Arts Programme: Implementation and Effectiveness Research (SHAPER) project is the world's largest hybrid study on the impact of the arts on mental health embedded into a national healthcare system. This programme, funded by the Wellcome Trust, aims to study the impact and the scalability of the arts as an intervention for mental health. The programme will be delivered by a team of clinicians, research scientists, charities, artists, patients and healthcare professionals in the UK's National Health Service (NHS) and the community, spanning academia, the NHS and the charity sector. SHAPER consists of three studies – Melodies for Mums, Dance for Parkinson's, and Stroke Odysseys – which will recruit over 800 participants, deliver the interventions and draw conclusions on their clinical impact, implementation effectiveness and cost-effectiveness. We hope that this work will inspire organisations and commissioners in the NHS and around the world to expand the remit of social prescribing to include evidence-based arts interventions.

The field of arts and mental health is a constantly and rapidly expanding area of research. We now have numerous publications, in the UK and globally, suggesting a strong link between arts-based interventions and improvement in mental and physical health outcomes.¹⁻⁹ This invaluable body of research has shown the clinical effectiveness of the arts for the treatment of an array of mental and physical health problems, as diverse as anxiety, depression, cancer, cerebral palsy and stroke, among others. However, such research has yet to offer solutions that are readily scalable, implementable and cost-effective, and that can be employed in primary and secondary care settings in the National Health Service (NHS) or equivalent health services in other countries. Furthermore, these art interventions face limitations, including the lack of a continuous stream of funding, limited partnerships with commissioners and funders, insufficient clinical evidence and difficulties in their implementation in existing clinical pathways.

The SHAPER project

The Scaling-up Health-Arts Programmes: Implementation and Effectiveness Research (SHAPER) project aims to start addressing the above gaps in the evidence base. SHAPER is a multidisciplinary programme funded by the Wellcome Trust, and is being run by the Institute of Psychiatry, Psychology & Neuroscience at King's College London and by the Department for Behavioural Science and Health and the Institute of Mental Health at University College London. The project aims to scale up three existing community arts interventions: Melodies for Mums (for women with postnatal depression), Dance for Parkinson's, and Stroke Odysseys. These three interventions have been developed and piloted on a small scale, offering promising results within their rehabilitation scopes.¹⁰⁻¹⁴

SHAPER was designed following an intensive 6-month scoping process involving stakeholders at different levels, including artists, clinicians, patients, researchers and commissioners. The aims were to create a programme that meets specific needs in the healthcare sector, to scale up interventions that already had promising efficacy pilot data and to involve high-quality arts interventions led by experienced partners (e.g. Breathe Arts Health Research, the English National Ballet and Stroke Odysseys). It has the ambition to be inclusive of the larger patient population (including those not already engaged in the arts) and, importantly, to be scalable and commissionable by the healthcare sector.

The ambition of the programme is thus to embed arts interventions within a large academic health science centre, King's Health Partners (KHP), establishing their delivery in the medium- to long-term future. As an academic health sciences centre, KHP's academic and clinical partners (King's College London, Guy's and St Thomas' NHS Foundation Trust, King's College Hospital NHS Foundation Trust, and South London and Maudsley NHS Foundation Trust) bring together research, education and clinical practice for the benefit of the patients. SHAPER's objective is to study the three arts interventions embedded within existing clinical pathways in order to scale them up to reach larger numbers of people across KHP and the community, examine possible mechanisms of efficacy and provide implementation evidence.

The SHAPER programme intends, ultimately, to enable clinical commissioning groups (CCGs; i.e. the 'payers' in the NHS) to commission the three interventions, so that they can continue to be delivered in the future. To attain the aims mentioned above, three levels of effectiveness must be assessed: (a) clinical effectiveness, considering the real-world impact on health outcomes and whether these are meaningful to clinical practice; (b) implementation effectiveness, in terms of uptake, suitability, acceptability and feasibility of the interventions; and (c) cost-effectiveness, to develop strong business plans for commissioners. Since the interventions selected are at different developmental stages, an additional ambition of SHAPER is that the implementation science methodologies developed in this programme will allow the creation and evaluation of an implementation model that could be used across future arts interventions, tailored to different stages of development and delivery.

The adopted research, a three-pronged hybrid type II effectiveness-implementation evaluation, is the gold standard of modern implementation science that blends components of clinical effectiveness and implementation research.¹⁵ This strategy will allow the research team to simultaneously test the clinical intervention and the implementation strategy, and our team has used it successfully in previous scale-up research at King's College London.^{15,16}

The programme is in the process of obtaining ethics committee approvals. Consent will be sought from all research participants and stakeholders involved in these studies.

Cross-cutting implementation and health economics evaluation

An innovative aspect of the SHAPER programme is that, in addition to the clinical effectiveness of the interventions, a systematic approach will be taken to simultaneously evaluate their implementation effectiveness and cost-effectiveness. Implementation effectiveness refers to the uptake, suitability, acceptability and feasibility of the interventions. This will help us to identify not just 'if', but also 'why' and 'how' the interventions work and for whom, and will support our understanding of how they can be successfully delivered within clinical pathways. This approach of simultaneously assessing clinical, implementation and cost-effectiveness of an intervention is supported by the recently emerged 'hybrid' research designs – which offer a framework for these different elements of effectiveness to be assessed in parallel.¹⁵ Overall, the SHAPER programme is conceptualised as a hybrid type II design, in which the clinical and implementation effectiveness are given equal weight in the design of the evaluation across the three focal interventions.

The evaluation of how the interventions are implemented within clinical pathways will further capture barriers and

drivers of implementation as well as unintended consequences for patients and providers. Existing implementation theory and direct work with a wide group of stakeholders of the interventions (including patients, arts and clinical providers) will inform the implementation evaluation throughout the programme.^{17,18} Along similar lines, the cost-effectiveness evaluation will cover health economic evaluations of the implementation and delivery costs and associated savings, service utilisation and related analyses. Implementation and cost data will be captured through a mixed-methods approach comprising a variety of qualitative and quantitative data collection techniques, including structured interviews and psychometrically established measurement scales.¹⁹

In bringing these three studies together, the SHAPER programme aims to bridge the gap between small-scale arts interventions and their large-scale implementation into pathways within the NHS for improved physical and mental health in people with postnatal depression, Parkinson's disease and stroke.

Here, we offer an overview of the three interventions and of the implementation and cost-effectiveness evaluation adopted within SHAPER.

Melodies for Mums (arts partner: Breathe Arts Health Research)

Postnatal depression affects at least 12.9% of new mothers, with symptoms including fatigue, anhedonia, insomnia and irritability.^{20,21} However, challenges surround the fact that there is still no complete treatment solution: although pharmacological treatments have had positive results, these are hampered by low uptake and adherence among mothers.^{22–24} Psychotherapy has also produced mixed results, as well as similar challenges regarding low uptake or delayed treatment.^{21,25–27} However, many mothers engage in community group activities with their babies, such as attending mother–infant play groups. These activities have been identified as ways of relaxing mothers, providing good sources of social interaction, decreasing the monotony of each day and providing a sense of personal fulfilment.²⁸

Moreover, there is a growing body of evidence demonstrating the effects of community group singing on mental health.^{29,30} Singing to new babies is practised in cultures around the world, and research has demonstrated valuable benefits, such as improving mother–infant interaction and reducing distress in babies.^{31–33} Listening to music during pregnancy is also associated with higher levels of well-being and reduced symptoms of postnatal depression in the first 3 months post-birth, while daily singing to babies is associated with fewer symptoms of postnatal depression and higher levels of well-being, self-esteem and perceived mother–infant bond.¹⁰ Consequently, there is a strong theoretical background indicating that singing could support mothers with postnatal depression.

Breathe Arts Health Research's Melodies for Mums offers free, community-based singing sessions to women with symptoms of postnatal depression in London boroughs (*Fig. 1*). A previous study led by researchers in the SHAPER team has shown that this intervention, already implemented in some London boroughs, results in faster improvements in symptoms when compared with usual care.¹¹ Specifically, the study recruited 134 women with symptoms of postnatal depression and found that, in women with moderate to severe depression, there was significantly faster improvement in symptoms in the singing group than in the group play workshops for mothers and babies. *Fig. 1* Melodies for Mums session delivered by Breathe Arts Health Research. Image credit: Richard Eaton.

The planned two-arm randomised clinical trial (SHAPER-PND) aims to establish effectiveness in a larger sample (400 participants) and to analyse the factors affecting economic and implementation potentials for this intervention. Participants will be assigned to either a 10-week singing intervention or a 10-week active waiting-list control group, where they will be encouraged to attend community mother–baby activities. Singing sessions will be delivered in children's or community centres and each group will have 8–12 mothers and their babies. Mothers and their babies will be invited to sit in a circle and learn songs from all over the world, from vocal 'motherese' style noises to lullabies and more complex songs. They will be invited to hug or stroke their babies while singing and to add simple musical instruments (maracas, drums, hand chimes and others) to increase mother–baby interactions. Mothers will also be invited to develop their own songs about motherhood and their babies, creating a shared experience with other participants, thereby increasing their sense of inclusion.

A package of demographic, mental health, biological and social measures will be collected from mothers and babies at set time points throughout the intervention, and up to 36 weeks post-randomisation. In addition to the clinical effectiveness outcome (an improvement in depressive symptom score according to the Edinburgh Postnatal Depression

Scale), we will put equal weight on the implementation science and economic data assessments. For biological outcomes, we will collect saliva and hair samples to assess stress and hormonal markers, including cortisol, oxytocin and cytokines. We will also conduct qualitative interviews with a subgroup of mothers who self-report particular risk factors for postnatal depression, to explore how singing interacts with specific contexts.

Dance for Parkinson's (arts partner: English National Ballet)

Parkinson's disease is a chronic neurodegenerative condition affecting over 145 000 people in the UK alone, with a prevalence expected to rise by around 18% between 2018 and 2025, to over 168 000, and to double by 2065.³⁴ Parkinson's disease is a complex disorder characterised by a range of motor symptoms, including slowness of movement (bradykinesia), tremor and gait impairment, and non-motor symptoms such as anxiety, depression, sleep dysfunction, autonomic problems, mood disturbances and cognitive decline, with a profound negative effect on quality of life.³⁵ Although there are no treatments that can affect the progression of this condition, evidence is emerging that physical activity and certain types of exercise, including a range of dance-based exercise, can improve motor symptoms, functional mobility and stability, and result in some cognitive improvements, reduced pain, depression and anxiety, decreased social isolation and improved quality of life.^{36–38}

Dance for Parkinson's is an existing programme delivered by the English National Ballet (ENB) for people with Parkinson's disease (*Fig. 2*) across multiple venues in the UK, including London, Ipswich, Cardiff, Liverpool and Oxford. The sessions are being delivered by ENB-trained dance artists and currently host people with Parkinson's and carers. These sessions are popular and lend themselves to the requirement of a large-scale randomised study so as to provide robust evidence of dance being accepted as a potential therapeutic option in the pathway of care for Parkinson's disease. *Fig. 2* Dance for Parkinson's session delivered by the English National Ballet. Image credit: Laurent Liotardo.

As part of the SHAPER project, the study will be supported by the Wellcome Trust and will take place at the internationally renowned Parkinson's Foundation Centre of Excellence at King's College Hospital and King's College London. It will be a two-arm randomised controlled trial (SHAPER-PD-Ballet) to investigate the clinical efficacy of the intervention in a larger sample (160 participants), graded by the severity of their Parkinson's (mild, moderate and severe). Participants will be randomly allocated to receive 12 weekly ballet classes delivered by a team of ENB-trained dance artists and musicians, lasting approximately 75 min and incorporating live music, dance, rhythm and voice. A comparator group will continue on conventional treatment regimes. Participants will be followed up for up to 6 months post-intervention, and those allocated to the comparator group will be offered participation in the ballet sessions at the end of the project.

The clinical aspect of the study will, for the first time, use a range of clinically validated outcome measures, including the comprehensive version of the Non-Motor Symptom Scale developed at King's College Hospital. Secondary outcome measures include assessments of both motor and non-motor symptoms, such as cognitive decline, mood, sleep and pain. Additionally, wearable sensors will provide an objective measure of the Parkinson's signs as well as mobility and balance. Assessment quality will be checked by a 'masked/blinded' rater.

A unique aspect will be that all participants will be offered participation in a substudy of electrodiagnostic measures, which will employ transcranial magnetic stimulation coupled with electroencephalography and electromyography to investigate the effects of the intervention on neural networks and brain activity.

Implementation and economic data will be collected to assess acceptability, appropriateness and feasibility of the intervention on a large scale and its potential to be adopted and sustained as a cost-effective and beneficial adjuvant therapy. All measurements will be conducted at baseline (before the start of the intervention), immediately post-intervention between 3 and 6 months post-intervention to explore the acute and chronic benefits.

To our knowledge, this is the first randomised controlled trial investigating the effects of ballet dancing on people with neurological disorders.

Stroke Odysseys (arts partner: Rosetta Life)

Stroke is a leading cause of disability in the UK and worldwide, and approximately two-thirds of stroke survivors leave hospital with disability.³⁹ There are over 1.2 million stroke survivors in the UK, projected to exceed 2 million by 2035. Stroke costs the UK an estimated £25.6 million annually.⁴⁰ Recent data from the Sentinel Stroke National Audit Programme shows that nearly 40% of patients between August and November 2017 left hospital with moderate to severe disability (modified Rankin scale, 3–5).⁴¹ Indeed, the transition from hospital to home after a life-changing event such as a stroke is extremely difficult both for the individual concerned and for their family, friends and caregivers. Fragmentation of health services often means that information provision relating to discharge is poor, which may also contribute to delays in discharge from hospital.

Stroke Odysseys, a post-stroke performance arts intervention, has been co-designed by artists and developed by the organisation Rosetta Life in a unique partnership with south London stroke communities. It is an intervention using performance arts to support recovery, agency and well-being in stroke survivors (*Fig. 3*). The intervention was initially developed and funded by King's and Guy's and St Thomas' Charity and has been delivered in four London boroughs.¹³ *Fig. 3* Stroke Odysseys tour performance. Image credit: Rosetta Life.

Stroke Odysseys has three stages – clinical intervention, community intervention and stroke ambassadors – all of which will be replicated in this study. During the clinical intervention, while the patient is in hospital, the sessions will run for 60 min for groups of 6–8 patients in neuro-rehabilitation wards. These sessions will be led by a trained movement artist and a singer, and will involve movement, performance exercises, vocal warm-ups and singing. Dance practices will be rooted in improvisation, somatic dance theory and carnival/folk dance. Then, in the community stage, patients will be invited to perform their own stories in a 12-week performance intervention, working with performance arts towards creating a new perception of their own identity post-stroke. The performance is based on skills acquired in movement, music, song and spoken word, which has not only demonstrated benefits on perception of disability and cognition, but also aims to manage the anxiety and depression that affects one-third of stroke survivors.^{42,43} Finally, in the third stage, participants who complete the community intervention will be invited for training to become advocates for life after stroke: 'stroke ambassadors'. Stroke ambassadors support the running of the programme in hospitals, assisting artists, recruiting participants and performing. Stroke ambassadors also speak at conferences and at regional stroke association groups and are members of an integrated performance company that create performance works to advocate for life after stroke. The study aims to recruit 75 new ambassadors. The main aim of the study is to evaluate the implementation, impact and experiences of a community-based performance arts programme (Stroke Odysseys for stroke survivors) using mixed methods (interviews, observations and surveys) prior to and after each programme stage, and carry out non-participant observations during the workshops. A series of implementation measures will be used as well as clinical outcome measures, including the Oxford Participation and Activities Questionnaire, a patient-reported outcome measure that assesses patients experiencing a range of health conditions. In addition, a health economic evaluation will be performed to cost the resources used in implementing the programme, and to evaluate wider service utilisation and associated costs before and after participants complete the programme and any changes in their quality of life profile.

Conclusions

Our ambition is that the SHAPER programme will not only provide conclusive clinical and mechanistic evidence on the three studies described above, but also offer an invaluable resource to shape the future of arts interventions within the realm of rehabilitation for a range of other mental and physical health conditions.

SHAPER also presents as a unique opportunity to build a strong evidence base on the clinical effectiveness, implementation and mechanisms of arts interventions. Such a knowledge base will bring arts interventions into mainstream psychiatric care and put them on an equal footing with other pharmacological and psychosocial approaches.

1.2.15 Femi Oyebode

Abdi Sanati¹

date

2021-02

Contents

- *Femi Oyebode*

Professor Femi Oyebode does not need any introduction. He is one of our greatest experts in the field of descriptive psychopathology. In recent years, he has taken over the influential psychopathology textbook *Sims' Symptoms in the Mind*. He is also an authority on delusional misidentification syndromes and rare psychiatric disorders. As someone who is interested in psychopathology, I have always found Professor Oyebode's writing very informative and an amazing read. I finally met him a few years ago at the International Congress of the Royal College of Psychiatrists. He has also edited a book on literature and psychiatry (*Mindreadings: Literature and Psychiatry*), written one on the theatre (*Madness at the Theatre*) and published six volumes of poetry.

Professor Oyebode, first I wanted to thank you for your time for this interview during the lockdown! Having read your work, I wanted to start the interview with a question on the humanities. How important do you think the humanities are for psychiatry?

I think the humanities are important for the whole of medicine, and not just psychiatry. The medical humanities include moral philosophy, ethics, medical history and literature, among others. I focus on literature, which is my expertise. The aim of literature in medical humanities is to help us grasp the living experience of others. It can help us with the living experience of our patients too. We can emphasise the subjective experience of our patients using literature as an entry point.

¹

Abdi Sanati meets Femi Oyebode, Honorary Professor of Psychiatry and consultant psychiatrist, Institute of Clinical Sciences, University of Birmingham, UK

Do you think reading fiction can help psychiatrists to improve their understanding of their patients' narratives, especially in the era of assembly-line psychiatry, when the narratives are lost in the rigid system?

It is a complex question and I will try to answer it in a roundabout way. If one is thinking of the best use of literature for psychiatry, I would recommend reading the autobiographies or memoirs of people who have suffered from mental illness. Even more so when the author is a professional writer. Writers have the gift of language to describe complexities of those experiences in words. Being familiar with those descriptions would help the psychiatrist to communicate better in their practice. Going back to fiction, I think you were right to bring it up. It is an interesting human activity. One of fiction's tasks, if I might put it like that, is to help us live the lives we have not experienced ourselves. It engages our brains and inner life to understand the reality we have not experienced and the possibilities that come out of that reality. Fiction enables us to appreciate a multiplicity of contexts without the need to experience them directly.

I think fiction is also important in helping us understand moral dilemmas. I have to admit I found more moral lessons in Victor Hugo's *Les Miserables* than in textbooks!

I agree that fictional accounts are important. My example is Albert Camus' *The Plague*. It is a multilayered and complex work. At one level, it is about Oran, a city in northern Algeria, facing the challenge of a plague epidemic. At another level, it is a metaphor for the Resistance in Nazi-occupied France during the Second World War. It explores the nature of freedom and the difficulties of choices one has to make. In the struggle with the COVID-19 pandemic we have faced similar choices – choices that include risking our lives as healthcare professionals while going out to work, which we do every day. Fiction has the power to help us see these choices and understand their complexities.

What do you think about the role of visual arts in helping us understand the human condition?

I have to admit I am not an expert in painting but as a West African I know a bit about sculpture. Nevertheless, I agree that the visual arts can be helpful. For example, when we look at a painting that captures the instant and fixes it in time, we can see details that we may miss on a casual, cursory view. Again, looking at a painting can potentially help us to understand human gestures and bodily attitudes and to see these in more detail. It sharpens the eye and enables us, in the clinic, to recognise postures and see subtleties we would not usually see.

As you know, I am the chair of the Philosophy Special Interest Group at the Royal College of Psychiatrists. One reason psychiatry attracted me was the philosophical issues embedded in it. Do you think we should teach philosophy in training?

It is not an easy subject to teach! It is not well known, but I have a PhD in Philosophy of Mind, so I am familiar with the academic side of philosophy and the teaching of philosophy. As psychiatry is conceptual, we need to think clearly and listen intently. And philosophy could help. However, I am not sure how easy it is to teach. In addition, many philosophers of psychiatry seem not to understand that psychiatry is a practice and is much more than mere concepts and ideas. You have to deal with the facts before you can make decisions. You cannot only take time to think. Philosophy benefits psychiatry immensely with regard to conceptual reasoning but I don't recommend formal teaching in the same way that I don't recommend formal teaching of literature in psychiatry training and having exams for it. Both subjects are very enriching but when we try to teach them they can feel very dry. For that reason, I doubt that we need to have formal teaching on them.

I do agree that we need to increase the interest in philosophy and literature and hopefully we will succeed. I am interested in your comment on philosophers without clinical experience. Looking at the philosophy of psychiatry's literature on delusions, you encounter several discussions on Capgras delusion, which is rare. I always wondered what is the reason for this preoccupation with Capgras delusion. There is also another issue when non-medics try to explain to me how medicine works. My colleague Dr Jonathan Hurlow coined the term 'non-medicsplaining' for this!

Yes, it is because when you come from purely thinking professions and you don't practise psychiatry, you might not know that in psychiatry, thinking is reactive to and constrained by the facts before you. If you don't do it properly, and in time, the patient would come to harm.

What do you think of the status of psychopathology in training? One of the reasons that I became interested in psychiatry was reading Andrew Sims' *Symptoms in The Mind*, which you are in charge of now. It saddens me to see psychopathology is somehow side-lined in training.

I think psychopathology is the heart of psychiatry and it is the case wherever you go. You need to know the phenomena you encounter in the clinical setting. Some make a mistake in comparing it to anatomy, as something that is already done and completed. It is an error to think that psychopathology is just a collection of definitions. It is a living and dynamic subject. This can pose a problem in writing about it. People always look for certainty, whereas psychopathology is dynamic and there is always some uncertainty in it. What I do is start with some definitions and then elaborate to show how complex it is.

In the world of what I call assembly-line psychiatry, patients move from team to team and from practitioner to practitioner and there is hardly any chance to make a proper psychopathological examination. What is your opinion on that?

I agree with you that the American DSM approach is very destructive, as it treats psychiatry like baking a cake and involves certain boxes to be ticked and certain recipes to be followed. It is a very basic approach. For example, in depression, the person must suffer from low mood for a certain period of time. But what is important is what is the nature of the experience of low mood. What does it consist in? What is it the person is feeling that we refer to as low mood? And, is it merely a variant of sadness or something intrinsically distinct? The checklist approach has weakened psychiatry.

When we talk of psychopathology we mainly focus on the Western tradition. What about psychopathology from non-Western countries? I remember in 2008 when I was in Accra, I attended the African Association of Psychiatrists and Allied Professionals. I have to say that they were very inclusive and had a patient as a keynote speaker. In that conference a colleague from Uganda, Dr Catherine Abbo, had research in which she translated case vignettes from textbooks and presented to local people in villages. Interestingly, they had local names for schizophrenia and mania. For depression, they said the person was ‘thinking too much’.

I did some work in this area many years ago. I have to add I didn't want to be pigeonholed as a cultural psychiatrist! Nevertheless, I wrote that there are deep problems with translation of words and technical terms. The translation of emotion terms can be problematic even across Western languages, which have a linguistic affinity. In English psychiatry, the term ‘anxiety’ is thought of as a psychological term. However, the word ‘anxiety’ derives from ‘angst’, which is originally a German word. In German, *angst* refers the feeling of choking. Surprisingly, a term that we take to mean an emotional experience actually refers to a physical experience. This means that we always need to be attentive to the concept that is sitting inside the word. Take the Yoruba language. If you speak Yoruba and want to translate it into English, the word for sadness, *Ìrònú*, can be translated literally as thinking hard or inner pain. But a Yoruba person does not think a person who is sad is thinking hard or has inner physical pain – he spontaneously understands that the term refers to sadness. In English, we think of mood as measured on a vertical axis, either up or down. But this notion makes no sense in Yoruba. The important question is whether the actual subjective experiences, across cultures, are similar or not, given the diversity of concepts underlying the language terms. Edward Sapir and Benjamin Whorf believed that language structured experience. This thesis of theirs is controversial and no longer accepted. For example, Eskimos have several words for snow. But does that mean that they can distinguish between different types of snow better than other people? I think when you have words for something it is probably easier to discriminate. The Western dominant view has probably influenced the way we experience the world.

That shows there is a good case for inviting more people from the non-Western world to our conferences.

The problem is money! In an ideal world that would be brilliant. We could have proper communication based on willingness to discuss.

Hopefully, with the development of technology we can do it more online.

It could be, but there are still problems. I am finishing the new edition of *Symptoms in the Mind*. My current content editor lives in India and we were scheduled to have a meeting online but the electricity there was cut off. There is still a disparity of access to resources that prevents optimal online communication.

I am glad that you are still writing new editions of *Symptoms in the Mind*. It is an important book for professionals and trainees alike.

I want to do one more. Currently, I am writing the seventh edition. Everything in life depends on health and I am not as young as I was. I am also writing a book on rare psychiatric symptoms.

Perhaps you need an understudy to learn and take over. That person has big shoes to fill! Thank you very much for your time.

1.2.16 Referral of patients with emotionally unstable personality disorder for specialist psychological therapy: why, when and how?

2021-02

Abstract

Although we commonly work with patients with emotionally unstable personality disorder (EUPD) in community mental health teams (CMHTs), only some enter evidence-based psychological therapies. Many patients are not considered ready to engage in specialist treatments and remain in CMHTs without any clear focus or structure to their treatment, which is unsatisfactory for patients, clinicians and services. We present a fictional case and synthesise available literature and lived experience to explore readiness and ways to promote it. We highlight relevant issues for trainees to consider in practice. Patients with EUPD who have not received specialist treatment can be considered in terms of the transtheoretical model's stages of change. Identifying a patient's stage can help guide how to increase readiness for referral and decide when to refer. Interventions available to all health-care professionals which may promote readiness include: psychoeducation, personal formulations, crisis planning, goal-setting, peer support, distress tolerance skills, motivational interviewing and mindfulness.

Case scenario

You are a psychiatry specialty trainee in a community mental health team (CMHT) seeing Miss ML in a routine appointment. She is a 29-year-old woman with emotionally unstable personality disorder (EUPD). She presents repeatedly with suicidal thoughts and has had numerous psychiatric admissions. She uses cannabis and alcohol in a binge pattern. She self-harms regularly, typically following difficult interpersonal events. You often feel unsure how you are helping Miss ML other than monitoring her mental state and risk and reviewing medication. At times you have felt irritated with her; she expects help but does not seem to help herself.

In the appointment, Miss ML requests therapy. She says she wants help with all the bad feelings, and wants to stop cutting but does not know how. She asks you why she feels like this, and what does personality disorder even mean? Miss ML complains that nobody understands her or is helping her. She asks you directly: 'Are you going to refer me for therapy?' You feel anxious as an earlier referral was declined by the personality disorder service. You feel an enormous pressure to say you will refer her again. What will you do?

In this paper we consider the following questions: •*Why* am I referring for psychological therapy? •*When* should I refer for psychological therapy? •*How* can I help a patient reach a stage where they are ready to engage in psychological therapy?

Introduction

We commonly work with patients with EUPD in secondary care mental health services. The prevalence of EUPD in this setting is estimated at 20%,¹ and it is associated with considerable suffering, psychosocial impairment and high resource use.² A number of evidence-based treatments are available, developed from cognitive or behavioural therapies (e.g. dialectical behaviour therapy, schema-focused therapy) or from psychodynamic/psychoanalytic origins (e.g. mentalisation-based treatment, transference-focused psychotherapy).³ A significant number of patients, however, will never enter such treatment. There are many different reasons for this, but a proportion of patients do not reach a stage where they are considered 'ready' to enter treatment. This potentially represents a lost opportunity to improve functioning and reduce suffering.

Patients with EUPD who are not ready for specialist treatment may remain in CMHTs, which poses recognised difficulties. Chaotic and risky behaviour and social problems often interfere with treatment. Resolving these 'exclusion criteria' can seem unrealistic.⁴ Professionals report feeling isolated and inexperienced and that CMHTs are an interim 'no man's land', where referrals for specialist treatment are difficult. Patients report experiences of not being helped and being passed around services (*Box 1*).⁴⁻⁶

When considering psychological treatment for EUPD, the National Institute for Health and Care Excellence (NICE) advises considering the patient's choice and preference, willingness to engage, motivation for change, ability to work within a therapeutic relationship and availability of support. However, they make no recommendations regarding how to increase a patient's readiness for psychological therapy.⁷

A systematic search was conducted to identify literature addressing enhancing readiness of patients with EUPD for therapy. The EMBASE, PsycINFO and CINAHL databases were searched using the National Health Service's Healthcare Databases Advanced Search from inception to January 2019, combining terms relevant to personality disorder (personality disorder*, EUPD), therapy (therap*, treat*) and readiness (readiness, prepar*). None of the studies identified specifically examined methods to increase readiness in EUPD. A theoretical model suggesting factors influencing treatment readiness in personality disorder was identified. Internal (patient) factors included: cognitive (problem recognition, belief in ability to change), affective (emotional states and regulation), volitional (motivation and pursuit of goals), traits (impulsivity), relating (ability to trust and form a therapeutic alliance) and comorbidity (co-occurring psychiatric or medical illnesses). External factors included those related to the patient (current life stressors, support network and practical barriers to attendance) and service factors (accessibility, availability, staff skill and motivation).⁸

Practical management

Why am I referring?

Clinicians should be mindful of why they are referring *this* patient at *this* time? Although specialist EUPD treatments have demonstrated effectiveness, referrals which are declined or do not lead to treatment may lead to patients developing negative views about services and damage confidence in their ability to change.

Indicators that a patient is not currently suitable for psychotherapy include: gross instability of accommodation or finances, marked chaotic or risky behaviour, and harmful or dependent alcohol or drug use.

If considering referral despite such factors, the clinician should regard their own countertransference and whether they are referring as a defence against feelings of anxiety, despair or even countertransference hate (see below). It may be more appropriate to acknowledge their own and the patient's feelings and construct a plan to work towards referral using the interventions suggested below. *Box 1* Patient perspective. 'It felt unjust, unfair and I was mystified when I was told I was not ready. The consultant spoke to me like a child. They explained it was better to wait than fail trying, which I appreciate more now but I was furious at the time. 'The main issue affecting my readiness was alcohol. I had tried and failed to stop drinking for years. Alcohol was my coping mechanism and they wanted to me to stop but without giving me other ways to cope. No service knew what to do with me and I was passed around. Eventually I found Alcoholics Anonymous who really helped, they tolerated my erratic behaviour and through them I met a community of other people with lived experience of alcohol misuse and some with personality disorder. A homeless charity provided practical support. Eventually my CMHT consultant arranged a joint meeting with the alcohol service and the personality disorder service to try and find a way forward. This felt like a special gesture and that they were serious about helping me. I wonder if I had sometimes been testing teams to see if they cared. 'Becoming ready for therapy took years and was like chipping away at a rock. I attempted suicide four times. Maybe if joint meetings and developing clear plans had occurred sooner I would have been passed around less and my journey would have been quicker and smoother.'

Patients may be displeased at a suggestion that they are 'not ready', and this this should be communicated with care and validation. Senior team member support may be beneficial. *Box 2* contains an example of how this could be discussed with a patient. *Box 2* Communication suggestions for clinicians about readiness. 'It is really positive you have asked for help with [list problems]. This is an important first step. To take things forward from here and to benefit from a specialist therapy, you would first need to address [specify issues]. The reasons for this are, e.g. •Therapy focuses on how you think and feel. For therapy to work, you need to be in touch with how you are thinking and feeling. [Alcohol/illicit substances] can block or numb your thoughts and feelings, which although it can help in the short-term, will stop therapy working. We want to work with you, but you will need to reduce [alcohol/illicit substances] and we can support you through this. •Therapy can at times make people feel very distressed and uncomfortable. At the moment, owing to [self-harm/active suicidality], we do not think it would be safe for you to start therapy as it could increase this. We will think with you about your crisis plan and ways to help you reduce [self-harm/suicidal thoughts]. I realise what I say may be frustrating, but there are things other than therapy that can help such as [suggest interventions], which may also help us in working towards a referral for therapy.'

When should I refer?

Readiness for referral can be considered in terms of the transtheoretical model of stages of change;^{9,10} in particular, the *precontemplation*, *contemplation* and *preparation* stages.

Patients in the precontemplation stage are not aware of having a problem, and there is no current intention to change behaviour. They would be unlikely to recognise a diagnosis of personality disorder or any contribution of personality traits to their problems. They do not see a requirement to change their behaviour or have psychological therapy. Some patients may report a wish to change in response to external pressure, e.g. from family or social services. Once external pressure is reduced, engagement may dwindle.

Patients in the contemplation stage are aware that a problem exists and are seriously thinking about overcoming it but have not made a commitment to take action. They have awareness of difficulties relating to personality traits and express

wishes to address these and change their behaviour. They are considering the benefits of change in comparison with the energy and effort of change.

Patients in the preparation stage combine intention and some behavioural change. They have made some reductions in problem behaviours but have not yet taken effective action, although they intend to do so soon. They would be likely to recognise a diagnosis of personality disorder, have the intention to change and be making small behavioural changes, e.g. reducing self-harm or substance misuse. We suggest that patients in this stage are most appropriate for referral.

The transtheoretical model has previously been applied to EUPD by Livesley in his integrated treatment model.¹¹ This highly developed framework for treating personality disorder combines and coordinates different treatment modalities. Our simpler pragmatic approach is aimed at generalists and is not a specialist treatment. Only one study has examined the stages of change in relation to EUPD; it showed that patients in precontemplation were most likely to drop out of specialist treatment.¹²

Readiness for referral is also related to the services available, which may have differing referral criteria and work with patients at different stages of readiness. Liaison with the local personality disorder service (see below) will help clarify this and determine the likelihood of successful referral.

How can I help a patient with EUPD become ready to engage in psychological therapy?

The transtheoretical model also describes the processes by which change occurs.^{9,10} The processes of change that are important in the precontemplation and contemplation stages include: consciousness raising (increasing awareness of the causes and consequences of their problems), self re-evaluation (assessment of self-image with and without problem behaviours) and environmental re-evaluation (assessment of how behaviour affects their environment, including relationships). Processes that are important at later stages but which seem significant in EUPD include: self-liberation (belief that change is possible and commitment to act), contingency management (consequences of taking steps in a particular direction), counterconditioning (learning healthier behaviours to substitute problem behaviours) and stimulus control (avoiding triggers of behaviour).

Many commonly used interventions (see below) utilise one or more of these processes, which may help patients to progress from one stage to the next. They can be used by any healthcare professional when trying to enhance readiness for referral. The choice of intervention will be guided by the patient's current stage of change, preference and available resources. We suggest focusing on one intervention at a time to avoid care becoming confused.

General principles

Some strategies and clinical issues are relevant at any stage of readiness.

Common service factors

Successful treatments for EUPD (specialist or generalist) have common factors including: •Focus on the therapeutic relationship, empathy and validation;•promotion of patient self-agency;•helping patients identify their emotions and the connections between events, emotions and behaviours;•clinicians observant of their own thoughts and feelings and an active system for support and supervision.¹³

Structured clinical management is a manualised generalist approach utilising these factors and may be effective.¹³

Transference and countertransference

Clinicians should be aware of their thoughts and feelings towards patients with EUPD and how these may influence interactions and decision-making. Thoughts and feelings commonly evoked by these patients include: anxiety, rescue fantasies, anger, guilt, failure and even hate.^{14,15} If not processed, clinician responses can be unhelpful or even dangerous; for instance, malice, when the clinician may be sadistic or cruel, and aversion, which tempts the clinician to abandon the patient.¹⁵ These dynamics can also be played out at a systems level and affect whole teams or services.

Managing countertransference is vital to accepting, tolerating and containing such feelings. A sudden decision to refer or discharge a patient needs to be assessed for whether it is an acting out of the countertransference. Although this is a complex field, one approach is for the clinician to first recognise their thoughts and feelings, digest and try to understand them, then consider their response to them and whether this seems appropriate or not.^{16,17} Supervision or Balint groups can be used to explore transference and countertransference reactions.

Trauma

Patients with EUPD may have experienced trauma and during the assessment phase should be sensitively asked whether they wish to disclose trauma. Trauma-informed approaches advocate thinking ‘what happened to you?’ as opposed to ‘what is wrong with you?’

A number of principles of trauma-informed care overlap with the general principles discussed above. These include trusting and transparent relationships between clinicians and patients, collaboration, patient empowerment and choice. Clinicians should also be mindful of the risk of inadvertent re-traumatisation in their interactions with patients.¹⁸

Some patients may agree with a formulation describing how traumatic experiences might influence interpersonal problems, and may meet caseness for EUPD but disagree with a ‘personality disorder’ diagnosis. In this situation, the authors suggest trying to ascertain which problems and goals are a priority for the patient to address, with further discussions delegated to specialist personality disorder and trauma services to determine which therapeutic approach may be appropriate initially. There is debate regarding the overlap of personality disorder and complex trauma, but this is beyond the scope of this article.

The possibility of active trauma, e.g. domestic violence, should also be considered, both for patient safety and as it would impair readiness. Clinicians can provide advice, support and signposting to relevant organisations and consider whether safeguarding is indicated.

Specialist personality disorder services

If a patient is not ready to engage in specialist treatment, personality disorder services should provide advice and support to CMHTs. This can include linking a personality disorder service team member to each CMHT. This liaison service can help by discussing referrals, advising on interventions and providing feedback if referrals have been declined or treatment not initiated. Joint meetings and shared planning on how to increase readiness should be offered. Some services use a shared active list of patients in the pre-treatment stage as a means of supporting and sharing responsibility with CMHT members. In addition, personality disorder services should develop and provide training locally.⁷

Continuity

Therapeutic alliance and relational continuity are of particular importance when working with patients with EUPD; change of team members can be experienced as a re-enactment of loss or abandonment and thus should be avoided where possible.^{13,19} However, this is challenging in CMHTs with turnover of staff and trainees.

Although junior doctors change rotation it is essential for their training to gain experience in assessing and managing patients with EUPD. The transition between trainees should be recognised as potentially difficult and planned for with clear communication and structure. Personal formulations, crisis plans and goals should be handed over to aid continuity.

NICE provides little guidance on the role of care coordinators in EUPD.⁷ More broadly, the Care Programme Approach is indicated for patients who are at high risk and require multi-agency support, active engagement, intense intervention and support with dual diagnoses.²⁰ Whether patients meet this threshold is decided on a case-by-case basis. A recent Royal College of Psychiatrists position statement recommends that all patients in Tier 2 services (and above) be allocated a long-term lead clinician who can support the patient through the engagement process.¹⁹ In our experience, patients with EUPD present with a very wide range of functioning, risk and support needs, and we suggest that care coordination is decided on a case-by-case basis. Most CMHTs would require a significant increase in the number of care coordinators to facilitate meaningful input for all patients with EUPD. Possible alternatives include use of support workers and peer support workers, with appropriate supervision, as a source of continuity and assistance with goals. However, if more than one clinician is working with a patient, clear communication and coordination are essential to avoid splitting or a confusing approach.

Validation

Patients with EUPD may have experienced invalidating environments.^{21,22} Validation and the process of listening and understanding is central to many therapies for EUPD.^{23,24} Levels of validation include: being attentive and alert, enquiring then reflecting back the patient's reported thoughts and feelings, reflecting back observed non-verbal communication, and validating the patient's experience based on the current context and their personal history.²⁴

Interventions suggested for patients in precontemplation stage

Psychoeducation

Educating patients (and significant others) about EUPD is an intervention in itself.²⁵ The diagnostic criteria, e.g. difficulty with relationships, emotion dysregulation, impulsivity and hypersensitivity, can be linked to examples offered by the patient.¹³ Giving the diagnosis can be used to stimulate reflection. Information can also be provided about the range and nature of treatments available.

Personal formulation

Providing a diagnosis alone is insufficient; co-constructing a personal formulation is key in exploring a person's understanding of their problems.¹⁹ One approach is the '5 Ps' model (problems, predisposing, precipitating, perpetuating and protective factors). Through this process, ways to avoid or challenge precipitating and perpetuating factors and strengthen protective factors can be identified, as can goals to work towards.¹⁷

Goal-setting

Clarifying a patient's goals, identifying obstacles to goal attainment and considering how therapy might assist with these may increase motivation to enter treatment.²⁶ Encouraging a patient to evaluate how they and their life may look different in relation to their goals could be part of this. Goals should be specific, with defined patient and professional responsibilities. The clinician can help identify manageable short-term treatment aims with achievable steps. Long-term goals, e.g. those relating to employment, can give direction to the treatment strategy.⁷

Crisis planning

Collaborative crisis planning is important as part of risk management and can be seen as an early form of treatment contracting. It promotes safety and quicker recovery from crises. Steps include identifying triggers, thoughts and feelings associated with an emerging crisis, actions that can avert an escalating crisis and actions to avoid when in crisis.¹³

Substance misuse

Clinicians should assess the level of misuse regularly and clarify its function. Active substance misuse reduces the benefits of therapy, and harmful or dependent users are unlikely to be accepted into specialist treatments. NICE advise referring patients with EUPD and dependence on alcohol or substances to appropriate services; the care coordinator should remain involved and provide information on community support networks, e.g. Alcoholics Anonymous.⁷ Distinctions can be made between patients using as a form of self-harm, using to manage emotions, and dependent use, although overlap does occur. If the use is viewed as self-harm, general strategies to reduce self-harm can be applied, such as delaying use after an urge, distraction, relaxation or finding other outlets. Chain analysis can explore and link events leading to use.¹³

Distress tolerance skills

These skills help patients to manage intense emotional states, recognise triggers and endure negative emotions so that problem-solving can occur. Distress tolerance skills include distraction, self-soothing, relaxation and acceptance.^{27,28}

Housing and finances

Stressors such as housing and finances may affect readiness for treatment.⁸ Support in stabilising a patient's social situation is a therapeutic intervention and may support building a therapeutic alliance.¹³ Maslow's hierarchy of needs could be used as a visual psychoeducational tool to explain the importance of addressing physiological and safety needs before focusing on 'higher' needs.²⁹

Interventions suggested for patients in contemplation stage

Motivational interviewing

Fluctuating engagement may be related to ambivalence about change.³⁰ Using an overly directing style with patients can result in resistance or passivity. Motivational interviewing involves helping patients to say what they want to change, identify why (pros and cons of change), gain confidence in their ability to change and consider how they might change.³¹ Motivational-based interventions can increase motivation and confidence, and decrease substance use and risky behaviours.^{26,32}

Mindfulness

Mindfulness emphasises being present in the moment and increases awareness and acceptance of experiences, which fosters emotional processing and distress tolerance.³³ Mindfulness offers insight into the ‘process’ of specialist treatments, as it creates a space between thoughts and feelings.³⁴ Improvement in attention and impulsivity was demonstrated when mindfulness was practised alongside general psychiatric care in patients with EUPD.³⁵

Peer support groups

Learning from other patients at different stages of change can provide patients with evidence that change is possible. Service user network (SUN) projects are community-based support groups for patients with EUPD. They can help patients develop ways of coping and reduce crises. Use of SUN projects is associated with improved functioning and reduced use of services.³⁶

Offering a range of interventions

Specialist treatments are a significant commitment for patients in terms of time and emotional expenditure. Initial use of lower-intensity or alternative therapies, e.g. art, music or movement, could provide an introduction to the nature of therapy, attending to a frame and developing a trusting relationship with a therapist. Therapies which are not based on verbal communication may also be more acceptable to some patients. Although these are not evidence-based treatments for EUPD, their completion could lead to referral for specialist treatment.

Volunteering or employment

Activities that help create structure and promote responsibility and confidence in ability to change may be beneficial. Some CMHTs have access to employment advisers with experience working with people with mental health problems, who can be particularly helpful.

Table 1 groups the interventions suggested above into internal and external factors and according to the stage of change of the patient. Table 1

Interventions which may increase readiness for referral for specialist treatment	Factors affecting readiness	Stage of change
<ul style="list-style-type: none"> • Psychoeducation regarding personality and diagnosis • Personal formulation • Collaborative goal-setting • Crisis planning • Distress tolerance skills • Address substance misuse • Psychoeducation regarding therapy • Collaborative goal-setting • Mindfulness • Motivational interviewing • Lower-intensity or alternative therapies, e.g. art, music or movement therapy • Peer support groups, e.g. SUN project 	Internal	Precontemplation
<ul style="list-style-type: none"> • Key worker or peer support worker • Support for dependents or carers • Support or signpost regarding domestic violence or other safety issues • Support or signpost regarding social stressors, e.g. accommodation, finances • Support with employment or volunteering • Address practical barriers to attendance, e.g. bus pass • Support or signpost regarding social stressors, e.g. accommodation, finances • Liaison with personality disorder service 	External	Contemplation

Should I discharge?

‘Precontemplation’ suggests that change will be considered at some time in the future. Experience suggests this does not always occur, raising the issue of how to manage such patients. To the best of our knowledge, no evidence exists regarding whether to continue to try to engage patients in a CMHT or discharge them. Opinions and practices vary.

We suggest that patients in precontemplation should be offered interventions as above, with an agreement between patient and clinician regarding timeframe and responsibilities, e.g. attending appointments, setting goals, and following crisis plans. After the agreed timeframe, if there has been no clear benefit or effort to work towards goals or adhere to responsibilities, then discharge could be considered. NICE advises discussing the discharge process with the patient and agreeing a care plan with steps to manage distress, cope with future crises and re-engage in the future.⁷ This should be clearly communicated to the general practitioner, including how they can access support.

However, this approach may be challenging for patients with repeated risky behaviour. It may be more pragmatic not to discharge but to focus on promoting safety, emotion and behaviour regulation, and social stability. It is noteworthy that being within a CMHT may offer some containment and stability, even if this is not readily apparent. That said, there are potential negative effects of prolonged unfocused CMHT input, including ineffective resource use and the fostering of dependence as opposed to recovery. As noted already, clinicians should also be mindful of discharging in response to their countertransference.

Limitations

There are limitations in applying the transtheoretical model to EUPD. It has typically been used in single health behaviours, e.g. smoking or alcohol misuse, whereas multiple complex behaviours are present in EUPD. We also note that a binary ready/not ready approach is an arbitrary and artificial oversimplification of what is a complex dynamic process, and it could be used inappropriately to obstruct access to treatment. However, our systematic search did not identify any evidence regarding increasing readiness in EUPD and, in the absence of other suggested frameworks, we believe our model is pragmatic and can aid clinical thinking and decision-making.

Conclusion

EUPD is commonly encountered in mental health services, but some patients are not at a stage where they are ready to engage in specialist treatments. No guidelines exist regarding how to manage such patients, and prolonged unfocused treatment in CMHTs is not ideal.

We suggest that readiness for referral can be considered in terms of the transtheoretical model of stages of change. A range of approaches and non-specialist interventions exist which can enhance readiness and which can be used in a shared plan working towards referral for specialist treatment. Further research is required into which approaches may best increase readiness and what best practice is for patients who, despite intervention, remain unable to engage in specialist treatment.

1.2.17 Healthcare poverty-inequality and government quick fixes

Claire Hilton

date

2021-02

Contents

- *Healthcare poverty-inequality and government quick fixes*

I welcome the editorial by Peter Byrne and Adrian James¹ on poverty-inequality, and their note about lessons from history. Reports indicating the damage to health caused by poverty-inequality in Britain go back at least as far as Benjamin Seebohm Rowntree's study of York around 1900, Julian Tudor Hart's 'inverse care law' in 1971, and the government-commissioned and suppressed Black Report of 1980.² The narrative of governments abandoning some of the most deprived and vulnerable people in society is ongoing.

As Byrne and James point out, people with severe mental illness today have an additional layer of disadvantage, a 'lower status conferred on them', a state of 'subcitizenship', due to stigma and marginalisation, associated with societal and government disinclination to resource care for them. This too is long term. In 1908, psychiatrist William Stoddart³ accused the asylum leadership (which had statutory responsibility for the care of mentally unwell people) of having 'excessively economical tendencies', neglecting their patients, the subcitizens of their time. This neglect was associated with adverse outcomes, such as excess morbidity and mortality from physical illness: in asylums, the death rate from tuberculosis, a poverty-related potentially preventable disease, was ten times higher than in the community. Then, as now, it was convenient for the authorities to attribute high rates of physical illness to a person's underlying mental disorder, rather than providing resources to allow services to support those patients adequately, whether in the asylums of the past or in the community today.

Government bodies have repeatedly sought the cheapest short-term measures for managing mental disorders, overlooking social and environmental root causes of the problems and failing to consider longer-term health and social benefits of adequate resourcing. Sometimes these principles extend to public health more generally. Perhaps the most outstanding recent demonstration of a quick-and-cheap government fix was the advice at the beginning of the COVID-19 pandemic for everyone to take vitamin D, based on the finding of high mortality from COVID-19 in Black and minority ethnic groups, who are particularly likely to have low levels. If vitamin D has any effect, it appears to be non-specific.⁴ In other words, the quick-and-cheap fix did not work. Rather, COVID-19 deaths, as Byrne and James remind us, are

associated with social deprivation, which may also be associated with low vitamin D. Vitamin D won't fix the real problems.

1.2.18 The climate crisis and forensic mental healthcare: what are we doing?

Jack Tomlin

Correspondence

Dr Jack Tomlin

(jack.tomlin@med.uni-rostock.de)

date

2021-02

Abstract

The climate crisis poses the greatest threat to human health this century. Mental health services will be called on to address the psychological consequences of its effects on peoples' lives, particularly the socially disadvantaged and those on low incomes. However, healthcare systems are also contributors to the climate crisis. This editorial discusses how services can continue to provide care while contributing less to climate change. Specifically, it suggests what services such as forensic mental healthcare, which is constrained by legal, political and resourcing concerns, can do differently.

Ten years ago, *The Lancet* identified climate change as the largest threat to human health in the 21st century.¹ Changes in the environment and biodiversity, alongside unpredictable natural disasters, will have consequences for both the somatic and mental health of the world's population. Individual and collective mental health are likely to suffer owing to anxiety over fluctuating living conditions, loss of means of income, broken social bonds and conflict linked to resource scarcity, with low income and socially disadvantaged groups most likely to be affected.²⁻⁴

Mental health systems will play a significant role in responding to the psychological fallout of the climate crisis. Services will have to respond to experiences of trauma following natural disasters and longer-term mental health concerns, such as depression and anxiety, linked to changes in lifestyles, environmental damage and resource scarcity.³ A study

conducted 1 year after the 2005 Hurricane Katrina in New Orleans, USA, found that 40% of 144 surveyed residents had a probable mental illness, half of which were classified as severe. This contrasted with a survey conducted between 2001 and 2003, which estimated that 16% of respondents in the region had any type of mental illness.⁵ The authors attributed this to destroyed or damaged housing and property, consequent dislocation and associated losses of employment and community ties.

The healthcare sector's contribution to the problem

Most causes of climate change are well acknowledged: overreliance on fossil fuels, poisonous greenhouse gas emissions, unsustainable agricultural practices. Yet paradoxically, while being tasked with managing much of the future damage to human well-being, healthcare systems are themselves contributors to the climate crisis. In the USA, a 'top emitter', 7.6% of national emissions (defined as carbon dioxide, methane and nitrous oxide) come from the healthcare sector (1.72 tCO₂e/capita).⁶ This is the equivalent to 141 coal power plants. In the UK, the healthcare system contributes 5.4% (0.66 tCO₂e/capita); the average across the European Union is slightly lower: 4.7% (0.49 tCO₂e/capita). A 'lower than average emitter', India's healthcare system contributes 1.5% to total emissions (58 times less than the USA per capita).

These contributions derive from the manufacture of pharmaceutical products; the large amounts of resources needed to run equipment, heat buildings and transport patients or staff to appointments; and the disposal of waste products.⁷ As health and social care services constitute a substantial part of every country's economic and social activity, the magnitude of their contribution may be understandable. However, given the preventive and life-saving functions that healthcare systems provide, significant questions remain – how can healthcare systems provide perennially improving, high-quality care while contributing less to the climate crisis? And what does this mean for sectors particularly constrained by legal, political and resourcing concerns, such as forensic mental health services – especially when the number of forensic in-patient beds has been increasing in many North American and European states?⁸

'Sustainability' in mental healthcare: the ideal...

Recent efforts have attempted to embed the concept of 'sustainability' into routine mental healthcare. Sustainable mental health services are those that weave sustainable thinking into decision-making at all levels. The Joint Commissioning Panel for Mental Health and the Centre for Sustainable Healthcare⁷ identify four basic principles that settings should adhere to. Services need to (a) promote patient self-management, (b) prioritise prevention instead of response to illness, (c) adopt sustainable methods of energy use and (d) increase efficiency in service provision (*Fig. 1*). These principles should not be understood as detracting from the necessity for gold-standard clinical care for those who need acute, urgent treatment to manage severe mental illness. This reactive medicine must still be available but with practitioners cognisant of a sustainable approach and alert to the notion that embracing these principles can help lower or buffer the growing future need for such care. *Fig. 1* Four basic principles for sustainable mental healthcare.

What do these principles look like in practice? Taken together, these recommendations aim to develop sustainable resource use. The more mental illness is prevented and managed in the community, the less secondary care services will be called on. When services are engaged, they should minimise and embrace clean-energy use and maximise efficiency, so that time, resources and medications are not wasted. Specific aims include avoiding hospital admissions that might have been identified earlier and managed in primary care; the development and monitoring of targets to reduce carbon emissions, including seeking more efficient methods of heating buildings and transporting food, medicines and materials, and reducing amounts of waste; enabling patients to self-manage symptoms in the community where possible; offering horticultural therapies, walking groups and psychological interventions instead of prescribing unnecessary medication; offering telephone or online interventions; and reducing the number of missed appointments.⁹

... and the reality in forensic settings

However, the transferability of these aims to forensic settings is not immediately apparent. Forensic services are high cost and provide care to patients who are, in law and fact, deprived of their liberty. Patients are placed in care following the commission of a crime or when risk of harm is too difficult to manage in general or out-patient services. Thus, forensic settings reflect failures elsewhere to prevent or manage mental illness and antisocial behaviour. They require resource-intensive security measures; services may be reticent or unable to promote patient self-management owing to seriousness of illness or the custodial attitudes of staff and policy makers; patients may be kept within inappropriately high levels of security because of political or media attention; and they typically rely less on volunteers and carers from the local community to help manage patient recovery and run services than other health services might. Accordingly, efforts to meet the aims of prevention, self-management and reducing carbon emissions could face extra barriers.

Some suggested steps forward

So, what can forensic services do? All services should develop a sustainable development plan. Such a plan details aims, objectives, strategies and priorities for improving local environmental and socioeconomic impacts and should set measurable targets.¹⁰ These should reference national or regional standards for reducing carbon emissions. These plans are already required by healthcare providers commissioned by standard contracts in the National Health Service in England and Wales. Patients should be involved in developing targets and action plans. This should be complemented by routine monitoring of procedural and substantive outcomes, including, for instance, whether sustainability is incorporated within a service's mission statement or the ways in which it is included in decision-making structures, reductions in waste and energy use, or the number of meals produced using food grown on-site. Plans can draw on the four basic principles described earlier (*Fig. 1*).

Steps should be taken to integrate patients into local communities to promote self-management of symptoms, prevent mental health problems or risky behaviour due to social isolation or deskilling, and thus reduce need for services. Peer support programmes run by former forensic services patients or carers, work for patients outside secure settings, and proactive attitudes towards granting leave could all be helpful. Treatment paradigms such as the recovery approach and the Good Lives Model that aim to improve the quality of patients' lives holistically, promote recovery and target criminogenic factors as well as treating mental disorders should be used to increase the chance of successful rehabilitation that carries through into the community and reduces future service use.^{11,12}

Punitive attitudes that discourage the placement of patients in lower levels of security closer to the community should be tackled by implementing training programmes that educate all staff on the antecedents, symptoms and prognoses of patient diagnoses and thus encourage a therapeutic mindset. The unnecessary use of medications should be avoided. When tension or aggression is present on a ward then the use of verbal de-escalation techniques by appropriately trained staff might avoid the requirement for 'as needed' (p.r.n.) medications.¹³

Finally, individuals working in secure services should develop a network to (a) share sustainable development plans and best practices, (b) identify challenges unique to forensic settings and (c) connect with individuals in general mental health and somatic care who have already developed such networks (e.g the Centre for Sustainable Healthcare in the UK). Forensic services should be aware of how they contribute to and can help alleviate the consequences of the greatest threat to human health in the 21st century. To avoid doing so would be to ignore our guiding principles of reducing harm and improving lives.

date

2021-02

Abstract**Aims and method**

To compare differences in clozapine doses and plasma levels between Bangladeshi and White British patients. Following ethical approval we identified all current Bangladeshi and White British patients on clozapine maintenance in an east London clinic. We carried out univariate and multivariate regression analyses to examine associations between clozapine doses and ethnicity, age, gender, smoking status and weight. We also compared plasma clozapine levels of the two groups.

Results

On univariate analysis White British patients had on average 85 mg higher doses than Bangladeshi patients ($P = 0.004$). Older age, male gender and smoking were also associated with higher dose. On multivariate analysis only age and smoking status remained significant. A greater proportion of Bangladeshi patients had high plasma clozapine levels compared with White British (30.76% *v.* 20.75%), although the difference was not statistically significant.

Clinical implications

Our findings point to the need for the broadening of data collection on ethnic differences in clozapine prescribing within big data-sets such as Prescribing Observatory for Mental Health (POM-UK). Ethnopharmacological variations can inform more person-centred guidance on prescribing.

Clozapine is a unique antipsychotic that demonstrates superior efficacy in people with treatment-resistant schizophrenia and is recommended for treatment in such cases.¹ The response rate in these individuals is around 40%.² Clozapine has been shown in several pharmacoepidemiological studies to show superior long-term efficacy in terms of reducing hospital admissions.³ It also surpasses other antipsychotics in reducing self-harm⁴ and overall mortality.⁵

The pharmacological basis for the unique efficacy of clozapine in treatment-resistant schizophrenia is not clearly understood.⁶ Clozapine treatment is associated with a number of adverse effects.^{7–9} Unlike for most other antipsychotics, the decision to stop clozapine is taken more often by prescribers than by patients, and for reasons of adverse effects more than for lack of efficacy.¹⁰ The Prescribing Observatory for Mental Health (POM-UK) conducts national audits of clozapine use in the UK, gathering detailed information, for example that clozapine prescribing for people with schizophrenia is higher in men than in women.¹¹ Although the POM-UK audit collects ethnicity data, it does not compare prescribing practices or variations between ethnicities.

Ethnopharmacology relates to the study of substances used medicinally by different ethnic groups and examines variations in our body's processing of drugs based on ethnicity, including pharmacogenetics. It is known that prescribing rates for clozapine vary, ranging from less than 10 patients per 100 000 people to nearly 180 patients per 100 000 people.¹² Variations in dosage may be due to variations in prescribing practice and/or the patient's metabolism. At either end of the spectrum patients may be 'poor metabolisers' or 'ultra-rapid metabolisers'. Metabolic variation can be genetic, but it can also be environmental (e.g. due to cigarette smoking). Ethnic variation in metabolism along the cytochrome P450 has been known for a few decades.¹³ Drug clearance is represented by the concentration-to-dose (C/D) ratio in blood plasma under steady-state and trough conditions. A very low C/D ratio indicates an ultra-rapid metaboliser, whereas a very high C/D ratio indicates a poor metaboliser. In the USA, clozapine C/D ratios, measured in (ng/mL)/(mg/day), typically range from 0.6 (male smokers) to 1.2 (female non-smokers). Inhibitors (including fluvoxamine and oral contraceptives) and inflammation can also increase clozapine C/D ratios.¹⁴

The British National Formulary recommends titrating clozapine to a dose of 300 mg/day if tolerated, which can be further increased up to a maximum dose of 900 mg/day.¹⁵ Despite varied estimates of response threshold, plasma levels can be useful in optimising treatment. According to the Maudsley Prescribing Guidelines, in those not responding to

clozapine, dose can be adjusted to give plasma levels in the range 0.35–0.5 mg/L (a range reflecting a consensus of the above findings). The guidelines also mention that plasma levels may help in decision-making in those who are not tolerating clozapine, for example by a reduction to a dose guided by the plasma level range mentioned above.¹⁶ It is documented that plasma levels of clozapine may be higher in ‘Asians’.¹⁷ This was a study from Singapore in which ‘Asian’ patients were noted to have more than twice the effective clozapine concentration-to-dose ratio than ‘Caucasian’ patients. This very high C/D ratio would suggest a higher prevalence of poor metabolisers in this population. We are not aware of any similar studies in South Asians or in the Bangladeshi population.

We looked at two self-assigned ethnicities as accepted by UK census.¹⁸ The London Borough of Tower Hamlets (an administrative unit within the city) has a unique ethnic composition, being home to the largest Bangladeshi population in England.¹⁹ The Bangladeshi population accounts for almost one-third of all residents, closely followed by the second largest ethnic group, White British (31%).²⁰ This unique ethnic composition provided a particular opportunity for research into differences in prescribing of clozapine and differences in plasma levels documented between these two ethnic groups. We recognise that our study is not equipped to look into actual genetic and epigenetic differences between the two populations. However, comparing distinct subgroups, i.e. White British and Bangladeshi, we minimise the heterogeneity in each group and make the results more relevant to the populations being studied.

The primary aim of this study was to compare prescribed doses of clozapine in the Bangladeshi population with those in the White British population. The secondary aim was to see whether the odds of plasma clozapine levels being above 0.5 mg/L (the upper limit of the recommended therapeutic range) were increased by belonging to Bangladeshi ethnicity compared with White British.

Method

All patients receiving clozapine (through the National Health Service) in Tower Hamlets are registered to the Tower Hamlets Clozapine Clinic. All such patients receive clozapine blood monitoring at the clinic and they are registered with the Zaponex Treatment Access System (ZTAS), which is an on-line patient data-base for monitoring treatment.

The study proposal was approved by the ethics committee of the local healthcare provider (East London NHS Foundation Trust). We collected cross-sectional data from the Tower Hamlets Clozapine Clinic as on 21 November 2018.

We defined ‘maintenance dose’ as a dose for which the patient is no longer having blood monitoring as frequently as weekly, which generally indicates that the patient has been taking clozapine for at least 18 weeks after dose titration. We took this as a proxy measure for maintenance dose of clozapine for the purpose of the study. On 21 November we identified 79 Bangladeshi and 52 White British patients receiving clozapine in their maintenance phase. We carried out univariate linear regression analyses for ethnicity, age, gender, smoking status and weight, followed by multivariate regression analyses on the variables that were statistically significant on univariate analysis.

For our secondary aim we searched for results of clozapine plasma level tests conducted on the participants. Of the results available in the clinic’s records, 78 were obtained from the people of Bangladeshi ethnicity and 53 were from the people of White British ethnicity. We calculated how many of these results were above 0.5 mg/L. Subsequently we analysed whether the odds of an individual recording a plasma level above 0.5 mg/L was increased if they were of Bangladeshi ethnicity compared with White British ethnicity.

The study did not gather any new data but analysed data that were already available in the clinic’s electronic patient records.

Results

Ethnicity, age, gender and smoking status were all significantly associated with clozapine dose (significance was borderline for gender) (Table 1). White British participants received on average 85 mg/day higher doses of clozapine than Bangladeshi participants. Older people received on average 39 mg/day higher doses for each decade of increasing age. Women received on average 67 mg/day lower doses than men, but the difference was only borderline significant. Non-smokers received on average 81 mg/day lower doses than smokers. Weight was not significantly associated with dose in our sample. Table 1

	Univariate analysis	Multivariate analysis
Mean dose, mg/day	435.18	435.4
Mean dose difference, mg/day	51.3	51.3
95% CI	(12.3 to 114.8)	(12.3 to 114.8)
Difference	0.11	0.11
95% CI	(0.004 to 0.216)	(0.004 to 0.216)
Dose by ethnicity		
White British (<i>n</i> = 52)	435.18	435.4
Bangladeshi (<i>n</i> = 79)	349.68	349.68
Dose by smoking status		
Smokers (<i>n</i> = 59)	427.97	427.97
Non-smokers (<i>n</i> = 72)	348.59	348.59
Dose by gender		
Female (<i>n</i> = 36)	334.72	334.72
Male (<i>n</i> = 95)	402.1	402.1
Dose by weight		
Weight (per 10 kg)	1.2	1.2
95% CI	(15.9 to 13.5)	(15.9 to 13.5)
Dose by age		
Age (per decade)	38.9	38.9
95% CI	(12.3 to 65.6)	(12.3 to 65.6)

58.8)0.048*¹

When we tested variables known to influence clozapine dose in a multivariate model comparing age (per decade), gender, smoking status and ethnicity, only age and smoking status remained statistically significant. Difference based on ethnicity was no longer statically significant at the 5% level, although the trend was towards White British having higher doses. As weight was not significantly associated in univariate analysis, we did not carry out multivariate analysis on this variable.

Of the 78 results of plasma clozapine level tests obtained from Bangladeshi participants, 24 (30.76%) had levels higher than the upper limit of the therapeutic range. Of the 53 results obtained from White British participants, 11 (20.75%) had levels higher than therapeutic range. The odds ratio of a higher (above 0.5 mg/L) plasma level in a Bangladeshi individual was calculated to be 1.697, although this was not statistically significant as the confidence interval crossed 1 (Table 2). Table 2

	Plasma level >0.5 mg/L, <i>n</i> (%)	OR (95% CI)
Bangladeshi (<i>n</i> = 78)	24 (30.76)	1.697 (0.748–3.852)
White British (<i>n</i> = 53)	11 (20.75)	

Discussion

Key findings

We are aware of several factors that could affect clozapine dose. We found that Bangladeshi participants, women, younger participants and non-smokers received lower doses. When we looked at our dosage data using the multivariate model only, smoking status and age were statistically significant. However, it is possible that we were not sufficiently powered with our sample size to demonstrate the difference in dosing between Bangladeshi and White British ethnicity. There was a trend towards White British participants needing higher doses. We are aware that other factors might also have influenced dosage (e.g. co-prescribing), but this information was not available in the clinic's regular monitoring records.

We examined records of plasma clozapine levels to explore whether higher plasma clozapine concentrations were more likely to be reported in those of Bangladeshi ethnicity compared to White British ethnicity. We found that, despite receiving lower doses, Bangladeshi patients were more likely to have higher plasma concentrations of clozapine when tested. This would support the suggestion of a higher prevalence of high C/D ratios and poor metaboliser status

among Bangladeshi patients taking clozapine. For simplicity of analysis, we used the Maudsley Prescribing Guidelines reference therapeutic plasma level to analyse the plasma level data as a binary variable. This study is not designed to assess the therapeutic plasma range for clozapine. The data-base for clozapine plasma levels did not have a record of associated variables. We used existing clinic data for our analysis and were limited by the data that were routinely collected.

Bangladesh and Bangladeshi populations

Bangladesh is a new country, created in 1971 from a division of Pakistan decided on the basis of linguistic differences (eastern Pakistan was predominantly Bengali-speaking), and previously separated from British India on the basis of religion when Colonial rule ended in 1947. Bangladesh is in the eastern part of South Asia, which has a high internal ethnic homogeneity, with 98% identifying themselves as ‘Bangalees’.²¹ In fact some residents of Tower Hamlets arrived in the UK before the country was formed and many are second generation. It is also recognised that people from the Sylhet region are the strongest subgroup within this population. However, they also identify themselves as Bangladeshi. Ethnicity is a different construct in each society and may merge with local notions of ‘race’, national identity or other invented traditions.²²

There is a body of literature in cultural psychiatry in which the UK’s Bangladeshi population has been studied (e.g. in Mental Health Act detention data). Information such as ours has implications in terms of global health and can inform prescribing in other countries, especially in Bangladesh, a country of 169 million people. Schizophrenia is the most common diagnosis in mental health settings in Bangladesh, according to a World Health Organization report across in-patient units, mental hospitals and community-based clinics.²³ We believe that such information and guidance has significant public health implications both in Bangladesh, as well as for migrant populations of Bangladeshi origin across the globe. We also believe that assuming large populations are monolithic, for example as implied by concepts such as ‘Asian’ and ‘Caucasian’, risks overgeneralisation and misses out on differences within these groups. Having smaller clearer groups might allow a granularity in our understanding that would otherwise not be possible.

Ethnicity, pharmacology and study populations

Ethnicity is reported to be an important, but often ignored factor in psychopharmacology. A number of ethnically specific variations have been found in the genetic and non-genetic mechanisms affecting pharmacokinetics and dynamics of psychotropic drugs, which might underlie differences in drug prescribing and response across ethnicities. Although some of these ethnic differences might be partially explained by genetic factors, a number of ethnically based variables such as diet and cultural attitudes could potentially have a significant impact.²⁴ This might include differences in smoking habits between Bangladeshi and White British patients or levels of comorbidity. Very few studies have analysed biological basis and metabolic variations in relation to clozapine. A notable exception is the above-mentioned 2005 study from Singapore and even then there are difficulties with what the terms Asian and Caucasian mean.¹⁷ We acknowledge that our study design does not offer the opportunity to explore these variables in detail. Although there has been some research into ethnic variation in clozapine tolerability and effective dosing, a significant evidence base is still lacking.

Most studies in the field are case–control studies such as ours, comparing small samples of broad ethnic entities or case series, sometimes with a more distinct ethnic group. The 2005 Singapore study comparing 20 ‘Asian’ patients from Singapore with 20 ‘Caucasian’ patients from Australia reported that the mean clozapine dose for the Asian group was 176 mg/day, whereas for the ‘Caucasian’ group it was 433 mg/day.¹⁷ A more recent study found that ‘East Asians’ (Chinese in the sample) had a clinically relevant reduced clozapine clearance (suggesting higher prevalence of poor metabolisers) compared with ‘Caucasians’ (Italians in the sample).²⁵ However, the ethnic groups ‘Asian’, ‘East Asian’ and ‘Caucasian’ are, in our opinion, too broad and heterogeneous to safely generalise the findings in a clinical setting.

We also discovered that findings were not always consistent. Results from a study conducted in south London by the South London and Maudsley NHS Trust reported no significant differences in clozapine dosage prescriptions between in-patients from White, Black and Asian ethnic groups.²⁶ Although the overall study sample was large, the clozapine sample for which ethnicity was noted was only 188 and included only in-patients, whereas we compared all patients on

clozapine (community and in-patients). As the south London study also included all ethnicities, once again we would argue the categories were too broad. The 11 'Asian' patients included in the study did receive a lower mean dose of clozapine but this was not statistically significant. In another recent study the researchers concluded that clozapine bioavailability did not vary between Maori and European patients.²⁷ Therefore one needs a more nuanced approach rather than generalising diverse minority groups as monolithic.

Studies that examined more coherent ethnic identities lacked control groups. A review of 1256 records from Novartis Pakistan (one of the monitoring systems for clozapine treatment) were analysed and the average maintenance dose was found to be 230 mg/day.²⁸ A study involving 162 Taiwanese patients with refractory schizophrenia reported a mean dose of 379.5 mg/day (range: 100–900 mg/day).²⁹ The only other study on the Bangladeshi population was a small case series comprising 21 patients in a tertiary care centre in Bangladesh, which revealed that most of the patients with treatment-resistant schizophrenia (64%) responded to clozapine doses of 50–200 mg/day and the remaining patients who responded to treatment required doses of 250–500 mg/day.³⁰ In these reports without a control group one can argue that prescriber factors such as prescribing culture, habits or even cost could have influenced the prescribed dose as opposed to patient factors.

Clinical and research implications

We believe that the information obtained from our study is important as it provides an opportunity to explore variation in tolerability and effective dosage controlled for prescriber factors. Even with relatively small numbers we found a statistically significant difference in dosing of clozapine. Although we did not find statistically significant odds of high plasma levels in Bangladeshi participants it is possible that the study was not sufficiently powered to elicit the statistical significance. Of note, high plasma levels were reported in Bangladeshi participants despite the lower mean prescribed dose, indicating a higher C/D ratio and possibly higher prevalence of poor metabolisers in the Bangladeshi population.

For more comprehensive exploration of these issues, we believe there is need to analyse 'big data'. POM-UK audits have the opportunity to do this. We would like this national audit to analyse dosage and tolerability variation data across ethnicity. Similarly, data on plasma clozapine levels held in central repositories might offer sufficiently large samples to enable study of ethnic variations and could steer research in cytochrome-P450 variations between populations. If such variation is clearly documented, it could inform prescribing guidelines on a more cautious and conservative approach when titrating patients of Bangladeshi ethnicity on clozapine.

We also suggest that studies of ethnic variations in clozapine doses and plasma levels should select more coherent ethnic groups and be mindful of heterogeneity within minority populations.

We thank Frank Röhrich, MD, FRCPsych, consultant psychiatrist, Medical Director and Honorary Professor of Psychiatry, and Anthony Khawaja, MA(Cantab), PhD, FRCOphth, consultant ophthalmic surgeon, for their advice on statistical analysis.

Claire Hilton

date

2021-02

Contents

- *Tom Arie, CBE, FRCP, FFPH, FRCPsych (Hon)*

Professor Emeritus of Health Care of the Elderly, University of Nottingham, UK

Tom Arie was an old age psychiatrist who steered proactive, treatment-focused mental health services for older people onto the UK policy agenda. This vital step ranks alongside other ‘firsts’ that created the specialty of old age psychiatry: in 1949, Aubrey Lewis established the first dedicated older people’s psychiatric assessment ward and appointed Felix Post consultant; in 1955, Martin Roth demonstrated the error of the premise that all mentally unwell older people were ‘senile’; and in 1958, Sam Robinson established the first comprehensive old age psychiatry service in the UK.

Tomas Arje was born into a Jewish family in Prague on 9 August 1933. In 1939, after 5 months living under Nazi occupation, Tom and his parents fled to England, 2 weeks before war broke out.¹ They settled in Reading, where his parents worked for the BBC, monitoring Nazi broadcasts. In 1952, he went up to Balliol College, Oxford, to read classics. After 2 years, with a first in ‘Honour Moderations’, he followed his growing yearning and swapped to medicine.

Interested in the study of the hospital as a small society, he trained in psychiatry at the Maudsley Hospital, London, and in social medicine at the London (now, Royal London) Hospital. At the Maudsley, working with Felix Post, he found old age psychiatry spellbinding. At the London, Professor Jerry Morris introduced him to social medicine and its leaders. By the time Tom was appointed consultant psychiatrist at Goodmayes Hospital, Essex, in 1969 (‘an unposh place [...] Most people thought I had taken leave of my senses!’)² he was personally acquainted with National Health Service and social policy leaders, including Chief Medical Officer Sir George Godber.

Tom and a few other newly appointed consultant psychogeriatricians – a ‘happy band of pilgrims’ as one described them – began to meet. Through Tom’s links, they negotiated the content for the Department of Health and Social Security’s blueprint for service development, *Services for Mental Illness Related to Old Age* (1972). A year later, and growing

in number, the group became the Royal College of Psychiatrists' Group (now Faculty) for the Psychiatry of Old Age. Tom chaired the first meeting – and then supported the election of Felix Post as chair, meanwhile continuing to inspire and nurture behind the scenes.

Away from policies and politics, Tom led an enthusiastic multidisciplinary clinical team characterised by a low hierarchical structure, high morale and positive expectations. Unusually for the 1970s, it included a plethora of part-time women junior doctors, who later became leaders in their own fields. The team pioneered ways to improve the health and well-being of older people, including using domiciliary assessments routinely. They achieved good clinical outcomes and their work highlighted the fallacy of commonplace ageist assumptions. They repeatedly evaluated all aspects of their work in a way that today would be labelled 'quality improvement', but for Tom was an instinctive, effective and fruitful way of working.^{3,4} His creative approach seeped into new teams led by those he inspired.^{3,4}

In 1977, Tom was appointed Professor of Health Care of the Elderly at Nottingham University. There, he modelled and led a joint geriatric–psychiatric team. His department was a magnet and inspiration for politicians and clinicians. In the 1980s, with wide admiration for UK psychogeriatrics and an international lack of trained psychogeriatricians, the British Council, the UK's international cultural relations body, sponsored psychogeriatric courses. These 'Arie courses', based on the 'Arie model', took place in the UK (Nottingham), Australia, Israel, Korea, Poland, Portugal and elsewhere, creating significant long-term impact. Tom was Vice President of the Royal College of Psychiatrists in 1985–1986. He was made CBE in 1995 for services to medicine. He was awarded a College honorary fellowship in 2001 and the Old Age Faculty lifetime achievement award in 2012. The British Geriatrics Society bestowed their highest honour on him, the Founder's Medal, in 2004.

Tom's goals were humane and idealistic. Some of his ideas were, perhaps, too idealistic, and could not break through bureaucratic, administrative and ideological fashions. He fought for dignity for older people, always sensitive to the moral and medical aspects of their care, not just advocating but also agitating for them. Tom's style, and what he enjoyed doing most, was to 'make grass grow in the desert – enthusing, fostering, encouraging, making things happen, fighting my corner'.² Providing for some of society's most vulnerable people seemed to be an echo from his childhood.

Outside work, Tom was a creator and collector, particularly of friends and paper. He and his wife Eleanor (also a doctor) were always wonderfully hospitable, with their enormous rustic kitchen being the social hub of their home. He read voraciously on many subjects. When a neighbour opened a 24/7 second-hand charity bookshop in her garden shed, he would wander over and browse. He took pleasure in rescuing books from there and the local charity shops that he thought needed love and attention in his hands and on his bookshelves. He kept vast swathes of his personal archives neatly filed, including his diaries; I e-mailed him recently: on what precise date in 1970 did he present a certain report on his work at Goodmayes? The answer flew back a few hours later.

'I count my blessings every day', Tom would say. His close-knit family meant the world to him – and he to them – Eleanor and his children Laura, Sophie and Sam, and grandchildren Blake, Zak, Max, Lucy, Eli and Milo, and his wider family. Tom died of cancer at home on 24 May 2020 with his family around him. Now, with his passing, may his memory and his teachings continue to be a blessing to others and inspiration to future generations.

1.2.21 Changing practice: assessing attitudes toward a NICE-informed collaborative treatment pathway for bipolar disorder

Adele Louise Elliott Stuart Watson Guy Dodgson Esther Cohen-Tovée Jonathan Ling **Correspondence:** Stuart Watson.
Email: stuart.watson@ncl.ac.uk

date

2021-03

Abstract**Background**

Bipolar disorder is a chronic mental health condition, which can result in functional impairment despite medication. A large evidence base supports use of psychological therapies and structured care in the treatment of mood disorders, but these are rarely implemented. e-Pathways are digital structures that inform and record patient progress through a healthcare system, although these have not yet been used for bipolar disorder.

Aims

To assess the perceived benefits and costs associated with implementing a collaborative NICE-informed e-pathway for bipolar disorder.

Method

Healthcare professionals and people with bipolar disorder attended a workshop to share feedback on e-pathways. Data were collected through questionnaires ($n = 26$) and transcription of a focus group, analysed qualitatively by a framework analysis.

Results

Patients and healthcare professionals welcomed the development of an e-pathway for bipolar disorder. There were five elements to the framework: quality and delivery of care, patient–clinician collaboration, flexibility and adaptability, impact on staff and impact on healthcare services.

Conclusions

Identification of benefits and costs ensures that future development of e-pathways addresses concerns of healthcare professionals and people with bipolar disorder, which would be essential for successful implementation. Recommendations for this development include making e-pathways less complicated for patients, ensuring sufficient training and ensuring clinicians do not feel their skills become invalidated. Limitations of the study, and directions for future research, are discussed.

Bipolar affective disorder

Bipolar affective disorder has a lifetime prevalence of between 1 and 2.5% of the population.^{1,2} It is diagnosed on the basis of current or prior manic or hypomanic episode(s);³ however, low mood that is frequently persistent⁴ and can meet criteria for a depressive episode is more common.^{5,6} The disorder is further characterised by functional impairment⁷ and increased mortality rates, including from suicide.⁸ The estimated cost to the UK is £5.2 billion annually, with direct National Health Service (NHS) costs of £342 million.^{9,10} Biological, psychological and social treatment paradigms are used,¹¹ and treatment pathways differ between patients in depressed versus manic episodes, and in patients who are between episodes.¹² Pharmacological interventions reduce relapse and treat episodes, if used appropriately¹² Similarly, psychological interventions specifically developed for adults with bipolar disorder improve symptoms and prevent relapse and admission to hospital.^{13,14} These interventions include enhanced relapse prevention, group or individual psychoeducation,^{15–17} cognitive–behavioural therapy and family-focussed therapy.¹⁸ Group psychoeducation arguably has the strongest evidence base. Research over the past 15 years has concentrated on resource light strategies, with groups integrated within existing treatment pathways (e.g.^{19,20}). However, these evidence-based treatments are not widely available within the NHS.

Care pathways

Care pathways represent a formalisation of the process that underlies care and usually incorporate one or more protocols and guidelines, provide a record of care and a variance record to show where deviations from the planned pathway have occurred.²¹ Computerisation, thereby creating e-pathways, should allow pathways to be integrated with guideline-based decision support, the electronic health record and the clinical workflow.²² The entry point to an e-pathway is through an initial care plan. The patient engages in the development of a formulation and the only outcome measure is CollaboRATE, a rating scale for patients that measures how involved they feel in their care. The e-pathways would be accessible to patients, both in the session and accessible through the Cumbria, Northumberland, Tyne and Wear NHS Foundation Trust website, therefore encouraging individuals to be aware of, and request, evidence-based care. The treatment strategies suggested by the e-pathway would be delivered as part of a collaborative care plan. e-Pathways therefore have the potential to improve access to, and use of, the current evidence base and guidelines, to embed values of co-production by building a shared understanding of the difficulties faced by people with bipolar disorder, and to allow formal evaluation of deviations. e-Pathways thus enable identification of resource gaps, training needs and guideline weaknesses. Our NHS mental health trust has an expressed commitment to develop a series of e-pathways that incorporate clinical algorithms. e-Pathways require collaboration between our NHS trust and the electronic patient record provider, and is still under development for bipolar disorder. A pilot showed that the original proposed software package was too time-consuming for clinicians to use. The focus is now shifting to examine options to develop the e-pathway, using the existing capabilities of the electronic patient record supported by a bespoke trust-led software package.

Algorithm based care

Algorithm-based care refers to the use of clinical algorithms either to aid diagnosis or treatment. Clinical algorithms often comprise step-by-step instructions, often presented in flow-chart form, to guide the clinician.²³ Studies of unipolar depression have revealed that the use of algorithms markedly improves outcome.^{24,25} In bipolar disorder, the Texas Medication Algorithm Project²⁶ has revealed feasibility and efficacy in a public health setting. This has been replicated in a Brazilian study.²⁷ Our model incorporates the concurrent use of three algorithms, biological, social and psychological, with different algorithms for patients who are currently in a depressive episode; in a manic, hypomanic or mixed episode; and out of episode (yielding a total of nine algorithms). The algorithms are being produced iteratively, and are based on National Institute for Health and Care Excellence (NICE) guidelines, with support as needed from other clinical guidelines – notably that produced by the British Association of Psychopharmacology¹² and by the extant evidence base. An example algorithm is shown in *Fig. 1*. Fig. 1 Psychological pathway for out-of-episode bipolar disorder. Note: Entry onto the pathway is determined by a healthcare practitioner that the patient has bipolar disorder and is currently not in episode. Green and red arrows demarcate ‘yes’ and ‘no’, respectively. A diamond box indicates a decision, and rectangular boxes indicate an action. Behind each of these boxes is the necessary information to make a collaborative decision or action, for example: behind ‘Positive screen for sleep disorder?’ there is a rationale for screening for sleep disorders, and a description and screening tools for sleep apnoea and restless leg syndrome. If patients screen positive, the algorithm takes them to the ‘Resolved?’ decision box, where initial advice is given to address the sleep disorder. If this fails to resolve the situation, the algorithm takes the patient and healthcare practitioner to ‘Refer to sleep clinic’, in which information is provided to inform the decision to refer to local clinic, and if appropriate, a referral form. The algorithm next presents a choice of five options, and the information behind the boxes allows the healthcare practitioner to action the choice, or to flag if the resource is not available, e.g. group psychoeducation. The individual can follow the flow chart, e.g. starting with CBT-I and progressing with some individual psychoeducation delivered by the care coordinator, until the individual has confidence to sign up to group psychoeducation. Once this is complete, the patient and healthcare practitioner may feel that psychoeducation or sleep-work is not appropriate. If ‘Further psychological input needed?’ is answered ‘no’, the patient is discharged from the psychological pathway, and continues on the biological and social pathways. An asterisk indicates that it is outside the scope of the National Institute for Health and Care Excellence guidelines. CBT-I, cognitive-behavioural therapy for insomnia; DBT, dialectical behaviour therapy; IPT, interpersonal therapy.

Practice change

The movement from the existing structure of care to an alternative in which treatment decisions are made within a framework provided by algorithms, which, in turn, are incorporated into an e-pathway, represents a significant change in practice within our large organisation. Implementation of such a change requires careful consideration.²⁸ In health-care, it has been argued that allowing staff to define problems and formulate solutions facilitates even those change processes that are initiated by managers.²⁹ Here, we therefore sought to explore the views of healthcare professionals and people with bipolar disorder; specifically looking at the benefits and costs that are relevant to the development and implementation of an e-pathway for bipolar disorder, to steer and facilitate this change.

Method

Study design and setting

Data collection took place in a single session, a day-long workshop organised by the e-pathways team, to present the bipolar disorder e-pathway for discussion.

Recruitment and participation

Various methods were used to invite healthcare professionals and people with bipolar disorder to the workshop. The workshop was advertised twice via the Trust's weekly bulletin, which is sent to all employees of the Trust. Individuals who had shown earlier interest in the event from a previous bulletin were also directly invited, and invitations were cascaded within the trust, such as via the allied Health Professional Senior Leadership Team. Finally, an open invitation was extended to a bipolar disorder patient/carer group, and other individuals who had previously shown an interest in e-pathways. A combination of open invites and targeted recruitment ensured that feedback from the workshops spanned a variety of occupations and provided a range of perspectives. In total, 28 people attended the workshop. Members of the e-pathway team were also in attendance. Not all attendees provided their job roles within the NHS Trust, although occupations of those in attendance included clinical psychologists, peer-support workers, student nurses, consultants and community psychiatric nurses. Two employees of the NHS Trust in attendance also indicated they had a diagnosis of bipolar disorder, allowing them to provide further insight from the perspectives of healthcare professional and patient. Finally, one person from the bipolar disorder support group was in attendance, as was a carer for a family member with bipolar disorder. In total, three participants had bipolar disorder.

Format of the workshop

The day included presentations from the bipolar e-pathways team, including presentation of the algorithms that were on display throughout the day, a presentation from a person with bipolar disorder within the Trust, and two focus groups, one of which gave feedback on the pathway during a semi-structured group discussion that incorporated open-ended questions, with prompting for further elaboration. The second focus group explored the training implications of the e-pathway; however, as this was not a focus of the present study, no data were recorded from this group, although all participants from this second focus group completed the questionnaire at the end of the workshop. Attendees had free choice of breakout group. Two of the participants with bipolar disorder attended the focus group that was transcribed.

Data collection

Transcription of focus group

At the start of the discussion, those within the focus group were made aware that the session was to be transcribed. Before beginning, participants were reassured that their responses would remain anonymous. Audio recording was not possible because of logistical constraints. As such, the researcher transcribed the discussion by hand. As much detail was gathered as possible, and where individual fragments were missed, a summary of the speaker's point was instead made. The handwritten transcription was later transferred to computer and checked for accuracy by the researcher.

Questionnaire

A questionnaire was designed before the workshop, to explore views about the development of an e-pathway for bipolar disorder. All respondents were made aware of the purpose of the questionnaire. The questionnaire (see *Table 1*) was distributed and completed at the end of the day. Following the session, responses were compiled into a document for analysis *Table 1* Bipolar e-pathway questionnaire
Question 1 How do you think an e-pathway for people with bipolar disorder will affect the quality of care you/the Trust deliver/receive?
2 Would you welcome the development of such a pathway? What do you see as the advantages?
3 Do you have any concerns about the pathway? Are there potential negative consequences?
4 In what way do you think support, guidance and/or training could be developed to improve the quality of care you deliver/receive?
5 Do you have any further comments about the Bipolar Pathway?
6 Would you be interested in helping to develop the pathway? If yes, please give your contact details below

Data were analysed by framework analysis,³⁰ to systematically establish relationships within the data to answer relevant questions through the generation of a framework. This method of analysis, developed for applied policy research, is becoming increasingly used within healthcare and medical research.³¹ It allows the flexibility to examine ideas that arise from the data during analysis.³² Themes can be described as concepts that aim to describe the data.³¹ We followed the five stages to framework analysis: familiarisation, identification of a thematic framework, indexing, charting, and mapping and interpretation.

Ethical approval

As a service evaluation, this study did not require consent to be granted from Newcastle University nor NHS Research Ethical Committees. However, all procedures contributing to this work comply with the ethical standards of the relevant national and institutional committees on human experimentation and with the Helsinki Declaration of 1975, as revised in 2008. Participants acknowledged their consent to discuss the topic before participating in group discussions.

Results

In total, 26 questionnaires were submitted at the end of the workshop. All respondents indicated that they welcomed the development of the e-pathway for bipolar disorder. Through analysis of the questionnaires and focus group, we developed an analytic framework that comprised five key concepts: quality and delivery of care, patient–clinician collaboration, flexibility and adaptability, impact on staff and impact on healthcare services.

Quality and delivery of care

Participants were asked how they felt the quality of care, and care delivery, would be affected as a result of implementation of e-pathways. Overall, healthcare professionals and patients felt that the implementation of an e-pathway for bipolar disorder would improve care. A key theme was that the consistency of care would improve, and that there would be a sense of equality of care. Another benefit for the implementation of e-pathways was that it was felt that clinicians would be more likely to deliver care concordant with NICE guidelines, which would be associated with improved outcomes for patients. “I’d hope it will create a more consistent baseline to good practice in offering evidence-based interventions whilst understanding the subtleties of why sometimes we alter our treatments’ (questionnaire, no role given).”

Furthermore, a theme arose from the discussion that having standardised care and the ability to record treatment progress would allow clinicians who regularly deviate from NICE guidelines, without sufficient justification, to be ‘flagged’. This could assist with highlighting areas where care is consistently substandard.

A further concept that arose was that e-pathways would be expected to facilitate the development of evidence-based and value-based treatment strategies. One healthcare professional indicated: “I think it has enormous potential in improving the quality of care of service users and helping staff in deciding/delivering evidence-based practice’ (questionnaire, consultant clinical psychologist).”

Furthermore, another respondent felt that the e-pathway would help to: “[i]mprove the consistency of approach – aligned to the evidence base of what works [and] support recording of decision making about treatment and variance from NICE recommendations’ (questionnaire, psychologist).”

Overall, following analysis, the idea that the quality and delivery of care would improve was widespread; however, care must be taken to ensure equality of availability of interventions.

Patient–clinician collaboration

The collaborative relationship between clinician and patient as a result of e-pathways, including a more holistic approach to care, increased co-production, and increased patient engagement also emerged from the data. A presumed benefit of e-pathways would be the ability to include the patient in the decision process of treatment, as both clinician and patient could view the algorithm within e-pathways, and discuss options relating to each stage or intervention. Most questionnaire respondents raised the idea of increased collaboration as a result of e-pathways, with many also indicating they believed it would be a more holistic model of care. “It should improve quality outcomes and service user experience by ensuring informed decisions about elements of care packages, ensuring consideration to be given to a holistic bio-psycho-social approach [...] better engagement with interventions and service due to collaborative transparent approach’ (questionnaire, no role given).”

However, a potential barrier arose in the physical appearance of the algorithm: “Showing [a] patient the visual form would be overwhelming. I feel overwhelmed looking at the flow chart. It could be easier to follow or more friendly looking or I would not show it to a patient’ (focus group, psychologist).”

Therefore, consideration must be given to the appearance of the decision-tree, or how it could be better presented to patients to prevent this being a barrier.

The final element of collaboration related to family members or carers, with one healthcare professional indicating e-pathways would be: “[An] extra resource to utilise when working with clients and their families’ (questionnaire, no role given).”

e-Pathways were perceived as providing an effective way to maintain collaboration between the patient and those involved in their care, including carers, family members and clinicians.

Flexibility and adaptability

Flexibility and adaptability refer to how e-pathways for bipolar disorder could change to provide optimal care. In relation to concerns regarding implementation of e-pathways, one respondent indicated: “‘Possibility of being a little rigid but [a] clinician can utilise [their] own clinical decision making to justify care and treatment going forward in care plans, progress notes, etc.’ (questionnaire, community psychiatric nurse).”

Participants emphasised the importance of ensuring that clinicians were aware of the scope to use their own clinical judgement to deviate from the treatment algorithm, with justification and to adapt treatment to suit specific groups and to be flexible to accommodate management of other co-morbidities. One concern that arose from several healthcare professionals related to individuals with co-morbidities and adapting e-pathways to suit other groups, such as adolescents or the elderly: “‘Need to ensure co-morbidities are understood and that people don’t forget about problems that don’t fit under this diagnosis’ (questionnaire, no role given).”

Healthcare professionals suggested that broadening the e-pathway process to support both pre-engagement and recovery would be important in improving care for patients with bipolar disorder. For example, pre-engagement could include enabling the patient to be able to access resources relating to the algorithms and/or interventions before commencing treatment. “‘If public-facing it could introduce the patient early for [their] own research or mood diaries’ (focus group, consultant).”

Similarly, healthcare professionals believed it would be beneficial if e-pathways could be adapted to support both post-engagement recovery.

Impact on staff

Respondents reported that they felt that the implementation of e-pathways would have an impact on staff such as clinicians and mental health nurses, and that clinicians would benefit from the more structured guidance and clearer expectations, which may increase clinician confidence. “‘I think a downstream advantage may be that clinicians come to supervision with clearer expectations and questions e.g. ‘We got stuck doing X, how can I approach this with the client?’, which would drive the quality of care’ (questionnaire, psychologist).” “[The] principle of an e-pathway which will guide clinicians is excellent, having information and interventions/guides will enhance confidence’ (questionnaire, consultant clinical psychologist).”

However, sufficient guidance was felt to be needed to ensure that individuals were aware of their job role expectation with regard to delivery of e-pathways: “‘There must be greater clarity re job role expectations – who is expected to deliver what and how this fits within [the] broader job role’ (questionnaire, psychologist).”

One benefit that was identified was the idea of an aspirational pathway, that e-pathways provided the standard of care that should be aspired to, which could give staff a clearer sense of purpose and boost morale. However, this could present a possible barrier: some clinicians stated that they may feel frustration if they are unable to deliver the recommended standard of care such as through a lack of resources. One respondent indicated that this could be ‘demoralising’ (focus group, practitioner adolescent services). Another indicated: “‘[The] clinician may become overwhelmed if there are no staff resources to develop care or do not have training to implement certain groups or one to one session’ (questionnaire, no role given).”

This sense of an impact on staff was mirrored by a potential impact on patients: disappointment if a recommended intervention was not available in all areas. This was thought likely to be especially difficult for individuals in rural areas, or those with limited mobility that are unable to travel: “‘[The] risk of it being a “postcode lottery” – shows what should be offered but if not available in that service [due to lack of funding in a particular location]; it would be frustrating for the service user’ (questionnaire, no role given).”

A further cost stemmed from concerns regarding increased pressure and demands on staff: “‘Support to engage with the pathway, staff feeling overwhelmed and overloaded and pressured to discharge’ (questionnaire, consultant clinical psychologist).” Although some indicated they felt implementation of e-pathways could be time-saving and reduce their workload, others indicated the pressures staff already faced could present an issue in terms of uptake. A further factor

that could affect staff is the idea of ‘process-driven care’. Several healthcare professionals voiced concerns that e-pathways would become a ‘tick-box exercise’ (questionnaire, perinatal mental health team). “‘We need to ensure we are using it with purpose, not because we have to’ (questionnaire, no role given).”

One issue was that the implementation of e-pathways would become a method of monitoring staff performance as opposed to a tool to provide guidance and resources. One respondent on the questionnaire indicated that, despite the stated purpose of e-pathways to provide support for and not to assess clinicians, they were concerned that it may ‘become part of a performance framework’ (questionnaire, no role given).

Also, a key issue to implementation was the concern that it ‘takes the art out of nursing’ (questionnaire, no role given) or ‘[I] worry that it might unwittingly invalidate care working skills’ (questionnaire, psychologist); namely, that it may lead to a loss of instinct and clinical judgement.

Impact on healthcare services

This concept relates to how implementation of e-pathways would affect healthcare services, with concerns relating to cost, training and resources. “‘My underlying concern is how it would be implemented, resources, staff, training [...] and being put into practice’ (focus group, practitioner adolescent services).” One key benefit raised was that implementation of a system such as e-pathways would facilitate the auditing process: “‘Agree it may help to highlight gaps in resources and help us think about how to tackle this’ (questionnaire, no role given).”

For example, if the treatment algorithm regularly recommends an intervention that is not available in one locality, it is easier to identify where care or resources are falling short.

A barrier with a potential to affect the implementation of e-pathways was training, with many healthcare professionals indicating the necessity of sufficient training to ensure correct implementation and use of e-pathways: “‘Need to establish [the] training needs of staff of different professions and peer support workers and experts by experience. Some of this will be awareness and care skills, some related to specific interventions’ (questionnaire, no role given).”

A specific concern related to training around interventions, as many believed there were currently insufficient practitioners trained in the interventions that would be recommended within the treatment algorithm. This relates to similar concerns regarding availability of resources. A further concern related to insufficient supervision being in place to support training and implementation.

Discussion

Overall, healthcare professionals and patients welcomed the development of the e-pathway for bipolar disorder, and helped to define several benefits supporting the implementation of e-pathways, including improvements in the quality and consistency of care, increase in good practice and NICE-concordant care, clearer guidelines resulting in increased satisfaction for clinicians, a more collaborative approach to care and ability to monitor care and resources. If e-pathways are to be successful, the benefits identified by patients must remain central to development and implementation. However, it is arguably of at least equal importance to establish the barriers that could hinder implementation in order for necessary solutions to be developed. Costs and possible recommendations are discussed below.

In keeping with previous research,³³ healthcare professionals feared loss or invalidation of care skills, clinical instinct and confidence in unsupported clinical decision-making by trainees. The potential liability consequent on deviations from the algorithm was also a concern. This highlights the importance for the pathway team of adequately communicating that the standard of care recommended in e-pathways is aspirational, and that healthcare professionals should feel able to use clinical judgement and deviate from the algorithm. This further emphasises the importance of collaborative algorithm development.

The algorithm was seen as ‘overwhelming’ for healthcare practitioners and patients because of its apparent complexity. A further concern was that irrelevant aspects of the treatment algorithm would still be visible for some patients, such as the inclusion of medications that could be contraindicated. One individual suggested that a more user-friendly version, such as a simplified paper handout, could be developed. A further suggestion was that a ‘step’ within the algorithm could change colour to indicate when it is completed, to make the visual aspect of the flow, charts more

intuitive and easier to follow from a patient perspective. These recommendations need to be considered in the e-pathway design and a combined approach may be needed in which the healthcare practitioner and patient are able to see the whole algorithm to give a sense of the treatment journey and future options with a more focused view of the immediately relevant treatment decisions. Healthcare practitioners felt that effective training and resources would be central to successful implementation for e-pathways. This replicated experience elsewhere,³⁴ and is a timely reminder that sufficient resources need to be allocated to training

It was notable that although the bipolar e-pathway team saw the identification of gaps between best practice and actual practice as an important function of the e-pathway – a way of identifying gaps in training and provision, and of informing service development – these gaps appeared to raise anxieties in the workshop attendees. This will need careful consideration during the process of e-pathway development.

This project had several limitations. First, as this was a valuable opportunity to have access to a task-specific group of healthcare professionals and people with bipolar disorder, the research had to be as pragmatic as possible. As such, only one researcher undertook data collection and because of logistical constraints, and data from only the most relevant focus group were transcribed. Further detail, which may have helped to answer the research questions, may have therefore been missed. Because of the lack of transcription, it may have been beneficial to validate the derived transcript and arising themes with participants; however, this was not possible within the current study. Additionally, one researcher carried out the qualitative analysis, which may have made it more susceptible to subjectivity. The researcher also developed the analytical framework, and this was discussed and refined with other members of the team.³⁵ A further limitation is that few people with bipolar disorder responded to the invitation to the workshop, and therefore feedback was primarily from healthcare professionals. Although clinicians will use e-pathways in day-to-day practice, implementation will affect patients through the care and interventions they receive. As such, it is vital to gain an understanding of the views of patients in the development and implementation process. Therefore, this process would have benefitted from further contributions from people with bipolar disorder. One patient in attendance agreed that they would take the concept of e-pathways to their bipolar support group, with feedback shared in a less formal setting, and their input will help to shape the development of the pathway.

This research assessed attitudes toward a treatment pathway that is yet to be implemented. Although it is essential to ascertain stakeholders' views throughout development, it is also important to assess the system once in practice. Future research should examine the use of e-pathways once implemented. This could either be a quantitative assessment of the magnitude of change in care, using outcome measures as described in studies above, such as ratings on self-report measures and rates of hospital admission. If the e-pathway functions correctly, it would be predicted that patients with bipolar disorder will have lower rates of readmission and relapse. A qualitative methodology, as used here, could examine healthcare professionals and patients' views (e.g. at the onset of implementation and 1 year later), to determine whether the perceived benefits of e-pathways are realised in practice, and if the costs identified in the current research are sufficiently overcome.

In conclusion, the provision of e-pathway-supported, algorithm-informed care has huge potential to inform service development, identify training needs, enhance collaborative clinical decision-making, streamline processes and improve quality of care. There are considerable hurdles to overcome before the development and subsequent delivery can occur, but an optimised e-pathway has the potential to improve outcomes and equity for patients with bipolar disorder.

Data availability

Data available on request due to privacy/ethical restrictions.

A.L.E. collected, collated and analysed the data, and wrote the first draft of the manuscript and co-ordinated input from other authors. J.L. supervised the qualitative analysis and data collection. S.W. provided overview of the project. G.D. led on the e-pathway development work and E.C.-T. led on its application to service development. All authors contributed to study design and write-up, and agreed the final version of the manuscript.

This project was funded using existing NHS Trust and University salaries, with no additional costs.

Declaration of interest

None.

date

2021-02

Abstract

We must remain open to revising and expanding the important but incompletely understood philosophical categories of agency and responsibility in light of what can be learned from atypical states and behaviour. A reflection on images – here, Goya’s great Madhouse scene, and photographs of Mad Pride events since the 1980s – is shown to provide assistance towards this end.

“‘vast regions of agentic self-awareness lie unmapped, and much work remains to be done before we have a clear idea of exactly what it is like to be an agent’ (Bayne: pp. 182).¹”

Agency, and its relationship to responsibility, are issues over which philosophers have yet to find entire agreement. The above passage by Timothy Bayne was written some time ago and preceded his own valuable clarifications. Yet the subjective experience (or phenomenology) of the personal action that philosophers call agency (the term is explained

more fully below) remains, as Bayne says, unmapped, as do related value-based (or normative) questions about responsibility. Nowhere is this more evident than at the juncture of agency, responsibility and mental disorder. And it is in the spirit of sketching some corners of Bayne's map that I offer a few remarks about agency and disorder, shortened here, at risk of oversimplifying, to 'mad agency'.

What follows is intended to complement recent research in which psychiatrist-philosopher Mohammed Rashed examines the philosophical concepts grounding mental health activism. The first analysis of its kind, his is a respectful but stringent account of the recognition sought by activists, locating their demands within contemporary political philosophy, and providing guidance as to how those demands might be met.² In the present essay, I suggest that some of the ambiguity and complexity entailed in the categories of madness, agency and responsibility can be approached and perhaps illuminated through a reflection on images. I use a familiar painting by Goya, on the one hand, and on the other, photographs of Mad Pride marches and public events since the 1980s. The message from what follows is simple. Even applied to normal states and behaviour, conceptions of agency and responsibility may be incompletely understood. We must remain open to revising and expanding them in light of what can be learned from atypical states and behaviour. And for this purpose, images seem able to offer powerful assistance.

Both agency, and responsibility in relation to it, are contested topics. But few would dispute that personal responsibility can be appropriately assigned only when there is some degree, or form, of (personal) agency. The converse may not hold; arguably, there can be agency in the absence of full responsibility. Philosophical accounts of agency and responsibility differ, but as is indicated by legal exculpating factors such as ignorance, compulsion and duress, ascriptions of responsibility will sometimes be withheld, even from what appear to be voluntary actions. In keeping with much discussion about agency and responsibility, the two terms are sometimes merged; in other places, as will become apparent, they need to be separated.

Some basic distinctions

A group of contrasts drawn from philosophical discussions of agency are introduced here: actions and movements; the proprietary phenomenal character of agency (how it feels subjectively) in contrast to interpretations about, or judgements over it; self- and other-assigned agency; mental and overt agency; agency emanating from more and less proximal and distal intentions; and more and less deliberative and absorbed agency.

Actions and movements

The 'sense' of agency, as we seem to experience it, is sometimes used by philosophers to mark the contrast between true actions (those we voluntarily undertake ourselves) and mere movements. This is the difference between lying down and unintentionally falling, for example.

Phenomenal character of agency

When agency is involved (in lying down), two distinct parts have been recognised: the phenomenological feeling of doing it oneself (known as its proprietary phenomenal character) and the interpretation or judgement we make about that feeling (the awareness that, rather than either falling, or having been pushed to the ground, one *lies down*). Both phenomenal feelings of agency, and the interpretation or judgement we – and others – make about our agency, enter into the following discussion.

Self- and other-assigned agency

Complicating questions about self-assigned agency and responsibility arise when we speak of agency and responsibility, whether as felt agency or as judgements about one's agency, and these are ostensibly magnified when mental health is part of the mix. Self-assigned agency and responsibility, whether as feelings or judgements, will not be entirely reliable guides if they are distorted by disorder. Examples of that distortion are the self-blaming depressive, who exaggerates their personal responsibility ('It's all my fault'), or the grandiosity of the narcissistic personality's boast ('All thanks to me') illustrate. Similarly, the proprietary phenomenal character of agency appears to be absent in some psychotic experience, as suggested by what are known as 'inserted thoughts'.

When agency (and responsibility) is judged to be present, by others or by oneself, may thus depend on the opinion of psychiatric experts. And asked whether those with psychiatric diagnoses possess agency, the expert's answer will usually be, it depends – on the situation, the nature of their disorder, the particularities of the thoughts and actions in question, and so on – and thus on case-by-case clinical observation and judgement.

Mental and overt agency

Discrepancies between felt agency (and responsibility) and agency (and responsibility) with normative force imply that some judgements about agency (and responsibility) may be inaccurate, or unreliable. (Philosophers speak of ascriptions of agency and responsibility as possessing normative force when they are *accurate* (as the moral realist might put it) or *appropriate*). Yet such inaccuracy or unreliability will arise from multiple factors. Mistaken or distorted self-assigned agency and responsibility are also associated with varying cognitive styles and socialised habits in normal populations; for example, the widespread tendency to deflect blame onto others, or take sole credit for achievements more accurately attributed to many. They will then be culturally local: other times, places and cultures might rely on different substantive norms. Not only disorder, and non-disordered personality bias, but also any number of social and cultural expectations can thus shape judgements of agency and responsibility, self- and other-assigned. And given that disorder, personality and culture are inextricably entwined in any given instance, these distorting factors may not be separated easily or, in many instances, helpfully.

With regard to judgements about agency, whether made by oneself or another, it will be worth noting that there are mental as well as more outward bodily, actions. When Thomas Jefferson spoke of the 'illimitable freedom of the human mind', he referred to our immediate ability to recall the past, envision the future, rehearse what might have been as well as what was – indeed our ability to direct our thoughts at all, to form intentions, revise and renounce earlier attitudes, to call up memories and imaginings. This kind of agency, associated with the notion of rational capacity, has sometimes been denied those with mental disorder, even while it was said to be possessed by prisoners in chains, and those trapped in ill and unresponsive bodies.

Ascriptions of responsibility also sometimes extend to these inner efforts of mental agency. For some mental actions, we hold ourselves responsible and are also held responsible by others ('This is an uncharitable thought, but ...' it might be said, or 'You mustn't think like that ...'). That said, whether such responsibility is ever rightly ascribed to one's own mental 'actions' is a contested matter, as is the applicability of the term 'agency' to them. (I am grateful to David Foreman for pointing out that ethical systems differ over this point. Only some Christian theology acknowledges the sinfulness of 'immoral thoughts,' for example.) And the exactness of the parallels between mental agency and the overt agency we exhibit to the world are similarly debated. The structure of mental action has been seen by some to differ in not involving intentions, or initiated by decisions, or reasons, for example, whereas others insist that mental agency is the originating source of all agency, outer as much as mental.^{3,4}

The details of these additional differences need not detain us here, as long as it is acknowledged that some of what we humans do involves our inner as well as our outer lives, and that the coherence of mental agency must be understood within the whole, including personal-level intentions and more overarching goals, that may not manifest in any way that is outwardly evident. Examples of such expansive goals over mental health might include the aim to maintain psychic stability and avoid or reduce personal suffering.

Proximal and distal agency

Another feature of agency, occurring with both mental and overt agency, are the less and more direct and immediate forms it takes, for each of which we are also, sometimes, held responsible, both by others and perhaps ourselves. Examples of less direct and immediate agency include Elster's 'imperfect rationality', when we outwit ourselves, anticipating and engineering outcomes we are unable to produce directly and immediately.⁵ Often, we do so aware (or not unaware) of the process as we manipulate our beliefs and feelings to achieve desired ends. The way cognitive-behavioural therapy is widely supposed to work employs this approach, both for mental agency, where the power a person has to change beliefs and attitudes is used to bring about changed feelings, as well as directing what is said and done. The effectiveness of such imperfect rationality cannot be guaranteed, of course. Cognitive-behavioural therapy has now quite self-consciously adopted its classical ancestor in the imperfect rationality practises of those who recommended care of the soul that aimed to expunge all negative and unproductive feelings (debatably, all feelings of any kind), through a programme of self-analysis and cognitive therapy. We are free to, can and should adjust the beliefs on which our feelings rest, it is supposed. (Even in their own time, and almost ever since, owing to the influence of Aristotelianism, the excessive responsibility for controlling thoughts and feelings accepted by the Stoics were derided as unrealistic and undesirable.) Outcomes of agency that are more and less immediate and direct have been described as emanating from intentions that are 'proximal' and 'distal', respectively, with imperfect rationality exhibiting the latter.^{6,7}

Deliberative and absorbed agency

As examples of more planful and less immediate (or proximal) agency illustrate, particular instances of agency, whether mental or overt, fall within complexes of goals, deliberations, purposes and plans – even very long-term aims and dreams. This nesting of agency within its broader setting has also been recognised to involve a consequence in terms of phenomenology: although recognisable feelings may be associated with agency, not all agency is immediately felt. Agency often occurs as part of a seemingly effortless, automatic and non-conscious flow of engagement with the world. In that case, it leaves little space for, and bears little resemblance to, conscious deliberation, or the felt sense of actively doing, rather than passively experiencing. Typically, indeed, felt agency is 'recessive', in being confined to the margins of attention.¹ Much of everyday life, and more than philosophers always acknowledge, involves this kind of agency, as the case of habitual action illustrates. With skills like driving, we usually proceed with little or no conscious awareness of our complex responses. When we engage in practical or creative endeavours with full, undistracted absorption, we have been described as undertaking 'skilled coping',⁸ and awareness in the latter experience is said to be immersed rather than detached.⁹

Images: 'dark freedom' in Goya's 'The Madhouse' and Mad Pride parades

The above contrasts have been drawn from within disparate theories, and only fuller accounts of each can determine their compatibility, and the final plausibility of the theses put forward here. Nonetheless, felt agency and 'freedom'; self- and other-assigned agency (and responsibility); the effects on agency and responsibility wrought by personality style and cultural norms as well as by disorder; mental agency and agency in the outside, shared world; and more and less direct, and more and less 'online' or conscious, and deliberative, forms of agency. all seem likely part of a rough sketch of the territory, although each element still wants for a fuller analysis.

In what follows, I try to elucidate some of the features of mad agency (and responsibility) with the help of images: a much-interpreted painting, showing the inside of a madhouse at the beginning of the 19th century; and photographs of Mad Pride parades. Why turn to images? Arguably, imagery can communicate qualities of agency that are hard to capture in language alone. And pictorial commentary, as we will see, offers suggestive associations worth exploring. Moreover, in addition to written descriptions, and long before the present-day use of images, pictorial traditions shaped how mental health and ill health, disorder and madness were apprehended and understood.¹⁰ This ancient, long-lived, visual record may have something more to teach us.

'The Madhouse', Goya's magnificent depiction of the madhouse in his hometown of Zaragoza, was painted between 1812 and 1813. Unlike the more positive images from the Reform era that followed, Goya's several pictures of that institution have been judged to depict unutterable suffering and awfulness, even depravity. In a typical description, the

painting's only light source is said to be: "a barred window high up on the wall, clearly meant to repress the figures below. These figures are distinct characters, all engaged in grotesque and pitiable behaviour - one wears what seems to be a wild-feathered headdress, another is fighting in a tricorne hat, another makes a gesture of blessing to the viewer, whilst many of the others are naked . . . this painting could be meant as a denunciation of then-current practice in that area . . . Some of the figures can also be interpreted allegorically, as a gallery of parodies of powerful figures in society, such as the clergy or the army (the man in the tricorne)." (Gilman: pp. 129–30).¹⁰

With its striking use of darkness and light, the picture shows 'a world of darkness opposed to the world of light', in keeping with Goya's 'emphasis on the soul as the dark hiding place of terror', for example.¹⁰

Echoing this negative interpretation, the actions of the inmates have been described by Robert Hughes as 'delusory gestures of power'.¹¹ However free, responsible and agentic these transgressive gestures appear to be, this 'power' (to use Hughes' word) will not guarantee that full, or perhaps any, responsibility could be appropriately ascribed, by the inmates themselves or by observers. There are bars on the window. The inmates' agency in the outer world is limited. Yet delusory or not, each seems to reflect a kind of inner, mental agency (power, or freedom). In trying to fathom those 'delusory' gestures, it is worth noting that Goya's fascination with, and many works depicting, madness, have been singled out for their humane and sympathetic attitudes. Goya located madness among the common presences of human life, it has been explained. He saw it a natural part of the human condition, reflecting his creed that nothing human was alien to him. (Hughes attributes to Goya a well-known medieval saying, attributed to Terence, to this effect.) And few subsequent depictions of madness behind bars are as sympathetic, at least until we reach 20th century pictures such as Bellows' 'Dance in a Madhouse' (1917) and other images showing asylum entertainments.

Arguably, then, Goya's attitude toward his subject matter was expressive of sympathy, not revulsion. Conforming to that positive conception is a revealing passage from another 20th century commentator. Presenting mad agency as a certain, transgressive 'dark liberty', Michel Foucault observes of the madman in the hat in Goya's painting: "[the figure] leaps out, by virtue of the silent language of his well-muscled form and the wild, marvelous freedom of his youth, a free human presence who affirms his birthright as though this were the beginning of new era. "The Madhouse" speaks . . . [of] those new bodies, brought into the light in all their vigour, and whose gestures, if they call up their dreams, sing above all of their dark liberty." (Foucault: pp. 530–1).¹²

What dark liberty is this? Where does the mad agency lauded by interpretations like Foucault's fit among the forms of agency sketched earlier? I propose that the 'freedom' expressed in the painting anticipates something that we only entirely recognise now as a consequence of political events: it is a demonstration of the powerfully 'freeing' and healing transgressiveness and ludic exhilaration celebrated in today's Mad Pride activism, rhetoric and writing.

We are tempted to agree with Hughes that the gesture of power is merely delusory – a mistaken parody of real agency – or even a feeling of agency distorted by disorder-wrought cognitive error. Yet, in light of writing by mad activists, we also perhaps begin to see a quality inviting attitudes of hope and delight, rather than abject despair, in the gestures of Goya's inmates. To cite just one example of such writing: "Madness is the new rock "n" roll! . . . All of us who've experienced "deep sea fishing" will know the sensation of heightened awareness, of consciousness enhanced . . . of feelings of wonder and terror that can't be verbalized . . ." (Morris: pp. 207).¹³

Generally, what we see in images is limited by what we expect to see, and what we suppose the artist wanted us to see. We might guess that the inmates in the asylum were performing for an audience, perhaps even engaging in such display for monetary reward, as did the inmates at English asylums during the same era.^{10,14} (I am grateful to David Foreman for drawing my attention to this possibility.) Were this so, the actions depicted by Goya are replete with the features of classic rational agency, and a pretence. But whether or not it is a pretence, later events and subsequent understanding allow us to go beyond the constraints imposed by what we would expect, and what, intentionally or not, Goya may have conveyed. From today's perspective and understanding, we can see it differently. To illustrate this interpretive shift, we might turn to Bellows' 'Dance in a Madhouse', where movements have been dismissed as 'wild and uncontrollable', and reflecting passive ('melancholic') postures.¹⁰ Yet here, too, and contrary to Gilman, the central female figure in Bellows' picture also reveals something joyous, triumphant, freeing, enlivening and, perhaps, empowering.

Goya's madhouse has parallels and echoes in today's Mad Pride activism, some of them quite evidently self-conscious. Here we find not only resistance to the mental health system, and solidarity, but repeated emphasis on 'the celebration of difference'. 'Celebration' is a useful encapsulation, suggesting exhilaration and joy. Its object is more than mere difference, however. What is being celebrated? Minimally, the 'creativity of mad people, pride in a unique way of

looking at life, the validity of such a distinct way of life ...' (Sen: pp. 5)¹⁵ are grounds for pride and reason for celebration. Enumerating elements of the demand for recognition of mad identity, Rashed emphasises that Mad Pride discourse includes a range of attitudes and interpretations. It emphasises mad identity, creativity, spirituality, suffering and the gifts that, although valuable, are dangerous.^{2,16} Each of those aspects (identity, creativity, spirituality, suffering and dangerous gifts) offers grounds to applaud and celebrate.

Images of broadly 'celebratory' Mad Pride parades (in Canada, the USA, the UK, Ireland, Belgium, France and Australia, for example), provide us with readily recognisable descendants of our madhouse scene. Here are flamboyant and excessive dress, gesture and performance; here are the seeming freedoms and agency associated with the transgressive, the parodic and ludic. Unlike the barred madhouse, the street now forms the stage for performance. The demands for political recognition, I suggest, provide examples of agentic forms identified earlier, and perhaps anticipated by Goya.

By recognising that agency works in many ways, indirect as well as direct, and through imperfect as well as perfect rationality, we may regard the mad gestures in Goya's painting as not only exhilarating, and felt, although ultimately delusional agency and freedom, but also as healing, consoling, emboldening, strengthening and even, yes, freeing. Like the antics of the marchers celebrating Mad Pride, these gestures may convey the shoring up of what is depleted, diminished and misunderstood by the surrounding culture, or concealed through prejudicial expectations.

Viewed as a kind of self-help or self-care, the gestures depicted in both Goya's and the later celebratory, Mad Pride images, can also be likened to the indirect agency of imperfect rationality. Arts-based healing rituals, healing effects and the mental health benefits of expressive therapies have been acknowledged since ancient times, and are well documented.¹⁷⁻¹⁹ Their proponents speak of the way such activities integrate mind and body in a unified, healing whole; the 'act of responding to what is given, imagining its possibilities and reshaping it in accordance with what is emerging', is described as akin to that found in all imaginative play, and improvisation (Levine: pp. 71).¹⁶

The agent may not seek anything further through their exuberant gesture, or even be alert to broader intentional or purposive context within which it occurs. Their agency may reflect the obliviousness of intense absorption. Moreover, it may not be agency with outer effects. In contrast to the powerless inhabitants of the madhouse, today's activists bring about real world, consequential political outcomes (changed cultural attitudes, for example, and more enlightened mental health policies). Yet even without doing so, the gestures of Goya's figures may be seen to intimate certain forms of distal, immersed agency, as Foucault's analysis may be taken to suggest.

Reviewing the discourse and tenets of Mad Pride activism, Rashed notes four main elements, as we saw: demands around identity and culture, creativity and spirituality, distress and disability, and finally, madness as a 'dangerous gift'.² Among the demands identified by Rashed and these activists, I have tried to suggest that none quite convey the healing and freeing power captured in the ludic, the parodic and the transgressive that are so evident in today's Mad Pride parades and celebrations and, in light of them, we are now able to recognise as foreseen in the dark liberty of Goya's madhouse.

About the dangerous gifts of madness, it has been explained that '... we are members of a group that has been misunderstood and persecuted throughout history but has also been responsible for some of its most brilliant creations' (Du Bru: pp. 259).²⁰ Any incautious ability to violate convention and social norms will be dangerous, including such gifts, it must be conceded, and will likely bring its own exhilarating phenomenology, as well as fateful and often self-defeating consequences. The demands of mad activism can be met, perhaps, only with the openness, imagination and negotiated agreement of the larger culture.

Such negotiated agreement requires a preparedness to revise and expand accepted ideas about social norms and concepts of mental health, as I have pointed out elsewhere.²¹ Among those social norms and concepts of mental health, it has been proposed here, are ideas about agency.

I am grateful for audience questions at the Royal College of Psychiatrists' Philosophy of Psychiatry Special Interest Group Biennial Conference in September 2019, 'Madness and Society: Pathways to Reconciliation'. My greatest thanks go to Dr David Foreman for his careful reading and insightful suggestions on an earlier draft of this paper.

date

2021-02

Abstract

Aims and Method

Twelve intellectual disability psychiatry trainee representatives and 13 training programme directors were surveyed to assess the current state of training, to establish what motivated specialty trainees to choose intellectual disability psychiatry, and to explore issues that might affect retention.

Results

The combined survey response rate was 83%. All trainees had chosen intellectual disability psychiatry after experience in either their personal or working life. Overall, specialty trainees were satisfied with their training; the majority felt supported to meet training requirements. Trainee isolation was the main concern for current trainees.

Clinical implications

Recruitment for specialty training in intellectual disability psychiatry is acknowledged to be a concern for workforce planning and could affect access to and quality of psychiatric care for people with intellectual disability. The results of this survey could be used as a guide to improve efforts to attract trainees. Acknowledging and reducing trainee isolation could improve trainee morale.

People with intellectual disability have higher rates of mental health problems than the general population, estimated at between 30 and 50%.^{1,2} The complex interplay of predisposing biological, psychological and social risk factors for an individual with intellectual disability will have a significant effect on their presentation, which may not fit the ‘classic’ models of psychiatric presentations. Associated physical health problems such as epilepsy and sensory and communication problems can further complicate the presentation of psychiatric disorders. Social and environmental factors have a major role. Mental capacity, choice and control are also important issues to consider. These factors can make working in the specialty of psychiatry of intellectual disability challenging yet highly interesting and rewarding. Owing to clinical complexity, psychiatrists rarely work alone; there is a strong emphasis on multidisciplinary working and regular co-working with social care. However, psychiatrists may work as the sole doctor within a multidisciplinary team. These teams may be geographically distinct, at some distance from each other and based away from mainstream psychiatry colleagues.³ This can pose particular challenges for trainees in intellectual disability psychiatry, and there is evidence to suggest that trainees can feel isolated.⁴

Speciality training in psychiatry of intellectual disability in the UK comprises 3 years of training after attaining membership of the Royal College of Psychiatrists. This is in order to attain the Certificate of Completion of Training in Psychiatry of Learning Disability awarded by the General Medical Council (GMC). Trainees apply for a training post in a specific geographical area of the UK and usually rotate between a range of community and in-patient posts.

Recruitment in psychiatry in the UK has long been acknowledged as a concern in terms of workforce planning, with a lack of trainees recruited to fill gaps left by those retiring.⁵ Recruitment at the level of core training continues to be less than required – in 2012, 78% of year 1 posts were filled⁶ – and has remained static, with 78% of posts being filled in 2018.⁷ The ‘Choose Psychiatry’ campaign by the Royal College of Psychiatrists has aimed to improve recruitment to the specialty and successfully bolstered numbers of doctors entering core training by 30% between 2017 and 2018; however, the overall picture is that entry rates into the specialty remain similar to those of 2012.⁸

Once trainees have completed core training, they apply for specialty training posts. The fill rates for specialty training posts in psychiatry of intellectual disability do not compare favourably with those of other similarly sized subspecialties. Whereas fill rates have fluctuated for the other psychiatric subspecialties, recruitment has been especially poor in psychiatry of intellectual disability, where there have never been more than 30% of vacancies filled in each recruitment round since 2017.⁹ This is in spite of it scoring higher than general adult psychiatry (GAP), old age psychiatry, or

child and adolescent psychiatry for overall trainee satisfaction in the 2019 GMC National Training Survey.¹⁰ Clearly, recruitment to the specialty is a challenge. It is predicted that there could be a shortfall in consultants in the specialty by 2033 of between four and 26 full-time-equivalent posts.¹¹ Such data suggests a significant effect on the psychiatric care this vulnerable population will receive.

In order to inform future efforts to improve recruitment, we undertook a survey to investigate the reasons current trainees chose psychiatry of intellectual disability. We also assessed the current status of intellectual disability training in the UK by surveying the opinions of individuals currently in training and their trainers.

Method

Setting

This survey was aimed at trainers and trainees currently working in psychiatry of intellectual disability in the UK. All training programme directors (TPDs) and the network of Regional Trainee Representatives for psychiatry of intellectual disability were approached in order to obtain a spread of opinion across the four nations.

Ethical considerations

An introduction to the survey gave potential respondents information regarding the aims and objectives of the survey. Implied consent was assumed by completion of the survey. The survey was created and agreed by the Specialty Advisory Committee of the Faculty of Psychiatry of Intellectual Disability.

Data protection

Participants were approached using the email address provided to the Faculty. Once the survey link had been used, no further identifiable personal information was required.

Survey design

A pilot survey of TPDs had been undertaken 1 year previously; the findings from this, along with information from the 2018 GMC Survey Specialty Specific Questions, were used to design the survey questions. The survey was created with SurveyMonkey and consisted of nominal and free-text questions. All questions requiring more than a 'yes' or 'no' response had free-text responses. Functionality and content validity were assessed by the authors, including both trainees and consultant psychiatrists.

The adaptive questionnaire design used two separate versions, depending upon whether the respondent identified as a trainee representative or as a TPD. Each version posed the same questions but from the perspective of either a trainee or a trainer. (The full survey is available in the supplementary material, available online at <http://doi.org/10.1192/bjb.2020.68>).

Survey distribution

The survey link was emailed to the regional trainee representatives and TPDs in the specialty for each of the regions. The survey remained open for 6 weeks during early 2019. There was no incentive offered to complete the survey. A reminder email with a link was sent 1 week prior to the closure of the survey period.

Response rate

There are 16 regions of the UK, with a total of 40 intellectual disability psychiatry specialty trainees, each represented locally by a trainee representative and a TPD. From the perspective of the trainee representatives, one region did not have an allocated representative, and one regional trainee representative was on long-term leave. Therefore, 12 of a possible 14 regional representatives responded, giving a trainee response rate of 86%. Of the TPDs, three individuals from the possible regions did not respond. The response rate for the trainers was 81%, giving a combined survey response of 83%. All returned surveys were fully completed with no missing answers.

Analysis

All nominal responses were collated using the SurveyMonkey software. Primarily quantitative data were produced. The free-text answers were analysed separately by the four authors, and responses from the participants were used to illustrate the qualitative findings of the study.

Results

Respondent demographics

Of the trainee respondents, one was an ST4 trainee, two were ST5 and nine were ST6. For one area of the UK, there was no response from either the trainee representative or the TPD.

Analysis of responses

Recruitment: the attraction of psychiatry of intellectual disability for a prospective trainee

Factors influencing choice of psychiatry of intellectual disability training

Trainees were asked about their core training experience. The majority of the trainees had completed a post in psychiatry of intellectual disability, or in both psychiatry of intellectual disability and child and adolescent mental health services (CAMHS). One trainee had completed neither. Trainees were asked to use free text to explain what factors had led them to choose higher training in psychiatry of intellectual disability. All 12 trainee representatives commented that their core training post had influenced their decision-making with respect to higher training options, from 'opening their eyes' to psychiatry of intellectual disability to 'cementing a decision'. Other factors influencing their choice included seeking a good work-life balance and working within a multidisciplinary team. Medical school experiences were viewed as important, with one trainee having been influenced by a lecture given in medical school.

Personal experience outside medical training also had a strong influence for some respondents, with one trainee having worked with people with intellectual disability in a social care setting as a medical student, and another having a close family member with intellectual disability.

Fifty-four per cent of TPDs reported that core trainees in their area were required to undertake a developmental psychiatry post (CAMHS or intellectual disability) as part of their training, whereas 31% reported that this was not mandatory within the local training programme. The remainder were unsure. Currently, although competencies in developmental

psychiatry are an important part of the core psychiatry curriculum and are best met through gaining experience in a developmental psychiatry post, this is not an essential training requirement.¹²

The role of dual training in improving recruitment

Dual training opportunities are now being considered as an option to improve the breadth of training, to meet the needs of a changing population and to improve recruitment. The only approved option currently available with psychiatry of intellectual disability is CAMHS, and very few training posts are advertised for this combination at present.

Trainees were asked whether they would have considered applying for dual training had it been available. Ten of the 12 trainees confirmed that they would have, with the majority opting for general adult psychiatry (GAP) or old age psychiatry. The reasons for choosing these subspecialties included the cross-over of cases, in particular, for individuals with mild or borderline intellectual disability in GAP, and those with dementia in old age psychiatry. More general reasons included a wider range of job opportunities for the future and an extension of training. From the perspective of trainers, 12 of the 13 TPDs responded that they would consider offering dual training posts. Most trainers also suggested considering dual training with forensic psychiatry. Other suggestions were GAP, old age psychiatry and CAMHS. Again, the reason cited for these choices was the overlap of the specialties. Dual training combining forensic psychiatry with intellectual disability was mentioned by one trainer as a need from the perspective of workforce planning in order to meet the requirements of the Transforming Care Programme.¹³

Retention: the current state of psychiatry of intellectual disability training in the UK

Special interest sessions

Special interest sessions are an opportunity for trainees to broaden their perspectives and portfolio, to gain further experience and to understand other specialties allied to psychiatry of intellectual disability. Trainees should be able to spend up to a day each week on a special interest session or research of their choice. All trainees responded that their special interest sessions met their training needs. *Figure 1* illustrates the breadth of options currently used by trainees. Fig. 1 Special interest sessions. ADHD, attention-deficit hyperactivity disorder; ASD, autism spectrum disorder; ID, intellectual disability; SOTP, sex offender treatment programme.

Trainers responded that a wide range of special interest opportunities were available in their area or in neighbouring areas. According to trainees, barriers to accessing the sessions included a lack of time, conflict with other clinical commitments and difficulties travelling outside one's own trust for specific services.

Psychotherapy training

Half of the trainees surveyed responded that adequate supervised psychotherapy learning opportunities were available to them. Of those able to access these opportunities, 100% responded that the modalities available met their training curriculum needs.

The barriers to adequate opportunities, according to trainees, included a lack of supervision, with team psychologists often having their own students to supervise. Trainees sought clarity on the requirements for psychotherapy training, with a lack of formally agreed methods of supervision being cited as a barrier to accessing adequate experience.

The TPD responses were similar, with 46% responding that there was limited or no availability of psychotherapy opportunities available. Free-text responses mentioned the need for clarification of exactly what was required in terms of training needs for the intellectual disability population, and that a broad interpretation of what a psychotherapy learning opportunity entailed was required in order to allow a trainee to gain adequate experience.

Research

As illustrated in *Fig. 2*, trainees were generally positive about accessing research opportunities in psychiatry of intellectual disability. Barriers cited by both trainees and trainers included a lack of protected time to undertake research and a clash with clinical commitments. Trainees found accessing research networks difficult, as well as knowing how to engage with an appropriate supervisor in the local area with specific intellectual disability research interests. It was acknowledged that it can be difficult to complete research projects during the 3 year training period. However, TPDs were very positive about research opportunities and all stated that they knew of research opportunities for trainees. *Fig. 2* Trainee responses: are you adequately supported to carry out research?

Clinical governance: audit and quality improvement

Responses indicated that audit networks have been established, and that 70% of trainees had a great deal or a lot of support to access these opportunities. Trainees reported that the consultant body tended to be experienced in this area and could offer support and project opportunities. Trainees also responded positively regarding access to quality improvement training, with 90% having lots of or moderate support. This appeared to be supported by pre-existing networks in place. However, with quality improvement being a relatively new entity, the lack of consultant experience in this area was cited as a barrier. This was reflected in the TPD responses, with two of the 13 (15%) respondents mentioning lack of experience and training of consultants in quality improvement as a barrier, along with a need for more clarity as regards training requirements in this area.

Out-of-hours experience

Psychiatry of intellectual disability trainees are required to gain experience of emergency psychiatry, part of which includes being on an on-call rota for out-of-hours work. The rotas can vary regionally. As shown in *Fig. 3*, most trainees participated in a GAP rota; the trainees undertaking this rota found it a positive experience owing the opportunity to gain to increased emergency psychiatry and Mental Health Act experience as a trainee. There were some opposing opinions, however, with some trainees stating that the GAP rota did not give them enough out-of-hours experience in psychiatry of intellectual disability. Overall, trainees were positive, and out-of-hours work was found to meet training needs. The responses of the TPDs reflected those of the trainees; overall, they felt that the experience met training requirements. *Fig. 3* Psychiatry of intellectual disability (ID) out-of-hours experience.

Less than full time (LTFT) training

Of the 12 trainees, three were LTFT trainees. All replied positively regarding whether the current psychiatry of intellectual disability training programme supported their training needs. TPD responses were generally positive, indicating a belief that LTFT trainees receive adequate support to meet their training needs. However, it was noted that it can be more difficult for these trainees to access conferences and courses. One TPD stated that the support offered to LTFT trainees was a strength of the training scheme.

Retention: trainee well-being and support

All trainees responded that they felt supported in the training programme. Regular contact with approachable TPDs was cited as important. Trainees mentioned regular academic programmes and meetings with other trainees and clinicians as important aspects of trainee support. Supervisors who were available and approachable maintained this support.

One area has introduced a scheme allowing trainees to give feedback to neutral senior colleagues about training needs, which is then fed directly to the local TPD and Specialist Training Committee; this was reported by the local TPD to have been received positively.

Trainers and trainees both acknowledged trainee isolation; 30% of TPDs and 36% of trainees stated that they had experienced or noted trainee isolation personally. Reasons given for this were that psychiatry of intellectual disability is a small training scheme spread over wide geographical areas; therefore, in some areas, there are limited opportunities to meet with other trainees regularly. Solutions currently in place include a continuing professional development forum and digital solutions such as intellectual disability trainee WhatsApp groups. A lack of appointments to certain geographical regions, or trainees leaving posts, has also added to isolation in some regions.

Discussion

The aim of this survey was to assess trainees' reasons for choosing psychiatry of intellectual disability and to find out more about the current state of intellectual disability training in the UK. The survey had a good overall response rate, with 86% of regional trainee representatives and 81% TPDs responding.

In terms of choice of specialty, it was apparent that previous experience within the specialty was critical to the choice of the majority of trainees. In the main, this was core training experience, but trainees highlighted other experiences such as medical school lectures as having an effect. The influence of experience in working with individuals with intellectual disability on choice of future work has been demonstrated widely, including in other health services, for instance, in Australia.¹⁴ It is concerning, therefore, to find that at least one-third of areas do not currently require core trainees to undertake a clinical placement in developmental psychiatry. At present, a review of the curricula is being undertaken by the Royal College of Psychiatrists; therefore, there is potential for this to change in the future.

Recruitment strategies need to include lobbying for more core psychiatry trainees to have opportunities to rotate through psychiatry of intellectual disability. Forging links with medical schools and offering regular experiential and teaching opportunities would also raise the profile of psychiatry of intellectual disability. Current intellectual disability trainees have presented at the National Student Psychiatry Conference in order to improve knowledge of the specialty and access to further experiences.

It was apparent that current trainees were very interested in the option of dual training with another specialty to broaden training opportunities and experiences. This finding is in keeping with the findings of a recent survey of dual trainees in old age psychiatry and GAP¹⁵ and fits with recommendations from the Shape of Training review (2013),¹⁶ which aimed to broaden training experiences to meet changing patient requirements. The option of dual training is currently being explored by the Psychiatry of Intellectual Disability Specialist Advisory Committee as part of the curriculum rewrite process and should also be considered by the wider Faculty. However, the current system of advertising training numbers may be a barrier to offering further dual training opportunities. The system allows very little flexibility, which will need to be addressed.

Overall, trainees and trainers responded positively to questions about current training. All the trainees felt supported, including positive responses from LTFT trainees. Trainees felt supported to undertake special interest sessions and had undertaken a broad range of these. Responses to questions about research opportunities were more varied, with common barriers cited by both trainees and trainers; these were mainly due to a lack of protected time to undertake research. Psychotherapy training, where available, was reported to be of a quality such that trainees were able to meet the requirements of the curriculum, but it was clear that there were some regions where trainees were unable to access adequate supervision and support. Out-of-hours experience varied between regions, but overall trainees felt that this met their training needs.

A third of both groups reported trainee isolation. Reduced recruitment to training posts in certain regions and trainees leaving the specialty were among the reasons given for this. Trainee isolation has been reported previously in the literature,⁴ and physical isolation can be further compounded by feelings of stigma by association – the process by which relatives, friends, support staff and associates feel stigmatised by contact with a stigmatised or marginalised group, such as those caring for a vulnerable patient group with intellectual disability who face marginalisation and disadvantage in their daily lives.³ Acknowledgment of this as an issue continues and there is ongoing work in this area. Psychiatry of intellectual disability trainees are now invited to join 'Basecamp', an online forum where trainees can communicate with each other, ask questions and raise concerns. It is managed by the national trainee representatives who meet regularly with the Faculty of Psychiatry Intellectual Disability Executive Committee and the Specialty Advisory Committee. On a more local level, regular meetings with TPDs, academic sessions and trainee networks have reduced trainee isolation

and have received positive feedback locally. Trainee support groups for issues specific to intellectual disability trainees have worked well for geographical networks of trainees.³

In the current climate of political and economic uncertainty, recruitment to medicine in general is a challenge. Doctors are choosing to take longer breaks between foundation and specialty training,¹⁷ and recruitment to core training posts remains static.^{6,7} Psychiatry has traditionally been considered a less glamorous ‘Cinderella specialty’, losing out in recruitment to the larger medical specialties. As a small subspecialty, intellectual disability psychiatry loses out again among the psychiatric subspecialties.⁹ Investment in recruitment with campaigns such as ‘Choose Psychiatry’¹⁸ will go some way towards increasing awareness of the benefits of training in psychiatry in general. It is also hoped that the introduction of foundation fellowships¹⁹ will encourage high-quality trainees into psychiatry.

For intellectual disability psychiatry training specifically, there is further scope to highlight the results of the GMC National Training Survey data⁷ and overall trainee satisfaction rates, which reflect favourably on intellectual disability training. The positive results of this survey also highlight the benefits of intellectual disability training in terms of trainee support, scope for LTFT training, and flexibility in special interest sessions and research. Opportunities to experience intellectual disability psychiatry are widening and include an intellectual disability psychiatry taster programme that has been developed successfully in the West Midlands.²⁰ The development of foundation programme posts in intellectual disability psychiatry could increase exposure to the specialty, and there is scope to broaden this further, with five foundation posts currently available in the UK. The 2019 National Intellectual Disability trainee conference, held in Cardiff, offered discounted entry for medical students and for foundation and core trainees. Such national events showcase the scope of opportunity within intellectual disability psychiatry and give opportunities for all, including medical students, to contribute posters and presentations, increasing audience participation and interest.

A strength of this survey was its good response rate, at 83%, with full completion of the returned questionnaires. The survey covered multiple geographical regions for both trainees and TPDs. There was one geographical region with no representation from either trainer or trainee. However, the accuracy and generalisability of the findings were limited by the low overall number of participants. The selection of only trainee representatives and TPDs could have led to bias, for example, toward selecting those trainees with a more positive training experience. The personal characteristics of a trainee representative could also cause bias, with such representatives potentially being more engaged and having more awareness of opportunities in their local area. TPDs may offer a better training experience to trainees on placement with them and therefore assume that all other posts in the respective deanery are also positive. Sending the survey out to all trainees was considered; however, when this has been attempted with similar surveys in the past, the response rate has been poor, and data protection requirements led to further complications. It was felt that targeting trainee representatives was likely to lead to a better response rate and a broader picture of training across the UK. The fact that certain regions did not have a response from both trainee and TPD could have biased results, with those regions potentially having empty posts or reflecting areas with more challenging training experiences or less engaged trainers. Broadening the scope of the survey to capture the views of core trainees who did not choose intellectual disability psychiatry, and the reasons why, would be of particular value for future recruitment.

Conclusions

This survey of trainers and trainees across the UK indicates that, overall, intellectual disability trainees are broadly positive about their training and feel supported, with adequate training opportunities. Trainee isolation is a theme that has been highlighted and might be remedied by the improvement of trainee networks. The survey demonstrates that there is scope to continue improving training opportunities, in particular for psychotherapy and research. The opportunity for dual training was popular with the survey cohort; this is a potential key finding in terms of recruitment.

Trainees have provided insight into their reasons for choosing the subspecialty. Hopefully, this will guide improvements in recruitment to this rewarding subspecialty of psychiatry. The survey showed that a key motivator for trainees selecting this specialty was having had a core training placement in intellectual disability. Increasing the availability of such opportunities may not only help to bring people into the subspecialty, but also ensure that all trainees have a good grasp of intellectual disability psychiatry, which is important whatever specialty of psychiatry they ultimately choose. Recruitment to psychiatry is a continuing concern, with current and long-term impact on patient care to be considered. This survey contributes to a much broader picture that needs further research to investigate key motivators and barriers regarding choice of higher training specialties.

Abstract

Aims and method

This systematic review examines the effectiveness and cost-effectiveness of behavioural health integration into primary healthcare in the management of depression and unhealthy alcohol use in low- and middle-income countries. Following PRISMA guidelines, this review included research that studied patients aged 18 years with unhealthy alcohol use and/or depression of any clinical severity. An exploration of the models of integration was used to characterise a typology of behavioural health integration specific for low- and middle-income countries.

Results

Fifty-eight articles met inclusion criteria. Studies evidenced increased effectiveness of integrated care over treatment as usual for both conditions. The economic evaluations found increased direct health costs but cost-effective estimates. The included studies used six distinct behavioural health integration models.

Clinical implications

Behavioural health integration may yield improved health outcomes, although it may require additional resources. The proposed typology can assist decision-makers to advance the implementation of integrated models.

Burden of depression and unhealthy alcohol use

Depression and unhealthy alcohol use are worldwide public health problems. Depression is the single most significant contributor to global disability, accounting for 7.5% of all years lived with disability.¹ Unhealthy alcohol use accounts for 5.9% of all global deaths and 5.1% of the entire global burden of disease,² and >80% of this occurs in low- and middle-income countries. Individuals suffering from depression and unhealthy alcohol use are at increased risk for poorer health outcomes from other illnesses, such as tuberculosis, maternal and infant conditions and HIV/AIDS.^{3,4} In low- and middle-income countries, societal impacts related to depression and unhealthy alcohol use can exceed healthcare costs.^{5,6} The affected populations have higher rates of unemployment, reduced job functioning and lower educational attainment.⁷

Despite the existence of cost-effective interventions for these conditions, up to 90% of individuals living with mental illnesses in low- and middle-income countries lack access to care.^{8,9} Moreover, in low- and low-middle-income countries, only 1% of the population with substance use disorders has access to minimally adequate treatment.¹⁰ Factors like low levels of public expenditures, reliance on out-of-pocket payments, preferential funding of hospital-based models of care and significant workforce shortages reduce the availability and accessibility of mental healthcare.^{11–13}

Typology of behavioural health integration in high-income countries

Behavioural health integration into primary care is thought to be an effective way to reduce the treatment gap in resource-constrained settings.¹⁴ Nonetheless, the vast majority of studies assessing the effectiveness of this integration originate in high-income countries. A meta-analysis, including mostly studies from high-income countries, found moderate-quality evidence that brief interventions in primary healthcare can reduce alcohol consumption in unhealthy drinkers compared with minimal or no intervention.¹⁵ Similarly, research studies from high-income countries revealed significantly better outcomes for adults with depression treated with collaborative care management compared with care as usual.^{16,17}

In high-income countries, different integration models have been classified based on the nature and level of coordination between highly specialised providers. Several high-income countries have developed their own classification adapted to their health system, and these typologies are commonly used in research and healthcare management. For example, the United States Substance Abuse and Mental Health Services Administration conceptualised a typology based on the degree of collaboration between primary care and behavioural healthcare specialists.¹⁸ At the most basic level, specialists refer patients to another location (coordinated care). At the intermediate level, providers deliver care at the same site but do not share treatment plans (colocated care). At the highest level of integration, specialists are part of the same team with a unique treatment plan, and the patient experiences a single system (integrated care). Collaborative care management, the most commonly studied integration models in high-income countries,¹⁹ is most often located in this highest level of integration. However, we are unaware of the existence of a typology built specifically for low- and middle-income countries.

Behavioural health integration in low- and middle-income countries

In low- and middle-income countries, researchers have studied task-shifting, often referred as task-sharing, which is the use of non-specialist primary health workers (such as general practitioners or nurses) and lay health workers to deliver mental health interventions and increase the availability of mental healthcare services.^{20–22} A review of evidence found that interventions delivered by lay health workers may increase the number of adults recovering from depression, reduce symptoms for mothers with perinatal depression and decrease the quantity of alcohol consumed by unhealthy drinkers.²³ In another review, Seidman and Atun²⁴ found task-shifting to hold potential for cost-saving and efficiency improvements in health systems in the care of tuberculosis and HIV/AIDS. Evidence for mental health conditions is unclear.²⁴ Both reviews found minimal relevant economic studies.

This systematic review aims to summarise the evidence of effectiveness and economic evaluation of the behavioural health integration of the management of depression and unhealthy alcohol use into primary healthcare in low- and middle-income countries. For the purpose of this review, all types of economic evaluations (such as cost-minimisation, cost–utility, cost–benefit and cost-effectiveness analysis) were included.²⁵ We included all types and levels of severity of depression and unhealthy alcohol use. Additionally, we propose a typology to characterise the models of behavioural health integration in low- and middle-income countries, using the evidence of the experimental studies included in the review. This typology could assist hospital and district managers, programme planners and policy makers in their decisions to improve the availability of mental healthcare services.

This systematic review is part of the formative phase of Project Detection and Integrated Care for Depression and Alcohol Use in Primary Care (DIADA), an implementation research project in Colombia, Peru and Chile, funded by the National Institute of Mental Health. Project DIADA studies technology-enhanced service delivery models for treating comorbid depression and unhealthy alcohol use in primary healthcare in multiple sites in urban and rural Colombia.²⁶

Method

Protocol and registration

We designed this systematic review according to Preferred Reporting Items for Systematic Reviews and Meta-Analyses guidelines.²⁷ We registered this review in the PROSPERO International Registry of Systematic Reviews (identifier CRD42017057340).

Phase 1: search strategy

This systematic review had five phases. In the first phase, medical librarians developed the search strategy, translating research concepts into controlled subject headings and natural language terms. The search included articles from 1990 to 2017. We chose to start the search at 1990 because before this date few, if any, studies in low- and middle-income countries were utilising behavioural health integration models. The following databases were searched for relevant abstracts: Medline – PubMed (search date 28 April 2017), Web of Science (search date 28 April 2017), PsycINFO (search date 28 April 2017), EMBASE (search date 4 May 2017), Cochrane Central Register of Controlled Trials (search date 28 April 2017) and the World Health Organization’s (WHO) Global Index Medicus (search date 28 April 2017). The search also included relevant conference proceedings, grey literature and review references in related articles (*Table 1*). Abstracts in English, French, Spanish and Portuguese were included based on co-authors’ proficiency in these languages. The search found 8786 abstracts after removing duplicates. Search keywords included, but were not limited to, ‘depression’, ‘alcohol use disorder’, ‘integrated care’ and ‘developing country’. A full list of search terms for all databases searched, including PubMed (Medline), can be found under Supplementary File 1 available at <https://doi.org/10.1192/bjb.2020.35>. *Table 1* Overview of databases searched

Eligibility criteria

We searched for experimental and non-experimental studies that examined the effectiveness or that performed economic evaluations of the implementation of a behavioural health integration model on the management of depression and unhealthy alcohol use in primary healthcare in low- and middle-income countries. Articles eligible for inclusion were required to meet the following criteria: (a) studies included patients aged 18 years, of any gender and with a diagnosis of alcohol use disorder and/or depression of any severity; (b) studies performed with a population living in low- and middle-income countries as per the World Bank country income classification²⁸ during the year that the study started; (c) studies included patients who received mental health services (in depression and/or alcohol use disorder) in fully or partially integrated primary health services in low- and middle-income countries²⁹ and (d) studies included the integration of pharmacological or psychological interventions, or a combination of both. All study designs were considered. We excluded single-case studies, presentations, abstracts, notes, corrections and studies that did not report effectiveness or economic evaluation outcomes.

Phases 2 and 3: abstract and full-text review

Using previously agreed inclusion criteria, three teams of two researchers per team each independently screened a third of the abstracts and titles (approximately 2918 abstracts). Disputed references (around 11%) were sent to an arbiter who settled the discrepancies. A total of 147 articles (roughly 1.7% of original abstracts) were selected for full-text appraisal of inclusion criteria. In each team in phase 3, one reviewer acted as the primary reviewer, the second reviewer evaluated the work for discrepancies and an arbiter settled the differences. This full-text review identified 58 articles meeting inclusion criteria, 40 of which met study design criteria and provided sufficient statistical data to be included in a subsequent meta-analysis (*Fig. 1*). *Fig. 1* Flow chart of search results.

¹ WHO Global Index Medicus search did not include low- and middle-income countries concept. DSR, Database of Systematic Reviews; EconEval, economic evaluations; WHO, World Health Organization; LILACS, Latin American & Caribbean Health Science Literature; WPRIM, Western Pacific Region Index Medicus; IMEMR, Index Medicus for the Eastern Mediterranean Region; IMSEAR, Index Medicus for the South-East Asian Region; AIM, African Index Medicus.

Phase 4: data extraction

In phase 4, we completed an in-depth data extraction with a previously designed form (*Table 2*). We also completed a standardised assessment of bias of all the included randomised controlled trials, using methods described in the Cochrane Collaboration's tool for assessing risk of bias.³⁰ This assessment of bias included a team of two of the authors independently evaluating the studies across seven categories: random sequence generation, allocation concealment, blinding of participants and personnel, blinding of outcome assessment, incomplete outcome data, selective reporting and other bias. Studies were rated across these categories as having a 'low risk of bias', 'unclear risk of bias' or 'high risk of bias', and all discrepancies on risk classifications were resolved by a third author. *Table 2* Phase 5: list of variables

 Composition of multidisciplinary teams
 Existence of patient education programmes
 What is the role of patient data in the care of the patient?²

Phase 5: patterns in the organisation of care of behavioural health integration models

During phase 4, we noticed patterns in the reorganisation of care that enabled the delivery of integrated mental health interventions in the treatment arms. We used the 2018 Joint Commission Ambulatory Accreditation Quality of Care Standards to assess the dimensions of quality of care involved in these reorganisations of care.³¹ We updated the data extraction form used in phase 4, adding variables related to organisation of care, and reviewed all articles once again (*Table 2*). We extracted data by structural coding. During phases 4 and 5, one researcher (L.C.) extracted these data, with a second reviewer (S.B.) assessing the data for discrepancies. An arbiter resolved any differences that the researchers found.

Results

Description of the included studies

The 58 included publications corresponded to 53 unique studies assessing the effectiveness or performing an economic evaluation of behavioural health integration in 19 low- and middle-income countries. Of the 58 articles, 20 took place in a rural setting, 3 took place in semi-urban settings, 23 took place in urban settings, 7 took place in both rural and urban settings, and the settings of the remaining 5 are unclear or unable to be categorised. The vast majority of the studies introduced interventions in primary healthcare, although some interventions were introduced in communities, over the phone or in public hospitals. Of the 55 articles for which this categorisation applies, 22 articles studied only women, 3 studied only men and 30 studied both women and men. Eleven articles came from low-income countries, 19 articles came from lower-middle income countries and 28 articles came from upper-middle income countries. Based on the WHO regional grouping classification,³² 22 articles came from Africa, 15 articles came from the Americas, 13 articles came from Southeast Asia, 8 articles came from the Eastern Mediterranean region and 2 articles came from the Western Pacific region. Two studies counted for both India and Pakistan, which are classified in two different WHO regions (*Supplementary Table 1*).

We found that of the 58 total articles, 46 focused on depression, 9 focused on unhealthy alcohol use and 3 focused on both illnesses. Further, 49 assessed the effectiveness of integration models, 6 performed economic evaluations, 2 performed both assessments and 1 presented a descriptive analysis. Of the 51 publications reporting effectiveness data (8 reported economic evaluation data), 40 focused on depression, 9 focused on alcohol use and 2 presented data related

² PHC, primary health center.

to both conditions. These 51 publications also varied in study design: 36 studies were randomised controlled trials, 7 were quasi-experimental studies and 8 were observational studies.

We found a high risk of selection bias among our studies, owing to a lack of blinding of ‘participants and personnel’; more than 75% of our studies had a ‘high risk’ of this type of bias. This finding was not surprising given the nature of the mental health interventions, for many of which it was not possible to blind the study participants. The effect on the evidence quality is low since the authors used standardised and objective methods for outcome measurement (*Fig. 2*). *Fig. 2* Consolidated risk of bias graph.

Results of the effectiveness studies

Depression

Forty-two articles presented effectiveness data on depression care (Supplementary Table 1). The most frequently studied primary outcome was severity of depression. The treatment arm usually received a psychological intervention like cognitive-behavioural therapy, problem-solving therapy, psychoeducation or interpersonal therapy, whereas the care for the control arm was enhanced with screening only. Thirty-six articles reported that the integration groups had a greater reduction in depression severity than the control groups. Of these 36 articles, 5 articles reported effect size. Overall, differences between arms sustained through secondary follow-ups ranged from 3 months to 36 months post-intervention. Three of the articles that found no difference between the control and treatment groups offered only a general training on mental healthcare to their lay or primary healthcare workers expecting to change their clinical behaviours.^{33–35} Two other publications lacking positive findings selected primary outcomes highly susceptible to confounding.^{36,37} In India, Pradeep et al³⁸ sought to improve treatment-seeking behaviours and adherence to antidepressant medications by enhancing usual care. In Iran, Malakouti et al³⁹ sought to reduce the number of suicides. In Pakistan, Husain et al⁴⁰ compared the effectiveness of psychotherapy to antidepressant medications in reducing depression and improving quality of life. This group compared two integrated interventions without contrasting it to usual care and found no difference between these two arms.

Alcohol use

Eleven articles reported effectiveness data related to unhealthy alcohol use.^{41–51} All 11 used a reduction in alcohol consumption as their primary outcome. Ten of these articles were randomised controlled trials (Supplementary Table 1). Of these, five favoured the intervention arm,^{41,42,45,48,50} five did not show differences between arms or after the intervention^{43,44,46,49,51} and one had unclear results.⁴⁷ For the studies that favoured the intervention arm, only one paper reported effect size ($d = 0.95$).⁵² For most studies, secondary follow-ups showed that statistically significant differences sustained over 3 months to 12 months post-intervention. The two most commonly delivered interventions were screening followed by brief intervention or by motivational interviewing. In Thailand, Noknoy et al,⁴¹ and in South Africa, Rendall-Mkose et al,⁴⁸ found that motivational interviewing arms produced better outcomes than enhanced usual care in improving patient outcomes. In Kenya, L’Engle et al⁴⁵ found that screening and a brief intervention can reduce self-reported alcohol consumption among female sex workers at risk for HIV. In South Africa, Mertens et al⁴⁴ found that patients receiving brief intervention had significantly reduced Alcohol, Smoking and Substance Involvement Screening Test scores. However, in South Africa, Peltzer et al,⁴⁶ and in Thailand, Assanangkornchai et al,⁵¹ found no difference between brief intervention and simple advice as both arms similarly reduced alcohol consumption. Similarly, in South Africa, Sorsdahl and Petersen,⁴⁹ in an uncontrolled before-and-after study, did not find a significant decrease in alcohol use in pregnant women following a brief intervention.

In Kenya, Papas et al⁵⁰ found effectiveness of cognitive-behavioural therapy over treatment as usual in reducing use and attaining abstinence in patients living with HIV. In India, Nadkarni et al⁴² developed a novel and culturally adapted psychotherapy for unhealthy alcohol use delivered by lay health workers, called counselling for alcohol problems. Patients receiving counselling for alcohol problems showed higher remission rates and higher proportion of alcohol-free days than individuals receiving enhanced usual care.

Results of the economic evaluation studies

We identified eight studies performing economic evaluations (Supplementary Table 1). These studies were conducted in Chile, India, Mexico, Nigeria and Pakistan. Six of these studies assessed interventions related to depression,^{52–57} one study evaluated interventions related to alcohol use⁴² and one publication evaluated both conditions.⁵⁸ Four of these studies used a healthcare perspective in their economic analysis,^{52,56–58} two used a societal perspective^{54,55} and two used both perspectives.^{42,53} In economic analysis, a healthcare perspective includes all costs and benefits directly affecting patients, providers and payers.²⁵ Conversely, a societal perspective takes a broader approach to include healthcare plus other private and public benefits and costs related to a given condition. Concerning the type of economic analysis, five studies performed a cost-effectiveness analysis,^{52,55–58} two completed a cost-utility analysis^{42,53} and one study performed both types of economic analysis.⁵⁴ Three studies used modelling techniques^{52,57,58} and five studies used experimental data from effectiveness trials.^{42,53–56}

Two of the articles using modelling techniques^{52,58} utilised the sectoral approach to cost-effectiveness analysis developed by the WHO's 'Choosing Interventions that are Cost-Effective' initiative.⁵⁹ These studies found that a combined intervention of medications and therapy plus proactive case management yielded the highest effectiveness among the alternative options. In a study in Nigeria, Gureje et al⁵⁸ found that a combination of tricyclic antidepressants, psychotherapy and proactive case management had the highest cost-effectiveness ratio, closely followed by tricyclic antidepressants only (approximately 0.5% less cost-effective). In Mexico, Del Carmen et al⁵² found that a medication-only intervention was the most cost-effective, followed by a combination of medication, psychotherapy and proactive case management (approximately 10.5% less cost-effective).

From a healthcare perspective, the economic analyses of the experimental studies showed that the intervention arms had increased effectiveness and costs.^{42,53,54,56} The increased direct costs were associated with increased utilisation of healthcare personnel and medications. These interventions were deemed cost-effective based on the acceptability threshold and commonly accepted values for cost-effectiveness. Using a Markov model, in Chile, Siskind et al⁵⁷ modeled the cost-effectiveness of a stepped-up care intervention throughout the lifetimes of a cohort of Chilean adult females. This study also evidenced increased direct healthcare costs, but found integration to be very cost-effective.

Notably, from a societal perspective, these interventions were found to reduce costs, usually associated with decreased time costs to patients and families, as well as fewer productivity losses.

Models of behavioural health integration

The control arm of the experimental studies included in this review used treatment as usual (minimal or no services) or enhanced usual care. In contrast, to integrate mental healthcare, the treatment arms redesigned their care by selecting at least one of the seven strategic intervention options (*Table 3*). Each strategic intervention option represents a discrete active enhancement to the primary healthcare affecting workforce capacity, information management or daily flow of care.³¹ The behavioural health integration models tested in the research are made up of one or more strategic intervention options. Furthermore, the treatment arms of the 53 studies included in this secondary analysis clustered around 6 of these integration models (*Table 4*). We were unable to include five studies in this secondary analysis: two owing to paucity of data^{55,60} and three owing to use of modelling methods for economic evaluation that did not study any specific behavioural health integration model.^{52,57,58}

Strategic intervention options	Description	Joint Commission standard of ambulatory quality of care (standard label)
1	General training on mental healthcare for lay and primary healthcare workers	Human resources (H.R. 01.05.03)
2	Specific training on mental healthcare skills and interventions for lay and primary healthcare workers	Human resources (H.R. 01.05.03)
3	Addition of dedicated lay or primary healthcare workers to provide mental health services	Human resources (H.R. 01.06.01)
4	Addition of specific mental healthcare tasks to existing lay or primary healthcare workers	Human resources (H.R. 01.05.03)
5	Increased coordination between lay or primary healthcare workers with mental health workers	Provision of care (P.C. 02.01.01)
6	Strategic data management to improve patient outcomes	Provision of care (P.C. 02.01.05)
7	Utilisation of care manager or care coordinator	Provision of care (P.C. 02.01.01)

Information management (I.M. 02.02.01)

Models 1–3 rely on building the capacity of non-specialist health workers in primary care, and they represent different task-sharing models. These models heavily depend on organisational strategic intervention options 1–4. Unlike models 4–6, the first three models do not depend on increased coordination between primary health workers, or between the primary healthcare site and other healthcare organisations. There are also minimal modifications in the daily flow of care. Starting in model 4, these integration models increasingly require collaboration and information flows across multidisciplinary teams. Patient-level data is strategically used to improve the care of patients in models 5 and 6.

Model 1: general training on mental healthcare for lay health workers and primary health workers

Seven studies met the criteria for model 1. This model utilises strategic intervention option 1. In this model, following training only, lay or primary healthcare workers (general physicians and nurses) are expected to have an increased ability to diagnose and treat mental health conditions adequately. For example, a study in Colombia⁶¹ compared the diagnostic accuracy and effectiveness of general physicians who had received formal training on mental healthcare to that of similar general physicians who did not. The study found that patients in the intervention arm received better treatment, had increased rates of retention and had lower depression scores than the control arm.

Model 2: mental healthcare interventions delivered by lay health workers

Twenty studies met the criteria for model 2. In addition to general training (strategic intervention option 1), lay health workers also receive specific training, ranging from a few days to 2 weeks (strategic intervention option 2), that prepares them to deliver targeted interventions, such as screening, problem-solving or interpersonal therapy. This model requires that the primary healthcare site either hires new lay health workers (strategic intervention option 3) or reassigns those currently delivering other services (strategic intervention option 4). This model may benefit from having primary health workers (general physicians or nurses) perform supervisory functions. Using this model, a study in rural South Africa⁶² compared the effectiveness of a 12-week course of interpersonal therapy delivered by lay health workers to enhanced care in the reduction of depression among low-income women. Patients in the intervention arm showed a significant decrease in depression symptoms upon completion of the 12-week course.

³

Those strategic options deemed essential for each model are marked with a 'Yes' sign. LHW, lay health worker; PHW, primary health worker; MHW, mental health worker.

Model 3: mental healthcare interventions delivered by primary health workers

Eleven studies met the criteria for model 3. This model uses strategic intervention options 1 and 2 plus either strategic intervention option 3 or 4. This model often uses flow of care modifications to carve out dedicated time for the primary health workers. A study in rural Thailand⁴¹ compared the effectiveness of nurse-delivered brief interventions versus treatment as usual (e.g. no brief intervention) in the reduction of alcohol consumption among low-income males. Patients in the intervention arm reported a more substantial decrease in drinks per drinking day and frequency of unhealthy drinking assessed 6 months after the intervention.

Model 4: consultant liaison

One study met the criteria for model 4. This model offers the primary health worker access to onsite or telemedicine consultation services from a mental health worker such as psychologists or psychiatrists (strategic intervention option 5), although the primary health worker continues to be the main provider. Consultation services include education, problem-solving and feedback to the primary health worker regarding diagnostic or treatment strategies.^{63,64} Strategic intervention option 5 is essential in this model. A study in Chile³⁶ compared the effectiveness of treatment delivered by general physicians with access to online psychiatric consultation services with that of those without access to this support in the management of urban women diagnosed with depression. Patients in the intervention arm had a statistically significant reduction in their depression scores compared with those in the control arm at 3 months of the intervention.

Model 5: stepped care

Eight studies met the criteria for model 5. This model provides a structured way to match treatment intensity with the patient's needs.⁶⁵ More complicated patients are cared for by a mental health worker (strategic intervention option 5), whereas more straightforward cases remain under the care of the primary health worker (strategic intervention option 4). Some studies used lay health workers, creating a three-level stepped care model (strategic intervention option 3). This model distinctively uses a set of clinical criteria and a pathway of care to systematically step up or step down each case. Thus, this model adds outcome tracking to inform the level of care provided to a patient (strategic intervention option 6). A post-rollout evaluation in Iran³⁹ assessed the effectiveness of a suicide prevention strategy for adults with depression. In this programme, a lay health worker reached out to patients to screen them for depression and referred positive cases to a primary health worker for management and stabilisation. In turn, the primary health worker referred refractory cases to psychiatrists who delivered specialised services.

Model 6: collaborative care management

Six studies met the criteria for model 6. There is variation in the literature regarding the components of collaborative care management, and there are different levels of complexity within collaborative care management itself.⁶⁶ For this systematic review, strategic intervention options 6 and 7 are considered critical. Other collaborative care management elements, such as linkage to community resources, patient self-management support, regular case consultation from a psychiatrist, provider decision support and healthcare organisation support, could also be present.

In China, a study⁶⁷ compared the effectiveness of two modalities of depression treatment for adults aged 60 years. In the intervention arm, general physicians (strategic intervention option 4), primary care nurses serving as care managers (strategic intervention option 7), and psychiatrists (strategic intervention options 5) comprised the treatment team. General physicians received written guidelines for the treatment of depression, as well as in-depth training in the prescription of antidepressants and the appropriate use of referrals to the psychiatrist (strategic intervention options 1–3). Nurses acting as care managers provided psychoeducation to patients and families, assistance with communication between patients and providers, and support for the patient's adherence to treatment. A study psychiatrist was made available in case of referrals. General physicians in the control arm only received written guidelines for depression

treatment, patients' PHQ-9 scores and major depression diagnoses from the screening stage. Patients in the intervention arm experienced significantly greater reductions in Hamilton Rating Scale for Depression scores than those in the control arm.

Discussion

Overview

The findings of this systematic review support the effectiveness of different models of integrating depression and unhealthy alcohol use care in primary healthcare in low- and middle-income countries. Patients receiving treatment in the integrated models tend to have better outcomes compared with those receiving regular care. The evidence appears more robust for depression than for unhealthy alcohol use. The economic analyses indicate that integrated models have higher direct costs to primary health, and that from the healthcare perspective, these models are cost-effective. It is also possible that behavioural health integration saves costs to society by increasing productivity and decreasing time losses, among other benefits. The typology proposed in this article can improve the understanding of the different models of behavioural health integration in low- and middle-income countries. This information can be valuable for policy makers and hospital managers responsible for the organisation and delivery of care. Additional implementation studies are required to further characterise the different models of integration and to understand better the conditions needed for the implementation of each of them.

Increased effectiveness across different settings and populations

The studies included in this review showed that integrated models can improve patient outcomes in different subtypes of depression such as perinatal depression, late-in-life depression, comorbid depression and HIV, and depression associated with trauma disorders in war-affected areas.^{68,69} Previous research shows that some psychological treatments can be as effective as antidepressant medications, with higher retention rates and better continuing outcomes.^{70,71} We found that different psychotherapies can be effectively delivered by an array of integration models. These can be more culturally adaptable,⁷² and possibly less stigmatising than medication-based treatments. They can also be potentially scalable in low- and middle-income countries contexts where community bonding is strong, labour is more available and procurement and distribution chains for pharmaceuticals are precarious.

This systematic review suggests that integration of care for unhealthy alcohol use might produce better outcomes for the general population, pregnant women and people living with HIV in low- and middle-income countries. The control arm of seven included trials compared screening and minimal psychoeducation to screening and brief intervention or motivational interviewing offered in the intervention arms.^{41-44,46,48,51} The enhancement of the control arms could account for the non-positive results, particularly in settings where neither screening nor minimal psychoeducation is routinely offered in primary healthcare. There is evidence that screening alone can affect the patients' behaviours, which could explain the lack of difference between arms in some studies.⁷³ Kaner et al¹⁵ found that screening and brief interventions can reduce alcohol consumption in hazardous and harmful drinkers compared with minimal or no interventions in primary healthcare in high-income countries. Although the findings of the articles included in this review are similar to those in high-income countries, we found few studies targeting unhealthy alcohol use that fulfilled our selection criteria, which may affect the generalisability of our findings. More research in the adequate care of unhealthy alcohol use in low- and middle-income countries is needed.

Increased funding is a necessary, but not sufficient condition to increase access to care

The economic evaluations included in this review indicate that integrated models may result in increased direct costs to primary health, stemming from increased utilisation of personnel and medications. Nevertheless, they may save costs to society.^{42,53,57} These findings are similar to those found in high-income countries.⁷⁴ Given the low levels of spending on mental healthcare in many low- and middle-income countries,¹¹ where the vast majority of primary healthcare sites do not provide access to mental health services, the finding that increasing the availability of mental health services increases direct costs should not surprise. Since low- and middle-income countries favour funding of mental health hospitals,¹¹ new resources should be earmarked to sustain behavioural health integration in primary care. Moreover, the way in which the health system pays or transfers funds to primary healthcare should also be carefully examined. Health economics literature has extensively shown that these payment mechanisms are key determinants of providers' behaviours.⁷⁵ The most commonly used payment mechanisms in many low- and middle-income countries are out-of-pocket, capitation and historically determined allocations;⁷⁶ however, since they are not explicitly linked to outputs or outcomes, they do not provide adequate incentives to increase the availability of integrated services. Recent research in high-income countries has studied the development of new payment mechanisms to promote increased integration and coordination of care for populations with multiple chronic comorbidities.^{77,78} Additional research is needed to specifically adapt payment mechanisms to offset the increased direct costs related to behavioural health integration, thus encouraging primary care in low- and middle-income countries to increase the availability of services.⁷⁵ Importantly, public and private providers may respond differently to these incentives, as evidenced in several studies included in this review where integration models affected patient outcomes in public, but not in private organisations.^{79,80}

Typology of integration for low- and middle-income countries: a tool for decision makers

The reviewed studies tested a variety of models of integrated care for depression and unhealthy alcohol use. We offer a typology of the models in *Table 4* and show how they are built from one or more of seven organisational strategic intervention options. The typology aims to assist decision makers in selecting the models that are likely to work over time in their setting. The strategic intervention options, and the models that flow from them, are not hierarchical but do vary in terms of cost, complexity and how much organisational capacity they require to implement and sustain. Decision makers can choose models that match the characteristics and capacity of their health system and primary healthcare. An appealing complex model may not be the right choice if it is too expensive or requires too much change from the workforce to be implemented or sustained.⁸¹ An integration model that fits well with current programmes and available resources might have a greater effect over time. Since complex strategic intervention options require more resources to implement and sustain, they are more likely to be chosen in higher income nations. Decision makers must consider effectiveness, acceptability, sustainability and scalability in choosing a model to meet their system's needs.

Limitations

This review has several limitations. Some of the studies included in this review were not rigorously designed trials and did not have adequate comparison conditions. For example, some of the studies were post-rollout evaluations and other were pragmatic or quasi-experimental trials. This review focused on the care of depression and alcohol use disorder. Therefore, our findings may not be generalisable to other mental or substance use disorders. Similarly, we excluded studies assessing the effectiveness of psychological interventions for these two conditions in low- and middle-income countries when they did not reflect the integration of these treatments into existing primary healthcare settings. Nonetheless, this systematic review offers important insights into the value and implementation of integrated models in global mental healthcare.

Implications for the global mental health policy field

The findings of this review build on a wealth of knowledge strongly supporting the value of integrating mental healthcare into primary care.^{77,78} The next generation of research should aim to understand the arrangements at the system and organisational levels necessary to scale up integrated models in low- and middle-income countries and to promote the delivery of quality healthcare. In particular, we need to strengthen the instruments used to measure the quality of integration in low- and middle-income countries. Similarly, understanding the reasons underpinning the rampant mental health workforce shortage is critical because behavioural health integration heavily relies on existing and newly available workforce. To a certain degree, a combination of additional funds and targeted payment mechanisms can provide the right incentives to overcome some of these implementation challenges and to sustain quality of mental healthcare. Further research related to payment mechanisms in primary care in low- and middle-income countries is therefore critically needed.

The global mental health field can learn from other successful global health movements. Efforts to address HIV, reduce child mortality and improve maternal health were able to permeate political spaces and become global health priorities, channelling substantive resources, some of which have been used to integrate these services into primary care. At the national level, the experiences of Chile and Zimbabwe where research studies influenced the governments to expand publicly funded mental healthcare programmes can illustrate processes that occupied the political agenda and affected public policy.^{82,83} Furthering our understanding of the operation of behavioural health integration into primary care and bettering our ability to scale up these integrated models can help close the treatment gap and raise the quality of mental care in low- and middle-income settings.

1.2.25 Follow the money: how is medical school teaching funded?

Aileen O'Brien Ania Korszun

Abstract

Growing student numbers are producing greater demand for teaching, and resources allocated for education are being placed under increasing strain. The need for more student clinical placements and more clinician teaching time is expanding. Psychiatrists have successfully drawn attention to the importance of parity between mental and physical illness. We now have a responsibility to ensure enhanced opportunities to teach psychiatry to our medical students. This is set against a background of an increasing number of psychiatry consultants leaving the profession and an already stretched National Health Service environment. Many consultants contribute to teaching but do not have this activity included in their job plans. Although clinics and clinical meetings are inevitably slower when students are present, there is often no backfill provided. As outlined below, trusts receive substantial funding to cover costs related to the teaching of medical students, but most of us don't know what actually happens to this money. Here, we discuss how teaching is currently funded and make recommendations regarding improving accountability.

As increasing student numbers cause greater demand for teaching, clinicians may struggle to meet the conflicting pressures on their time. This is against a background of an increasing number of psychiatry consultants leaving the profession and an already stretched National Health Service (NHS) environment.

Many consultants who contribute to teaching do not have this activity included in their job plans. Clinics and clinical meetings are inevitably slower when students are present, but there is often no backfill provided. The psychiatry recruitment crisis has been successfully challenged by the Choose Psychiatry campaign;¹ however, to sustain this and encourage retention, jobs need to be manageable and stimulating with contributions to education adequately recognised.

Trusts receive substantial funding to cover teaching medical students, but most of us don't know what actually happens to this money.

In the 1970's film *All the President's Men*, 'follow the money' was the catchphrase, suggesting that the way to shine a light on questionable dealing is to follow financial transfers. Although we are not suggesting that the allocation of funding for medical student education is as questionable, systems for funding education are mostly opaque and surprisingly poorly understood.

So, for those who would like to increase their understanding, we offer some answers to the most frequently asked questions.

Who funds undergraduate teaching?

The world of medical education is nothing if not acronym heavy (*Box 1*). Health Education England (HEE) was established in the *Health and Social Care Act 2012* as a special health authority within the Department of Health. It is a non-departmental public body which supports the delivery of education, training and development of the NHS health and public health workforce.² It provides oversight of strategic planning and development of the health and public health workforce, and allocates (and accounts for) funding for education and training resources on behalf of the Department of Health and Social Care (DHSC). **Box 1** Educational Bodies
HEE Higher Education England An executive body of the Department of Health. It provides coordination for education and training within the health and public health workforce in England.
LETBE Local Education and Training Board Statutory regional committees of HEE, responsible for workforce planning, and education and training.
OFS Office for Students Regulator established in January 2018. It merged HEFCE and OFFA, and inherited their responsibilities, also taking charge of the granting of degree-awarding powers and university titles.
SIFT (now undergraduate medical tariff) Service Increment for Teaching NHS levy that was given out as extra funds to NHS institutions that participate in training undergraduate students
OFFA Office for Fair Access Safeguarded and promoted fair access to higher education by approving and monitoring access agreements
HEFCE Higher Education Funding Council for England Distributed public money for teaching and research to universities and colleges.

From April 2018, the Office for Students (OFS) became the regulatory body for higher education in the UK, bringing together the functions of the Higher Education Funding Council for England (HEFCE), the Office for Fair Access, the

Department for Education and the Privy Council in a single organisation.

Undergraduate medical training is essentially funded in England and Wales by: •DHSC (via HEE) – for clinical placement costs, more for the final years;•OFS – this is because medicine counts as a ‘high cost’ course as opposed to, for example, many arts courses;³•tuition fees paid by the students.

The OFS gives each university a grant based on the number of medical students at their institution. The numbers of students that universities can admit are regulated by the OFS and controlled through its intake targets.

How are placements funded?

The money from HEE is now known as the undergraduate medical tariff or ‘the tariff’ (formerly and often still in fact known by professionals as SIFT (Service Increment for Teaching)). The tariff, set by the Secretary of State for Health, is not a direct payment for teaching but is supposed to cover the additional costs incurred by trusts and other placement providers in delivering medical student teaching.

The money is paid directly to the trusts by HEE, and the amount is based on student numbers that are provided by the university (but not on quality of teaching). So, although the universities are responsible for monitoring the quality of their students’ clinical placements, they have little influence on how the tariff funds are disbursed at trust level. The universities do liaise directly with trusts to determine the number of placements offered and monitor the quality of the teaching provided at those placements. If quality standards are not met by the trusts, the university can in theory withdraw those placements and, consequently, the funding that goes with them. However, for many universities there are no alternative trusts that they can approach. The overall training activity provided by trusts, including that for medical students and doctors in training, is governed by individual learning development agreements between trusts and HEE, which list all education, training and learning activities commissioned by HEE.

Increasingly, patients are cared for in primary care, or by third sector or independent providers. This can lead to practical challenges such as enabling patient contact in patients’ homes. Undergraduate education is rarely considered at the commissioning level, so many providers can decide whether or not to participate in teaching; this adds another level of complexity to the university’s obligation to monitor the quality of teaching, as well as the practical difficulties of securing placements.

What is included in the tariff?

The tariff for undergraduate medical placements was introduced in 2013–2014. Tariffs are adjusted by a market forces factor to compensate for the differences in cost of providing training placements in different parts of the country.

The tariff covers funding for all direct costs involved in delivering education and training, and the list provided by the government is comprehensive:⁴ •direct staff teaching time within a clinical placement;•teaching and student facilities, including access to library services;•administration costs;•infrastructure costs;•pastoral and supervisory support;•trainee study leave and time for clinical exams;•health and well-being (excluding any occupational health assessments);•course fees and expenses (as required to achieve professional registration);•student/trainee accommodation costs;•in-course feedback and assessment;•formal examining;•staff training and development relating to their educational role.

What is the tariff worth (for a year's worth of placements)?

In 2019–2020, a non-medical tariff (for an allied health professional (AHP)) is set at £3720, the medical postgraduate tariff is £11 418 and a medical undergraduate tariff is £33 286.

In summary, in England, teaching one medical student in the clinical years is currently supported by:⁵ •the OFS teaching grant – £1500 per student for the non-clinical years and £10 000 per student during the clinical years (depending on holiday entitlement at different schools, this is about £250 per week for the clinical years); •placement tariff – healthcare providers receive an average tariff of around £36 000 to provide a year's worth of placements to students in the clinical years; •tuition fees – £9250 per year for all years.

AHPs are a core part of the NHS people plan,⁶ and traditional 'medical' tasks and roles are increasingly being taken on by physician associates, advanced nurse associates, nurse prescribers and other AHPs. Although this is welcomed, with many doctors recognising the necessity in terms of long-term workload reduction, in the immediate term, doctors are increasingly asked to teach and supervise AHPs despite the non-medical tariff being substantially lower.

Where does all the money go and how is it regulated?

In 2007, the British Medical Association investigated the use of the tariff (or SIFT, as it was then known) using the Freedom of Information Act. Of the 33 trusts contacted, 23 either did not respond, did not know or did not detail how the money was spent. From the ten trusts that did respond, the most frequent response was that funding had historically been incorporated into their baseline budgets, and its use was therefore not recorded separately. As one trust responded (Orwell would be impressed), 'this income . . . constitutes part of the totality of the Trust's income base and therefore is embedded within the totality of the Trust's expenditure'. Only seven of the 23 trusts could give any information about consultant teaching time, and this tended to consist of a statement that consultants nominally have one PA per week allocated for teaching.⁷

That was over 10 years ago. Have things moved on?

There has been some progress in that most medical schools have developed a 'minimum teaching standards' document that they use as a shared document between them and trusts. New medical schools have had to start this process from scratch and work with their trusts to provide clear explanations of where and how the money is spent. Tariff funding is still often absorbed into trusts' finances, but increasingly trusts are being asked to demonstrate where the money is actually going.

That's England; what about the rest of the UK?

Medical universities in Scotland, Wales and Northern Ireland are funded by the devolved governments in very similar ways to HEFCE, although the fee element of their income varies from no fees (Scotland) to lower fees (Wales) to the same as England (Northern Ireland).

Funding for medical education to the medical universities comes from the higher education budget and then goes to the NHS institutions through an equivalent of the tariff. The scheme in Wales is still named SIFT-W (for Wales); in Scotland, it is the ACT (Additional Costs of Teaching); and the Supplement for Undergraduate Medical and Dental Education (SUMDE) in Northern Ireland.⁸

Conclusion: use it or lose it!

The level of scrutiny regarding this teaching funding currently only goes in one direction. We believe that trusts need to wake up to the fact that if they are being paid for providing teaching to students, they need to be able to demonstrate this in a transparent way. In *All the President's Men*, the assiduous undercover reporters expose Watergate, leading to the downfall of the president of the USA. Following the money when it comes to trust teaching tariffs is likely to show that the funding is generally poorly accounted for and monitored, rather than deliberately diverted. However, in the current financial climate, trusts are unlikely to continue getting these large amounts of money unless they can demonstrate that funds are going where they are meant to go, and where they say they are going, and that the teaching provided is of at least an adequate standard. In the coming year, HEE will be formally gathering information from trusts on how money is being spent, and many trusts are likely to be unprepared. Effective and clear job planning is probably the most obvious way to demonstrate that the funding is going towards the most expensive and essential resource: clinician time. This needs to be evidenced and protected.

With the current workforce challenges, alternatives to consultant teaching should also be considered, and medical students also need teaching and experience of working in a multidisciplinary team. Clinical teaching fellows are higher trainees funded by the tariff, with protected teaching time in their week (typically around 60%), and anecdotally they make a big difference to student experience. AHPs too can usefully support medical student teaching. The use of simulation training and involvement of expert patients, as well as buying sessions for students to attend specialist clinics in other sectors, may also represent good ways of spending the money available.

There is no doubt that by continuing to 'follow the money' we can also improve and track where these precious resources are being used to train safe and competent doctors with the necessary skills to look after our patients' complex needs in the future.

Addendum in the time of COVID-19

We originally wrote this piece in the now seemingly distant days before the COVID-19 pandemic. The points we made in the conclusion are now even more relevant. New problems arise as we are forced into a situation where the necessary teaching of basic psychiatry skills must be accomplished without students being able to attend hospitals and clinics to get direct clinical experience in psychiatry. Also, these students will be qualifying as doctors at a time when there will be even greater needs for the skills necessary to deal with the epidemic of mental illness that will follow COVID-19. It is therefore essential to accelerate our efforts in developing alternative ways of teaching, but this is a time when consultants and their teams have even greater pressure on their 'time to teach' as they prioritise new clinical commitments that arise from the COVID-19 pandemic.

The use of digital technologies can no doubt play an increasingly valuable role in teaching. However, distance learning alone will not be adequate; this is a time when the input of all our clinical colleagues remains vital. Students are not currently on clinical placements and their dates of return are uncertain. However, the tariff continues to be paid to Trusts and they should not lose sight of their responsibility for active involvement in creatively addressing educational and training needs. In particular, the mental health risks of their patients will persist and be even greater after COVID-19. These will be further exacerbated if we allow our students to leave medical school with inadequate training in psychiatry.

1.2.26 Patients with young-onset dementia in an older people's mental health service

date

2021-04

Abstract

Aims and method

Currently, no separate service exists for patients with young-onset dementia in Cambridgeshire. These patients are managed together with late-onset dementia patients within old age psychiatry services. To inform service design, we sought to characterise young-onset dementia patients in our population. We first analysed service-level data and supplemented this with a detailed case review of 90 patients.

Results

Young-onset dementia remains a relatively rare condition. Only a small proportion of those referred for assessment receive a diagnosis of dementia. Data collected on presenting complaints, comorbidities, medication and Health of the Nation Outcome Scales scores associated young-onset dementia with a greater incidence of depression than late-onset dementia. Outcomes in the two groups did not appear to differ.

Clinical implications

The data presented here do not suggest a need to create a separate service. Practitioners should be aware of the increased incidence of depression observed in this group.

Dementia is a growing national and international problem with associated personal and societal costs. For example, in Cambridgeshire, the number of individuals with dementia is predicted to increase by 86% from 8600 in 2016 to 16 110 by 2031.¹ Of specific interest are those who develop dementia at a young age. Young-onset dementia (YoD) is defined as a diagnosis prior to the age of 65, a cut-off based on the previous retirement age and not on any biological underpinning.² Both YoD and late-onset dementia (LoD) represent heterogeneous groups of patients, which differ from each other in various features besides age. Although the incidence of dementia increases with age, those who develop dementia at a young age have a different profile of diagnosis compared with older people. A greater proportion of YoD patients suffer from frontotemporal lobar degeneration, and they may experience delays in diagnosis.^{3,4} Furthermore, studies have shown a higher neuropsychiatric symptom burden and greater carer stress.⁵ These differences have prompted discussions regarding the need for a separate specialist service for those with YoD.⁶

Currently, YoD patients are treated together with LoD patients within old age psychiatry services. Referrals are made to the same memory clinic, where patients are assessed by a consultant specialising in old age psychiatry, or by a trainee or middle-grade doctor under their supervision. Over the past 4 years, older people's mental health (OPMH) services have undergone a radical transformation in Cambridgeshire.⁷ In order to inform future service design, we therefore sought to evaluate our patients with established YoD and patients under 65 referred for memory assessment, in comparison with those with LoD.

Methods

This project was conducted as a service evaluation with the relevant internal trust approvals from Cambridgeshire and Peterborough NHS Foundation Trust. The trust covers a population of ~1 000 000 people, of whom >165 000 are over the age of 65. The trust provides the countywide memory assessment service, which receives ~2000 referrals per year. Other condition-specific services exist (for example, for Huntington's disease) and sit within the neurology department at the local acute trust.

Referral data are routinely collected by the trust. Health of the Nation Outcome Scales (HoNOS) data were collected as previously described.⁸ We manually reviewed a sample of 90 electronic patient records. This was divided into data for 30 consecutive patients with an established diagnosis of YoD, 30 consecutive patients with a diagnosis of LoD, and 30 consecutive patients under the age of 65 who had been referred to the memory clinic for diagnostic assessment. For each patient, we searched their records to identify the following: presenting complaint, diagnosis, presence of comorbidities, time from symptom onset to diagnosis, current medication, and scores on the Addenbrooke's Cognitive Examination (ACE) and HoNOS. We attempted to minimise the possibility of interrater variability by looking for specific data and using the same source data in the records (the core assessment). The date of symptom onset was determined from the information provided in the core assessment, which is a mandatory form that includes a detailed patient history,

completed by a clinician for each patient. Data for individuals identified with dementia in the young referral group were combined with data from the YoD group during statistical analysis in order to increase statistical power. ²-test, unpaired t-test and Fisher's exact test were used as appropriate for statistical analysis of the data (see supplementary material, available online at <https://doi.org/10.1192/bjb.2020.89>). *P*-values were not adjusted for multiple testing.

Results

We began by looking at high-level data regarding case-load, referrals and outcomes of people with YoD. In March of 2020, the trust had a total of 5818 registered patients with a diagnosis of dementia, i.e. patients on our electronic patient record but not necessarily currently receiving a service. Of these, 135 (2.3%) were under the age of 65. Of 7473 individuals referred for memory assessment between 2016 and 2020, 210 were under the age of 65, corresponding to 2.8% of all referrals. We re-analysed a large data set of HoNOS scores which we had previously reported, in order to investigate differences in presentation and outcomes between YoD and LoD. This comprised data for 173 patients with YoD and 3553 patients with LoD,⁸ representing the subset of total referrals that had a HoNOS score on admission and discharge. Using this methodology, we found significant differences in HoNOS scores on entry to the services (data not previously presented), with higher scores on the behaviour ($P = 0.01$), cognition ($P < 0.001$), hallucinations ($P = 0.01$) and living conditions ($P = 0.04$) domains in the LoD group; and higher scores for depression ($P < 0.001$), occupation ($P = 0.01$) and 'other' ($P < 0.001$) in the YoD group (Fig. 1). There were no significant differences in the other domains. We have previously published data looking at outcomes based on HoNOS scores for both YoD and LoD. Both groups improved in all domains except cognition, disability and activities of daily living. Although some of these changes did not reach statistical significance in the YoD group, this is likely to reflect the lower numbers in that group.⁸ Fig. 1 Bar chart showing mean scores across HoNOS scales for late- and young-onset dementia on presentation. Late-onset dementia: $N = 3553$. Young-onset dementia: $N = 173$. $*P < 0.05$, $**P < 0.01$, $***P < 0.001$. ADLs, activities of daily living.

In order to conduct a more comprehensive investigation into the differences between our YoD and LoD patients, we undertook a detailed case-note review of 30 cases from each group. The demographic details are given in Table 1. We found significant differences between the YoD and LoD groups in terms of comorbidities ($P = 0.002$ for both cardiovascular and depressive) and medication ($P = 0.0003$ for antidepressants, $P = 0.004$ for donepezil and $P = 0.03$ for benzodiazepines). Specifically, we saw a higher incidence of mood as a presentation (Fig. 2a), a greater variety of diagnoses with less Alzheimer's disease (Fig. 2b), fewer cardiovascular and more depressive comorbidities (Fig. 2c), a generally shorter time from symptom onset to diagnosis (40% diagnosed in less than 1 year for YoD compared with 30% for LoD, although these differences were not significant, nor was the difference in mean time to diagnosis of 27 v. 28 months for YoD v. LoD, respectively, Fig. 2d), and more treatment with donepezil, antidepressants and sedative medication in the YoD group (Fig. 2e). We found no statistical difference in total ACE scores or subscores between YoD and LoD (Fig. 2f). Two patients in the YoD group who initially received a diagnosis of dementia subsequently had that diagnosis removed, as it became clear that their symptoms were a result of other psychiatric disorders. Fig. 2(a) Bar chart showing presenting complaints in each group. (b) Bar chart showing proportions of different diagnoses in each group. (c) Bar chart showing number of individuals associated with different comorbidities in each group. (d) Bar chart showing time from symptom onset to diagnosis in each group. (e) Bar chart showing percentage of patients prescribed different medication classes in each group. (f) Bar chart showing mean ACE scores in each category for each group. $*P < 0.05$, $**P < 0.01$, $***P < 0.001$. Table 1 Sample demographics of late-onset dementia, young-onset dementia and young referrals without dementia groups

	Late-onset dementia	Young-onset dementia	Young referral without dementia
Mean age at diagnosis (s.d.)	83.4 (±6.8)	56.4 (±5.4)	55.8 (±7.8)
Minimum age	72	45	35
Maximum age	97	64	64
Male	141	16	17
Female	161	14	13
Mean age of males	82.4	56.0	54.2

We also evaluated 30 cases of patients under 65 years of age referred for memory assessment. When comparing patients referred to our service under the age of 65 with those in the same age group who had received a diagnosis of dementia, we found a number of differences. First, despite the similar average ages of the two groups, there was a greater range in those referred, with one individual as young as 35 years of age who was not subsequently diagnosed with dementia. For total and subscores on the ACE and cognitive scores on HoNOS, those referred scored significantly higher (mean \pm s.d. for total ACE: 84 ± 11 v. 69 ± 17), were less likely to have difficulties with memory as a presenting complaint and were more likely to have neurological comorbidities. The prevalence of diagnosis of dementia in this group was low (27%). No other significant differences were found.

Discussion

The absolute numbers of patients with YoD referred or managed are low, representing just over 2% of referrals and case-load. This is lower than the figure found in the national memory service audit for referral (7%) and at the lower end of the range (0–22%).⁹ It is also lower than many estimates of the prevalence of dementia in this age group.¹⁰ For example, there are an estimated 210 individuals with YoD in Cambridgeshire, but only 135 (64%) of these are currently known to the trust. This difference might be explained by many of the estimates of prevalence being based on epidemiological data, meaning there are likely to be individuals who have the condition but have not yet been diagnosed. Given the increased prevalence of certain conditions leading to dementia in this group, including Huntington's disease and frontotemporal dementia, it is also possible that they are looked after in the relevant specialist neurological clinic rather than by generic mental health services. This may also explain the low percentage in terms of referrals, if doctors in primary care are preferentially referring young patients to neurology rather than psychiatry for assessment.

For the cohort under 65 who were referred for diagnostic assessment, only eight out of 30 (27%) received a dementia diagnosis. This is much lower than national figures for generic memory clinics or those from our previously published audits of our own service, where 60–70% of those referred received a diagnosis of dementia.¹¹ However, this supports previous data from the London memory audit services, where only 15% of those referred under 65 received a dementia diagnosis.¹² Instead, the majority in this group were diagnosed with mild cognitive impairment or other psychiatric disorders. Our analysis of HoNOS scores of patients on entry to the service did not broadly support the idea that YoD patients, at least at presentation, suffer from more neuropsychiatric disturbance. However, the evidence presented here based on HoNOS scores, presenting complaint, comorbidity and medication suggests that this group is associated with a greater burden of depression.

The association of depression with LoD has been well documented, with large-scale studies suggesting that depression is both a prodromal symptom of and a risk factor for dementia, while dementia is itself a risk factor for depression.¹³ A recent meta-analysis reported a prevalence of depression of 25% in those with LoD.¹⁴ This is in contrast to studies of YoD, where depression was found in 66% of individuals.¹⁵ Although assessing depression is difficult in those with dementia, and criteria differ among studies, our data support the idea that patients with YoD may suffer more from depression. From a diagnostic perspective, this is potentially an important consideration when seeing patients in later mid-life who are suffering from mood disorder, which may be comorbid with or indeed be a presentation of YoD. This is also important in terms of management, as depression is both under-diagnosed and under-treated in this population, which may negatively affect prognosis.¹⁵

However, our study did not support previous suggestions of a delayed diagnosis in those with YoD, although we acknowledge the small sample size and difficulty people experience in precisely recalling when the onset of an insidious condition might have been. One possible explanation is that a greater proportion of those with Alzheimer's disease are seen in our service, and fewer of those with rarer and therefore more difficult to diagnose dementias such as frontotemporal lobar degeneration, who may instead be referred to a different service such as neurology.⁴ Another possibility is that our patient population may not be representative of studies in other populations. In terms of socioeconomic background, Cambridgeshire and Peterborough benefit from a slightly higher than average employment rate (78.5% in those aged 16–64 compared with 76% nationwide), as well as a higher percentage working in professional occupations (25.1% compared with 21.5% nationwide).¹⁶ A better socioeconomic background may provide the freedom for individuals to access health services at an earlier stage of the disease, which may be more difficult for those from less advantaged backgrounds. However, this would not explain why a difference between YoD and LoD groups was seen,

as there is no reason to expect a greater effect in one group over another, and we are unaware of any facility for private dementia assessments available in the county.

We were interested to see that two cases initially diagnosed as YoD were subsequently reclassified with a diagnosis of another psychiatric disorder. This is a rare event in LoD and may reflect the lower pre-test probability of dementia in younger people, as well as the frequency of cognitive impairment in other psychiatric conditions. We were reassured that outcomes between patients with YoD and LoD did not appear to differ significantly.

In Cambridgeshire, we have used these data to inform the design of our services for YoD patients. We do not have a specialist YoD team. The low number of patients spread across more than 1300 square miles of a predominantly rural county makes having a specialist team practically challenging. A separate service dealing with YoD would be small by its nature and therefore not robust to any challenge such as staff sickness. Similarly, we do not have specialist clinics within the trust for those with YoD. The data suggesting a high level of psychiatric morbidity in this group make assessment by a consultant psychiatrist appropriate, and we have close links with local neurologists, including cognitive neurologists, for second opinions on cases which might represent Huntington's disease or unusual tau- or synucleinopathies. We do recognise the differences we see in our population and more broadly in the literature in those with YoD and the specific challenges this group can face. Our solution for their management has been to identify an advanced practitioner in each of our community memory teams who leads for YoD. This allows that practitioner to acquire expertise and experience in this area, forming part of a specialist professional group, as well as being part of a larger, multidisciplinary, clinical dementia service, which means the service offer is robust. We have also forged links with our local acute trust to ensure that patients seen in other related services, such as neurology, who receive a diagnosis of dementia are referred to our trust for post-diagnostic support and follow-up. One significant weakness in the data presented here was the lack of direct patient feedback. We do routinely collect quantitative and qualitative data from patients and caregivers. However, owing to incomplete returns from an already small group and not differentiating respondents in terms of age, this remains a significant gap in our knowledge. We will seek to address this in time with a targeted and more detailed assessment of patient experience, as well as detailed exploration of patients' and carers' ideas for service development.

In summary, our data suggest that patients with YoD form a small minority of our OPMH dementia work, and that the size of the population would make the creation of specialist teams difficult when operating over a large area. Young patients referred for assessment were less likely to receive a dementia diagnosis than older patients and were more likely to have psychiatric comorbidities. For those with YoD, their presenting complaint, medication, comorbidity and HoNOS scores all suggested a greater burden of depression. This information has helped us to inform and adapt our generic memory services to ensure a robust response led by staff experienced in this condition.

1.2.27 What have we learnt from Covid?

Mark Steven Salter

date

2021-04

Contents

- *What have we learnt from Covid?*

Early on in the pandemic, many prisoners were glad to learn of their early discharge. Not long after they reached the imagined freedom of their homes, they found themselves in another prison, their incarceration now managed by an invisible viral cloud. We can learn much from this.

In March, I saw a newly released 33-year-old drug dealer. Via video, his daytime flat looked as dark as a cell. He reported anxiety, but his nightmares were worse – he dreaded return to the time he left his cousin to bleed out in a car park, calling the ambulance before he ran. That was 5 years ago, he said, but why is this coming back to me now?

Over months, peering into the homes of patients like never before, I saw how, denied of their routine contacts with the world, long-managed trauma and abuse were reappearing everywhere. Covid reminds us that all of daily life is an adaptive coping strategy; Palmer¹ dryly calculated that even a patient seeing their general practitioner fortnightly for a year would spend 99.95053272% of their life beyond the medical gaze. We should ask patients less about their symptoms and much more about what they actually do all day.

My drug dealer wasn't hemmed in by fear of some bug. He was responding to social imperatives described by Durkheim² over 100 years ago: the sharing of any strong emotion causes predictable changes in that group; consider the nation's behaviour after Diana's death, or that of Sir Captain Tom. My patient was kept under house arrest by the weekly banging of pots and the sudden ubiquity of fear-linked stimuli: what Daniel Kahneman³ describes as an 'availability avalanche'. We were entranced by Boris at six, exhorting us to 'stay home, stay safe'. We hurried back to an elderly couple of wise institutions: the National Health Service and the BBC, which only months earlier Boris had considered cutting. We can discern another lesson here, at a social scale. We should spend less time exploring our patient's heads and pay more attention to the world around them. We have, after all, chosen to treat the only organ in the body that can vote.

Our sudden distance from our patients was no mere social distancing. Unlike the rest of medicine, psychiatry has almost no tests or devices to refine its efforts. Instead, we rely on our ears, our eyes and sometimes our noses. We started looking and listening from behind a screen. The bravest had only a mask. How odd it felt to be suddenly deprived of – and made to appreciate – those countless tiny cues, the sighs, the diverted gaze and its flinching return, and, most of all, the silences. It was not easy to gauge the pain and poignance of those quiet moments that are the stock

of our trade. Like musicians, so much of our work goes on in between the notes. How do you assure someone of your understanding when you have unleashed waves of grief and tears 4 miles away?

For all the optimistic talk of ‘virtual clinics’ in the future, psychiatrists must be wary. Our work is not like the rest of medicine. Distance deprives us of our most important tool, a potent mix of knowledge, interest, empathy and proximity. Without this, we cannot properly grasp the thoughts, feelings and hopes of our patients.

If medical science has taught us one thing over the past hundred years, it is that human suffering is incredibly complex. Many of our responses, our resort to explanatory biological myths and diagnoses of questionable validity,⁴ or the shrinking of our discharge summaries, all are signs of our instinctive retreat from the bewilderment we feel when confronted by complexity. Psychiatry is stigmatised for its apparent inability to match the ‘precision’ of our more bodily focused colleagues.

Although we claim to give equal weight to the biological and the psychosocial elements of our assessments, the truth is that we are drawn to the former, because they seem less challenging.⁵ Covid’s lesson for psychiatry is clear: psychiatry must face the true complexity of mental illness head-on. If we are seen to do this by the rest of the medical profession, our uncertainty in the face of it could become psychiatry’s touchstone rather than its millstone.

1.2.28 The case for cautious paternalism in the emergency management of patients with borderline personality disorder

Giles Newton-Howes

Correspondence

Giles Newton-Howes

(giles.newton-howes@otago.ac.nz)

date

2021-04

Abstract

Principlism is the dominant ethical theory in modern medicine. Autonomy is ‘king’ of the principles espoused and operationalised in consent. Consent is the mechanism by which all medical interactions occur. In borderline personality disorder (BPD) there is often a diffuse sense of self, emotional instability and impulsivity that can lead to medically dangerous non-suicidal self-injury, acute medical intervention and then a withdrawal of consent while the potential threat to the person’s well-being remains high. Claims of lack of capacity lack veracity, and simply acting against the patient’s will may be illegal. Understanding the will and preferences of patients is a step forward, but it is not always possible in time-sensitive situations. A cautious paternalism is therefore warranted both to ensure the patient’s well-being while being honest as to the reasons for this, and to possibly build epistemic trust between the medical system and the patient with BPD.

Principlism has been the dominant force in medical ethics for more than half a century.¹ Its four principles – autonomy, beneficence, non-maleficence and justice – form a common touchstone in medicine, particularly when hard choices need to be made.² Although neither Beauchamp nor Childress, the authors of this bioethical approach, weighted any one of these principles as more important than any other, autonomy has risen as the prominent principle.³ This is not surprising, as autonomy is operationalised into informed consent, the tool doctors use to assess capacity and then engage in clinical action.⁴ Capacity assessment based on principlism is purely process driven, based on whether a patient understands, retains, weighs and answers questions. The content of the decision is explicitly ignored. Where doctor and patient agree, or where the patient agrees with the doctor, an assessment of autonomy through capacity is rarely detailed. There is little need, as all parties agree as to the best approach to take. This is not true, however, when the patient disagrees with the doctor. In these cases, the medical mind is more likely to focus on the issue of capacity, as if it is not present a ‘duty of care’ may suggest a course of action that contravenes the patient’s explicitly stated desires.⁵ Most conventional wisdom and practice dictate that a loss of capacity is, largely, the only legitimate rationale for acting in such a way, and to act differently requires confirmation by the court. Specific mental health legislation is a glaring exception, and efforts to restrict its use or abolish this legislation are occurring in multiple jurisdictions (for example, the new fusion legislation of Northern Ireland). As the risks of a poor outcome increase, so does the doctor’s desire to act differently from the patient’s stated desire, if her desire may have a possible catastrophic outcome. Even if this is the case, the court may honour the patients’ autonomy, despite a guaranteed outcome of death. Put simply, autonomy is king, and to dethrone the king is socially and legally increasingly less acceptable. The question is whether this approach is the best one for patients with borderline personality disorder (BPD).

The challenge of BPD

BPD is characterised by a diffuse sense of self, difficulty in understanding affect, intense unstable interpersonal relationships and impulsivity.⁶ These features of the disorder are pervasive, reaching into all areas of a person’s life. They commonly, but not exclusively, arise in adolescence and cause considerable morbidity to a young population.⁷ Health services are often engaged in the management of patients with BPD, as they are treatment-seeking, recognising their emotional and interactive difficulties and experiencing significant distress because of them. Psychotherapeutic approaches support long-term improvement; however, personal responses to short-term distress often include thoughts of suicide and non-suicidal self-injury (NSSI). Both expressions of suicide and NSSI cause significant distress to health-care workers inside and outside mental health and can be difficult to manage. For actions that lead to self-harm, it can be difficult to ascertain whether the antecedent to the action is an effort to end life, or some other cause such as to regulate emotional distress or ‘feel something’. If the purpose of NSSI is to regulate emotion, then the support and investigation of emergency services may provide sufficient supportive human contact to allow the emotional storm to pass. Now the patient sees no need for treatment, and this can be very distressing to medical staff, particularly if the NSSI is potentially lethal. Life-threatening overdose is an excellent example of this. In these circumstances, medical staff can see the potential danger of non-adherence to emergency treatment, whereas the patient, with a clear sensorium and who clearly understands the information provided, may still demand to go home as their immediate emotional needs have been met.

The clinical conundrum

This is a clinical conundrum: in observing the patient's autonomy, one appears ethically obliged to do what may be (or certainly is) life-threatening. Disregarding the patient's autonomy to preserve life appears ethically dubious, as autonomy is after all king.

Questioning capacity

In such cases, the default position has largely been to question capacity. This is internally consistent with the bioethics of principlism, which is built on a normative moral philosophy. Such normative moralities are not dependent on a series of complex ethical foundations, rather, central to their claim is the idea that the morality of a society's members, common sense and tradition are its basis (see Ref. 2, pp. 3–10, where the notion of a 'common morality' is spelt out). Principlism is, however, in direct conflict with the growth of a human rights ethic, which values autonomy as separate from any such normative requirement. Indeed, this human rights ethic challenges the normative position of enabling one person to do something to another without their consent. This recognises the increasingly diverse components of society and the need to ensure all have equal rights. The Convention on the Rights of Persons with Disabilities (CRPD)⁸ is the clearest example of this. The CRPD, of which most nation states are signatories, requires signatories to uphold the equal rights of those with disabilities, including those with mental health conditions, as being equal to those without such disorders. The basis of this is a social model of disability.⁹ The social model directly challenges the normative tradition of our bioethics, on which ethical clinical practice is based. It suggests that a key problem with the medical model is the way society limits freedom and choices. For example, a medical model states that those who cannot see should not drive. This seems obvious and incontrovertible. The social model of disability challenges this to say that those who cannot see should be allowed to drive, in cars appropriately equipped to ensure they and others are safe, for instance, self-navigating cars. This combination of a human rights ethic and the social model of disability challenges the ethical validity of principlism, its common morality.

In the clinical conundrum described above, the appeal to a failure of capacity usually relates to an inability to weigh the evidence in the balance (by way of process). On these grounds, capacity – and ergo autonomy – fails, and the doctor has a duty of care to step in. This stance is not the case for many people with BPD, who largely retain this ability. This means that preventing a patient with BPD from leaving hospital, as described above, breaches their human right to autonomy. This 'medical model' approach is also challenged by the social model of disability. This model places the need for care in society (for example, by providing care at home) and would not support retaining someone in hospital despite the potentially life-threatening consequences of leaving. There are, therefore, no ethical grounds to act in such a way using either a principlist or a human rights ethic. So, if patients with BPD can make cross-sectional autonomous choices that may have catastrophic consequences, should they be freely allowed to do so?

The third way: will and preferences

Using a purely process approach to capacity clearly fails to ensure the well-being of a patient with BPD in a situation such as a life-threatening overdose if she refuses medical treatment. Simply withdrawing treatment may also fail to ensure the well-being of patients with BPD in the same circumstances. Are clinical staff doomed to fail such patients? The answer to this seems to lie in a clearer consideration of the notion of autonomy. Regardless of whether autonomy is normative (as the bioethicists purport) or idiosyncratic (as the human rights proponents purport), it implies a sense of self, a notion of understanding 'who I am and what I want'. Further, it implies a sense of continuity to these expressed desires, desires that could be reasonably expected to change only slowly over time. Without these two implied requirements, a clear sense of self and a temporal stability to this sense of self, both idiosyncratic and normative judgement become mere chaos, a changeable noise without foundation. This identifies a third way forward: rather than focusing on the capacity process, an understanding of the content of the decision and the context of the person may allow a more nuanced understanding of autonomy and, subsequently, capacity. The focus then shifts from a response to the cross-sectional assessment of how you are now to an assessment of what you may want across time. Such a shift necessarily requires consideration of the content of the decision, as well as the process of decision-making. This has been described as weighing an individual's will and preferences,¹⁰ as opposed to focusing on the process of decision-making in capacity or a cross-sectional assessment of this decision at this time. This appears to be a more

authentic form of considering decision-making capacity.¹¹ In the case of the patient who has taken a life-threatening overdose, this might lead to a completely different decision. Rather than allowing such a person to leave the emergency department, considering their process of decision-making to be intact, they may be kept to ensure their safety based on their longer-term will and preferences (for example, plans for the future). This move towards will and preferences-based decision-making in medicine appears to be a significant step forward. It recognises the individual and idiosyncratic rights of the person. It supports the person to make the best choices for them in their context, and enables the medical system to be clear that it is doing the best for the patient, not simply leaving them to their fate. Although only required in cases of disagreement, this process is likely to be lengthy, and requires information from collateral sources and repeated interviews to develop such a nuanced sense of will and preferences.

The case for a cautious paternalism

None of this is likely to be possible in emergency settings where decisions are time critical. Added to this in people with BPD is a diffuse sense of self, a core characteristic. Such a clear understanding of will and preferences is likely to be an order of magnitude more difficult to understand in such circumstances. The patient herself may not understand her own drives or why life is so emotionally and interpersonally distressing. In these circumstances, the reality of clarifying will and preferences in an appropriate and consistent manner is very unlikely. Rather than defaulting to an obviously flawed argument to suggest the patient lacks capacity, a cautious paternalism may be more honest, supportive and applicable. Despite some of the difficulties for people with BPD in general, a sense of understanding others is clear, and using a flawed system, in which they are considered to lack capacity, simply increases distrust in the medical system and medical model of care. Cautious paternalism recognises the difficulties of a consistent sense of self for people with BPD and of understanding their will and preferences in a timely manner. It does not rely on a tautological suggestion of a lack of capacity for patients who disagree with medical decisions (because you disagree with me, you *ipso facto* lack capacity). Rather, it provides medical support for well-being and potentially increases epistemic trust¹² between the patient and the medical system, a trust that people with BPD have significant problems with. This is likely to require the time and skill to engage with the patient to persuade them of the need for review and reassure them of the intent to support autonomy while at the same time recognising the limits to this inherent in their presentation. If they leave, then accessing support (for example, via family or police) to return them to the emergency department recognises the limits to autonomy implied by this presentation and prevents possible ill-considered catastrophic harm.

Such a cautious paternalism may help to find a way forward that enables people with BPD to both receive adequate medical care in emergencies and develop trust in a system with the possibility of longer-term therapeutic support.

1.2.29 Psychoanalysis in the treatment of autism: why is France a cultural outlier?

D. V. M. Bishop Joel Swendsen

Correspondence

Dorothy Bishop

(dorothy.bishop@psy.ox.ac.uk)

date

2021-04

Abstract

In most countries, social or behavioural interventions are recommended for autism. However, in France, psychoanalysis is still used, despite objections by patients, families and mental health experts. Supporters of psychoanalysis maintain that the choice of therapeutic approach is a matter of cultural preference, and that objections to psychoanalysis arise from misunderstandings. We argue that more deep-rooted problems are the lack of an evidence base for psychoanalysis and its focus on sexual relationships between children and adults, which demonises mothers and can put children at risk of abuse. Furthermore, psychoanalysis in France is protected from criticism by powerful educational and political networks.

Psychoanalysis as an intervention for child language disorders

There have always been geographical differences in the practice of medicine, even within Western societies, but in psychiatry, especially child psychiatry, national variations are taken to extremes. The first author realised the enormity of the divide between French and British practices in 2001, when asked to write an endorsement for *The Silent Child: Exploring the World of Children Who Do Not Speak* by Laurent Danon-Boileau.¹ The book's author was described as one of France's most respected child psychoanalysts, with a particular interest in language. The book contained a series of case studies of children who did not have any formal diagnoses but appeared to fit criteria for autism, intellectual disability or dyslexia. As Law² noted in a review, there was no recognition of developments in social cognition and developmental psycholinguistics. Rather, there were confident assertions about the child's inner state, and children's lack of communication was generally attributed to affective and motivational causes relating to psychodynamic factors, rather than to any problems with understanding or formulating language.

To a child language expert, it is surprising that anyone should imagine psychoanalysis, the quintessential talking therapy, would help a child with impaired communication. Yet psychoanalysis is still taken seriously as an intervention for autism in a few countries, with France being the most notable example. This was documented in a film, *Le Mur*,³ produced in 2011 by journalist Sophie Robert. In a series of interviews, child psychoanalysts interpreted language limitations in their young clients through the lens of psychoanalytic theory. The parents were directly implicated in causing autism, and the child's communicative problems were regarded as a reflection of a difficult parent-child relationship. The flavour of the content is conveyed by a few direct quotes from the English transcript. "‘What we can notice when we take care of autistic children is precisely that autistic children are sick of language. That autism is a way to defend themselves from language.’ (Esthela Solano) ‘At the beginning, the child thinks that he is his mother's phallus. Namely that he is this object that would give everything, fill his mother with joy, make her have orgasm . . . The father is there to forbid and at the same time protect the child. That is, to protect the child from the incestuous desire of the mother.’ (Yann Bogopolsky)"

Laurent Danon-Boileau was one of the interviewees. It was illuminating to hear him describe a session with an autistic child; he did not seem to see his part as to facilitate the child's development, but rather to adopt a passive, interpretative role.

Le Mur was shocking for autism experts outside France. Although there are child psychoanalysts in the English-speaking world, they are a small minority and recommendations by the National Institute for Health and Care Excellence⁴ for intervention in autism make no mention of this approach. In the UK, autism is regarded as a neurodevelopmental condition with a predominantly genetic aetiology, and intervention focuses on working directly with social communication and behaviour. The goal is to bring about an improved developmental trajectory, rather than gaining any insights into the deeper meaning of the symptoms.

French cultural and political influences on acceptance of psychoanalysis

It is worth reflecting on how such differences in practice have come about. Language barriers play a part in preventing the flow of ideas across national borders, but this cannot account for the unique status of psychoanalysis in France, where it is celebrated and protected.

Houzel,⁵ in recounting the history of psychoanalysis as a treatment for autism, noted that French society has ‘a very marked cultural identity that results in a certain impermeability to external currents of thought’ (p. 742). For Houzel, himself a psychoanalyst, this has certain benefits: ‘One advantage is a capacity to resist certain fashions that is no doubt greater than elsewhere. That is why France remains today a country where the application of psychoanalysis to the treatment of autists persists in spite of all the attacks that it is subjected to’ (p. 742).

Houzel further noted how French intellectuals are drawn to abstraction and speculative theorisations; these are exemplified by the work of Jacques Lacan, who did not himself work with children but developed an influential system of thought, based on Freudian theory, with its own specific French flavour. Its appeal to French intellectuals remains a mystery to those of us with a less credulous frame of mind, who suspect that when an author writes obscurely it is not because the ideas are brilliant, but because they are using verbiage to hide muddled thinking. As Billig⁶ concluded: ‘academic authors do not advance the cause of critique by putting their readers in a subservient position where authority has to be taken on trust and where obscurity takes priority over clarity’ (p. 22).

Houzel's paper put the development of psychoanalysis in France in a historical context and noted its cultural and political influences, but it also emphasised the extent to which psychoanalysis, as a treatment for autism and related developmental disorders, has come under repeated criticism over recent decades. Some parent organisations have attacked psychoanalysis on the basis that their children are denied the kind of interventions that are routinely available in other countries.⁷ In 2012, a political bill was put forward to the French National Assembly calling on the government to ‘condemn and prohibit psychoanalytic practices in all their forms concerning the treatment of autism’.⁸ In parallel with these developments, there have been a series of National Autism Plans, starting in 2005; there is now significant funding of research from the perspective of autism as a neurodevelopmental disorder and a cadre of French autism researchers with international standing.⁹ Yet French psychoanalysts remain politically powerful and have waged a campaign against those who challenge them, including an attempt to sue director Sophie Robert on the grounds that *Le Mur* misrepresented their views.⁷

Psychoanalytic interpretations of maternal factors in aetiology

Houzel⁵ suggested that the chief reason for rejection of psychoanalysis is a mistaken belief that psychoanalysis blames mothers for their children's difficulties. He argued that this is not the case: psychoanalysis is not adequate for identifying aetiologies, and 'Its quest is more in the direction of meaning than that of cause' (p. 731).

To maintain that psychoanalysis does not blame parents seems disingenuous. There are many varieties of psychoanalysts, and it is true that some, including most British psychoanalysts, overtly state that parents should not be blamed for their child's difficulties.¹⁰ Nevertheless, in France, the role of parents, especially mothers, in causing disorders has been a core feature of psychoanalytic work with children. Briggs¹¹ noted how the work of Bruno Bettelheim had been influential in France, with his view of cold, rejecting mothers (the classic 'refrigerator mother' of Kanner) from whom the child withdraws into his shell. Bates⁷ cited numerous examples of mothers being told bluntly that they were responsible for their child's autism, although the more common accusation was that mothers were overinvolved and 'smothering', with an unhealthy desire for the child that led to the child being unable to achieve a separate identity. *Le Mur*, and a more recent film by Sophie Robert, *Le Phallus et le Néant*,¹² contain several examples of psychoanalysts putting forward such viewpoints.

Bates⁷ noted that these ideas fell on fertile soil in France, as they fitted well with notions of toxic mothers already endorsed by French psychoanalysts. Several relevant quotes by Françoise Dolto, one of the most influential French child psychoanalysts of the last century, can be found on the Freud Quotidien website,¹³ including this on autism: "'The child wants what they see the adult wanting. If they focus the desire of the adult, the source of the desire in them dries up and what remains of it is inflected on their own vegetative material person, causing autism, that is to say disorders of its spatio-temporal reference and of communication. This mental illness, leading in the worst case to infantile dementia in a previously open and intelligent baby, is established in the infant separated from all their references. It has also been called "hospitalism" which, at all levels, depending on the duration of the pain, is in fact a disease of the desire. While needs are preserved, desire loses in this child its magnetic vector calling for communication. but "hospitalism" can also be observed in a family environment, in infants whom the mother or rather the neurotic employee isolates in an obsessive way by exclusive possessiveness, or who is the object of perfect care, technically speaking, given without joy by a depressive adult' (translated by Julien Basch)."

Rejection of the need for a conventional evidence base for psychoanalysis

Houzel also bypassed two further objections to psychoanalysis, which are particularly concerning to any dispassionate observer of French child psychiatry. The first is the lack of any accepted evidence base for psychoanalytic treatments. Houzel⁵ regarded behavioural approaches to intervention as mere fashions in reductionist thinking, and noted that they have not been strikingly successful in gaining understanding of the nature or causes of autism, nor in creating improved outcomes for children. This point has some justification – progress has certainly been slow and there is no miracle cure.¹⁴ The difference compared with psychoanalysis, however, is that these developments occur within a scientific framework that allows one to test the ideas and reject those where the evidence does not fit. Popper¹⁵ used psychoanalysis as one of his classic examples of pseudoscience, able to explain all phenomena but with no possibility of being disproven: if the scientific framework is itself rejected, then any viewpoint is as valid as another. Billig⁶ pointed out that Lacan's supporters ignored attempts by experimental psychologists to evaluate his work, because they regarded orthodox psychology as invalid; yet, even when considered in its own terms, Lacan's citation of evidence was sloppy and inaccurate. Sokal and Bricmont¹⁶ were particularly harsh on Lacan, for producing obscure writings with all the trappings of technical language and concepts but no coherent meaning. Consistent with this, Law² noted that Danon-Boileau¹ did not engage in any discussion of evidence-based practice and indeed seemed to make a virtue of his lack of reading in the area. The impression is that many French psychoanalysts regard themselves as revolutionary thinkers who, in rejecting mainstream science, are challenging the conventional power structures in society. But they ignore the potential for abuse of adults' power over children, who are defenceless against having their thoughts and motivations interpreted in terms of the analyst's unevidenced theory.

Psychoanalytic accounts of sexual relations between adults and children

A different type of critique of French psychoanalysis is highlighted in Robert's most recent film, namely, that it has been used to validate incest and child abuse. Freud, and his follower Lacan, regarded children as sexual beings, strongly influenced by erotic desire for a parent and preoccupied by concerns about castration, lack of a penis or violence. Given that these are seen as universal human desires, incest and paedophilia are regarded as natural phenomena. According to this view, psychic conflicts are largely due to the need to fit in with the norms of a society that strictly prohibits such behaviours and hence to repress natural instincts. The focus on child sexuality was one reason that many of Freud's contemporaries ultimately broke away from him;¹⁷ he was seen as imposing his own dogmatic views, derived from his self-analysis, on others, treating concepts such as the Oedipus complex and castration anxiety as universal, to the neglect of other, non-sexual risk factors for mental disturbances. In *Le Phallus et le Néant*, we see how this viewpoint can open the way for abusive relationships between a powerful therapist and vulnerable children.

The risk of abuse needs to be viewed in relation to a distinct French cultural perspective with regard to an age of consent.¹⁸ In 1977, a group of 60 prominent intellectuals signed a petition that was published in *Le Monde*, coinciding with the trial of three men who had been accused of having sex with 13- to 14-year-old children. The argument in the petition was that children had the capacity to consent to sex, and that adoption of an age of consent was patriarchal and a denial of children's rights. A similar petition was published 1979, in support of a man on trial for having sex with girls between the ages of six and 12. 'Desire and sexual games have their place in the relationship between children and adults' was the argument put forward, with the claim reiterated that children's rights were being abused by denying them sexual gratification.

One signatory of the 1977 petition was Françoise Dolto, a media-friendly psychoanalyst who regularly appeared on a radio programme between 1976 and 1978, where she answered parents' questions. In 1979 she was interviewed by the magazine *Choisir* on the topic of incest; a transcript can be found online.¹⁹ Her responses indicated that she regarded children as willing participants in sexual activity who should take responsibility for their actions. The same website reported quotes from a 1999 book, *L'Enfant, le Juge et la Psychanalyste*, in which Dolto discussed with judge André Ruffo the legal implications of sexual relationships between adults and children. Dolto recommended that children should be taught early that sexual contact with an adult is against the law, so that there will be no doubt about their complicity if they do engage in such activities: "If children knew that the law prohibited sensual privacy between adults and children, well, from the moment an adult asks her, if she accepts, that makes her an accomplice, she doesn't have anything to complain about' (authors' translation)." Dolto continues to be held in high regard in France. Not only has Paris named a street after her, but in 2018 the government printed a special postal stamp in her honour. *Le Phallus et le Néant* makes it clear to what extent her legacy lives on, with interviewees maintaining that children are sexual beings who are capable of behaving provocatively towards their parents, who must repress their 'inner paedophile drive'.

Such discourse is not merely symbolic: it has real consequences for children. Growing unease in French society about the cultish status of psychoanalysis came to a head this year with the publication of a book *Le Consentement* by Vanessa Springora,²⁰ who described how at the age of 14 she was drawn into a sexual relationship with a celebrated 50-year-old writer, Gabriel Matzneff. Matzneff was one of the signatories of the 1977 petition for decriminalising paedophilia. He defended himself by arguing that his relationship with the teenaged Springora and others of her age were love affairs.

No doubt there are many child psychoanalysts who would be horrified at the notion that their methods were being used to defend incest and child abuse. The problem, though, is that if someone were inclined towards paedophilia, then Dolto's version of psychoanalysis would appear very attractive, promoting as it does the idea that sexual relationships between adults and children, while prohibited by society, are a natural and therefore blameless aspect of the human condition. Psychoanalysis can provide professional respectability, a good income and access to vulnerable children. We should be clear: we are not saying that these views are common among French child psychoanalysts. Nevertheless, so long as the psychoanalytic movement in France sets no limits as to what can count as psychoanalysis, it runs the risk of causing harm to children, as well as to its profession.

Continuing power of psychoanalysis in French political and academic life

The key question is no longer how France arrived at this point but rather how it cannot seem to fully get beyond it. Although psychoanalysis is now marginal in France for psychiatry as a whole, it is a different story for the subdiscipline of child psychiatry that has been dominated by this orientation for decades. In 2012, the High Health Authority of France implemented recommendations for the treatment of autism, but they were not obligatory and inefficient psychoanalytical therapies continued to be proposed for individuals with autism.²¹ Even though new generations of physicians are trained in evidence-based treatments, the older generations that were trained to see psychoanalysis as a viable treatment for autism are still in practice. This presence is visible at all levels of the French healthcare system, including public hospitals, clinics and private practice. Perhaps the biggest problem in France concerns the training of clinical psychologists. Psychologists are ten times more numerous than psychiatrists, and they occupy a large number of positions in clinics and hospitals treating children with autism. The second author, an expert for the National University Council (Conseil National des Universités), recently provided a scientific criticism of psychoanalysis as well as quantitative analysis of the training received by clinical psychologists in French universities.²² This analysis demonstrated that of the 26 universities charged with the training of clinical psychologists, half still provide substantial psychoanalytic training. In nine of these universities, the training provided in clinical psychology is *exclusively* psychoanalytic in orientation. Clinicians trained in these institutions are not routinely exposed to evidence-based approaches in the treatment of autism (or other mental disorders, for that matter), and no national examinations or professional licensing criteria require them to have such training before assuming positions at hospitals throughout the country. The French government and university presidents have turned a blind eye to this psychoanalytic monopoly at institutions of higher education.

In sum, the defence of psychoanalysis as a treatment for autism rests on the idea that choice of one form of therapy over another is purely due to cultural preferences and fashion. A deeper investigation, however, reveals that psychoanalysis is qualitatively different from other forms of therapy. It is not only bereft of any evidence of effectiveness, but it is so ill-defined that it is unclear what such evidence would look like. It is only legitimised because it is promoted by authority figures and maintained by circles of power and influence. Moreover, in its more extreme forms, it has potential to cause damage to parents, especially mothers, who are demonised both for being too involved with and too remote from their children, and to children themselves, who are regarded as seducers rather than victims when involved in sexual relationships with adults.

1.2.30 Denise Assunta Coia (Macdonald), DBE, FRCPsych, FRCPSG, FRSE

Alexander L. Macdonald Andrew C. Macdonald

date

2021-04

Contents

- *Denise Assunta Coia (Macdonald), DBE, FRCPsych, FRCPSG, FRSE*

Formerly Consultant Psychiatrist and Principal Medical Officer to the Scottish Government

Denise Coia, who died peacefully on 9 April 2020 at the age of 67 after a short illness, was a leading Scottish psychiatrist with an international reputation. From 2011, on its foundation, she was the first Chair of Healthcare Improvement Scotland (HIS). In this capacity, with great tenacity, she skilfully built a strong and internationally respected organisation that drove through improvements in the quality of healthcare in Scotland. She was courageous enough to assert the organisation's independence from government and Ministers, through the publication of some hard-hitting hospital inspection reports.

She found interesting metaphors to express her thoughts and was often open and candid in doing so. Fearing that, without reform, the National Health Service (NHS) could consume infinitely more resources, she took the opportunity – in an HIS public annual review meeting with the government – to give Ministers a warning about a possible parallel with the fate of the world's only seven-masted schooner, the *Thomas W. Lawson*. In simply adding more masts to compete with steamships, the schooner had not kept pace with the revolution in maritime trade. Ultimately, it failed, sinking in a storm. Denise's message was abundantly clear – there was a need for the NHS to redesign and change with the times to survive.

Throughout her career, and especially in her later years, she championed the mental health of children and young people. Denise passionately believed in investing more in child and adolescent mental health services. She was therefore a natural choice to Chair the Scottish Government/Convention of Scottish Local Authorities (COSLA) Taskforce on Children and Young People's Mental Health. In her last few years, she also served as Convenor of Children in Scotland. In her typically energetic and inclusive way, she initiated a huge listening exercise across Scotland and relished the

chance to talk to hundreds of people but most importantly children, young people and families. Her response when hearing excuses about service failures was that she was listening to what children and young people were telling her and, under her watch, the failures they had experienced would not be repeated.

Earlier in her career as consultant psychiatrist at the Florence St Day Hospital and Leverndale Hospital, Glasgow, where she served from 1987 to 2011, she was largely based in the Gorbals, one of the most deprived communities in Glasgow. It was there that she developed her life-long commitment to improving the mental health of the most vulnerable and disadvantaged in society. She was one of the pioneers of specialist community mental health services across Glasgow. From 1998 to 2006, she served as part-time Mental Health Advisor to Greater Glasgow Health Board. Then, on secondment from her consultant post, from 2006 until her retirement in 2011, she was part-time Principal Medical Officer Mental Health to the Scottish Government. She was an honorary senior lecturer in the Department of Psychiatry in the University of Glasgow.

Denise took considerable interest in medical education and in supporting the development and training of junior doctors. She chaired the General Medical Council (GMC) Quality Scrutiny Group overseeing the quality of postgraduate and undergraduate medical training in the UK. With Professor Michael West, she also led an extensive review into the mental well-being of medical students and doctors, which was published in 2019 under the title *Caring for Doctors, Caring for Patients*.

An only child, Denise Coia was born in Glasgow on 4 June 1952. Her father Joe and her mother Jill (née Dummer) ran a local fish and chip shop in Milngavie, where she was brought up. She attended Glasgow's Notre Dame High School and subsequently won a place to study medicine at the University of Glasgow. She graduated in 1976 and initially trained for a career in obstetrics, but finding this 'boring', she switched to train in clinical psychiatry. She trained in the South Glasgow registrar training scheme based at Leverndale & Southern General Hospital, followed by senior registrar training in the West of Scotland scheme.

Denise had a passionate interest in art. In Glasgow's European City of Culture year in 1990 she established an exhibition from her mental health centre base of artwork by those who had suffered mental ill health and their carers.

Among many official positions, Denise served as Vice President of the Royal College of Psychiatrists UK and Chair of the Royal College of Psychiatrists in Scotland. She was in receipt of many public honours, being appointed Dame Commander of the Order of the British Empire in 2016. She was elected a Fellow of the Royal Society of Edinburgh in 2018.

Even with all her achievements, Denise remained firmly down to earth. She brought *joie de vivre*, laughter and a wonderful sense of humour – always with a sparkle and not without a hint of mischief and self-deprecation. Denise drew admiration and respect from all quarters for her personal courage and straight talking. She had a formidable intellect and enjoyed robust debate but was always ready to see the other side of a well-argued case. She loved socialising and catching up across her wide network of friends and colleagues – and particularly enjoyed exchanging news. This was still evident even in the weeks before her health finally deteriorated – she was always planning the next coffee or lunch. She had many outside interests, including tennis, art, horse riding, skiing and reading.

She met her future husband Archie Macdonald, originally from Benbecula, a marine engineer with Caledonian MacBrayne, at Glasgow University. They married in 1977. She was immensely proud of their two sons, Alexander, a paediatric surgeon in London, and Andrew, an interventional radiologist in Oxford.

Denise leaves behind her beloved husband Archie, her sons Alexander and Andrew and three grandchildren.

1.2.31 Are summer schools a way to improve recruitment in psychiatry?

Aileen O'Brien

Correspondence

Aileen O'Brien (aobrien@sgul.ac.uk)

date

2021-04

Abstract

Summer schools are traditionally used to encourage sixth form students to consider a career in medicine. Is it worth attracting students earlier in their school career, concentrating on psychiatry? Wyke et al describe an innovative project attempting to do just that.

Contents

- *Are summer schools a way to improve recruitment in psychiatry?*
 - *Supplementary material*

Summer schools – where prospective students are invited to a university or other setting during the holidays – are a well-established way of encouraging students to consider applying for a particular course. They are usually a week long and are aimed at particular groups of students, for example, international students or those from more deprived backgrounds. Although they are traditionally held on campus, there would be scope in the future to run them remotely, depending on the COVID-19 situation.

Medicine has traditionally been and remains a competitive course, but medical schools are also in competition with each other to attract students. The most prized students for financial reasons are international students, as they pay higher fees (one of the reasons COVID-19 presents a financial risk to many universities).

The widening participation agenda – attracting students from more deprived backgrounds – is another financial inducement for universities. Unless universities can prove their commitment to this, which is surprisingly hard to measure and evidence, they are not allowed to charge high-rate tuition fees. Students from such backgrounds are a group often targeted for invitation to summer schools by universities.

The #ChoosePsychiatry campaign has tried to encourage doctors to choose the specialty – and to an admirable extent has succeeded, with rates of juniors going into psychiatry increasing.¹ The campaign to choose psychiatry includes a target audience of sixth formers who have already chosen to study medicine. As the conversation about mental health, especially post COVID-19, becomes part of the national *zeitgeist*, are we missing a trick in not trying to interest psychologically minded students into medicine earlier than sixth form? Wyke et al describe an innovative 1 week summer school for GCSE students, not all of whom had decided on medicine as a potential career.² The week included talks from psychiatrists at different levels of training, groups and debates, and the students met patients and medical students. At the end of the week, students were more likely than before to choose psychiatry as a career, had changed their views regarding social restriction in mental health and had uniformly positive attitudes towards the course.

Some of these students will presumably have gone to the summer school in order to build their CV, having already decided to apply for medicine, but who knows whether a psychiatry spark has been lit in a budding doctor who wouldn't have considered the specialty otherwise?

It may be well be that the resources and expense required for the project, which were not evaluated in Wykes's paper, are not worth the long-term results. It will be very interesting to see how many of these teenagers do study medicine and choose psychiatry. We know that many students interested in psychiatry at the start of medical school are put off by the 'badmouthing' of the specialty by their educators and peers,³ so hopefully those enthusiastic students will not have their initial enthusiasm knocked out of them along the way. Others may ultimately decide not to study medicine, or to study medicine but not choose psychiatry; if so, at least a group of bright adolescents have had their eyes opened to the subject and had stigmatising clichés about psychiatry challenged.

Aileen O'Brien is a Reader in Psychiatry and Education at St. George's University of London, UK.

None.

Abstract

Mental health staff may have limited exposure to emergencies associated with obsessive–compulsive disorder (OCD) during postgraduate training. The first time they encounter a person in the midst of severe obsessions, or one who has compulsively self-harmed in response to such obsessions, might be when working on call covering the emergency department. This educational article presents the lived experience of one of the authors as a clinical scenario. The scenario is then used to illustrate the severity of disability and the rates of self-harm and suicide-related mortality caused by OCD. The recognition and assessment of OCD is described, along with what helps in emergency situations. Written informed consent was obtained for the publication of clinical details.

Scenario

Doctor’s perspective

You are the doctor on call for psychiatry. The emergency department registrar has referred a 37-year-old professional who is in resus with police in a state of extreme distress, with self-inflicted chemical burns from corrosive alkali on her arms and torso, and haemoptysis caused by the associated fumes. This is her 133rd attendance in 4 years. She is repeatedly saying, ‘It’s all contaminated, I need to go’. A member of the crisis team has advised you to refuse the referral, because seeing the patient would reward her attention-seeking behaviour. When you access her records, there is a ‘yellow flag’ advance plan which states she attends the emergency department frequently and should not be seen by psychiatry.

Patient’s perspective

I am the patient. I don’t want to be here. The police restrained me, put me in a cage in the back of a van and brought me to hospital ‘voluntarily’, after finding me walking down the street coughing up blood on my hands and clothes. I’m terrified. I’ve been worrying for several days that I’ve hurt or killed people. I’ve had worries like this since primary school, but things have got worse again lately. Because I keep thinking I’ve killed someone, when the police stopped me I thought they were arresting me for murder. Now I’m in resus, I’m worried the other patients here are hurt because of me. I can feel contamination under my skin that is hurting people, and I have been trying to get it out. I used to use soaps and bleaches, but they didn’t work, so I now use corrosive alkali to try to remove the contamination. I needed to go to the shop to buy more when the police stopped me. I’m scared the staff will get contaminated too, and I don’t want them to touch me. They want me to take off my clothes, and they’re holding me down to try to put a line in my arm, and I can’t. I just need to go. I need to sort out the contamination and I don’t want anyone else to be hurt.

Question 1: How would you respond to the emergency department registrar? (a)Refuse the referral because seeing the patient would reward her attention-seeking behaviour.(b)Refuse the referral because there is a care plan saying the patient should not be seen.(c)Accept the referral and go to assist the emergency department staff as soon as possible.(d)Accept the referral and tell the emergency registrar that you will see the patient only after she has been ‘medically cleared’.

Answer: (c)

Best practice guidance is clear: people attending hospital after an episode of self-harm should all receive a biopsychosocial assessment by a clinician with adequate skill and experience, and this should not be delayed by waiting for medical treatment to be completed.¹⁻⁴ Although the last health service contact for many people who die by suicide was with a general hospital, only around half of people attending emergency departments with self-harm receive a psychosocial assessment.^{5,6} Pejorative terms such as ‘attention-seeking’ persist in clinical practice; they do not justify the withholding of psychiatric assistance, may be related more to animosity and shaming directed by healthcare staff towards people who self-harm, and have no place in advance care planning.⁷ Advance care planning for people who

have attended emergency departments frequently should be co-produced, should never be used to exclude a person from treatment, and must include a preventive care plan as well as a response plan if it is to be effective.⁸ Mental health flagging should be used cautiously: in some settings it has been found to harm rather than help.⁹ In reality, each occasion offers an opportunity to engage, to support, to advocate, to challenge stigma and discrimination, and to play one's part in establishing a trusting, compassionate and respectful relationship with healthcare services.

Doctor's perspective

You go to see the patient as soon as you can. She is clearly distressed, still coughing up blood, asking staff to leave her alone and repeatedly saying 'I need to go, it's all contaminated'. The medical team recommend a chest X-ray to assess haemoptysis, and transfer to the burns unit. Although she is in no state to give a coherent psychiatric history, she is clearly in need of help and your emergency department colleagues are reassured that you have come to assist. You offer her lorazepam and she declines, saying 'I need to go, I'm hurting people'. You assess her capacity to decide whether to stay or go and conclude that she cannot currently use or weigh information about her health, and that it is in her best interests to stay for emergency medical treatment. By remaining with her to explain what is happening, listening to her concerns and encouraging your emergency department colleagues to be patient, you are able to gradually help her calm down sufficiently to accept medical attention without restraining or sedating her.

Patient's perspective

Turning up to advise the medical staff and to help me makes a huge difference. When I'm worried about contamination and in a cycle of compulsions, being in the emergency department is terrifying. 'Medically cleared' is unhelpful: if I leave hospital as soon as I can for fear that I am contaminating and killing the staff and other patients, there will never be a point where I become sufficiently 'medically cleared' to receive psychiatric help. There is an element of immediacy in what is needed, in guiding medical staff to help and to consider my capacity. Looking back now at the injuries I have and how they have affected my ability to work in my profession, I wish more had been done to understand how much I could weigh information when I had serious injuries, but I was also feeling I needed to decline treatment and leave because I was contaminating people.

Doctor's perspective

On mental state examination, she has repetitive intrusive thoughts that she has unintentionally hurt or killed people, and a deeply unpleasant crawling sensation just beneath her skin, which she believes is an unexplained contamination that can spread to others without physical contact. The purpose of chemically burning her skin is not to address emotional distress, nor to inflict pain or injury, but to neutralise this contamination, thus ensuring the safety of others. She describes the risk of dying or losing a limb as 'collateral' for ensuring others are safe. On systematic enquiry, you identify that she eats minimally and only from sealed packets for fear that food is contaminated. She spends long periods walking or running outdoors until she has reached a 'safe' (prime) number of miles. She has significant anxiety associated with non-prime numbers, which feel 'unsafe' and may somehow harm others. In the past she has deleted entire dissertations and research manuscripts before submission because she feared that making a mistake might cause people to die. It is clear from the absence of emotional dysregulation and her history of stable long-term relationships in the social domains of professional work, friendship and personal relationships that she does not have a personality disorder. It is also clear from the absence of hallucinations and the fact that her fears are obsessional rather than delusional that she does not have a psychosis. Therefore you believe that she has obsessive-compulsive disorder (OCD).

Question 2: What is your role in this scenario? (a)Advising medical staff on capacity to make decisions about medical treatment.(b)Diagnostic assessment alongside assessment of needs and risk.(c)Explaining the nature of OCD to the patient, offering hope and ensuring she can access effective treatment following discharge.(d)All of the above.

Answer: (d)

Severity of OCD

Severe mental illness is not defined by diagnosis but by the degree of distress, disability and interference in a person's life. Without treatment, OCD can be severe, disabling and enduring, with major effects on physical health; as well as self-harming, people with OCD may restrict fluid or food intake because of either neglect or obsessions about contamination. Others may have excessive slowness or be ruminating all day and unable to function. Although most people respond to community-based treatment, some people with OCD may need admission to a psychiatric ward to engage in specialist cognitive-behavioural therapy (CBT) and for supervision of pharmacotherapy. The World Health Organization has classified OCD among the top 10 most disabling illnesses in terms of lost income and decreased quality of life.¹⁰ People with OCD may experience significant delays to diagnosis, both from a fear of asking for help and also from delays in healthcare staff identifying the condition.¹¹ One study found that the average time to receiving first treatment for OCD was more than 17 years from the onset of first symptoms, and more than 11 years after fully meeting diagnostic criteria.¹²

OCD and self-harm

In clinical practice, self-harm may be erroneously viewed as always being a means of coping with emotional distress. Self-harm accompanies a wide range of psychiatric disorders, including psychotic, neurodevelopmental, affective, anxiety and personality disorders. People who have self-harmed sometimes encounter prejudice and discrimination from healthcare staff, which inhibits access to effective assessment and treatment.^{13,14} A key issue in formulation and diagnosis is understanding the circumstances, precipitants, intention and motivation behind the self-harm.

Despite commonly experiencing ego-dystonic obsessional fears about causing harm, people with OCD rarely harm others.¹⁵ On the other hand, self-harm is common in OCD, with an estimated prevalence of 7.3%, and takes many forms¹⁶; it is usually ego-dystonic and compulsive in nature. The manifestations can be encountered by many other specialties, especially dermatology; it has been estimated that between 9 and 35% of patients with OCD will present for treatment of complications related to skin damage.¹⁷ Compulsive washing or decontamination with irritant substances such as disinfectants or bleach are among the most commonly recognised compulsions, and people with OCD may present with atopic dermatitis, irritant toxic dermatitis or dry skin eczema.¹⁸ Compulsive self-cutting and decontamination by chemical burning are less common; understanding the intention behind the behaviour is important in making the diagnosis.

Excoriation disorder (skin-picking or dermatillomania) is relatively frequent, with a prevalence between 1.4 and 5.4%;^{19,20} it has gained increasing attention and has been defined as a specific type of obsessive-compulsive and related disorders in the DSM-5 and the proposed ICD-11.²¹ Excoriation disorder can lead to serious complications including infection, physical disfigurement and physical disability.^{22,23} Trichotillomania (hair pulling disorder) has a point prevalence of 0.5–2.0% and predominantly affects female patients;²⁴ similar to excoriation disorder, it has been identified as an OCD type. Rarely, self-surgery such as autocastration has been described as a complication of OCD.²⁵

OCD and suicide

It is important to recognise that people with OCD are at increased risk of suicide.²⁶ A Swedish population-based study found that suicide attempt rates were five times higher and suicide mortality rates ten times higher in people with OCD compared with the general population.²⁷ A systematic review found median rates of suicidal ideation and suicide attempts of 27.9% and 10.3%, respectively, in people with OCD.²³ Comorbid conditions such as harmful or dependent use of alcohol or other drugs, personality disorders or affective disorders increase suicide mortality rates in OCD to between 40 and 82%; however, the risk remains high when OCD is the only condition present.^{22,28}

Assessment of obsessions and compulsions

Obsessions are thoughts which come into one's head over and over again, and will not go away. Often experienced as paralysing and terrifying, they can be about apparently mundane things, such as the idea that something is not clean or that an appliance has been left on. They can also be more obviously upsetting, such as believing that one might stab someone (despite not wanting to) or might have unintentionally killed or harmed someone. Inappropriate sexual thoughts may take a similar form but be difficult to disclose in view of the associated shame. Obsessions can be about one's own body – for instance, having an infectious disease or something dangerous under the skin – and can be associated with intense physical sensations such as a visceral feeling of disgust, crawling skin, feeling contaminated or unclean, or intense physical anxiety or shame.

As well as physical contamination from direct contact with dirt or perceived contaminants, a person may experience mental contamination – feelings and fears that arise without physical contact.²⁹ The source of contamination is human rather than inanimate, and the feelings of dirtiness may come from the individual with OCD. Mental contamination is often associated with another person having abused, betrayed or humiliated the patient. The self may be regarded as 'bad' or 'immoral', and the essence of this badness may be transferred to objects and then passed to others. In this case, the patient's motivation is to decontaminate her 'self' to prevent harm being transferred to others; she also has an over-inflated sense of responsibility and influence in believing herself responsible for this harm.³⁰ Compulsive washing is often less effective in mental contamination, hence in this case the escalation to chemical burning.

Obsessions can follow convoluted paths to extreme consequences. For example, a worry that a light was not turned off might lead to obsessions that a spark of electricity could start a fire and kill people inside the building. A worry that one has left the door unlocked may lead to obsessions that a murderer could break into the house and kill one's family. Common features of obsessions are that they are unpleasant, upsetting and cannot be ignored. A key feature is the recognition that these ideas are not correct, do not make sense or are about something which the person does not want to do; they are 'ego-dystonic'. A patient may say that the rational part of their brain can see that it does not make sense, but that does not stop them from experiencing intense fears that the thought may be true.

Compulsions are repetitive, purposeful physical or mental actions that the individual feels compelled to engage in according to rules or until it feels 'safe', 'comfortable' or 'just right', in order to quell the anxiety, fear, disgust or terror associated with an obsession. Compulsions can involve checking, touching, arranging, decontamination, walking, counting or other physical actions. Alternatively, compulsions may involve mental actions such as praying, reciting or making number patterns. Compulsions are linked to obsessions in that they are used to try to get rid of them or fill the need they create. Compulsions can be resisted temporarily or deferred but almost always end up being performed, as the distress from not doing them is great and continuous. They feel voluntary to the person; they are not being controlled. This means people with OCD often blame themselves or are seen as acting irrationally but with capacity by healthcare staff. Although performing compulsions leads to temporary relief of distress, in the longer term it maintains distress by reinforcing the need to act to seek relief.

When differentiating obsessions, ruminations, delusions and thought interference, it is important to enquire about the nature of the thought. Some people with severe OCD refer to obsessions as 'voices' or speak about compulsions as though they are being ordered; it is important not to assume that these are command hallucinations without detailed examination of phenomenology. In addition to asking whether a patient recognises thoughts as their own, ask how easy it is to distract themselves, whether the thoughts are repeatedly intrusive or ruminative, and whether they fear worse consequences if they do not perform a certain act. When enquiring about compulsions, ask what will happen if the patient doesn't do the action, and how they feel once they have done the action.³¹ Becoming familiar with a symptom checklist such as the Yale–Brown Obsessive–Compulsive Scale will help in developing a systematic approach to enquiry about obsessions and compulsions.³²

Practical management of OCD

When someone is in the midst of terrifying obsessions, calm listening and explanation will help the obsessions and associated anxiety pass. If severe, this may take several hours. In an emergency situation, anxiolytic drugs may help to alleviate anxiety and allow a person to accept medical care, although they may also cause disinhibition and exacerbate compulsions. Anxiolytics should not be used routinely for obsessions outside emergencies.

Although there is discussion about the pros and cons of diagnosis in some psychiatric conditions, OCD is a condition where diagnosis allows for a clear explanation and treatment plan. When meeting a patient whom you suspect has OCD, it is important to confirm the diagnosis; ask for senior help if you are not sure. Once confirmed, you can give the patient hope: explain that it is a treatable condition, give written information about self-help, and ensure that follow-up and access to effective treatment are available. If OCD is identified while on call and an immediate management plan made, the patient should be handed over to the liaison psychiatry team for ongoing support in hospital, initiation or review of drug treatment, and arrangement of appropriate aftercare.

It is essential to ensure that appropriate follow-up and treatment are arranged, including specialist CBT for OCD that includes exposure and response prevention (ERP). Longer-term treatment should follow the recommendations in the National Institute for Health and Care Excellence guidelines:³³ treatment with CBT for OCD that includes ERP, plus the maximum tolerated dose of two trials of selective serotonin reuptake inhibitors or clomipramine for at least 12 weeks each. If a patient still has clinically significant symptoms interfering with functioning, a multidisciplinary review should be undertaken, and the patient should be referred to a multidisciplinary team with specific expertise in the treatment of OCD for assessment and further treatment planning, including augmenting drug treatment and intensive CBT for OCD.

Reflections and considerations

We have used the lived experience of OCD, self-harm and mental health services to illustrate a scenario which may be encountered by mental health staff working on call in emergency departments. This highlights several learning points about OCD, self-harm and on-call working. When on call, working collaboratively alongside other medical specialties is of benefit to patients. When seeing people who have self-harmed, retaining compassion, curiosity and hope for change, and ensuring a skilled assessment every time, can improve both patient experience and clinical outcomes. The recognition and diagnosis of OCD are essential elements of mental health staff's clinical skills; identifying and treating OCD can alleviate significant suffering and disability, and can save lives.

Patient's reflections and considerations

What matters to me in the emergency department isn't just about 'assessment' but is about providing help. There is a longer-term element in considering my ability to recover and to continue working: ensuring that I receive effective long-term treatment for OCD. Being correctly diagnosed with OCD has been life-saving for me. Until that point I was caught in a cycle of obsessions and compulsions which were causing me so much harm as to become life-threatening. I couldn't see a way out other than taking my own life to prevent me hurting or killing other people, but the correct diagnosis has improved things in ways I wouldn't have believed were possible. In the 4 years up to that point I had been brought to the emergency department over 133 times. I nearly died and was ventilated in intensive care after taking overdoses. The police arrested and prosecuted me when I was suicidal and afraid because I couldn't get the right help, and the chemical burns which I believed were necessary to stop the contamination spreading and killing others have caused permanent physical disability, ending my career.^{34,35} In the 2 years since I received the right diagnosis, explanation and drug treatment, although I am still waiting for specialist cognitive behaviour therapy and still spend hours every night terrified I have killed people, I have completely stopped compulsive chemical burning, I have not tried to kill myself, I have not been brought back to the emergency department at all and I have developed an alternative career.

In this context I am the patient, but I've been called worse: 'Frequent Flyer', 'A Waste of Valuable Clinical Time and Resources', 'Very Clever and Manipulative' (written in my notes while I was unresponsive in resus following an overdose), 'That' (as in, 'I'm not touching That'). Self-harm, particularly repeat self-harm, attracts stigma that

is unacceptable, along with stereotypes and assumptions which can distract from the clinical picture. What I need from you is not only your clinical expertise, but your clinical leadership in modelling respect for me and challenging discriminatory behaviour. Your work may be hard, but it is crucial; the difference your attitude and assistance makes can be life-saving and life-changing.

1.2.33 Predicting short-term suicide risk: allowing for ongoing variation in severity of intent

date

2021-04

Abstract

This article considers the role that assessment of suicidal ideation may have in short-term prediction of suicide. Suicide risk assessment is a multifactorial process and it is assumed that assessment of suicidal ideation is one component. Denial that suicidal ideation has any useful role in risk assessment fails to allow for the marked ongoing short-term variability in severity of intent, which is a common feature of the suicidal state of mind. It is concluded that the assessment of suicidal ideation, provided it is carried out correctly and applied appropriately, should continue to be regarded as a central component of the overall prediction process. A 'two-take' approach to short-term

risk assessment and mitigation is proposed that takes variability in severity of intent into account and includes anticipatory treatment planning for any problems that may occur in the near future.

When a suicide occurs in one of our patients, as clinicians it is only too easy to blame ourselves even though our care had been exemplary. Nagging doubts easily linger as to whether the suicide might have been prevented if we had done this or that in a different way. It is very important in such circumstances to take a step back, accept that it can indeed be very difficult to predict suicide, let alone prevent it, and acknowledge that occasionally quite inevitably we will not succeed.¹

However, in our day-to-day work we are probably more effective in preventing suicide than we allow ourselves to acknowledge. Such a happening goes unnoticed and is never recorded: a prevented suicide is a statistical non- event for which we get no credit. Yet no doubt it can occur. So even though the task is difficult, it is important that we should continue to scrutinise the effectiveness of our clinical skills, strive to achieve their further improvement and only discard them with caution.

This review focuses particularly on assessment of suicidal ideation, evaluating its role in the care of suicidal individuals and in predicting short-term suicide risk. Assessment of suicidal ideation is regarded as a central clinical component of the overall risk assessment process, which is of course multifactorial and has a wide clinical/social base.² Long-term prediction is a highly questionable exercise and I do not consider it here.

In in-patient care, surely there can be no controversy regarding the importance of suicidal ideation: careful monitoring of any suicidal ideation that may be present is essential. Management of serious immediate risk is incomplete without minute-by-minute awareness of level of intent, and awareness of risk level should be part of any decision concerning a patient being allowed leave the ward. In the out-patient clinic evaluation of risk level, provided it can be shown to achieve an acceptable degree of reliability, should not only help us to determine the risk level at the time the patient is seen: but further it should also guide us regarding ongoing risk, thereby helping to decide the optimal length of time to the next out-patient appointment, as well as clarifying the most appropriate treatment.

Assessment of suicidal ideation criticised

A review of several meta-analyses concerning suicide prediction reached the following conclusion: ‘None of the meta-analyses found that any individual clinical risk factor, including suicidal thoughts and behaviours, was sufficiently accurate as a basis to allocate interventions’.³

Further cautionary advice comes from the National Institute for Health and Care Excellence (NICE), which states in its 2011 guidelines on self-harm: ‘Do not use risk assessment tools and scales to predict future suicide or repetition of self-harm [or] to determine who should or should not be offered treatment or who should be discharged’.⁴

A number of other studies have found that the majority of patients who died by suicide had denied having suicidal ideas at the time of the final interview.⁵⁻⁷ This has been taken to mean that assessment of suicidal ideation is not to be recommended as part of suicide prediction because of its unreliability.

In the face of such a consistent body of evidence suggesting that it has no value, I will review the part that assessment of suicidal ideation might play in short-term suicide prediction. In doing so I will scrutinise the way it is used and asks whether this is appropriate.

Assessment of suicidal ideation looked at anew

Criticisms answered

The assessment of suicidal ideation, although it is a fundamental element of any comprehensive attempt to assess risk, often seems to be taken for granted and not described in any detail even in research literature. The procedure itself has been subjected to criticism and this needs to be answered.

There is no reason to believe that appropriate enquiry concerning the presence of suicidal ideation increases suicide risk. Nor is a person who volunteers to having suicidal ideas necessarily at low risk. Exploration of suicidal ideation is not an isolated exercise. Throughout it must be carried out in full knowledge of the total clinical picture and integrated into the whole therapeutic effort. It is a sensitive empathic reaching out to encourage sharing of distressing and often frightening ideas, as dynamic as any other form of intervention can be. It should not be a questionnaire-type Yes/No interrogation. It should involve progressive exploration of suicidal ideas themselves, their intrusiveness, frequency and acceptance as reasonable, and also of feelings of loss of control, perhaps part of delusional thinking, or of seeing suicide as the only way out of an impossible life situation. The role of ambivalence and personality traits tending towards the impulsive should never be ignored. All this requires gentle patience and warm concern. It is not intended to be a matter of focusing on a patient’s weaknesses rather than strengths: it is simply a guide that can help us make things safe. At all points we need to remember that it is for the benefit of the patient and not, for example, just a way primarily of coping with our own anxieties concerning adverse sequelae if things go wrong. A confident, realistically encouraging attitude is essential: an ambivalent patient will soon pick up doubts on our part and the whole exercise can then become counterproductive. It is never appropriate as a carer to identify with a patient’s despair. It needs to be recognised that aggressive behaviour can occur in parallel with significant suicide risk. Clarify any risk to others. A brusque hurried approach can leave the patient feeling stigmatised and undervalued, as well as encouraging denial of intent or even encouraging suicidal motivation. Discussing together any reasons why denial may occur and how to mitigate them, being available and offering urgent help at any time should suicidal thoughts recur, both represent a mark of respect for the patient’s intrinsic worth.

Although all of this is a complex and difficult clinical task it would be a mistake to lose sight of the important positive part that discussing suicidal ideation can have in caring for suicidal individuals. To carry it out properly is comparable to having responsibility for dispensing medicines: the results of maladministration of either could be dire. So, it is reasonable to expect that each psychiatric hospital ward should ensure that all clinical staff have been well trained in assessing suicidal ideation. Appropriate privacy is important if this sensitive and complex task is to be carried out reliably.

Allowing for variability in severity of intent

To base assessment of ongoing risk on the individual's mental state during a single interview is clearly likely to be highly unreliable. It can mislead not because suicidal ideation is intrinsically valueless in prediction and should be discarded, but rather because such an approach makes no allowance for the marked short-lasting and ongoing variation in severity of intent that is a common feature of the suicidal state of mind. The following case series and studies illustrate this in suicidal individuals during the weeks before death.

Over a 10-year period (1968–1978), 12 deaths by suicide occurred among patients who were under my sole consultant care, either while they were resident in a single psychiatric hospital ward or within 2 months of discharge. They had all expressed suicidal ideation. I knew each of them well, day in, day out, usually over several weeks, yet in spite of my close continuing contact with them and the majority reassuring me about their safety, they ended their lives. In an attempt to understand all this further, I put all their case records together and looked at them as a whole.⁸ A half showed marked variability in severity of suicidal intent, in some even over the course of a single day, with short episodes of corresponding misleading clinical improvement in which suicidal ideas were denied. Variable contact and unresolved stress factors and impulse seemed relevant. For example, one patient happily organised a charity walk from the hospital only to take her own life the following weekend when, still apparently well, she went home on leave to be confronted with an unresolved domestic crisis.

Two later case series consisted of all psychiatric in-patients in the City of Bristol during two separate periods (1982–1984 and 1991–1993) who died by suicide either from hospital wards or within 2 months of discharge.^{9,10} In the two studies, 52 and 61% respectively showed episodes of misleading clinical improvement. Stress was a common background to relapse: 44 and 50% respectively killed themselves when clinically improved but with stress factors unresolved.

Although the number of cases in these three studies was small (12, 27 and 18 respectively) and they bridged a time span of 30 years, the findings were derived from detailed observations at ward level by clinicians responsible for the patients' clinical care and were remarkably consistent. They confirmed that short-term variability of intent exists in a considerable proportion of suicidal patients. This reinforces the view that to judge assessment of suicidal ideation as a predictor of ongoing suicide risk merely on its efficacy when recorded in a single interview ignores a common clinical feature of the suicidal state of mind, namely its variability in severity of intent. To put it bluntly, it asks the impossible of it.

The following discussion focuses particularly on out-patient work but its principles apply to the in-patient situation too. We need to ask: In the face of such practical difficulties what can we do to make prediction of suicide more reliable so that we can rely on it over the short term until the next out-patient interview?

An attempt to take things forward

The approach which is proposed here tries to take into account variability in severity of intent when predicting suicide risk. It is suggested that, in addition to assessing risk specific to the time of interview, any attempt at predicting ongoing short-term risk should also invariably include a projected evaluation of whether suicidal ideation is likely to recur if difficulties are encountered before the next clinical contact with the patient. This represents an attempt to ameliorate the confounding effect of ongoing variation in severity of intent. It also allows anticipatory treatment plans to be laid for any difficulties that may recur, thereby targeting therapeutic efforts more efficiently. Assessment of suicidal ideation remains a central component of the whole process. The following proposed guidance incorporates this approach with regard to follow-up of patients who have recently experienced an episode of significant suicidal feelings. It is provisional, its aim being to highlight the points made in this article and to stimulate debate regarding them. It has not been used clinically nor evaluated in any way. However, it is hoped that, after wider evaluation and any necessary amendments have been made, its principles might prove to be of practical value in taking forward the difficult task of predicting short-term suicide risk.

Out-patient care of suicidal individuals: guidance on assessment of short-term ongoing risk

Remember that predicting ongoing risk of suicide merely on the basis of the patient's mental state at the time of a single interview can be very unreliable. Evaluation of suicidal ideation and intent should be more broadly based and cover the whole of the follow-up period. Remember that ongoing day-to-day variation in severity of intent can be marked. Always give serious consideration to any evidence of suicidal intent, expressed or otherwise. Keep in mind the possible reasons specific to each case why relapse might occur, as well as the overall risk assessment picture. An important trigger for relapse is stress, particularly stress that has previously been present and has not been resolved. Try to assess the likelihood that difficulties, stress related or otherwise, will recur before the next appointment and whether suicidal ideation will complicate them. Overall evaluation should invariably take such anticipated risk into account. Clarify what urgent help could be made available in such a forthcoming crisis, ensure that it would be acceptable to the patient, work through any hesitation expressed regarding seeking that help and review the appropriateness as well as any security provision related to prescribed medication. All this should be integral to the assessment process.

Implementing the suggested guidance

This guidance is put forward in the hope that it might improve our ability both to predict suicide risk in the short term and to target more effectively the ongoing treatment we offer. It is no more than a care plan, but one that not only focuses on the present: it also insists on searching for potential risk at some point in the future. According to it, no assessment of ongoing suicide risk would be regarded as complete without such a 'two-take' approach covering the follow-up period and aimed at what amounts to a moving target. This allows plans to be laid in advance for an acceptable form of urgent help should problems recur. Predicted suicidal ideation at any level of severity without stratification and particularly ideation that is triggered by a stressful event should be taken as sufficient to indicate significant continuing risk.

As mentioned above, variability in severity of intent has been found to occur in about half of patients with suicidal ideation who proceed to suicide.^{8,9,10} In the remaining patients, environmental stress factors that presumably trigger such variability are presumably either absent or do not cause significant problems for the patient. Does the proposed guidance therefore have value only for half of patients? Not necessarily. It is possible that, in other patients, careful anticipatory enquiry might reveal a need to plan help for problems that otherwise would have remained unexpected.

From what has been presented here it is clear that the process of predicting suicide risk even in the short term is a difficult clinical exercise. Regarding someone whose stress factors have not been fully resolved, a letter to the general practitioner (GP) taking all relevant issues into consideration might read as follows: "Suicidal intent appears to be low or non-existent today. This is not in itself a reliable predictor of ongoing suicide risk, which could recur again for a variety of reasons relevant to the illness itself or significant stress. Our discussion today showed that such stress might well recur prior to the next appointment and the patient was anxious about having to face it. Recurrence of suicidal ideation could not be ruled out. We discussed ways in which we could offer urgent help in such circumstances and as a result the patient felt more confident about being able to get through it all. Overall, however, the predicted level of suicide risk must still be regarded as significant, requiring vigilance until I next see him/her."

Great care should be taken before one is ever tempted to suggest that ongoing risk is totally absent in someone who has experienced suicidal ideation in the recent past. In such a situation a letter to the GP might read along the following lines: "The patient denied having suicidal ideas today, stress factors appear to have been resolved, family/social support has always been strong and remains so, and adverse events that might lead to relapse seem unlikely to recur during the follow-up period before I see him/her again. In spite of this reassuring picture, vigilance is required during the follow-up period. This is because relapse, especially if stress related, can occur unexpectedly in anyone who has been at risk of suicide and it is early days since he/she experienced suicidal ideation. I have discussed with him/her the availability of urgent help and as a result he/she feels confident about being able to cope until the next time we meet. For the moment, the predicted level of suicide risk must remain as uncertain."

Conclusions

It is hoped that the dynamic ‘two-take’ approach to predicting ongoing short-term suicide risk that is proposed here might prove to be a useful contribution to the overall risk assessment process by helping to ameliorate the ‘moving target’ problem due to varying levels of intent over short periods of time. Ongoing treatment should also be targeted more precisely as a result of its forward-looking approach. There are several other ways in which assessment of suicidal ideation can have a useful role in caring for suicidal individuals. Its value in detecting a certain group of in-patients especially vulnerable to suicide has been described elsewhere.¹¹ Whatever the setting, shared knowledge of suicidal ideation can also contribute to a therapeutic alliance with the patient, promoting a readiness to discuss suicidal ideas fully and thereby helping to alienate such ideas, making defensive denial less likely. Such mutual collaboration and trust not only have therapeutic and preventive value: they can then also facilitate the process of prediction.

Given this overall picture it seems reasonable to conclude that the assessment of suicidal ideas, provided it is carried out correctly, applied appropriately and always used within the wider context of risk assessment as a whole, can play a valued part in the overall care and prediction of risk in suicidal individuals. Surely it is here to stay.

I am grateful to the late Dr Chris Vassilas for his much valued advice and support. I also thank Dr Pamela Priest and Ruth Stanton, Research Fellows, for their major contributions to research studies mentioned in this paper, the Avon consultant psychiatrists, Emma Place, Librarian Bristol University, HM Coroners in Bristol and the South Western Regional Health Authority Research Committee for research funding over the years.

- *Invisible youth during times of Covid*

Covid-19 continues to devastate, the elderly and those in care homes being particularly vulnerable. However, there is an unexpected population that is at great risk of morbidity due to Covid-19, the adolescent forensic population. This increased morbidity is a result of the care offered by statutory agencies being greatly diminished across all settings owing to the pandemic.

One of the first things that you learn in adolescent forensic psychiatry is that perpetrators are also victims, and it can be hard to distinguish between the two. This does not excuse the crimes they have committed but does add an extra complexity to their treatment. Young people who present with complex forensic issues are particularly vulnerable, often having histories that include early trauma, repeated loss, attachment issues, learning difficulties and mental health problems.¹ This population is notoriously difficult for professionals to engage with, for many of the above reasons but also because of the possible consequences for them and their families of talking about the criminal aspects of their lives. The reduced consistency that services currently provide has affected their engagement and the possibility of a therapeutic alliance, thus increasing risk for themselves and the public.

A further contributing factor to increased morbidity has been school closures and agencies working remotely, leading to reduced access to support and structure, which has exacerbated vulnerabilities. Challenging behaviours were previously mitigated by the provision of education and other prosocial activities; the reduction has led to increased episodes of violence.² This has particularly affected young people with neurodevelopmental disorders and special educational needs, with the effects likely to be long term, complicated by loneliness and a disconnection from their community.

Youth custody has had to be increasingly vigilant to ensure the safety of detainees and prevent Covid transmission. There is a need to isolate those being transferred into custody in the first 2 weeks to prevent transmission of Covid.³ It is known that this is the time of greatest risk of suicide for young people in custody, when young people are now needing to isolate for Covid, thus increasing isolation and risk. Staff shortages, education closure and the need for Covid ‘bubbles’ has meant extended time alone in cells even after those first few weeks, which increases the risk of self-harm and suicide.⁴ Furthermore, the pandemic has led to a backlog in the courts, and concern over community services has meant that more young people are being remanded and for longer periods. It is of note that the majority (63%) of children given custodial remand did not subsequently receive a custodial outcome in 2018.⁵ These factors – extra time in cells and longer time on remand – can mean the compounding of an already traumatic experience for many in youth custody.

Young people with a combination of mental health and forensic issues are placed in secure adolescent psychiatric units to receive appropriate treatment. The effect of the Covid pandemic on staffing in these units has negatively affected the availability of support, and things that are often a lifeline for these young people, such as community access, planned leave and family visits, have been cancelled. A bottleneck has occurred, with transition back to the community being stalled owing to the services around the young person not being readily available to facilitate these moves or provide the relevant opportunities in the community.

Isolated young people with social communication, cognitive or emotional difficulties are at increased risk of exploitation by others in all settings. In the community, risks relevant to this group go beyond the risk of offending and risk to others and include being groomed into gang-related activities. Such gangs appear to have been more active and accessible to this group of young people during this time (including county lines and other criminal exploitation).

We realise that everyone is having a difficult time at the moment but believe it is essential to highlight some of the

issues that this frequently invisible population is experiencing, in the hope that they will not be forgotten.

However, it is not all doom and gloom; with any change there are gains as well as losses, and the gains have highlighted the dedication of the professionals working with this population. They have stepped up to the mark, through increased productivity, improved multi-agency working, increased uptake of virtual conferencing and appropriate information-sharing, with the aim of keeping these young people safe. The young people have noted these efforts and there has been feedback that this way of working has made them feel safer, so we hope, as a network, that we will be able to maintain the benefits as we return to the new normality.

This letter was compiled by the London Youth Justice Child and Adolescent Mental Health Services (CAMHS) Forum, which comprises professionals working in the following services: Youth Justice Liaison and Diversion, Youth Offending Teams (YOTs), Community Forensic CAMHS (FCAMHS), Youth Offending Institutions (YOIs, including SECURE STAIRS implementation) and secure adolescent units.

1.2.35 Electroconvulsive therapy for severe depression, psychosis and chorea in a patient with Huntington's disease: case report and review of the literature

Walied Mowafi Jon Millard

Correspondence

Walied Mowafi (wmowafi20@gmail.com)

date

2021-04

Abstract

Aims and method

The psychiatric manifestations of Huntington's disease are myriad and difficult to control. The use of electroconvulsive therapy (ECT) is not commonly considered for this condition. We describe a patient with severe depression, psychomotor retardation, delusions and weight loss who responded to ECT with good control of her symptoms.

Results

Both our case and the literature appear to confirm the efficacy of ECT in the treatment of depression in Huntington's disease and suggest that other psychiatric manifestations of Huntington's are also responsive.

Clinical implications

ECT is an effective and safe treatment that should be considered earlier in the course of the disease in cases that show limited response to pharmacological therapy. It should also be considered as an adjunct to medical therapy that may simplify polypharmacy and allow better control in patients with debilitating psychiatric manifestations of the disease. There is limited and conflicting evidence for its efficacy in chorea.

Case report

Seven years ago, a 57-year-old woman with a family history of Huntington's disease presented with depression, changes in personality, apathy, anxiety, poor memory and clumsiness. Her genetics confirmed Huntington's disease, with a CAG repeat number of 17/46. Over the subsequent 4 years, her condition was marked by psychiatric symptoms and mild chorea, which responded well to tetrabenazine 25 mg once daily, reaching 25 mg twice daily by 2014. Her mood was controlled with citalopram followed by sertraline. Her main complaints were bouts of introversion and tearfulness, but she remained socially engaged with friends. By early 2015, her swallowing had ostensibly become problematic. However, a speech and language assessment and a gastroscopy determined that her swallowing was normal. By spring 2016, she was starting to fall often, with worsening athetoid movements and increased somnolence. These changes led to a switch in medication to olanzapine at 15 mg per day and an increase in her dose of sertraline to 100 mg a day.

By summer of 2017, her choreoathetoid movements had worsened and were accompanied by weight loss and a deterioration in her mood. She required a short in-patient stay for fluids via a nasogastric tube. A psychiatric review diagnosed

her with a depressive psychosis with retarded affect, mood-congruent delusions and auditory command hallucinations. She believed she did not deserve to eat and drink, and the command hallucinations ordered her not to do so. She had extracampine hallucinations, sensing people at the end of her garden. In light of her clinical state of emaciation and the requirement for support, a trial of bilateral electroconvulsive therapy (ECT) was suggested for her depressive psychosis. A twice-weekly regimen was started, with the aim of optimising seizure length to between 30 and 60 s. In winter of 2017, she received an initial 12 courses of biweekly bilateral ECT treatments using between 75 and 150 mC. Her initial response was favourable and she became euthymic, with remission of her psychomotor retardation, but her psychotic symptoms persisted in the form of command hallucinations despite developing insight. Her delusion of guilt also resolved and, by the tenth dose of ECT, she started to eat and drink again. The initial course of treatment was complete by early February 2018 and, with the exception of her hallucinations, her psychiatric symptoms ceased and insight was retained.

However, the persistence of psychotic symptoms in the absence of a significant mood component led to an additional 12 sessions of bilateral ECT (administered biweekly with 150–225 mC; maintenance treatment consisting of bilateral 150–300 mC treatment biweekly continued into late 2019) with the aim of eradicating the hallucinations. She then developed a respiratory tract infection, which led to a relapse in her psychiatric symptoms with agitation, hallucinations, and marked choreoathetosis and dyskinesia that led to the reintroduction of tetrabenazine. Despite this setback, she did improve following the last 12 doses of ECT. This course was completed in late spring 2019. She was kept on maintenance ECT once per week, with partial remission of the auditory hallucinations, which had reduced in frequency and no longer distressed her. There was a subsequent increase in the frequency of the hallucinations, with preservation of insight, and a corresponding reduction in ECT to fortnightly. She has remained stable on this regimen to date. Her involuntary movements have also improved over that time, although she remains on tetrabenazine, haloperidol and sertraline.

Method

A literature search of PubMed for ‘Electroconvulsive therapy and Huntington’s’ and ‘ECT and Huntington’s’ led to the discovery of 20 papers, 18 of which were in English. Six publications were based on *in vitro* studies and animal studies, leaving 12 publications for review. A further three papers that were not listed in the PubMed search were sourced from references in papers from earlier years. All publications were either single-case reports or retrospective case series; there were no randomised controlled trials or prospective studies.

Consent for publication

Signed informed consent was obtained from the patient described in our case report.

Results

Table 1 shows a breakdown by demographic and disease characteristics of the 37 patients described in 15 studies. Tables 2–5 summarise the predominant psychiatric complaints, the effects of ECT on the number of medications used during ECT treatment, the CAG copy number, ECT treatment and seizure duration. Supplementary Table 1 (available online at <https://doi.org/10.1192/bjb.2020.51>) summarises individual patient details from the literature, including our aforementioned case. Table 1 Summary of patient characteristics and ECT treatment

Characteristic	Median	Sex	43%

The time to ECT treatment after the diagnosis of Huntington's disease was between 0 and 17 years, with a median of 3 years and mean of 4.42 years. However, the sixth patient of Ranen et al. had previously had ECT for depression before she was diagnosed.¹ The age of psychiatric symptoms at presentation for ECT varied from 0 to 22 years prior, with a median of 2.5 years and a mean of 5.73 years.

³ N/A, not available.

⁴ Double stimulus was administered in Ranen et al's patients, but no further details were provided.

⁵ Assumed to be the USA version with 0.9 A and charge of 504 mC. The lowest percentage given to Merida-Puga et al's patient was calculated according to the half-life method. While no figure was given for the lowest percentage, 25% was the maximum stated.

⁶ Text does not state machine used or charge or current characteristics but states 'stimulus intensities comparable to patients without HD'. 0.8 A is presumed for the purpose of calculation.

⁷

As per specification sheet from the manufacturer, the maximum output is 504 mC with the range calculated based on quoted percentage delivered. This machine is capable of double stimulus, but this was not mentioned in Adrissi et al's paper.

It should be noted that the diagnostic confirmation of Huntington's was solely clinical prior to 1993; however, despite the availability of genetic testing after 1993 (Huntington disease Collaborative Research Group), diagnosis only preceded presentation in this group of patients after 2013 (Cusin et al's first patient²). Prior to 2013, patients first presented on average 7.4 years *before* the diagnosis of Huntington's was made. After 2013, all patients with psychiatric complaints who went on to have ECT presented an average of 6.6 years *after* the diagnosis of Huntington's had been established. Six patients in total were diagnosed at the time of presentation, although five of them were diagnosed prior to 2013. For example, Beale et al's patient had choreiform movements (and no psychiatric manifestations) from the age of 35, but was not diagnosed until the age of 56 in 1995.³ However, this apparent lag after the introduction of genetic testing is likely to reflect the 16-year gap between Beale et al's paper in 1995 and those of Merida-Puga et al and Nakano et al in 2011 and 2013, respectively.³⁻⁵ Merida-Puga et al's patient was diagnosed following postpartum psychosis and a family history suggestive of Huntington's in her father; she went on to have ECT for catatonia. Nakano et al's patient was diagnosed owing to his brother's recent diagnosis with Huntington's at another hospital, having already received ECT for treatment-refractory psychosis.

Reason for referral for ECT

Table 2 shows a breakdown of the main characteristics of the clinical presentations; 48.6% of patients were referred for depression alone without psychotic features, and psychosis was the main cause of referral in 16%. Many of the referrals for depression alone were from some of the earliest reports, which lacked a clear description of the referral characteristics.^{6,7} The remainder of patients had numerous coexisting factors such as paranoia, delusions and other manifestations of psychosis, including hallucinations^{1,2,4,5,8-11}.

Coexistent motor symptoms were present in 20 patients^{1-3,5,9,10,12-15} (including our case), with chorea being the most commonly used term. Involuntary movement and impaired gait were also terms used without further clarification (e.g. Cusin et al uses both terms for different patients within the same series²). Psychomotor retardation was reported in four patients^{1,2,10} (including our case), with one patient being described as having neurovegetative symptoms (Cusin et al,² patient 3), and coexistent dysarthria/dysphagia in two patients. Catatonia was mentioned in four patients^{1,2,4} (fourth and fifth patient of series, 1 postpartum⁴ and the second patient of series²) but was the primary focus of treatment only in Merida-Puga et al⁴; see Supplementary Table 1.

Effects on psychiatric symptoms

The primary reason for prescribing ECT in all but seven patients (six for psychosis and one for chorea) was depression (Table 2 and Supplementary Table 1). There were universally favourable outcomes in the use of ECT for this purpose. It was reported to be successful in most cases, and the patients who were reported to relapse did so on shorter courses of ECT.^{12,13} However, these were early reports, and there have been numerous subsequent reports of relatively short courses with no relapse. For example, Ranen et al's third patient, who had depression, psychosis and catatonia, only needed five ECT treatments to achieve symptom resolution.

Psychosis responded to ECT in all six patients^{2,4,8,11} who were reported to have it as the primary presentation, which included our case. When coexistent disease such as depression was considered, 12 patients in total had prominent psychosis, and all responded to varying degrees, including our case.^{1,5,9,10} Merida-Puga et al reported refractory psychosis thought to be due to use of depot dopamine antagonists, although the focus of their treatment was the refractory catatonia.⁴

Hallucinations, either auditory (three cases including our case),^{1,11,13} visual (two cases)^{2,10} or both visual and auditory (two cases),^{4,8} also responded well to treatment. The exception was Ranen et al's fourth patient, where this was unclear, although the hallucinations probably improved with the patient's other symptoms.

There were four cases of reported psychomotor retardation, including our patient^{1,10,12} (in addition, speech retardation was reported in Nakano et al); all were described as improved following ECT without further clarification. Benson and Blumer's first patient had a 'temporary recovery'.

Catatonia (second and fourth patients of Ranen et al; second patient of Cusin et al^{1,2,4}) was described in four patients and improved in all. This improvement often paralleled the response to ECT of depression, suicidality and psychosis.

Two of these cases were resolved by relatively short courses of ECT (five treatments for Ranen et al's fourth patient – though their condition was, surprisingly, described as refractory – and seven treatments for Cusin et al's second patient). However, the presence of catatonia was refractory in the remaining two patients. Both Ranen et al's second patient (who relapsed repeatedly) and Merida-Puga et al's patient⁴ (who required withdrawal from long-acting antipsychotics) needed extended ECT courses (4 years for Ranen et al's patient but just over 3 months of an in-patient stay for the latter) to resolve the catatonia, with 35 and 42 ECT treatments, respectively. Merida-Puga et al's patient had a Busch–Francis catatonia score of 26 (total severity) on first admission, falling to 4 after a second hospital admission and discharge.

Our patient required repeated doses of ECT following a relapse of psychosis over 2 years. Eventually, she showed a partial response, with improvements in her mobility and psychomotor retardation. She started to gain weight, although her delusions persisted. Improved gait was reported in six cases, including Lewis et al and the first, fourth, fifth and sixth patients of Cusin et al, who had bilateral frontotemporal and right unilateral (RUL) placement, respectively.^{2,14}

Disorders of eating and/or speech were mentioned for a total of ten patients. Dysphagia was mentioned in two cases (Cusin et al's² second patient and ours) and dysarthria in another two (Cusin et al's third and sixth patients). Both dysarthria and dysphagia were reported for two patients (Cusin et al's fourth and fifth patients). For all six of these patients, their symptoms were described as resolving or dramatically improved. Refusal to eat was described in two patients (Ranen et al's second patient and Magid et al's patient^{1,8}), while poor appetite was described in another two (Ranen et al's sixth patient and Adrissi et al's second¹⁰). Both of Ranen et al's patients were described as improved, but there was no further clarification regarding outcome for the remaining two.

Aggression,^{1,2,10–12,15} inappropriate sexual behaviour^{2,15} and agitation¹⁵ were also mentioned and described as improved.

Only two reports documented improvement using psychiatric rating scales, with the BPRS-E (Brief Psychiatric Rating Scale, Expanded) score dropping from 88 to 38 after 12 ECT sessions in Petit et al's patient, and BPRS dropping from 139 to 68 in Nakano et al's patient (the PANS (Positive and Negative Syndrome Scale) score fell from 139 to 68 in the latter).^{5,9} Both Beale et al and Lewis et al documented improvement in the Hamilton rating scale for depression from 36 pre-treatment to 13 post-treatment in Beale et al and 36 to 10 post-treatment in Lewis et al.^{3,14}

Effects on motor symptoms

Chorea was mentioned in 14 cases,^{1–3,5,9–11,13–15} including our case (three patients of Cusin et al and two of Adrissi et al^{2,10}). Improvement was documented in three cases (Beale et al, Petit et al and Shah et al), although five were described as showing no change (Ranen et al, Lewis et al, Nakano et al, Cusin et al's fifth patient and Adrissi et al's first patient). In two cases, chorea was described as worse (Adrissi et al's second patient and Evans et al). In the remaining four patients, no details were given, despite this symptom initially having been described as present.

Only one patient was treated with ECT specifically for chorea. This patient demonstrated improvement initially and, despite worsening, their chorea never returned to the original level and was sustained at the improved level for a year.³

Our patient showed some response with respect to the choreoathetoid movements, which had become unresponsive to tetrabenazine. The medication had been withdrawn given her depression and fears of worsening those symptoms. Olanzapine, however, did not lead to any improvement in her chorea or psychiatric symptoms. Following a favourable response of the chorea to ECT, a low dose of tetrabenazine was reintroduced with good effect and had no further influence on her mood. Her gait and mobility also improved.

The use of rating scales for motor function was mentioned in only three cases. The Unified Huntington's Disease Rating Scale (UHDRS) motor score was recorded before and after only for Adrissi et al's second patient (27/31 out of a total of 124; their first case had an initial score of 49 with no follow-up score), while Petit et al's patient's UHDRS score decreased from 47 to 37 after 12 treatments and then rose to 57 after 1 year.^{9,10} For most cases, there was no mention of any response, which is not surprising because this was the focus of the treatment in only one of the studies. Surprisingly, despite admitting their patient specifically for the treatment of chorea (there were no psychiatric manifestations), Beale et al used no rating scales to document improvement.³

Effects on cognition

Many of the case reports mentioned problems with cognition, but few documented it with formal scores either before or after treatment. Scores were recorded before and after treatment by Nakano et al (Mini-Mental State Examination (MMSE) 27/26), Lewis et al (MMSE 23/24) and Ranen et al (second and fourth patients; MMSE 20/30 rose to 26 by discharge in the former and was 20/30 rising to 24–26/30 (administered twice) in the latter^{1,5,14}). Cusin et al used the Montreal Cognitive Assessment (MoCA) scale for their patients and described the scores as improved, although they did not publish the values.²

Ranen et al's third patient showed a drop in MMSE from 26/30 to 18/28, with an episode of delirium after his eighth ECT treatment. No further scores were recorded, but the patient was described as 'not completely recovered cognitively'.¹ Adrissi et al's second patient had an initial MoCA of 17/20, but no further score was documented.¹⁰

Effect on medication used

Table 3 documents the treatment at admission; changes, if any, that occurred during the course of treatment for the psychiatric manifestations of disease; and discharge medication for those patients where it was recorded.

In those patients who required a number of drugs to treat the psychiatric manifestations of Huntington's disease, implying difficulty in management, there was not necessarily a requirement for more ECT doses or prolonged ECT treatment. However, in patients with pharmacological treatment resistance and the requirement for many drugs to manage symptoms, there does appear to be scope for significant rationalisation of pharmacological therapy when ECT is used adjunctively. Beale et al's patient and Cusin et al's first and sixth patients all presented between 10.5 and 19 years after diagnosis but responded well to limited ECT treatments and were discharged on much less medication.^{2,3} Only Adrissi et al's third patient, Ranen et al's second patient and ours required extended ECT. It is not clear why there was resistance to conventional treatment in these cases.^{1,10}

However, this was not a consistent outcome; for example, Cusin et al's seventh patient was discharged on more medication after ECT than prior, and Adrissi et al's third and fourth patients were discharged on a comparable number of drugs to those given on admission.^{2,10}

Effect of CAG copy number on disease or treatment

The earliest reference to CAG copy number, and therefore genetic confirmation of the diagnosis, comes from Lewis et al in 1994 – in keeping with testing, which became available after the discovery of the trinucleotide repeat a year earlier by the Huntington Disease Collaborative Research Group. Copy numbers of trinucleotide repeats have no effect on the severity of the disease, but the age of presentation is inversely correlated with increasing copy number.¹⁶

Table 4 shows copy number, number of ECT treatments and length of psychiatric symptoms for cases where this information was documented. Although those requiring more cumulative ECT treatments may appear to be clustered with those with higher repeat copy numbers, Petit et al's and Adrissi et al's second and first patients represent evidence to the contrary.^{9,10} Given that there was only a difference of seven CAG repeats among the 11 patients, there appears to be no significance to this. In keeping with this, the youngest patient in the review, who at 20 years old was likely to have had genetic testing, although the results of this were not documented, responded well to ECT, with his symptoms described as resolved after only seven treatments (Cusin et al's second patient²).

ECT treatment course

Treatment courses varied between three and 42 treatments in total, with a median of eight. Relapse was mentioned in seven cases (Cusin et al's fifth and sixth patients).^{2,4,12,13,15} For Heathfield's patient (who had three treatments) and Benson and Blumer's patients, relapse was described in general terms, with no description of the treatment course in the latter's series.^{12,13} In the remaining patients, it is not clear why they relapsed, except for having received relatively short courses of between five and nine ECT treatments. Merida-Puga et al's patient had treatment-resistant catatonia exacerbated by dopamine antagonists prescribed for her psychosis; this led to relapses and an extended in-patient stay.

Most patients had treatment for up to 1 year (22 patients), although our patient has been undergoing continuing maintenance treatment at increasing intervals for more than 2 years to date. Ranen et al's second patient required treatment for 4 years and Petit et al's patient for more than 1 year.^{1,9} Those requiring extended treatment presumably did so because of continued symptoms^{1,10} (see below).

Patients who had an extended course, arbitrarily taken to be more than 20 treatments (seven patients including ours^{1,4,9,10}), did not have different characteristics from patients with similar symptoms but much less cumulative ECT treatment. Characteristics such as the nature of symptoms, length of time from diagnosis, length of time of psychiatric symptoms, age and sex did not appear to affect the number of ECT treatments. However, refractory catatonia complicating psychosis may have been a factor in extended treatment, with Ranen et al's second patient and Merida-Puga et al's patient⁴ requiring 35 and 42 treatments, respectively.

The four patients who had ECT more than 10 years after diagnosis^{1,2} (Ranen et al's sixth, Cusin et al's first, fifth and seventh patients) also showed excellent responses to ECT with between 8 and 13 treatments.

Length of seizure in seconds

Table 5 shows the seizure duration in the cases where it was recorded.^{1,3,4,10,11,14} Only Beale et al mentioned a reduction in seizure time from 57 s at the beginning of treatment to 19 s by the end. This was for the sole case in which ECT was administered for chorea.³ Our patient required ongoing treatment with increasing doses of ECT, although control of delusions was eventually achieved with seizure lengths between 30 and 60 s.

Dose of ECT treatment

It was not always possible to discern the dose of treatment given, as doses were rarely documented and were not necessarily consistent with other reports.^{1-4,10,11,14} For example, Beale et al's patient was stated as needing 72 mC initially, rising to 233 mC, with a corresponding drop in seizure duration from 57 s initially to 19 s at the end.³ When recorded, the frequency and pulse width varied. Alternatively, descriptions of percentage of maximum charge, where stated, together with the machine used (and its specifications), allowed for calculation of this figure where it was not explicitly stated (*Table 5*).

There did not appear to be any factors to explain why five patients, including our patient, required higher cumulative ECT treatments (Ranen et al's second patient, Adrissi et al's first, second and third patients).^{1,10} More generally, most patients were started on relatively low doses of ECT and titrated as treatment progressed, though this was not always documented. Only Adrissi et al's third patient was started on maximum charge dose of 100% (504 mC) due to refractory psychosis. This was later cut down to 50% (252 mC) owing to a bout of delirium that was subsequently felt to be due to medication. The presence of catatonia in Merida-Puga et al and Ranen et al's second patient may be considered a proxy for severity, but this was not the case for the other two catatonic patients (see above). Likewise, short treatment courses were reported in the earlier studies to be more likely to lead to relapse, but this was not borne out by later studies (see above). Getting the dose and the induced seizure length right appears to take more time in the out-patient setting, as may be expected. The three intense in-patient stays for our patient, Merida-Puga et al's patient and Adrissi et al's third patient (3 months in the latter two cases) allowed this to be achieved more rapidly, but the cumulative doses were all high.^{4,10} Overall, there appear to be no overt factors that predict who is likely to respond quickly or otherwise, although most patients will not require extended treatment based on this review.

Lead positioning

The predominant positions were RUL in 12 patients, one RUL unilateral and bilateral (unspecified), four bilateral (one bilateral frontotemporal, three bilateral) and two bitemporal (Supplementary Table 1).

Conclusion

The diagnosis of Huntington's disease is usually preceded by psychiatric symptoms in cases where family history is absent, sometimes by years.¹⁷ However, as we found in this review, patients are now likely to have an established diagnosis of Huntington's by the time they are considered for ECT. Although a CAG repeat number greater than 36 in the Huntington gene confirms the disease, an increased number of repeats is negatively correlated with age at presentation rather than severity of disease.¹⁶

Psychiatric manifestations of Huntington's disease vary according to the stage of the disease; apathy, for example, is found in 50% of patients by stage four on the UHDRS. Also present are obsessive-compulsive behaviour, irritability and aggression. Depression also increases over time, with only psychosis remaining consistent throughout at 11%.¹⁸

The prevalence of depression is about 50%, compared with anxiety at 17–61%, irritability at 35–73%, obsessive-compulsive disorders at 7–50% and psychosis at 3–11%. The prevalence of hypersexuality is between 2.1 and 30% and is slightly lower in women, whereas the prevalence of hyposexuality is higher at 63% in men and 75% in women.¹⁹ The use of ECT, however, is recommended only for depression on the basis of two of the above series.^{1,14,20}

There appeared to be little in the way of any effect on cognition with the use of ECT, although this was not a primary concern in this patient group. In the few reports where cognition was mentioned, the patients responded well and appeared to retain comparable pre-treatment scores over time, although the numbers were too small for us to draw any firm conclusions. However, Nakano et al's patient, despite comparable pre- and post-treatment MMSE scores (and significantly improved PANSS and BPRS scores), had greatly decreased 99 mTc uptake in the basal ganglia, cingulate gyrus and thalamus on SPECT after 21 ECT treatments compared to pre-treatment SPECT.⁵

There is little consistent evidence regarding the use of ECT for the motor manifestations of the disease. Chorea, a hyperkinetic movement disorder, shows variable response. In the studies considered in this review, chorea often responded to ECT (including for our patient), but this finding was not always documented and thus it cannot be extrapolated to a recommendation given the small number of patients. However, psychomotor retardation and catatonia, which are manifestations of psychiatric disease, all responded favourably, although the presence of catatonia may require more protracted ECT treatment. The reported swallowing issues and weight loss in our patient and others responded well. A situation that appeared terminal in our case has been managed effectively for the patient and her family with good control, for over 2 years following the first dose of ECT.

All the studies considered in the current review were either single-case reports or retrospective case series. There were no comparison or prospective studies. The most striking aspect of this literature was how the choice of ECT as a treatment came to be prescribed. In nearly all cases, ECT was a last resort when all else had failed, with the exception of one case in which it was used for the specific management of chorea.³ Consequently, strict psychiatric criteria were lacking prior to the decision to start ECT. The main concern in using ECT was related to controlling the manifestations of psychosis or depression/suicidality, with concerns regarding other manifestations, such as outward aggression, in only a few cases. Clinical success was documented by a general clinical sense of improvement, serving as an indication of efficacy, with no clearly defined end points. Similarly, the cognitive and motor scoring of patients was haphazard and inconsistent, with only limited numbers of patients having clear objective scoring on any scales – motor, cognitive or psychiatric performance – either before or after ECT was administered in order to monitor patient responses.

It is clear that the preliminary though limited evidence from this review supports the use of ECT for relieving depressive symptoms. However, this is often considered as a last resort when all other interventions have failed. The current review suggests that additional consideration be given to the use of ECT as an adjunct in conventional treatment-resistant cases of depression, as well as for wider psychiatric manifestations of the disease, especially where depressive and psychotic symptoms coexist. These wider psychiatric manifestations and complications, which include psychomotor retardation and hallucinations, appear to respond well to the use of ECT. Where there are wider psychiatric manifestations of Huntington's disease, ECT may not only control these more effectively but could also lead to rationalisation

of polypharmacy. Chorea may be less likely to respond to ECT, and so its use for this cannot be recommended based on the current review. Further investigative work with clear criteria and monitoring may lead to ECT being considered earlier and more often for patients with difficult-to-manage psychiatric manifestations of Huntington's disease.

- *Derek Bolton*

Derek Bolton is Professor of Philosophy and Psychopathology at King's College London, UK. He is one of the pioneers of the discipline of philosophy of psychiatry. He founded the MSc programme in Philosophy of Mental Disorders at King's, which was one of the few in the world. It was while taking that course that I first met him. He has remained a great teacher and mentor for me and many other colleagues throughout the years. His publications on the concept of mental disorder and the biopsychosocial model are great works of practical philosophy. We managed to catch up in the midst of the COVID-19 crisis and thankfully the technology didn't let us down!

Professor Bolton, you wrote your book on the concept of mental disorder¹ in 2008. What is your view of the development of the knowledge in that field?

When I wrote the book, it was prepared over several years of the MSc course that you attended and which started in the 1990s. At that time, the main contender in the philosophical and conceptual field about the concept of mental disorder was Jerome Wakefield's 'harmful dysfunction' account.² He proposed a naturalistic view according to which,

apart from any value that concerned human goods and harm, the concept of mental disorder also presupposed a natural fact, a dysfunction, which in his version was elucidated in evolutionary theoretical terms. Wakefield's account was a response to the challenges of 1960s and 1970s, which questioned whether mental disorders were 'natural kinds' as opposed to social constructs. My main task was to interrogate the assumptions of Wakefield's account. As it turned out, I was unable to make it work and came to the conclusion that mental disorder could not be pinned down by 'natural facts' as opposed to 'social facts' and the best way to capture it was in terms of impairment and distress, as in the DSM and ICD, which are as much personal and social as they are natural. What has changed since then (and I do not claim it is because of my book, which was at best an expression of shifting sands) is that attempts to disentangle natural facts about mental disorders have become less attractive, and what remains, the personal and social involvement of mental disorder – what might be called the psychological and social phenomenology – is more accepted. This leaves us with both challenges and opportunities.

What are these challenges and opportunities?

For opportunity, I think the person and the social context emerge as more central. The focus shifts from a disordered brain, or a disordered set of beliefs/behaviour, to the person in a social context with impairment/distress. The social context includes that it is not only (or not even) the patient who is distressed, but the family and extended society. The challenge is that the boundaries between illness and health, between what is and what is not the proper domain of healthcare, are more blurred, more socio-politically contentious. This of course has been recognised as an issue for psychiatry, but increasingly now in discourse about risks to physical health, evident for example in controversies over how to best manage the current pandemic.

Speaking of the boundaries between illness and health, that reminds me of a fairly recent book called *Vagueness in Psychiatry*.³ It argues that there is an inherent vagueness in terms such as health and disorder, which are semantic properties that cannot be corrected by gathering more facts and there always will be borderline cases. The existence of vagueness would not devalue the concept on its own. Do you agree?

It is true. I was brought up in the later Wittgenstein's philosophy school and my PhD was on works of Wittgenstein. In Wittgenstein's early work (the *Tractatus Logico-Philosophicus*) – like in the philosophy of logician and philosopher Gottlob Frege – it was assumed that concepts of course had clear boundaries. In what are called his later works (*Philosophical Investigations* is the major one), Wittgenstein dismantled the idea of clear boundaries. He likened language to a toolbox with lots of different tools for different purposes. If you look at language like that you lose the idea that concepts must have or ought to have sharp boundaries.

With reference to definitions, in some schools of philosophy definition is identifying necessary and sufficient conditions. Could this be part of the problem, where we try to find necessary and sufficient conditions for mental disorder – could moving towards a descriptive way be helpful?

It is an interesting question. If we think of philosophy as a canon and choose the great philosophers of the past few hundred years we see that the use of necessary and sufficient conditions does not feature or hardly features in their work. Philosophers such as Wittgenstein, Heidegger and Russell are example of this. Generally, I don't think concepts are usefully explained in terms of necessary and sufficient conditions. So, in the present context, when Robert Spitzer worked on the concept of mental disorder for DSM-III he was apparently not trying to identify necessary and sufficient conditions, but to identify criteria for its use (I believe he may have used the term 'conceptualisation' rather than 'definition').⁴ When we talk of definition of mental disorder, I think we are typically trying to conceptualise it and identify how it relates to other areas of interest, including personal distress and social impairments, as well as the various life and human sciences. Looked at like this, it is clear that mental disorder is not a fixed thing: the conceptual geography changes with changes in science and culture.

The discussion of social context brings me to your work on the biopsychosocial model. You recently co-authored a book with Grant Gillett titled *The Biopsychosocial Model of Health and Disease*.⁵ What made you interested in it?

In 2010, there was a book published with the title *The Rise and Fall of Biopsychosocial Model* by Nassir Ghaemi, whom I know.⁶ He argued that the biopsychosocial model was empty and without much use. That did puzzle me, as most people I know and whose work I had read seemed to suppose that the biopsychosocial model meant something and was the correct model for science and for practice. Nassir's book was a challenge to what the biopsychosocial model actually meant. He also added that it was a cover for loose thinking.

I remember attending a lecture of his where he argued that the biopsychosocial model was eclectic. If I remember correctly, it followed that the model was to some degree vacuous.

The historical context given in Nassir's book focused on the model mainly in the USA. He saw it as a framework within which competing models of psychoanalysis, social psychiatry and biological psychiatry could coexist and all be true.

In your book with Grant Gillett,⁵ you explored causation at different levels. I was interested in how you separated causation at the biological level from causation at the level of physics and chemistry.

The idea was worked out while writing the book. In his original paper, Engel identified reductionism as a problem for biomedicine, specifically reducing biology to physics and chemistry.⁷ That would exclude a distinctive biological causation and especially would exclude psychological and social causes. The core idea of the book was that there was a causation at the biological level that was above physics and chemistry. For the past 50 years or so biomedicine has developed as an exquisite combination of physics and chemistry but plus a whole new science of regulatory control, bringing in concepts such as functions, ends, positive and negative feedback systems and information flow. Importantly for the biopsychosocial model, these same causal explanatory frameworks also apply in the psychological and social domains. This is a way out of reductionism that can make sense of biopsychosocial causal interactions and the accumulating evidence of them in epidemiology and clinical therapeutics.

I was interested that you found the core of psychological causation in agency. How did you come up with that?

We didn't think about it at first. The primary task was to clarify causation and theoretical concepts of the various associated systems at the biological level. Once it became clearer as above, the psychological had to be understood as a system for regulating (causing) behaviour in the 'outside world'. 'Agency' is a shorthand for this. Also, various pieces of the contemporary scientific jigsaw puzzle fell into place, such as that neuroscience and psychology merge into one another, and that cognition is embodied. As to health problems and biopsychosocial medicine, this approach highlights emerging findings that many physical health problems, and especially the extent of experienced pain and associated impairment, key drivers of service use in long-term conditions, involve psychosocial as well as biological factors, implicating central involvement as well as biological systems below the neck.

In the book,⁵ you mentioned that we do not need to have an explicit theory of causation to accept causes in psychological and social levels. What do you think of psychiatry's engagement with the philosophy of causation?

All medicine purports to make a difference in the lives of patients and in this sense at least it needs some causal assumptions. It is true that we do not know how some treatments work, but when we intervene in different ways, we are supposing that it makes a difference and that is why we do it. The causal assumption is essential in these kinds of applied sciences. It is not unusual to not know how a treatment works but we should not lose confidence if we have evidence from, for example, randomised controlled trials that it is effective.

That reminds me of an anecdote on vaccination. It took several decades to know how the smallpox vaccine worked. If we wanted to wait to know the exact mechanism, millions would have died.

True. And if we contrast it with the present state that different vaccines are proposed for COVID-19, based on detailed models of cellular mechanisms of disease progression and how to interfere with them, it shows how much this field has progressed.

Going back to the reductionism, I found it interesting that you used emergentism as a way to challenge reductionism.

That was interesting. I didn't try to defend emergentism, which is a slippery idea with a complex history. I understood the position simply in terms of evolution, in which increasingly complex forms of life appear, each with characteristic phenotypic traits and associated causal powers.

I think your formulation of the biopsychosocial model is very useful. It could be very informative with concepts such as trauma.

Trauma is of course an important and interesting topic, with a long history in psychiatry and psychology. In terms of the biopsychosocial model we propose, trauma is an environmental stressor that has a direct negative impact on agency. In defining trauma in the context of PTSD, DSM and ICD regard 'helplessness' as a key feature. The position is that the most salient and important outcome in the situation (the person's own survival) is out of their control. This

occurs in acute situations like trauma but also in chronic exposure to severe stressors, implicated in upregulation of psychobiological stress mechanisms and raising risk of many kinds of both mental and physical health problems.

Thank you very much for your time.

1.2.37 Donald West, MD, LittD, FRCPsych

Jeffrey Weeks Philip Graham

- *Donald West, MD, LittD, FRCPsych*

Formerly Director of the Institute of Criminology, Cambridge, UK

Credit: Institute of Criminology, Cambridge.

Donald West, who died on 31 January 2020 aged 95 years, made a substantial contribution to knowledge in two areas of relevance to psychiatrists. In 1955 he published *Homosexuality*, a book for the general public. This was a sober, cautious, thorough presentation of the evidence about homosexuality in history, society and psychology, with some case studies from ‘self-confessed’ homosexuals to leaven the dough. It concluded that no doctor should advise a young person to be content with his sexual orientation without a ‘grave warning’ – ‘about the frustration and tragedy that so often attend this way of life’. West’s intention, as he described later in his memoir *Gay Life, Straight Work* (2012), was in fact more ambitious: to help the cause of greater understanding and legal reform, and he risked his career to do so. As he put it in his memoir, ‘For a young, unmarried professional to have stuck his neck out so recklessly seems, in retrospect, quite crazy [. . .]. I was protected by the hypocritical medical label’. Two years later, the Wolfenden Committee, which was sitting at the time *Homosexuality* was published, set up to reconsider the law, made recommendations for modest reform.

West’s book played an important part in changing the climate of opinion towards homosexuality in Britain. Many gay people of his generation and younger found it comforting to read something that confirmed their ‘normality’. It was, however, a further 10 years before male homosexuality was decriminalised in the Sexual Offences Act 1967. Subsequently, West continued to teach and conduct research on sexuality, publishing *Sexual Crimes and Confrontations: A Study of Victims and Offenders* in 1987 and (with Buz de Villiers) *Male Prostitution* in 1992. He also carried out, with Richard Green, a comparative study of controls on homosexuality across countries, published as *Sociolegal Control of Homosexuality: A Multi-Nation Comparison* (1997).

West’s other contribution to knowledge was his study of juvenile delinquency. In 1961, he set up the Cambridge Study in Delinquent Development. This study became one of the major, continuing, prospective longitudinal studies internationally in the field of developmental criminology. It began as a prospective survey of 411 south London boys, aged 8 years in 1961, who have since been interviewed at intervals through their lives. Their own children have been interviewed in more recent years, enabling a rich and extensive range of findings about antecedents and causes of criminality and desistance. Working together with his colleague David Farrington, who joined him in 1969, a number of major publications have emerged, including *Who Becomes Delinquent* in 1973, *The Delinquent Way of Life* in 1977 and *Delinquency: Its Roots, Careers and Prospects* in 1982.

Donald West trained in medicine at the University of Liverpool Medical School, qualifying as a doctor in 1947. While he was studying medicine, he had developed an interest in psychical research, finding in it an alternative to the religious enthusiasms of his parents. He had a lifelong interest in the paranormal, his first post being as research officer to the Society for Psychical Research (SPR). His first book was *Psychical Research Today*, published in 1954. His sceptical attitude to findings in this field did not, however, find favour with his employers and he was advised to find employment elsewhere. Although he doubted the claims of many spiritualist enthusiasts, he was convinced that extrasensory perception had a genuine psychological basis, deserving scientific laboratory research and statistical analysis. Indeed,

he remained committed to studying the paranormal throughout his career, and served several times as the president of the SPR.

He then trained in psychiatry at the Maudsley Hospital and Institute of Psychiatry, where he worked with Peter Scott, the leading forensic psychiatrist of the day. After completing his training, he worked at the Marlborough Clinic in Hampstead. In 1960 he joined the newly established Institute of Criminology in Cambridge as Assistant Director of Research. The founder and director of this institute was Sir Leon Radzinowicz, who was a strong believer in interdisciplinary research. West spent the rest of his career there, as lecturer, reader then Professor of Clinical Criminology. He was Director of the Institute from 1981 until his formal retirement in 1984. At Cambridge he became a Fellow of Darwin College, and was promoted to a personal Chair in Clinical Criminology. He also worked in an out-patient clinic at Addenbrooke's Hospital, Cambridge, as an honorary consultant psychiatrist. He was appointed to the Parole Board on its foundation in 1968 and, after his retirement from the Institute, served as a Mental Health Commissioner (1992–1997).

Donald was born in Liverpool, in a traditional red-brick workers' house near the docks, the only child of John, a catering manager with Cunard, and Jessie. His parents were of working-class origins with high aspirations. He was a sickly child, cosseted by his religious mother, who died when Donald was 11. His father later remarried. He felt the manner of his upbringing left him with chronic shyness and feelings of inadequacy. He won a scholarship to the fee-paying Merchant Taylors' school in Liverpool, from where went on to study medicine at Liverpool University.

His memoir was written with the encouragement of a gay writers' workshop in a manner quite different from his academic style. For many years he attended social meetings of Opening Doors London, the leading organisation for older LGBT+ people. West appeared an austere and, in his own words, a not particularly clubbable person, but he had a dry wit and a wide and eclectic network of friends.

He was in a relationship with the art historian Pietro Raffo for more than 45 years, until Raffo's death in 2000. In 2006, he entered into a civil partnership with Vincenzo. He died on 31 January 2020. Vincenzo survives him.

This obituary is based on one published in *The Guardian* on 23 April 2020 (<https://www.theguardian.com/books/2020/mar/11/donald-west-obituary>).

The contributors to this refreshing, courageous and remarkable book break the silence about young people living with parental mental illness and the distress they and their immediate and future families experience. The central theme is to enable conversations about difficult experiences of parents and children. Airing personal reflections and experiences risks rejection, stigma, hurt and isolation. Traumatic experiences are often associated with avoidance of reminders and a desire to imagine the world to be different and just, rather than the more abrupt reality of moral fractures in a world where fragile and vulnerable minds are overwhelmed. Parents wanting so much for their children find themselves unable to live up to their own expectations, and at the same time lament that they may be hurting their children inadvertently, just by living with mental illness. Yet, these sentiments are not easily realised, and much time is spent by parents and children in evading or not knowing how the other feels and sees the world, including in their relationships.

The contributors include young people who were raised by people with mental illnesses, some of whom have gone on to become parents and enter the professions that work with children not dissimilar to their past selves. Additionally, in the book, parents offer commentary and children in return reflect on their parents' dilemmas and distress. Although it is painful to confront such realities, all contributors are optimistic, full of gratitude, being mindful of how the world looking back seems so different from how it felt in the moment.

Through a network of conversations, observations, reflections and counter-reflections, the editors provide a form of

scaffolding that helps. They create and display the very process that needs to take place between parents and children facing fears and isolation that come with parental mental illnesses. They reveal how intimate and important sentiments surfaced and were discussed in a reflective fashion by families to arrive at what seems like a more settled and peaceful coexistence, an appreciation of each other's strengths, and ultimately the enduring respect and love that evolve as they show they care so much for each other. That they matter more than they realise.

There is much here for professionals, parents and children, as well as commissioners and policy makers. The first-person accounts are invaluable, articulate and perhaps even a little refined and polite, having been worked at for some time. This makes it easier to hear about some very harrowing moments in the lives of those bearing witness to and living with the silent struggles. I do hope that those affected will read the book and discover they need not be alone and have much to give and have more courage than they might realise.

Abstract

Aims and Method

This study evaluated a pilot psychiatry summer school for GCSE students in terms of participant experience, effects on attitudes to mental illness and perception of psychiatry as a career option. This was done using the Community Attitudes towards the Mentally Ill scale, career choice questionnaires and a discussion group following the week-long programme attended by 26 students.

¹ See editorial, this issue.

² Joint first authors.

Results

Students were significantly more likely to choose psychiatry after the summer school ($P = 0.01$). There were statistically significant changes in scores for social restrictiveness ($P = 0.04$) and community mental health ideology ($P = 0.02$). Qualitative analysis generated four themes: variation in expectations, limited prior knowledge, perception of the summer school itself and uniformly positive attitudes to psychiatry after the summer school.

Clinical implications

Targeting students at this early stage appears to be an underexplored positive intervention for improving both attitudes towards mental illness and recruitment to psychiatry.

Introduction

Summer schools allow students to access educational experiences that are not otherwise available to them. They are a successful facet of the Royal College of Psychiatrists' #ChoosePsychiatry campaign¹ and, if well designed, can improve attitudes to psychiatry among medical students.² However, as summer schools are primarily aimed at medical students and foundation doctors, opportunities to experience psychiatry while at school remain limited. A psychiatry scheme for school leavers³ and work experience placements focusing on mental health for A-level students⁴ have been reported with positive outcomes. However, these examples concentrate mostly on those already committed to applying to medical school. Such programmes, especially those with entrance processes requiring evidence of prior interest, tend to favour those already motivated to work in psychiatry. Thus, there is recruitment potential in prioritising those that have little prior knowledge of the subject.⁵ Studies have shown that medical students reporting an interest in psychiatry before medical school are more likely to subspecialise in it in the future.^{6,7} Therefore, the evidence suggests that a summer school for students following their GCSEs would allow them to obtain valuable early experience of psychiatry and hopefully garner a potential untapped interest in psychiatry as a career. The aim of this study was to evaluate the

experiences of GCSE students attending a psychiatry summer school, with a secondary aim of assessing its influence on attitudes to mental illness and perception of psychiatry as a career.

Methods

Setting

The summer school was a joint venture by the Institute of Psychiatry, Psychology and Neuroscience (IoPPN) and the local mental health trust, South London and the Maudsley NHS Foundation Trust. It was a free 5 day programme (see *Table 1*) for GCSE students, with participants recruited from state and private secondary schools within south-east London. *Table 1* Summer school timetable

Selection of participants

Letters were sent to careers advisors at all 15 eligible schools within a 1.5 mile radius of the IoPPN, inviting them to nominate two participants and two waiting-list students each for the summer school. Non-eligible schools were those that only catered for pupils with special education needs or were sixth form only. Each school independently decided on the selection procedure, with the only proviso being that the student should be academically capable of entering a medicine degree course. They did not have to have expressed any interest in medicine as a career.

Curriculum development and structure of summer school

The curriculum was developed and implemented by a volunteer committee of psychiatry trainees, led by the Director of Undergraduate Psychiatry. The programme included a mixture of lectures and small group workshops, in addition to three joint sessions with an established summer school for medical students being held in parallel. Content included daily sessions with patients and their psychiatrists and the breadth of psychiatry subspecialties, but also addressed the wider context of mental illness such as social factors, transcultural applications and the history of psychiatric practice.

Assessment

This was a mixed quantitative and qualitative methods evaluation with ethical approval obtained through the Research Ethics Office at King's College London.

All participants were invited to take part in the evaluation, and participants gave written informed consent. Pre-programme, demographic information and prior exposure to mental illness were collected. Participants' top three career choices, likelihood of choosing a career in psychiatry and score on the Community Attitudes towards the Mentally Ill (CAMI) scale⁸ were obtained pre and post programme.

The CAMI scale comprises 40 items representing the following four dimensions: authoritarianism (the view that the mentally ill are different and require coercive measures), benevolence (sympathetic views towards the mentally ill), social restrictiveness (that the mentally ill are dangerous and need to be separated from society) and community mental health ideology (importance of community care for the mentally ill).^{8,9} It was selected for its utility within a community rather than a professional population, as the sample consisted of school students with no medical training.

On the final day, a short discussion group was run to gather feedback on the summer school experience. All students were informed of the group, and six randomly selected volunteers contributed. The facilitator (G.-L.d.B.) was known to the students, so left the room after posing each question to enable free unconstrained responses, which were recorded.

The contributors were asked three open questions, which were designed to enable discussion and aimed to assess 'before and after' attitudes in relation to the summer school and psychiatry. •Why did you want to come to the summer school and are you glad that you came?•What did you hope to get out of the summer school and what did you actually get out of it?•How did you feel about psychiatry before and after the summer school?

³ CAMHS, child and adolescent mental health services; FND, functional neurological disorder; PTSD, post-traumatic stress disorder.

Statistical analyses

Only one of the participants did not complete post-training preferences for medicine and psychiatry, and these missing values were not imputed. Participants' characteristics and other variables were initially analysed by descriptive statistics. We checked whether the continuous study variables followed a Gaussian distribution by Shapiro–Wilk tests. We employed appropriate non-parametric tests when the continuous study variables did not follow a Gaussian distribution. Changes in the career choices of the participants between the two time points were analysed by McNemar's test or Wilcoxon signed-rank test. Changes in CAMI subscale scores between the two time points were analysed by appropriate tests of statistical significance. All analyses were performed using the statistical software STATA 15.1 (StataCorp, TX, USA).

After transcription of the discussion group, the responses were initially analysed using open coding by a researcher independent of the summer school programme (C.H.). Alongside a second researcher, who had overseen the discussion (G.-L.d.B.), these open codes were grouped into axial codes, which were then further distilled into themes.

Results

Quantitative

Of the 26 participants, ten (38%) were from private schools and the remainder were from state schools. Of the participants, 20 (77%) voluntarily completed both the pre- and post-programme questionnaires. Of these students, 12 (60%) were from non-White ethnicities. Data on demographics and career choices can be found within *Tables 2 and 3*. The majority (70%) reported life experience of mental illness before attendance at the summer school, and 50% had received some school teaching on the subject. *Table 2* Demographic characteristics Demographic characteristic (%) Total number
20 Gender Male 7 (35) Female 12 (60) Not specified 1 (5) Age (years) 15 1 (5) 16 1 (5) 19 9 (45) Ethnicity White 8 (40) Mixed 2 (10) Black/African/Caribbean 6 (30) Asian 4 (20) Experience in mental health Life experience (personal/friends/family) 14 (70) Work experience/volunteering 2 (10) School teaching on mental health 10 (50) Family member working in mental health 6 (30) *Table 3* Career choices Before programme ($N = 20$) After programme ($N = 19$) Choice n (%) 95% CI n (%) 95% CI α First 2 10.00 1.23–31.70 5 26.32 9.15–51.20 Second 2 10.00 1.23–31.70 2 10.53 1.30–33.14 Third 0 0.00 0.00–16.84 4 21.05 3.10–33.14 Within 3 42.00 5.73–43.66 9 47.37 24.45–71.14^{4,5}

According to the measure of a student's likelihood to choose psychiatry as a career, participants were significantly more likely to choose psychiatry after the summer school week ($z = 2.46$; $P = 0.01$). Pre-course, four participants ranked psychiatry within their top three career choices. This increased to nine post-course, which was a statistically significant change (McNemar's $\chi^2 = 5.00$; $P = 0.03$). Two participants ranked psychiatry as their top career choice pre-course, and this increased to five post-course. However, this change was not statistically significant (McNemar's $\chi^2 = 3.00$; $P = 0.08$).

On review of the CAMI scale, there were statistically significant changes in scores pre- and post-programme for both social restrictiveness (viewed less positively, pre: 18.6, post: 16.05, $t = 2.25$; d.f. = 19; $P = 0.04$) and community mental health ideology (viewed more positively, pre: 38.45, post: 40.5, $t = 2.48$; d.f. = 19; $P = 0.02$). There were no significant changes for benevolence (pre: 41.15, post 41.55, $P = 0.54$) or authoritarianism (pre: 20.8, post: 19.8, $P = 0.33$).

Qualitative

Qualitative analysis of the discussion group generated 29 open codes and ten axial codes, from which four themes were generated.

Theme 1: Variation in expectations of summer school

The group was divided between those who had positive expectations for the programme and others who described initially feeling less enthusiastic about attendance. Those with an existing interest in medicine or mental health tended to express expectations that the summer school would enhance their knowledge of mental health conditions and provide further insight. *“I definitely wanted to go into medicine so I just wanted to see about the different areas”* *“I hoped to get more informed about different mental disorders... because I’ve been interested in that for a while”*

Others had a more generic reason for signing up to the programme, with half mentioning wanting to keep themselves occupied over the summer holiday or participate in an activity that was both enjoyable and worthwhile. One participant admitted being coerced by his mother to attend. The students discussed their negative preconceptions; some anticipated that the sessions would be wholly didactic in nature, with senior doctors leading and no element of interaction. There was also a concern voiced that, as school students, they may have felt patronised. *“My expectation coming in was that it would be a lot less involved than I thought it would be. I thought it would just be doctors talking over us instead and to us instead of actually letting us discuss”* *“I hoped that I would be treated in a way that wasn’t a GCSE student that’s like dumb and doesn’t know anything, doesn’t really know what they want to do and over dumbed-down for them”*

Theme 2: Limited prior knowledge and exposure to psychiatry

As a group, the participants admitted to very limited previous knowledge about mental illnesses, the scope of psychiatry and the management options available. Most brought up a lack of understanding of the difference between the disciplines of psychology and psychiatry, including those who had been exposed to the topic in lessons and school talks. *“I didn’t know that a psychiatrist was actually a doctor, I didn’t know that mental illnesses were such a wide range and they were so important and there are different ways of dealing with them”* In their personal lives, there was one suggestion of first-hand experience of mental health difficulties and one student whose parent worked in the field. However, familiarity was not necessarily advantageous – the aforementioned parent allegedly refused to talk about their job to their child. Some referenced impressions of psychiatry that had been created and influenced by the media. *“I thought it [psychiatry] was about medicating people and torturing them in a way and putting them to sleep (laughing) I’m serious, I’m actually being serious, because of the movies”*

Theme 3: Perception and experience of summer school

Perception of the summer school retrospectively was consistently positive across the cohort. All felt they had benefited in at least one respect, such as better knowledge of mental health conditions, increased interest in the area or even a sense of privilege from involvement in the programme.

Repeated comments were made about the rare opportunity to associate with professionals and medical students, which was found to be a valuable way of gaining insight from those directly involved in clinical work. Interest was expressed in not only the substance of their work but also personal experiences and perspectives. *“... to talk to actual patients, talk to actual doctors, actual medical students and I think it’s a really amazing opportunity and I wish there were more that were just as easily accessible and just as free and as local”* The daily sessions with past or current patients exploring their experiences of mental illness and treatment were frequently mentioned as a highlight of the programme. The participants appreciated the university-style teaching methods, particularly the interactive components and being given space for further discussion on the topics broached. *“... we have had the opportunity to talk and express our own opinions about other stuff which I didn’t think we’d be able to, and while doing that, also shown a lot of really good stuff about what it’s like to be a doctor or a psychiatrist”* *“We were in actual lecture theatres listening to lectures university style, we were looking at patients... It was really amazing, I got a lot more knowledge and experience out*

of this week then I could have possibly thought. I just hoped I'd get an opportunity to talk about psychiatry but nothing on this kind of scale"

Theme 4: Uniformly positive attitudes towards psychiatry following summer school

In addition to their experience of the summer school as a programme, all participants had a positive impression of psychiatry in itself. Those who began with a limited or negative perspective indicated that prior misconceptions had been challenged and questions had been answered. Psychiatry was compared favourably with other areas of medicine, and psychiatrists as a group were looked upon positively. *"The treatment of the patients has been fulfilling to them [psychiatrists] personally as well. It might be a lot more interesting than the other professions or the other parts of being a doctor, which I guess is a change" "It's also the relationships that they have with the patients. They talk about it like they actually remember them and they actually care which is really nice to know"*

Although not specifically asked about career intentions in the discussion group, most volunteered that they were considering psychiatry as an option for the future as a result of the summer school. This included those who were not previously interested in medicine and also those who had considered becoming a doctor but were focused on other branches of practice. Some had even forged interests in specific subspecialties. *"From the very first day and the very first session, my eyes were really opened as to what exactly psychiatry is about and how it can appeal to somebody like me, especially considering I wanted to be doing a different kind of speciality, like surgery, but now I think I have a much more open viewpoint on the different specialities, especially psychiatry" "This week has changed my perspective so much that I'm actually wanting to go into military psychiatry so yeah it's changed me as a person"*

Discussion

Our evaluation of this inaugural summer school has demonstrated that an educational project such as this has the potential to encourage students yet to start their A-levels to consider a career in psychiatry.

Despite increasing awareness of the importance of mental health in the public domain, participants showed limited knowledge about mental illnesses, including misconceptions about the role of a psychiatrist, a lack of knowledge about treatment options and influence from negative media portrayals of the profession. This indicates that campaigns and media interest¹⁰ do not necessarily translate into awareness of career opportunities, which must be a separate strand of work in parallel with stigma reduction. The improvement in understanding and awareness shown by the time of the discussion group demonstrates the direct effect of the summer school.

Although clinical contact has not always been an essential factor in improving attitudes towards psychiatry,² our experience was that witnessing the doctor–patient relationship and hearing about the effects of the work of a psychiatrist were key strengths of the summer school identified by the participants. In keeping with medical student and trainee experience,¹¹ it appears that role models are also important early on to enable students to visualise their own potential next steps.

This evaluation adds to the body of evidence that educational interventions can change the attitudes of adolescents towards mental illness.^{5,11–15} Although this was not the primary purpose of the summer school, it was a welcome side-effect. It is noted that not all subscales of the CAMI showed significant change pre and post course. However, given how little current comparative data exist on attitudes to mental illness in our population group, further research is required to fully explain these results.

The Royal College of Psychiatrists' current recruitment strategy¹ is inclusive of school students, having aimed to roll out regional sixth-form career events by the end of 2019. We propose that GCSE student events are an area worth exploring further. These may serve to inspire students who perhaps have a less fixed commitment to one career path, have not considered medicine previously or have little knowledge of the scope of psychiatry and still have time to change their A level choices. We felt the following aspects were crucial to making the summer school accessible to a range of students and meeting the national efforts to widen participation.¹⁶ •Enabling students of all socioeconomic backgrounds to participate; it was free of charge and food was provided. •Ensuring there was no competition between private and state schools for places. •Proactive chasing of schools that did not immediately respond (these tended to

be state schools, who were less likely to have a dedicated careers advisor).•Timing the summer school before A-level choices so students had the option to change these if they wanted.

The main limiting factor in this study was the small sample size of 20 students. Our qualitative data from the discussion group did not reach saturation, demonstrating that not all potential data were garnered from this aspect of the evaluation. More discussion groups would be required in further research. In addition, although our cohort comprised a mixed demographic from a diverse part of south-east London, even if they had a variety of motivations, expectations and career interests, the students were still a self-selecting group, with all agreeing to attend a week-long summer school on psychiatry. We did not collect information such as family history of higher education and parental occupations, but doing so would help to assess whether students from all socioeconomic backgrounds were accessing the summer school. A barrier to transferability is that areas without potential funding from a major educational institution such as the IoPPN and a large pool of academics and clinicians to draw upon may find it challenging to provide this intensity of programme for a relatively small number of participants. Finally, as this is a little-studied population, it is unclear which assessment tool is most suited to explore school students' attitudes towards psychiatry.

Conclusion

Targeting students at this early stage appears to be an under-utilised intervention for psychiatry recruitment, and one which offers exciting potential for further work. The participants reported universally positive experiences of the summer school and demonstrated a shift towards considering psychiatry as a future career. There was also a valuable side-effect of more positive attitudes towards those with mental illness. We plan to repeat this summer school in future years and undertake longer-term follow-up in regard to participants' A-level and degree choices and ongoing interest in psychiatry as a career.

Abstract

Aims and method

Education leads for undergraduate psychiatry in UK medical schools completed questionnaires on adaptations made to undergraduate psychiatry education, their impact and what lessons could be learnt for the future.

Results

Respondents from 24 medical schools across the UK reported a major shift to online teaching delivery, with reduced workplace learning and increased use of teleconferencing, online tasks and self-directed learning. Changes were implemented with some faculty training provided, but little additional funding or resources from medical schools or National Health Service trusts. A variety of challenges and opportunities were reported.

Clinical implications

Despite the extraordinary efforts of education leads to maintain undergraduate psychiatry education, the pandemic may affect the development of students' professional competencies and recruitment into psychiatry. Individual clinicians, trusts and medical and foundation schools have much to offer, and need to work with students to replace what has been lost during the pandemic.

In the UK, the first lockdown in response to the COVID-19 pandemic was announced on 23 March 2020. This prompted rapid changes in medical education, including withdrawal of students from clinical placements and a shift to online teaching. As the pandemic continues, undergraduate medical educators face difficult choices to ensure a continuing supply of competent medical professionals for the future healthcare system.¹ Clinical skills in psychiatry will particularly be needed to address the significant impact of the pandemic on mental health. Increased depression and anxiety symptoms have been reported, including in young people,^{2–4} and long-term consequences are emerging in those who have recovered from COVID-19.⁵ Furthermore, many healthcare professionals are themselves experiencing symptoms of anxiety spectrum disorders.^{6,7}

To prepare our future doctors for the expected rise in demand, high-quality psychiatric education must not only continue, but also be prioritised. There is no consensus or guidance yet on what and how adaptations to undergraduate psychiatry teaching should be implemented during the pandemic. Although individual institutions outside of the UK have shared their experiences,^{8–11} there has been no work published to date from the UK or on the collective experiences of different institutions. Understanding the experiences of multiple institutions provides a powerful opportunity to share learning and identify the needs of this cohort of students.¹²

Objectives

Our aims were to identify what and how adaptations to undergraduate psychiatry teaching were made in response to the pandemic restrictions, their impact and what lessons could be learnt from the collective experiences of UK medical schools.

Method

We conducted an online cross-sectional questionnaire survey of education leads for undergraduate psychiatry who represent their medical schools on the Royal College of Psychiatrists Undergraduate Education Forum (UEF). The questionnaire was drafted on Microsoft Forms (Microsoft, Richmond, Washington, U.S.; see <https://forms.microsoft.com/>). Questions were based on areas of adaptations identified in Gordon et al's scoping review¹³ and current reports of adaptations in psychiatry teaching from other countries.^{8–10} The UEF contributed to the final design of the questionnaire, which consisted of both open and closed questions, and included the following themes: changes to teaching delivery and content, changes to the psychiatry rotation, changes to assessment, support for learners, faculty development, funding and resources, and impact of adaptations.

Respondents were asked to consider adaptations in the current academic year. As clinical placements in psychiatry in most schools occur in the penultimate year, responses were included only from the 33 registered and publicly funded UK medical schools established before 2018.¹⁴ The Queen Mary Ethics of Research Committee advised that as an evaluation of teaching, research ethics review was not required. The full survey is available in Supplementary File 1 available at <https://doi.org/10.1192/bjb.2021.67>.

The survey was distributed via email to the members of the UEF on 20 November 2020, with one reminder email a month later. It remained open for 2 months and participation was voluntary. Where omissions were present in returned questionnaires, respondents were contacted for clarification.

Data were exported from Microsoft Forms to Microsoft Excel version 16.33 for Mac, which was used to calculate descriptive statistics and create graphs. Open-ended text responses were reviewed to describe adaptations in more detail, and to compile a summary of opportunities and challenges for psychiatry teaching during the pandemic.

Results

Respondents

A total of 24 education leads completed the survey (72.7% response rate). Respondents from schools in all four nations of the UK participated, with 19 from England, 2 from Wales, 2 from Scotland and 1 from Northern Ireland.

Moving to online delivery

Figure 1 shows the changes that were made to delivery of different teaching approaches, with a major shift to online delivery. Fig. 1 Method of delivery of different teaching approaches before and during the pandemic.

Schools differed widely in the percentage of online teaching delivered synchronously, with an average of 66.1% and range of 10–100% ($n = 22$). In the 23 schools where it was used, asynchronous teaching employed a range of existing resources, primarily e-learning resources (82.6%) and recordings of previous content (82.6%) from respondents' own medical schools and e-learning resources obtained through the UEF (73.9%). Of the schools that used asynchronous teaching, 87% created new resources for this purpose. These included new recordings of teaching sessions, simulated patient videos, online modules, workbooks to consolidate materials and guide learning, revision notes, quizzes, question banks and serious games.

Course content

A total of 83.3% of schools reported no change in the content of the psychiatry curriculum; in three of the four schools where a change was made, these had already been planned before the pandemic, and were implemented during the pandemic or brought forward.

The amount of teaching across the six psychiatric subspecialties stayed the same in the majority of schools (*Fig. 2*). For every subspecialty, more schools increased rather than decreased teaching; 25% of schools increased teaching in general adult psychiatry, with no schools decreasing teaching in this subspecialty. The subspecialties that had most decreases in teaching were psychiatry of intellectual disabilities (12.5%), forensic psychiatry (8.3%) and medical psychotherapy (8.3%). *Fig. 2* Responses to the question 'Has the amount of teaching in the following subspecialties increased, decreased or stayed the same?'

Learning approaches

Although 66.7% of schools made no change to the length of the overall psychiatry module, 12.5% increased and 20.8% reduced the length. Also, 66.7% of schools did not change the length of clinical placements; however, respondents noted that in practice, there was reduced time in clinical settings and more time in self-directed learning. This is reflected in 87.5% of schools decreasing the proportion of time students spent in workplace learning (*Fig. 3*). In addition, 33.3% of schools decreased the length of clinical placements. All schools increased the proportion of time students spent completing online tasks, and 62.5% of schools increased sessions officially designated for self-directed learning. More schools increased small group teaching (41.7%) than lectures (21.7%). *Fig. 3* Responses to the question 'Has the proportion of time spent by students learning using the following approaches increased, decreased or stayed the same?'

Clinical placements

A total of 37.5% of schools increased numbers of students placed in in-patient wards, and 33.3% of schools decreased numbers placed in community teams (*Fig. 4*). For most schools, numbers of students placed in home treatment teams (58.3%) and liaison psychiatry (58.3%) stayed the same. *Fig. 4* Responses to the question 'In the current academic year, have the number of students placed in the following clinical environments/subspecialties increased, decreased or stayed the same?'

Most schools placed the same number of students in general adult psychiatry (62.5%), old age psychiatry (54.2%) and child and adolescent psychiatry (54.2%) during the pandemic (*Fig. 4*). General adult psychiatry had the most schools increasing numbers of students placed in the subspecialty (25%), whereas old age psychiatry (25%) and child and adolescent psychiatry (25%) had the most schools decreasing numbers placed.

Teleconferencing in clinical placements

A total of 75% of schools had teleconferencing in some clinical placements, with 20.8% in all placements. The only school where there was no teleconferencing had moved all placements to the in-patient setting. Teleconferencing allowed students to engage in clinical activities remotely from home or from the same location as the clinician. Students observed and participated in out-patient reviews, and joined meetings and ward rounds. One school recruited patients who could be interviewed by students via teleconferencing.

Assessment

Regarding assessment, 66.7% of schools reported that assessment of the psychiatry rotation changed during the pandemic. Changes included reduced demands, such as reduced emphasis on documenting experiences, reduced numbers of workplace-based assessments or case presentations, and reduced attendance monitoring. Despite reduced assessment demands, respondents were clear that standards would not be lowered or compromised.

Some schools shifted toward formative assessments; for example, using an assessed clinic letter or a portfolio of cases, reflections and workplace-based assessments rather than a clinician-observed long case. Greater onus was placed on individual supervisors to oversee satisfactory student performance. Like teaching delivery, assessment moved online. Online platforms, video stations and virtual cases were used to assess clinical skills, case-based discussions and presentations, and logbooks were completed online.

Supporting learners

In 41.7% of schools, psychiatry teachers were involved in developing resources or interventions to support learners' mental health and well-being during the pandemic. Respondents described developing well-being talks and workshops. They established well-being drop-ins, well-being champions, virtual student messes, and pastoral and reflective groups, including for students volunteering in the National Health Service (NHS). Well-being information was provided through newsletters and online platforms. Existing mechanisms to support learners were bolstered or reiterated to students.

Faculty development

In 50% of schools, faculty received some training in adapting teaching in response to COVID-19, with training in online teaching provided in 58.3% of schools. Training led by medical schools included sessions or e-learning modules on delivering remote learning (e.g. blended learning design, platforms), access to e-learning authoring tools, individual discussions with education leads and opportunities to share practice. Such training was less accessible to clinical staff, who received additional support from psychiatry education leads. This included training on online platforms, reflective groups to share practice and ensuring adequate technology at clinical sites.

Funding and resources

A total of 95.8% of education leads received no additional funding or resources from their medical school to deliver psychiatry teaching during the pandemic; only one school reported such support, which was additional funding to develop e-learning materials. Further, 79.2% of education leads received no additional funding or resources from their affiliated NHS trusts. In those trusts that provided additional support, this included laptops for students, computer equipment, funding for consultant psychiatrist time to coordinate placements and support clinicians, and funding for actors or patients to be interviewed by students practising clinical skills.

Student involvement and response

Half (50%) of education leads agreed that students were involved in adapting the psychiatry course (*Fig. 5*). Education leads reported that students had responded positively to adaptations, with 87.5% agreeing or strongly agreeing with the statement. *Fig. 5* Responses to the question 'To what extent do you agree or disagree with the following statements?'

The future

A total of 62.5% of respondents agreed or strongly agreed that the pandemic will change psychiatry education for the better (Fig. 5), and 54.2% of respondents agreed or strongly agreed that the pandemic has raised the profile of psychiatry among medical students.

In 87.5% of schools, the psychiatry rotation will not return to exactly how it was before the pandemic. Changes will include increased blended learning, with respondents noting the advantages of facilitating access from distant placements and the ability to accommodate increases in student numbers. Other changes include keeping modifications in placement structure, online logbooks and the use of resources from other schools.

Discussion

This survey of adaptations to psychiatry teaching from 24 medical schools across the four nations of the UK demonstrates the seismic impact of the pandemic on psychiatry education. *Table 1* summarises both the opportunities and challenges that emerge from the survey data, with proposed solutions to meet the challenges. *Table 1* Opportunities, challenges and proposed solutions for undergraduate psychiatry education during the pandemic

Opportunities	Challenges	Proposed solutions
Students	Accessibility and flexibility of online delivery	Reduced travel
Asynchronous teaching accessible at convenient times	Clinical experiences available remotely, including for self-isolating students	Gaining familiarity with telemedicine
Educational advantages of blended learning and flipped classrooms	Requirements needed for online delivery	Adequate bandwidth and hardware
Limited access to technology in clinical environments	Time spent learning new technology	Experiences of online delivery ‘Zoom fatigue’
Negative impact of isolation on student well-being	Less engaging than face-to-face delivery	Difficulty in engaging with self-directed learning
Clinical placements	Reduced contact with patients, so reduced opportunities to develop clinical skills	In in-patient settings, space constraints and need for social distancing may prevent students from accessing opportunities such as ward rounds in person
In community settings, there are fewer opportunities to engage with patients face to face and learn to be in the room with patients	Travel to face-to-face placements during pandemic	Service changes resulting in last-minute cancellations and timetabling changes
Difficult to get signed off by busy clinicians	Experiences of teleconferencing on clinical placement	Less engaging than face to face
Juggling multiple IT accounts	More difficult for students to participate in clinical tasks	Missing out on pre-brief and debrief before and after consultations
Hard to feel part of the team remotely	Online delivery	Investment in dedicated educational facilities at hospital sites
Scheduling adequate breaks	Interventions to address student well-being	Systems to identify students who are engaging poorly with online learning
Educating students about how to approach online and self-directed learning	Clinical placements	Inclusion of training in psychiatry in foundation programmes and beyond
Increased clinical and communication skills training delivered outside of clinical placements	Honest dialogue with students about the potential for disruption to their learning during the pandemic	Making use of all available opportunities for face-to-face contact with patients, e.g. students shadowing on-call staff
Pairing in-patient and community placements	Ring-fenced time for undergraduate education in clinicians’ job plans	Teleconferencing on clinical placement
Training teachers to include student participation in consultations	Deliberate inclusion of pre-brief and debrief time	Including students in all team activities, e.g. meetings
Including multidisciplinary team members in teaching	Teachers	Accessibility of online delivery
Gaining familiarity with telemedicine	Opportunities for interactivity in online delivery	Increased clinical pressures
Online delivery	Time spent learning new technology with little training	Some students engage less with synchronous teaching, e.g. cameras switched off
Managing unprofessional behaviours	Teleconferencing	Logistical demands of setting up teleconferencing
Difficult to build teacher–student relationships remotely	Increased training on online delivery	Setting of expectations for student engagement with teaching and digital professionalism
Promoting continuity to encourage the building of teacher–student relationships. e.g. same tutor throughout placement	Ring-fenced time for undergraduate education in clinicians’ job plans	Course content
Accessibility of online delivery facilitates	Webinars with external speakers	Attendance at mental health tribunals
Increased involvement of experts by experience	Increased teaching in some subspecialties	Asynchronous teaching
Expanded offer available to students	Standardisation of teaching quality	Service changes (e.g. ward closures) limit some learning opportunities
Access to other learning opportunities (tasters) not possible because of social distancing	Increased online teaching on certain areas to compensate for lost learning opportunities	Inclusion of training in psychiatry in foundation programmes and beyond
Course organisation	Booking and availability of rooms no longer of concern	Same lectures do not need to be recorded multiple times
More immediate student feedback leading to rapid improvement of quali-		

tyExposing underfunding in undergraduate education to justify additional resourcesShowing that online learning can be a solution to accommodating increases in student numbersIncreased collaboration between schools, e.g. sharing resources Some clinicians are less keen to host students and engage in teleconferencingNeed for faculty development for online teachingIncreased administrative burden of organising online delivery and redesigning clinical placements in accordance with public health measures, e.g. staff working from home, social distancing and bubbles Incentives for clinicians to contribute to undergraduate teachingIncreased training on online deliveryIncreased administrative support and resources from medical schools and National Health Service trustsPromoting psychiatry Improved attendance by studentsIncreased recognition of the importance of reflective practice across all specialtiesIncreased focus on student and staff well-beingShowcasing psychiatry as an exemplar of innovations in adapting teaching Reduced opportunities to meet role models with less time on clinical placementReduced opportunities to combat stigma toward mental illness with reduced contact with patients Maximising learning opportunities during shortened clinical placementsIncreased activity of student-led psychiatry societies to promote psychiatryBuilding in opportunities to meet psychiatrists and experts by experienceImplementing specific training on stigma toward mental illnessIncreased postgraduate training in psychiatry clinical skills

Developing clinical skills in psychiatry

The Royal College of Psychiatrists' curriculum recommendations, informed by the General Medical Council's (GMC) 'Outcomes for Graduates',¹⁵ states that an important aim of undergraduate psychiatry education is for 'students to develop the necessary skills to apply [professional] knowledge in clinical situations'.¹⁶

Clinical placements form the bulk of students' experience in psychiatry in the UK,¹⁷ offering opportunities for experiential learning and participation in authentic clinical environments.¹⁸ However, 87.5% of schools were forced to decrease the proportion of time that students spent on clinical placement. Even when clinical placements were possible, service changes and social distancing requirements changed the nature of their learning opportunities. Without these experiences, students may have difficulty in understanding how to apply their professional knowledge in clinical contexts. Indeed, the Medical Schools Council notes that 'it is not possible for students to meet the requirements set out in the GMC's Outcomes for Graduates without undertaking clinical placements'.¹⁹

During the pandemic, schools continued to provide clinical skills, role-play or simulation teaching, with 45.8% delivering these fully online. Although online skills teaching can alleviate students' concerns about reduced patient contact,²⁰ learners feel less prepared to use skills learnt in practice.²¹ In a survey of UK medical students in May 2020, three-quarters felt that online teaching had not successfully replaced the clinical teaching that they received from direct patient contact.²²

A total of 95.8% of schools used teleconferencing on clinical placements, which, though useful, has limitations. For instance, the court judgment on remote Mental Health Act assessments noted that 'a psychiatric assessment may often depend on much more than simply listening to what the patient says ... [and] may involve a multi-sensory assessment'.²³ In consultations by teleconferencing, clinicians face difficulties in reading non-verbal communication, using silence and incorporating physical examination.²⁴ Without the opportunity to see clinicians demonstrating these skills and to practise these skills themselves, students are left with an experience that translates poorly to the face-to-face situations they will encounter in the future. Moreover, clinicians cannot model some skills that are important in face-to-face work, such as preparing consultation rooms or judging physical distances between patient and clinician. Nevertheless, telepsychiatry is likely to be used more widely in the future.²⁵ Early training can foster specific skills, such as conducting mental state examinations by telephone.²⁶ These should supplement, but not supplant, the acquisition of skills for face-to-face interactions.

The shift away from workplace learning was accompanied by an increase in self-directed learning and the use of online tasks. Self-directed learning prepares students for lifelong learning, and online tasks provide the opportunity to develop a broader knowledge base. However, some schools decreased teaching in the subspecialties, with psychiatry of intellectual disabilities, forensic psychiatry and medical psychotherapy most affected. This means that the only available opportunities to learn skills in these subspecialties may have been lost; for example, learning to communicate with people with intellectual disabilities and understanding unconscious aspects of the doctor-patient relationship.

The fact that assessments have continued with no change in standards during the pandemic is reassuring. Indeed, the

greater emphasis on formative assessments and developmental conversations with individual clinicians may provide more opportunities for students to receive feedback.

Attitudes toward mental illness

Reductions in time spent in clinical placements mean that students get less contact with people with psychiatric conditions, which is so important in dispelling stigma toward mental illness.²⁷ The relative shift away from placements in community teams toward in-patient wards during the pandemic may also have unintended consequences; in a meta-analysis conducted before the pandemic, in-patient placements had less effect in challenging stigmatising attitudes than community or mixed placements.²⁸

On the other hand, the greater emphasis placed on the mental well-being of students²⁹ and healthcare staff³⁰ during the pandemic may encourage students to pay attention to their own health and well-being, and raise their awareness of the importance of mental health. Psychiatry teachers are particularly well-equipped, with expertise in both mental health and undergraduate education, to support students.

Recruitment into psychiatry

Experiences during clinical placements affect career choices, with just over half of students reporting that they were more inclined to choose a career in psychiatry following their placement.³¹ Placement factors that encourage students to choose psychiatry include perceived clinical responsibility and influence of teachers as role models.^{32,33} Although an international survey found no relationship between placement length and choosing psychiatry,³² a placement should be sufficiently long for students to get involved in the team and follow patients' progress.³⁴ Shifting away from workplace learning reduces such opportunities and may affect recruitment into psychiatry.

The pandemic has also limited opportunities (e.g. through lack of availability of electives) for fully exploring different subspecialties.³⁵ Tasters, where students spend short periods of time experiencing subspecialties outside of their main clinical placement, demonstrate to students the breadth of opportunities that a career in psychiatry entails.³⁶ Social distancing measures limit access to tasters. Despite these limitations, most education leads agreed that the pandemic had raised the profile of psychiatry among medical students. Increased awareness of reflective practice and a renewed focus on student well-being may have contributed to this. Whether this will translate into more positive attitudes toward psychiatry from other specialties is unclear.³⁷

A call to action in a time of change

The pandemic has been a catalyst for spurring innovations in medical education.³⁸ Even after the pandemic, there will be changes to psychiatry teaching in the majority of schools. Most education leads are optimistic that the pandemic will change psychiatry education for the better. Students have responded positively to the adaptations to teaching and, mirroring the changes predicted by our respondents, want to continue with online lectures and increased access to online resources in the future.³⁹ It remains to be seen whether reactive adaptations implemented during the pandemic will be sustainable, and help to manage another impending challenge: the surge in student numbers resulting from the government temporarily lifting the cap on medical school places.⁴⁰

One year on from the first national lockdown, the course of the pandemic remains uncertain. But what is becoming more certain is the profound impact that the pandemic has had on the way we teach psychiatry. This is most marked in the reduction of clinical placements, which may affect the attainment of key competencies relevant to practice in all branches of the profession, exposure to clinical role models and the challenging of stigmatising attitudes to mental illness and psychiatry. Reduction in clinical placement may also pose a threat to future recruitment into psychiatry at a time when there will be an even greater need for psychiatric skills, to manage increased demand following the pandemic.^{41,42}

This is the time for all of us in psychiatry to unite and rise to the challenges that lie ahead. We call upon individual clinicians, NHS trusts and medical and foundation schools to work closely together and with students, to give this generation the training that they need to best care for patients in the post-pandemic landscape.

Individual clinicians can offer so much to maximise the quality of learning during shortened placements. They can offer opportunities for students to participate fully in the care of patients and foster experiential learning. Trusts continue to receive payment for educating students, even with reduced time spent in clinical settings, and can ensure a more equitable distribution of finances to front-line educators.⁴³ Teaching during the pandemic has required considerable planning and effort from education leads, yet in our survey, few reported receiving additional funding or resources.

Medical schools should incorporate opportunities, wherever possible, for students to meet psychiatrists and experts by experience, to implement training on stigma and support the activities of student-led psychiatry societies.⁴⁴ Lost learning opportunities should be prioritised for inclusion in online teaching programmes both during and beyond medical school. Foundation schools should similarly increase postgraduate psychiatry teaching and the number of posts in psychiatry. Greater collaboration between foundation programme leads and undergraduate educators is important to replace what has been lost during the pandemic.

Undergraduate psychiatry teaching in the UK has undergone extensive adaptations in response to COVID-19. Educators have done a remarkable job to maintain the integrity of teaching in the face of considerable adversity. Lessons learnt during the pandemic will shape teaching in the future. As we start our journey into the post-pandemic world, we hope that readers will heed our call to action. We must not let the pandemic set back decades of progress in the care of people with mental illness.

Strengths and limitations

To our knowledge, this is the first nationwide survey of adaptations in undergraduate psychiatry teaching in any country. There was a good response rate of 72.7%, with responses from all four nations of the UK. By asking education leads about specific areas of adaptations, we may not have captured all the adaptations made at individual schools. Similarly, there was variable completion of open questions and depth in respondents' descriptions of adaptations. As a survey of education leads, we have not explored first-hand the views of students and other clinicians on the impact of adaptations. Lastly, the survey offers a snapshot of adaptations at a particular moment in time, and does not capture longitudinal changes in response to the course of the pandemic.

About the authors

pmc We thank Dr MacFarlane for his response¹ and welcome his comments about various providers and pharmaceutical agencies as well as freedom of speech.

We did not review the neuroscience of brain sex differences but draw interested readers' attention to a recent review² and accessible analyses of available research.^{3,4} We agree that the art of psychiatric diagnosis depends on the clinician accepting the truth of the patient's own experience. In the absence of objective diagnostic tests, believing and trusting the patient's own subjective narrative is central to the doctor–patient relationship. However, this starts to lose coherence when the doctor must readjust their own understanding of material reality in order to accommodate another's subjective belief. Declaring that 'Despite having the body of a man, I am in all other respects a woman' supposes some inherent essence of gender that many would reject. Reorganising psychiatry to give primacy of gender identity over sex risks breaching the necessary boundaries that exist to maintain the safety and dignity of individuals, groups of people and society more generally.

Without a clear definition of conversion therapy, it is not possible to know the extent of the practice in the UK. Proponents of affirmative care have argued that conversion therapy is anything that might act as a barrier to medical transition.^{5,6} It would follow that attempts to assess and treat coexistent mental illness, or even the process of making an accurate initial diagnosis of gender dysphoria, could be described as conversion therapy rather than the basic standard of clinical care that would apply for any other presentation.⁷

The authors remain opposed to any treatment model designed to coercively alter the sexual orientation of bisexuals, gay men or lesbians. It is crucial to distinguish between sexual orientation and gender identity when the latter comes with an expectation for complex, irreversible medical interventions, described as ‘affirmative’. If sustained, long-term benefits of medical and surgical transition could be clearly and independently demonstrated, it would be appropriate to offer these interventions early, but the evidence is not convincing.⁸ Therefore it is reasonable to exercise therapeutic caution, especially in light of growing concerns about complications and regret,⁹ particularly in younger patients.

Given government moves to criminalise conversion therapy in medical settings, the nature of ‘barriers to treatment’ must be clearly described.⁹ New laws will need detailed supplementary guidance for the benefit of patients, doctors and the criminal justice system. We propose that organisations representing clinicians should help legislators make explicit that neutrally framed therapeutic or exploratory work is not conversion therapy, irrespective of how an individual ultimately feels about their own identity.

In the absence of evidence-based guidelines underpinned by solid research, we cannot make recommendations about treatment pathways, and do not advocate one particular model over any other. We draw readers’ attention to the unexplained increase in referral numbers, the higher numbers of children and young people seeking interventions, and the shift in sex ratio,¹⁰ as such demographic changes are significant and deserving of research and explanation. Doctors should ‘first do no harm’. The bar for informed consent to life-changing, irreversible medical and surgical interventions is necessarily high.⁹ Enhanced service provision and new care pathways should be informed by robust research in this patient group.

 - *Amendments and clarifications, by Marcus Evans*

pmc .. _sec1:

Editor's note

The article 'Freedom to think: the need for thorough assessment and treatment of gender dysphoric children' was published online on 21 July 2020. In response, the *BJPsych Bulletin* received a number of letters both for and against the paper. The letters of complaint raised several similar issues, which were presented to the author for response. At our request, the author has addressed some omissions in the original article, particularly in relation to a declaration of interest of which we had been unaware. Also, some clarifications and additional references have been added to support a number of statements. An updated article is being published and we are publishing this corrigendum outlining the changes made – the original article remains available, as supplementary material to the updated article. We are keen to pursue an informed, transparent debate via the eLetters section, in line with the journal's eLetters policy. See also my editorial 'Publishing controversy' (<https://doi.org/10.1192/bjb.2020.127>).

Norman Poole, Editor of the *BJPsych Bulletin*

Amendments and clarifications, by Marcus Evans

The opening sentences "There has been a 400% rise in referrals to the national gender identity service at the Tavistock and Portman NHS Trust in London over the past 5 years. The profile of referrals has also undergone a major transformation: we have seen a reversal of the gender ratio from two-thirds male:female to two thirds female:male, with a new diagnostic category, 'recent-onset gender dysphoria', making up a substantial proportion." should read: "There has been a 3264% rise in referrals to the national gender identity service at the Tavistock and Portman NHS Trust in London over the past 10 years (from 77 in 2009–2010 to 2590 in 2018–2019).^{c1} The profile of referrals has also undergone a major transformation: we have seen a reversal of the gender ratio from two-thirds male:female to two-thirds female:male, with a recently described clinical phenomenon of as yet uncertain diagnostic significance making up a substantial proportion. This gender dysphoria of recent onset among adolescents (sometimes termed 'recent-onset gender dysphoria' or ROGD, 'rapid-onset adolescent dysphoria'^{c2} or 'adolescent-onset transgender history'^{c3}) lacks an agreed name or established diagnostic criteria, but its emergence has been documented by a number of gender clinics worldwide.^{c4}"

The following should then be added: "Bernadette Wren, the then associate director of the Tavistock and Portman NHS Foundation Trust's Gender Identity Development Service (GIDS), gave evidence to a House of Commons select committee in which she summarised the GIDS intake in the following terms: "many of the young people, and increasing numbers of them, have had a gender-uncontentious childhood, if you like, and it is only when they come into puberty and post-puberty that they begin to question. That now represents a substantial proportion of our group".^{c5}"

The sentence 'The affirmative approach to gender dysphoria has been adopted by the majority of children's services in the UK.' should read: "The affirmative approach to gender dysphoria appears to have been adopted by the majority of NHS and privately provided children's services in the UK. Again, Bernadette Wren stated in the House of Commons: "I work in a service where a lot of the young people – and anybody who wants it – have physical intervention. We have no record of turning people down for physical intervention".^{c5}"

The section 'Cantor says "Although almost all clinics and professional associations in the world use what's called the 'watchful waiting approach' to helping gender diverse children, the AAP statement instead rejected that consensus, endorsing gender affirmation as the only acceptable approach'.¹ This is despite research findings which strongly suggests that most of these cases would eventually desist if left untreated.^{2,3}' should read: "Cantor says "Although almost all clinics and professional associations in the world use what's called the 'watchful waiting approach' to helping gender diverse children, the AAP statement instead rejected that consensus, endorsing gender affirmation as the only acceptable approach'.^{c6} This is despite research findings which strongly suggest that most of these cases would eventually desist if left untreated.^{c7,c8}"

The sentence 'The British Psychological Society's review of the literature found the current medical approach to be "well-intentioned advice [which] is based on extremely limited evidence".¹⁵' should read: "'*Research Digest*, published by the British Psychological Society, reported on an Australian review which concluded that the current medical approach is based on extremely limited evidence.¹⁵"

The sentence 'There is considerable evidence that children are signing up to treatments with long-term implications,

with very little real understanding of the consequences for their future adult lives.’ should read: “‘Children are signing up for treatments that permanently modify their bodies, but they may not fully understand the life-long consequences of their decision or acknowledge the potential risks and uncertainties of treatment. Their ability to provide informed consent has been questioned, including by some clinicians working in gender clinics.’^{c9,c10,c11}”

The following sentence should be added after the first paragraph of the section ‘Patients that regret treatment’: “‘A number of clinicians have called for research into desistance, detransition and regret among gender dysphoric adolescents. The US National Institutes of Health (NIH) Sexual & Gender Minority Research Office (SGMRO) recently named detransition in its report outlining scientific research gap areas in the field of sexual and gender minority health.’^{c12} The 8th edition of WPATH’s Standards of Care will include a section on detransitioning.’^{c13}”

The following was omitted from the declaration of interest statement and should be included: “‘M.E. and his wife Sue Evans have provided witness statements for a UK judicial review examining whether minors are able to provide informed consent for gender-affirming treatments. M.E. has previously raised concerns about such treatments with the Board of Governors and the CEO of the Tavistock Trust. Sue Evans administrates the online pages for a crowd justice fund, which will be used to pay the legal fees of the judicial review. Neither M.E. nor Sue Evans has received or will receive any financial reward for participation in the case.’”

1.2.42 Publishing controversy

Norman A. Poole

Correspondence

Dr Norman A. Poole

(bjpbulletin@rcpsych.ac.uk)

date

2021-10

Abstract

Two recent papers on a controversial topic in this journal attracted significant criticism from readers. This editorial addresses these criticisms and describes changes to be made to the journal’s editorial and review procedures in light of the complaints received.

Contents

- *Publishing controversy*
 - *Changes to editorial procedures*
 - *Declaration of interest*

pmc Psychiatry, like other branches of medicine, is no stranger to controversy. Anthony Clare’s *Psychiatry in Dis-sent*¹ ran the gamut of contested areas – from the validity of psychiatric diagnosis to electroconvulsive therapy and psychosurgery – which are, to varying degrees, still with us. Some have argued that disputes over the concept of mental disorder generally² and certain specific categories³ merely demonstrate that psychiatry is a pseudoscience: psychiatric

diagnosis, unlike the remainder of medicine, is a matter of value judgements rather than ‘hard facts’. In this view, psychiatrists are really just pathologising people who transgress some sort of social norm.

Since the heyday of such arguments, it has been increasingly understood that, yes, values are involved in diagnosis, but this is true also in other medical specialties. In Peter Sedgwick’s memorable phrase, ‘The fracture of a septuagenarian’s femur has, within the world of nature, no more significance than the snapping of an autumn leaf from its twig’.⁴ But we deprecate the first, so consider it disordered. Yet psychiatry remains the more controversial specialty. Bill Fulford draws an analogy between the different ways we use the word ‘good’ when thinking about a ‘good strawberry’ versus a ‘good painting’.⁵ It turns out that there is greater agreement about the former than the latter, hence less conflict and controversy. And what constitutes a person’s very nature and identity is a lot more like paintings than strawberries.

The *BJPsych Bulletin*, representing views within and about psychiatry, cannot evade controversial issues, but neither should we court them for their own sake. At the heart of such controversies are real people with real lives, often ostracised and denigrated. So, we have a duty to be respectful and balanced when articles on controversial topics are accepted for publication. We recently published two papers⁶ on gender incongruence that have attracted a significant number of letters and complaints, particularly regarding Marcus Evans’ opinion piece ‘Freedom to think: the need for thorough assessment and treatment of gender dysphoric children’.⁷ In light of the criticisms, we reviewed the article and have published a corrigendum of clarifications and additional information that provides a stronger evidence base for his arguments. Importantly, Evans has also provided a declaration of interest statement addressing his involvement in a judicial review of gender-affirming treatment for minors.

Changes to editorial procedures

Criticisms of the paper have been discussed by the editorial board. It was never the intention for the board to review the evidence for and against gender-affirming treatment. We appreciate that there are gaps in the evidence base concerning psychological outcomes of gender-affirming surgery,⁸ so see the journal’s role as enabling discussion. We seek to present the suffering caused by prejudice and failings in care systems, address omissions in the evidence base, and enable clinicians and patients to express concerns about ethical practice. The journal’s position is not to censor one or other argument – albeit clarity and care are needed when discussing emotive issues and the potential harms of psychiatric practice. The editorial board have discussed how handling editors should deal with submissions about such controversial topics, and agreed the following recommendations. The Special Articles category currently combines both review and opinion pieces. We will reintroduce Review and Opinion type papers to clarify for readers the nature of the content. We have added to the instructions for authors that Opinion pieces can include references from news items and blogs. We will not accept an Opinion article with reviews solely by the author’s suggested reviewers. As a general rule, editors do avoid this. However, it is now a firm policy for Opinion pieces to ensure that an independent review is always sought, even though this may lead to delays to the peer review process. We may call on editorial board members as required to provide reviews. Reviewer invitation templates will be revised to include a link to the COPE Ethical Guidelines for Peer Reviewers and the Reviewer Support Hub on Cambridge Core (in development). We will encourage reviewers and editors to use sites such as <https://mediabiasfactcheck.com/> to check the level of bias of non-scholarly sites. If an article involves a controversial issue, handling editors will seek to balance it, either in reviews or with a counterbalancing article, commentary or eLetter, although we acknowledge that this may not always be possible.

I appreciate that the published corrigendum and review of editorial processes will, for some, not go far enough. Many of the complainants sought retraction rather than correction and pointed to the distress such papers can cause an already marginalised group of people. I am deeply sorry for the hurt caused and have invited authors of the complaint letters to submit counterbalancing articles and/or eLetters to ensure that the spectrum of opinions is presented. Readers are welcome to submit correspondence by clicking the e-letters tab when accessing the article via the following link: <https://doi.org/10.1192/bjb.2020.72>.

COPE, the Committee on Publication Ethics, has guidelines⁹ for editors considering retraction of an academic paper. Its criteria cover situations where there is clear evidence of unreliability or falsification of data, plagiarism, copyright infringement or manipulation of the peer review process. These do not apply here. Failure to disclose a major conflict of interest can also lead to retraction where non-disclosure has ‘unduly affected interpretations of the work’ by editors and peer reviewers. However, Evans has been candid about his opinions, which are of a piece with his involvement in the judicial review.

Derek Bolton's *What is Mental Disorder?*¹⁰ has long struck me as a fine argument for the constructive value of disagreement. Where concepts are contended, they are subject to competing pressures from the various stakeholders, including patients, carers, doctors, psychologists, social scientists, the general public and politicians. He was referring to disputes about the boundary between order and disorder, health and illness, but it applies to controversial issues within psychiatry generally. In this spirit, the *BJPsych Bulletin* will always strive for open, transparent and respectful dialogue.

Norman A. Poole is Editor of the *BJPsych Bulletin* and a consultant neuropsychiatrist at St George's Hospital, South West London and St George's Mental Health NHS Trust, UK.

Abstract

The National Health Service (NHS) was created 70 years ago to provide universal healthcare to the UK, and over the years it has relied upon international medical graduates (IMGs) to be able to meet its needs. Despite the benefits these professionals bring to the NHS, they often face barriers that hinder their well-being and performance. In this editorial, we discuss some of the most common challenges and the adverse effects these have on IMGs' lives and careers. However, we also propose practical measures to improve IMGs' experiences of working in psychiatry.

pmc The staff of the National Health Service (NHS) includes many doctors who have trained abroad. Unfortunately, despite their contributions, many international medical graduates (IMGs) face considerably greater difficulties than UK graduates. Longitudinal data clearly show differential attainment of IMG doctors in both postgraduate examinations and more senior clinical, academic and managerial positions.^{1,2} They are also more likely to be reported to the General Medical Council (GMC) for misconduct and to have such complaints upheld.³ This is detrimental to their well-being and risks affecting the quality of care provided by them.

There are many contributing factors, from direct discrimination, through a lack of familiarity with and support from the UK system, to a failure to harness IMGs’ strengths. This editorial will explore this, taking the available evidence and experiences of the authors to propose positive next steps for individuals and organisations.

IMGs: who are they?

Definitions of IMGs: a heterogeneous group

The GMC defines an IMG as someone who has obtained their primary medical qualification outside the European Economic Area (EEA).⁴ However, that simple definition covers a range of complexities. It can encompass a childhood in another culture and different intersectional experiences of nationality, religion, gender and skin colour. It involves medicine studied in a different healthcare system, with nuanced variations in communication and therapeutic relationships. Some things, however, are common to most IMGs: personal and professional loss from the country they left; a need to build a network of friends and embrace a new life; exposure to a new environment and health system; and the hope for a better future, which despite any adversity keeps many motivated to continue. However, every IMG’s journey is unique, and the challenges faced will depend on the interplay of many factors; for example, we note that technically the term ‘IMG’ applies to a White British citizen who studies abroad and returns to work in the UK, yet such an individual is less likely to face attainment gaps.

There is no single route for an IMG to transition into the NHS. Those from an EEA country or Switzerland (not considered IMGs by the GMC) are eligible for full GMC registration and licence to practise medicine in the UK as long as they demonstrate proficiency in English. For other IMGs, the most common method of obtaining registration is by passing the Professional and Linguistic Assessments Board (PLAB) examination,⁵ an initiative designed to ensure parity of medical education and training standards. Post-PLAB doctors are then free to apply to appropriate training schemes, and to work as specialty and associate specialist (SAS) or locally employed doctors. Another route is the Medical Training Initiative (MTI) scheme sponsored by a UK Medical Royal College, faculty or GMC-approved institution for postgraduate training. Some IMGs can also gain registration if they hold a relevant postgraduate qualification from an approved overseas awarding body.⁶ Finally, IMGs can get their registration by applying for a Certificate of Eligibility for Specialist Registration. This requires doctors to demonstrate that their training matches the UK equivalent.⁷

However, once an IMG starts working in the NHS, they are expected to adhere to the norms outlined in the GMC’s

Good Medical Practice guide.⁸ Some trusts invest in providing appropriate induction and extra support; however, there is currently no clear national guidance or requirement for either organisations or IMGs on how to support this transition into the UK.

Data on IMG numbers and specialties/roles

A report from the House of Commons noted that of doctors in non-primary care settings, 13% are from Asia, 9.1% are from the European Union and 4.8% are from Africa.⁹ IMGs account for 60% of non-consultant and non-training doctors currently working in the UK.¹⁰ It is not clear why IMGs are more likely to work as SAS or locally employed doctors. Some might have found these roles more suitable to gain experience before enrolling in formal training, while some might be less interested in the recognised challenges that come with traditional training and consultant roles. However, some people may prefer a more flexible role for reasons including childcare, especially as they might have less family and informal support than British doctors; while others might find it practically easier to obtain such a job. Having said this, it is also likely that for a fair few it is a second-choice career pathway on account of failure to succeed in passing the relevant postgraduate examinations. Having a non-UK primary medical qualification has the largest influence on postgraduate examination attainment; the pass rate in some postgraduate examinations is 35% for IMGs, compared with 80% for UK graduates.¹¹ These attainment differences have also been identified between IMGs and UK graduate doctors training in psychiatry.¹²

Psychiatry is particularly popular among IMGs,¹² who account for 44% of psychiatry trainees.¹⁰ A preference for psychiatry has also been demonstrated in the USA¹³ and among UK doctors from Black and minority ethnic (BAME) backgrounds.¹⁴ The reason for this is not clear, although psychiatry has long had a particular recruitment problem,¹⁵ and it is possible that a need to pass the residence labour market test may be encouraging some to take posts that are more easily available. The authors' own discussions include the reflection that many IMGs may come from cultures where mind and body are not so separated, and find a natural affinity with psychiatry.

IMGs: challenges they face

Practical and cultural aspects to change

Initially, many IMGs need to find a place to live, to become orientated with public transport and potentially to learn to drive on the left side of the road. They need to open a bank account, get a UK telephone and identify where and how to access shops, sport clubs, religious centres and schools. They must adapt to the UK's many regional accents, and learn both local idioms and British colloquialisms. In addition, the first few years are often clouded by financial and visa-related stresses.

IMGs go through adaptation (changes in individuals or groups due to environmental demands) and acculturation (cultural changes resulting from encounters with members of different groups).¹⁶ This includes learning appropriate new behaviours and unlearning behaviours that are no longer appropriate. Refugee doctors merit additional comment. They are also IMGs, but they have had to flee their home countries and lives to escape persecution or other threats. So they often have experienced trauma, more financial difficulties and less certainty regarding visas, leading them to face greater isolation. Cohn et al¹⁷ noted that owing to having to leave their homes rapidly and in fear, refugee doctors might not have all the paperwork required for registration, or may not be able to contact people in their home countries to get relevant documents, which may complicate their ability to fulfil GMC requirements.

Loss of status, discrimination and racism

IMGs often not only leave behind family and friends, they almost always leave a social status, identity and trust that they previously earned and enjoyed. Many take up posts of lower grade or status than expected or warranted by their expertise.^{18,19} IMGs have reported a loss of autonomy in their decision-making,²⁰ and a professional devaluation which can lead to a loss of their confidence to perform or even defend themselves in cases of harassment or where their practice is being scrutinised.¹⁹

Many IMGs still suffer greater levels of direct and indirect discrimination and harassment. IMGs have reported feeling discriminated against by colleagues and at an institutional level.²⁰ Institutional racism has also been evidenced by bias regarding hiring practices of doctors with foreign names.²¹ Subjective bias due to racial discrimination has also been considered a factor associated with the failure of the clinical skills assessment for UK BAME and IMG doctors.²² A third of SAS and locally employed doctors in the UK, who are predominately IMGs, have reported experienced bullying or harassment in their workplaces, mainly characterised by rudeness.²³

Greater rates of complaints

The GMC's *Fair to Refer* report³ shows a disproportionate number of fitness to practise referrals for overseas doctors (2.5 times greater) and doctors from BAME backgrounds (two times greater) compared with White UK graduates, and they are more likely to face harsher sanctions. It is less clear whether this is compounded in IMGs from non-White backgrounds. The report offers potential explanations, including inadequate induction and support, lack of honest and effective feedback, working patterns or contracts that lead to isolation, pervasive insider–outsider dynamics, and a lack of confidence in raising concerns or challenging accusations. This last factor fits with the finding of Jalal et al that IMGs are less likely than UK graduates to report bullying.²⁴ The GMC report has been criticised for not addressing why the GMC tends to give harsher sanctions to referred IMGs and BAME doctors.²⁵

Existing evidence and initiatives

IMGs' perspectives

Wolf et al²⁶ found that IMGs and BAME trainees reported more difficulties, cultural differences and lack of trust with senior doctors, as well as biased assessments and recruitment processes. Hashim²⁷ identified challenges for IMGs in understanding the NHS system and values, learning environments (with a lack of direct guidance), receiving feedback and feelings of being undervalued by colleagues. A survey of IMGs' understanding of the GMC regulatory framework found that many were surprised or confused by the range and specificity of the regulations, including the emphasis on individual patient autonomy.²⁸ It also identified that IMGs could have difficulties with nuances of non-verbal communication and UK social and behavioural norms. A key aspect was the lack of relevant information prior to registration, variable levels of training and support, and isolation in non-training posts.

International literature on interventions

There is a limited evidence base to support interventions, including international examples from Canada,²⁹ the USA,²⁰ and South Africa.³⁰ Two recent literature reviews^{18,24} summarised the following recommendations: individual assessments prior to induction with follow-up; making relevant information available; providing comprehensive information about the role and job; addressing the culture gap (providing supervisors and mentors, understanding clinical and cultural differences); considering different learning styles; buddy systems (for guidance and help); improving cultural awareness from the organisation; and establishing a national induction programme, complementary to local inductions. With regard to refugee doctors, Butt et al (2019) showed that formal support to gain their licence to practise was an effective intervention. Although all these could be potentially effective interventions to improve IMGs' well-being, there still seems to be no consensus regarding which organisations are responsible for implementing them or overseeing these changes.

Work by UK professional bodies

Some GMC initiatives have been put in place to address the differential attainment; these include the optional ‘Welcome to UK Practice’ workshop,³¹ which according to a recent report³² is highly valued by doctors and their supervisors, improving knowledge on ethical issues, GMC guidance and UK practice in general, as well as communication and a focus on patient centredness. It provided opportunities to meet colleagues, share learning and gain support, but the report also suggested that IMGs feel a general lack of support once they are in practice.

The MTI by the Association of Medical Royal Colleges³³ is specifically for IMGs and provides a helpful guide³⁴ to aid with preparation for relocation, as well as providing mentorship on starting the scheme. A recent evaluation of the MTI psychiatry scheme reported that enrolled IMGs highly rated their clinical supervision and overall experience with this initiative.³⁵ The British Medical Association (BMA) website also has a section focusing on IMGs, including information regarding life and work in the UK,³⁶ while we were preparing this manuscript, the BMA sent their very first IMG newsletter, focused on key news and information relevant to IMGs. Online communities are mushrooming to support IMGs while they redefine their identities in a new culture with its evident uniqueness.

This differential IMG attainment also affects membership and representation within the Royal Colleges, as SAS doctors do not have the same rights as fully registered members of some Royal Colleges. Positively, we note that the roles and representation of SAS doctors within the Royal College of Psychiatrists is currently under review. The Royal College of Psychiatrists has a trainee support group which provides guidance regarding the needs of IMG trainees to heads of schools of psychiatry across the UK to improve differential attainment, while the Psychiatric Trainee Committee is currently drafting a guide that will contain sections to support IMGs, including cultural induction to the UK, training pathways, exams and visa information. The college also organises workshops to help supervisors to gain the knowledge and skills to mentor and supervise an IMG doctor, and conferences to foster networking among IMGs. We also recognise that the College has recently established two new professional leads on race equality.

Next steps

Recognising the wider societal issues: Black Lives Matter and Covid-19

The Black Lives Matter movement has re-emphasised the social disparities between White British people and those of BAME and immigrant backgrounds. It reminds us that many of the adverse experiences of IMGs are also encountered by UK BAME medical graduates, notably, discrimination, racism and differential attainment. Compared with their White counterparts, UK BAME doctors underperform academically;³⁵ are more likely to fail their clinical skills assessments;²² are less likely to be accepted into a specialty training programme, apply for consultant posts, or be short-listed for and offered consultant posts; and earn less.³⁷ Wolf et al³⁸ found that perceived difficulty in talking about race with trainees and isolation or non-specificity of interventions were the main barriers to improvement. The Covid-19 pandemic has also shown the different vulnerabilities of BAME staff and patients, many of which are due to fundamental societal inequities, and the need for appropriate support and care.³⁹ As a positive note, it was heartening to see the *BMJ* recently commit a whole issue to the topic of racism.⁴⁰

Recognising IMGs’ strengths: the ‘problem’ is not in the individual

Most discussion still unconsciously locates the ‘problem’ in the IMG rather than adopting a systemic perspective and working to embrace IMGs’ strengths and their knowledge and experience of working in other socioeconomic and healthcare systems.

Many IMGs not only achieve their goals but also go on to subsequently become prominent and respected doctors, leaders in their field and admired by their peers. Within psychiatry, we have many such examples who have succeeded and developed internationally high-profile careers as clinicians and academics; the simplest scan of UK psychiatry’s output and reputation will show its gains from many IMGs. The strengths of an internationally trained, multicultural and multilingual workforce need to be harnessed. *Box 1* summarises our recommendations for positive change,

based on an assimilation of the existing literature, our experiences as IMGs (all but one author) and practising clinicians in the UK, and our application to UK psychiatry. We have provided a suggested clustering of which organisations and individuals might be best placed to provide these. Box 1 Recommendations for positive change, clustered by provider.

Regulatory bodies Continued evaluation and addressing the disproportionality of GMC (and local) complaints and investigations into IMGs. An open and transparent process of data collection and a clear accountability framework to ensure that progress, or its lack, in these areas can be monitored. Host IMG-specific resources and disseminate via NHS trust websites, including sharing of examples of good practice (for example, the MTI, while recognising that there can be specialty-specific challenges and opportunities. The Royal College of Psychiatrists Explicit investigation into differential attainment in the MRCPsych examinations. Explicit inclusion of IMGs in examination and curriculum design. Publishing data on IMG representation on College bodies. Have IMG-specific events, resources and examples of best practice for psychiatrists. NHS trusts Trusts have an IMG champion working with Human Resources to inform all IMG appointments. Trusts' HR staff to receive training to enable them to deal competently with IMG issues. Trusts have explicit policy and action targeting racism, with open publication and updates. Local induction programme specifically for IMGs, mainly during the first 2 years of their career in the UK/NHS. Focused support and mentoring for IMGs new to the NHS. Encourage and facilitate IMGs' interaction with UK graduates (e.g. universities host a Welcome Day for international students). Host events dedicated to local IMGs – to celebrate successful journeys and to foster a sense of community. Continuing professional development events to learn how IMGs' experience in their home countries can contribute positively to improved patient care in the NHS. Individual services, teams, supervisors/mentors and IMGs Link up IMGs with appraisers at the time of starting work so that appropriate mentoring can be organised. Inclusion of modules focused on IMG issues for educational and clinical supervisors. Encourage IMGs to attend local Balint groups. Encourage IMGs to attend local academic days for trainees in specific specialities.¹

Conclusion

Our personal experience – all but one of us are IMGs – has been that UK society is marked by a focus on fairness. This has motivated us to raise some of the issues that many IMGs are currently facing. We are grateful that British society and culture has, largely, welcomed IMGs and given us the freedom to make these comments. However, we also feel that for many local doctors, IMGs can become invisible and their specific strengths and learning needs go unnoticed. We do recognise that each IMG has had a different journey, with many factors affecting their own challenges – gender, ethnicity, skin colour, religion and sexual orientation – just like every non-IMG doctor. Motivated by personal challenges, dreams of a new life or even external factors uncontrolled by them, each IMG has to go through a process of acculturation, and loss of former identity and building of a new one, influenced by their professional and personal experiences.

For IMGs, there is much to learn personally and professionally upon coming to the UK. In healthcare, this includes familiarising oneself with the 'process of regulation, challenging, making appeals' and fostering a culture of 'learning not blaming'. In society, every citizen has the responsibility to respect the rights of others and to treat others with fairness; in return, the UK offers freedom of speech and freedom from unfair discrimination.

UK healthcare systems, regulatory bodies, Royal Colleges, NHS trusts, medical leaders and indeed all of us are responsible for being aware of IMGs' struggles, as these can have long-lasting effects not only on IMGs' careers and lives but also on the care of the patients they serve. If we can start to demonstrate a degree of compassionate curiosity about IMGs, appreciating their diversity and strengths, the new knowledge, skills and wisdom that we will acquire can only lead to better patient care and a happier workforce.

1.2.44 The value and benefit of narrative medicine for psychiatric practice

Sabina Dosani

Correspondence

Sabina Dosani (s.dosani@uea.ac.uk)

date

2021-10

Abstract

This article describes how applying techniques from literary studies and considering patient histories as texts helps me understand and formulate systemic issues in psychiatric assessments. Psychiatrists are not generally taught to pay close attention to aspects of language, including metaphor and syntax, but I argue that paying attention to the form, as well as to the content, of the stories patients bring us, can make us better attuned to the contexts of their needs and distress, and therefore better placed to help.

– Declaration of interest

pmc My clinic list says that the mother I am about to meet has come for an autism assessment for her son. As it turns out, she has come to tell a story, one she cannot yet make sense of. This particular mother tells me a nativity story. Her opening scene is an acute abdominal pain, ‘like a fire’, bending her in half and making her scream, at an office Christmas party. Not appendicitis, but a surprise of a baby son, born into precarious temporary accommodation, to a single young woman, in late December. Her story included a vivid retelling of his first visitors: ‘three wise women from East London’, she joked, ‘a midwife, a health visitor, a social worker’.

‘Did they come bearing gifts?’ I asked.

‘Forms!’ she replied, but also told me about the three wise women’s support for her instinct, two Christmases later, that something was not quite right with her son. ‘You could call it an epiphany’, she said.

You might wonder why I let her talk like this, encouraged it even, with my gift-bearing question. It took her less than 8 minutes to summarise her first concerns about her son and the following 6 years of worries, that were mostly dismissed by ‘the system’ as naughtiness, wilfulness or lax parenting. As a psychiatrist, my job is to make a diagnosis and formulation, but I also spend time thinking about the narratology in consultations, by which I mean how clinical histories and related stories are framed and presented, because narratives are consequential. They have the capacity to heal or harm. ‘Narrative employment’ is the creation of narratives that help people accommodate and make sense of distress, pain or loss, and find a new sense of inclusion, hope and agency. Too often, this process is carried out against the grain of clinical work.

The privilege and joy of psychiatry is that we look after whole people. We gain skills in decoding subtle nuances of language for evidence of psychopathology and we are trained in understanding symptoms in the contexts of patients’ lives and cultures. Yet, at times, our training and psychiatric practice, with the current hyperfocus on biological aetiology and treatments, hint that we might be dealing with brains in isolation, risking objectifying patients. Literature, which emphasises the use of language, reminds us of their humanity and our own.

In common with other medical humanities, narrative medicine in general, and literary studies in particular, allows psychiatrists to widen the epistemic genres we traditionally draw from, in formulating and answering academic and clinical questions. This is especially important in the 21st century, as our patients live longer, with more illness complexity and comorbidity than in previous generations. Narrative medicine can help us to respond to contemporary health challenges by looking beyond traditional medical sciences.

For example, by attending to the manner in which the mother framed her story as a Biblical illusion, and by acknowledging this with my gift-bearing question, I was better able to read between the lines of the developmental history she gave, hearing her previously unspoken fears of divine punishment and her secret hope for a miracle cure.

Reading illness narratives

Writing in the *BMJ* about the evidence-based treatment of neonatal jaundice and the safety of infants on aeroplanes, Thomas Newman, Professor of Epidemiology and Biostatistics, made a cogent case for the power of stories over statistics, concluding that ‘the brains of human beings seem built to process stories better than other forms of input’.¹ Dreadful things happen, Newman concludes, but when they happen to a storyteller this enables connections with readers beyond what would be possible if the story were recounted by a dispassionate observer. A narrative trajectory offers solutions or hope, which statistics cannot offer.

Arthur Frank develops Newman’s theory further, suggesting that, ‘telling stories is the attempt, initiated by the body’s disease, to give voice to an experience that medicine cannot describe’.² In his classic text *The Wounded Storyteller*, Frank suggests a typology of medical narrative, classifying illness narratives into ‘chaos narratives’, ‘quest narratives’ and ‘restitution narratives’. The restitution narrative, in which the doctor is presented as a hero and the end result is healing, could not be more distinct from the stories psychiatrists often hear in clinic, stories that Frank would classify as chaos narratives, in which one terrible thing after another happens, events which are often temporally dislocated. Frank’s so-called quest narratives are more hopeful, written by patients who have been able to learn from their illnesses and reconstruct a new future. As a psychiatrist, the question of how to respond to ‘the experience medicine cannot

describe' is important. Frank, however, advocates keeping professionals away from written illness narratives. His suggestion seems to be that scientific scrutiny will diminish and devalue patients' accounts. I think he is overly pessimistic and commend his thesis to colleagues seeking to understand, without reframing and rewriting.

Patients as texts

Literary studies have had a direct and unexpected impact on my clinical practice. For example, in my work as a child and adolescent psychiatrist, I apply close reading techniques from literary studies when listening to parents' histories and children's stories. I was influenced by Professor Rita Charon, a physician with a doctorate in English literature.

In her book *Narrative Medicine*, Charon offers a drill for reading texts and likens it to the familiar drill that medical students are taught when reading chest X-rays.³ She invites us to consider a patient's history as a text, deciding, for example, which genre it comes into. It might be a short story, an obituary, an epistolary novel, a Gothic tale, a black comedy, a lyric poem or a parable. She asks us to consider how the patient's narrative is framed, asking: where did this text come from? How did it appear? What does it answer? How was it answered? How does it change the meaning of other texts? What is left out of this text? I use the literary techniques of close reading, where one pays attention to all aspects of the literary devices in a text, including ambiguity, irony, paradox, tone, semiotics, gender, sexuality, colonial status of the narrator. Attending to close reading teaches us to query the meaning of breaks, tempo and the message in the rhythm. Charon invites us to question the narrator's engagement in the story, her access to events, her point of view (vocalisation). Is she remote, sceptical, unforgiving, judging? Charon's point throughout is that studying literature can make us better doctors.

Following Charon's drill has taught me to interrogate patient narratives differently and gave me new insights into their construction. The mother I described at the beginning of this article framed her story as a Biblical natal scene. Her 8-year-old son told a different story, delivering crisp classroom anecdotes in the style of a successful stand-up comic. He had a tabloid headline writer's love of puns and spoke about his aspiration to be a writer of Christmas cracker jokes, a nod, perhaps, to his mother's nativity story. When I shared my formulation, I encouraged him to write it down in his own words, with a punning title. We looked at some YouTube videos of comedians who have spoken about their shared diagnosis.

His most recent school report was written in the form of a lament, a chorus of cries from an exasperated class teacher, appended with a headteacher's refrain of despair. When I sent a copy of my assessment report to the school, I wrote a brief covering note, acknowledging the profound sense of sadness, frustration and failure in the school report and raising the possibility of his disruptive classroom humour being a form of tragicomedy, possibly because the boy himself shared these same feelings. His class teacher wrote a reply framed in educational academic discourse, about performative spaces and classrooms. My hope is that by writing differently about him, she might be thinking differently about him too.

I do not know yet how this clinic story ends. The pages of this little boy's life are still turning. Unlike novels, I am rarely there to witness concluding chapters or the many plot turns of these young lives. The last time his mother and I met, she referred back to her nativity story, reframing the birth as a gift and telling a parable about neurodiversity. The language of implied self-blame and defeat was edited out of her new story. There may be times in future when she writes them back in. I think part of my job is making sure those close to her notice if and when she does.

Narrative education

Thirty years have passed since David Fraser and Leah Smith presented their findings from their surveys of medical graduate cohorts from 1955 to 1982, asking 'what changes would you have made to your education?'.⁴ The responses were overwhelmingly in favour of having more humanities education, particularly in history, art, music and literature. Doctors felt that their education failed to meet the need for their 'skill in dealing with people'. Asked about their regrets about their education, the cohorts said they were taught too much biology and too much chemistry for admission to medical school. For a more satisfying personal life they would have chosen art, history, literature and music, and to work better with patients, they would have chosen philosophy, modern languages, art and psychology.

This is old research, arguably ‘yesterday’s news’, conducted in the USA, and has yet to be repeated in UK graduate cohorts. However, Richard Horton, writing in *The Lancet* a decade later, expressed similar views, lamenting the poverty of scholarship in Western medical schools, which, in my view, remains largely unchanged.⁵ Horton’s arguments feel as current today as when he noted more than two decades ago that medicine is unusual among academic disciplines in that it has no canon of texts. Horton calls this ‘a curious exception’. Horton said that ‘a canonical work should display originality, rigorous argument and a strong writing style’. I would like to suggest that the time has come for us to define a canon of works in psychiatry, spanning novels, creative non-fiction and illness narratives, the study of which can offer real benefit and value to psychiatrists.

As a doctor, there are ethical challenges inherent in writing about patients. I have considered the General Medical Council’s instruction to ‘make the care of your patient your first concern’. Patients are often mandated by court to see me, or are allocated to see me in clinic, with limited choice. Given the power dynamics inherent in these assessments of children and young people who are often vulnerable, I have concluded that most of my patients would be unable to give meaningful and free consent to be written about, even in retrospect. For these reasons, I have written about a fictional patient for the purpose of this article. To do so, I studied many of my assessment reports from the past three years and then wrote new fictitious clinical scenarios, drawing on real themes.

Sabina Dosani is a consultant child and adolescent psychiatrist with Clinical Partners, London, and a PhD candidate in creative and critical writing in the Department of Drama, Literature and Creative Writing, University of East Anglia, UK.

- *Raymond Tallis*

pmc Professor Raymond Tallis is one of the most eminent polymaths in the UK. He is an Emeritus Professor of Geriatric Medicine, poet, novelist, philosopher and cultural critic. He has published numerous books and articles in different fields, including his regular contribution to *Philosophy Now* under the title of Tallis in Wonderland. I first came across his work in his book *Aping Mankind*.¹ Professor Tallis is politically active and his co-edited book *NHS SOS*,² written at the time of Andrew Lansley's reorganisation of the NHS, continues to be relevant. I met Professor Tallis virtually in the middle of the lockdown.

Professor Tallis, thank you for your time. In the Royal College of Psychiatrists, we recently had a kind of surge in neuroscience and I remember 10 years ago, in *Aping Mankind*, you wrote of 'neuromania'. I wonder if you could elaborate for the readers.

Of course. First of all, I am a great admirer of neuroscience: it is perhaps the greatest cognitive achievement of humanity, because it brings together so many sciences in an area that has such importance. All my own research has been within clinical neuroscience, stroke and epilepsy being my major areas of research. I therefore have no problem with neuroscience. My target is neuromania. What is the difference between neuroscience and neuromania? Neuroscience does acknowledge that the brain is a necessary condition of normal consciousness and behaviour. If you chop my head off my IQ falls precipitously, probably down to zero, I guess! In addition, we are very familiar with the effects of damage: there is often very precise correlation between severe damage to the brain and deficits that follow. There are lower-level deficits in sensation and motor activity and higher-level deficits in cognitive function. So that is neuroscience: it acknowledges the brain as a necessary condition of normal human consciousness, behaviour, awareness and so on. Neuromania, however, claims that the brain is not merely a necessary condition, but a sufficient condition of these things. All that we are as persons can be translated into neural activity.

It might be helpful for your readers to clarify the difference between necessary and sufficient conditions. Let me give you an example. To be knocked down by a bus outside the Royal College of Psychiatrists, it is necessary that I should be outside the Royal College of Psychiatrists. I am very pleased to say that it is not a sufficient condition. Otherwise, everybody outside the Royal College of Psychiatrists would be knocked down by a bus. According to those who embrace neuromania, the stand-alone brain is the sufficient condition for human consciousness, the person and so on. Neuroscience tells us the brain is merely a necessary condition.

One thing we have witnessed is a huge surge in imaging studies, fMRI studies in particular. And they want to say that, for instance, this is what love looks like. Or in terms of psychiatry, this is what, for instance, depression looks like. It is kind of reductionism.

It is, and of course, imaging is particularly seductive. Someone once described the fMRI scan as a fast-acting solvent of the critical faculty. So, if you see an image on a screen you start believing that you are gaining direct access to the truth about our humanity. You mentioned love and it reminds me of a study by Semir Zeki and his colleagues that led them to identify the experience of romantic love with activity in certain parts of the nervous system. The experimental design was, to put it mildly, rather crude. They compared the responses of the brain, recorded by fMRI, when individuals were exposed to pictures of partners with whom they were deeply in love with the responses to pictures of friends. By this means, they claimed to identify brain activity corresponding to romantic love. But of course, that's nonsense. Being in love is like a response to a stimulus. It's not even a continuous condition like being a bit chilly or being a bit cross. It is a very complicated business. It has narrative and cultural contents. And it is associated with all sorts of things, like deciding not to talk to somebody because you are very cross with them. All of those things are incredibly complex, and remote from responding to an external stimulus such as a picture. But Zeki et al's experiment is a good example of how neuromania tries to reduce the life of a person to a succession of cerebral discharges.

I have been thinking about depression because it has many different dimensions. The experience of someone who is depressed is very complex. Trying to reduce it to certain kinds of activities of the brain won't work. They are very different.

Depression has a major narrative content in it. It reflects your interpretation of the world and of your place in it. It encompasses what you are telling yourself about yourself, what you tell yourself about others and what you tell

yourself about the world. These are not going to be connected in any direct or simple way to alterations in neural activity explained by depletions in particular neurotransmitter pathways, even though this may have a causal role.

Another issue that we have in psychiatry and we deal with it a lot, especially in forensic psychiatry, is the issue of free will and responsibility. I have talked to many people and they said, well, neuroscience has solved the problem; there is no such thing as free will. What is your opinion on that?

You will not be surprised to know what my opinion is. I have just finished a book on free will.³ I devoted a section to so-called neurodeterminism and to the neurological experiments that are supposed to demonstrate that we do not have free will.

It is worthwhile looking at the most famous ones conducted by Benjamin Libet, 30 or more years ago, but repeated many times since in different forms. What Libet did was to ask study participants to make a very simple movement, just basically flexing their wrist or flexing their finger, but in their own time, so it was a genuinely voluntary movement. He also asked them to do something else: to time the moment when they felt the *urge* to make the movement by noting the position of a spot moving on a clock face on a screen. At the same time, Libet recorded the so-called readiness potential, which is supposed to be a marker in the prefrontal cortex of preparedness to make a movement. What he found was that the readiness potential preceded the urge to make the move. It was as if the brain were getting geared up to make a move, even before the person was aware of the urge to do so. And it has been concluded from this that the brain, not the conscious person, was calling the shots. The decision to move had already been made before the person had experienced the urge to do so. The readiness potential was ahead by only 0.3 s and there are many reasons for thinking that this might not be significant. But then John-Dylan Haynes and colleagues performed similar experiments around 20 years later. Instead of relying on EEG he employed fMRI. He found that the interval between seemingly relevant neural activity and the urge to make a movement (timed by noting letters passing down a screen) was between something like 5 and 10 s and that looked really serious. In Haynes's study, participants were asked to choose to move either their right hand or their left hand to press a button. That study seemed to indicate that the brain was getting all geared up to make a movement well before the person had made a decision to move.

There are two types of fundamental problem with these studies. There are the methodological problems. But more interesting are the philosophical problems arising from a complete misunderstanding of the nature of human action.

Let me first talk about the methodological problems. There are problems about timing an urge. How long does it take you, as it were, to register an urge to enable you to time it? There was also some question about the nature of the readiness potential. It may well be the case that when I decide to make my movement, it is because I feel like I'm taking advantage of the readiness potential: I am, as it were, sort of surfing a wave. And there are many other methodological problems.

But there are more important problems due to a misunderstanding of the nature of action. Think about the experiment from the point of view of the participant taking part in it. Mrs Smith decides that she is going to volunteer for Professor Libet's experiment. She rings up the laboratory, having seen the advert in the newspaper, makes an appointment for 2 weeks' time, sets her alarm the night before to make sure she does not oversleep and upset Professor Libet. She sets out in the car, having made arrangements for the children to be looked after. She arrives at the research centre and has a blazing row with somebody in the car park because they have taken the parking spot that has been set aside for her. She eventually finds her way to the laboratory. She sits down and listens to Professor Libet, and is persuaded that it is a safe experiment to take part in, despite all the people in white coats and all the intimidating machinery around her and the electrodes placed on her head. She pays attention so that she understands what she has to do. This background makes it evident that her action is not just moving a finger. It's 'taking part in Professor Libet's experiment', and clearly that is not something that is the product of an atomic urge, a bit of willing causing a little movement. Taking part in the experiment is actually much more reflective of the complexity evident in even the most ordinary human actions. Most striking is the temporal depth of the action – setting the alarm to get to the lab on time and so on. And then there's the question of motivation. Perhaps Mrs Smith decided she wanted to take part in the experiment so those clever scientists might find something about brain entity, which might help a little boy next door who has brain injury problems.

It will be evident from this that most of what voluntary human action is about cannot possibly be captured in experiments like Libet's. And what about the other participants in the experiments – Professor Libet and Professor Haynes? They too are agents, and they probably had to apply for a grant a couple of years before the experiments. They had to work out the experiments and undergo training in order to understand how to investigate the questions they wanted to explore.

They had to perform these experiments, and then they had to write all this stuff up.

The point is this: human agency is very complex, and it is not made of little atomic urges and twitches. That is why arguments for determinism based on these kinds of so-called empirical experiments don't impress me the slightest bit. I think they have nothing to say about whether we do or do not have free will.

I assume that Libet and Haynes were not dualists, or perhaps to put it better, substance dualists. They are more physicalists in terms of philosophy of mind. What would they expect to see? Did they expect the person to decide before their brain? In that case, where would be the locus of decision? I wonder what would they expect to see in the case of free will? They said because the brain activity happened before the desire there's no free will. But what about the other way around? Would that be satisfying, if the urge happens before the brain activity? What would the source of the urge be?

It has been said that Libet was a dualist and he somehow thought you and your urges are separate and independent from the things you do. I do not think we can ascribe a clear metaphysics to Libet, apart from a commitment to identifying ourselves with neural activity. And once you identify yourself with neural activity, you identify it with physical events, which are necessarily causally stitched into the flow of other physical events. If I say that my free will is to be identified with neural activity, then of course I have already given up on the possibility of free will.

There are many reasons why we cannot identify exercise of free will or normal agency with neural activity. First, when I'm performing an action, that action is associated with an intention, an intention that is not localised in this moment in time. It reaches back to a past that makes sense of my intention and towards something that doesn't yet exist, a future, which also makes sense of my intention. And without that temporal depth, which doesn't exist in the material world, there will be no such thing as meaningful intentional action.

There is another topic I wanted to discuss. I think in 2012, you edited a book with Jacky Davis called NHS SOS.² How do you see the progress and development of the NHS since then?

I have spent an awful lot of time in the intervening 8 or 9 years, marching, waving banners, writing to MPs and so on, though not in the past year of course, because of COVID. And it seems to me that we've gradually moved to a much more privatised NHS. But it's been done much more subtly. After the Lansley Bill [the Health and Social Care Bill of 2011], and there was an enormous amount of anger about it, they decided they needed to be more subtle. But it's interesting how in the COVID crisis, we've had a brilliant demonstration of how the NHS works and how privatisation and outsourcing doesn't. If you want to waste £37 billion, give it to the private sector – Serco and others – and get them to run Test and Trace. If you want to actually have something that's really successful, get it run by the NHS – that's why the vaccination scheme, which has been disseminated through the vascular tree of the NHS, has worked so well. So, we've had a very interesting comparison between things that are outsourced to the private sector, incredibly expensive, totally wasteful, and things that have remained within the NHS and have been very successful.

Yes, we have this new White Paper 4 that wants to integrate cooperation instead of competition. I might well be wrong but I don't think competition worked.

You're absolutely right. The White Paper at first sight looks really good. They said let's say farewell to obligatory competitive external tendering. Great. Let's say farewell to internal market. Great. Let's integrate health and social care. Great. But... but... but. We need to be very careful for two reasons. First, when you integrate health and social care you're integrating something which is free at the point of need and still mainly publicly provided (health) with something that is overwhelmingly privately provided and is means tested (social care). But when you bring those two together there's the danger that it could go either way: to an entirely publicly provided, free at the point of need service; or to entirely privately provided services subjected to means testing. The second reason relates to the question of who is actually responsible for the 'integrated care system'. It is not impossible that the system could be run from outside the NHS, even from an American firm. We can see how real this possibility is by the gigantic privatisation initiative that is the disastrous Test and Trace. And the recent takeover of nearly 50 general practices in London by Centene in the past few weeks.⁵ So, whereas I like the overall principles in the White Paper, I worry that it could be the opportunity for the biggest privatisation of all.

There is a risk of that. And one thing I have observed is the amount of bureaucracy. That is exponentially growing. People talk about being more lean but I think this is only when they are discussing finances – not many are thinking lean when it comes to paperwork.

If you compare the percentage of funding that is spent on administration with that spent on clinical care, it is much greater in privatised health services than in the NHS as it was. We are still a long way behind, for example, the USA in terms of the proportion of our funding that is spent on administration, but the internal market and the external market with compulsory competitive tendering has closed the gap. So, one would hope that the new White Paper⁴ would genuinely liberate funds, taking them away from bureaucracy and administration and bring them back to the front line of clinical care. But there's no doubt about it – if we have a systemic privatisation, which I feel we could have with an integrated care system, as opposed to episodic privatisation, as we have at the moment, we will spend yet more on administration – as well as converting more of taxpayer's money into profits to be hidden in off-shore tax havens. And also, it'll be more expensive. I mean, think of the States – they spend 18% of their GDP on healthcare, and they have a worse system. Many US citizens have only minimal healthcare coverage.

Thank you very much for your time.

1.2.46 Mental health services for children in care: investigation to elicit outcomes of direct and indirect interventions

Abstract

Aims and method

The aim of this study was to compare the efficacy of direct therapy and indirect consultation for treating mental health difficulties among looked after children (LAC), and also to identify any demographic or clinical predictor variables for outcomes in this cohort. A retrospective evaluation of mental health outcomes for 104 LAC was conducted. All children received network consultation in combination with or without direct therapeutic work. Outcomes were compared between the groups with and without direct therapeutic intervention.

Results

Those receiving both treatments displayed significantly greater Strengths and Difficulties Questionnaire (SDQ)-rated improvements than those receiving just consultation. Nonetheless, improvements in scores for the latter group were significant relative to baseline. Treatment duration, younger age at referral and start SDQ were all correlated with positive outcomes, while number of address changes predicted higher start SDQ scores.

Clinical implications

Despite the retrospective design of this study, its results can be considered as preliminary findings to guide treatment decisions in LAC.

pmc .. _sec1-1:

Looked after children (LAC) and mental health

Irrespective of circumstances, LAC appear to be disproportionately burdened by an array of adversity, disrupted development and problematic relationships. These challenges commonly manifest as attachment-related disorders, emotional difficulties and maladaptive behaviours. Given the particular vulnerability of this population and the urgency required when dealing with insecure attachment, any research involving an untreated control group would be inherently unethical. Quantitative research in this field has therefore remained sparse, with the vast majority of the literature instead opting to assess case studies and qualitative data. The retrospective nature of the present study means it is able to contribute treatment-related outcome data from a relatively large sample of LAC. Although this naturalistic design is limited in terms of fully controlling confounding variables, it avoids the risk of bias from insufficient blinding and ensures that no child misses out on potentially beneficial treatment.

A comprehensive meta-analysis conducted by Vasileva and Petermann¹ accumulated data from 22 samples of abused and neglected LAC under 7 years old. Across 11 studies, 38.5% of the 3211 eligible child participants were found to have either motor or cognitive developmental delays; these were consistently more prevalent in children fostered by strangers than in those looked after by kin. Similarly, 39% displayed clinically significant internalising or externalising problems, and only 35% of LAC met criteria for secure attachment. The findings of Tarren-Sweeney² indicate that when mental illness goes untreated during these early years, a child's social and emotional development may be jeopardised, and the possibility of a secure attachment appears to reduce with each placement breakdown. Children that entered care at a later age and were exposed to maltreatment were found to score significantly higher on both the Child Behaviour Checklist and the Assessment Checklist for Children, whereas having a permanent placement was highlighted as an important protective factor. Given the cross-sectional design, however, it was difficult to infer causation, and it is equally possible that children with better mental health are more manageable and thus less at risk of having placements break down.

Attachment security appears to be a crucial factor mediating the mental health outcomes of children placed in foster care. Both internalising problems and frequency of mental illness diagnoses diminished significantly for girls removed from institutional care into foster care, but not for boys, in a sample of Romanian children aged 3 and below.³ Subsequent analysis using the strange situation test⁴ revealed that the demonstrated improvements in mental health for fostered girls was fully mediated by the formation of secure attachment. Guyon-Harris et al⁵ examined the longitudinal trajectories of reactive attachment disorder (RAD) based on semi-structured interviews with caregivers. In line with and extending previous conclusions, the sharpest declines in symptoms of RAD were found for children placed in foster care, which was sustained long-term at 8- and 12-year follow-up (73% retention). The vast majority of children with rapidly decreasing symptoms of RAD had been relatively younger when placed in foster care, whereas children entering at an older age displayed persistent and elevated symptoms. Almost all of the original group left in residential care displayed persistent symptoms.

Direct interventions for mental health difficulties in LAC

The MTFC-P, a direct intervention facilitating healthy, securely attached foster parent–child relationships, included 12 hours of training, daily telephone contact with a consultant and a weekly support group for foster carers, while the child attended weekly therapeutic play group sessions.⁶ Secure and avoidant attachment behaviours were assessed at five time points with 3-month intervals. Pre-schoolers in the MTFC-P condition exhibited significantly more secure and less avoidant behaviours than those in regular foster care. Furthermore, the frequency of secure attachment behaviours increased over time for those receiving the MTFC-P intervention but decreased for the comparison group.

Study on Theraplay have shown statistically significant improvements in communication, interpersonal relationships and behaviour as rated by adoptive mothers, but problem-solving, emotional awareness and general functioning were not found to change.⁷ In a related study, on the other hand, weekly Theraplay sessions delivered to 20 LAC over a period of up to 8 months resulted in no significant change on any of the subscales of the Strengths and Difficulties Questionnaire (SDQ).⁸ Follow-up subgroup analysis indicated that girls showed significantly more teacher-rated improvements than boys in terms of hyperactivity, conduct and prosocial behaviour. Taken together with the findings of McLaughlin and colleagues,³ this suggests that girls may perhaps be more able to securely attach to a foster family and so may benefit more substantially from direct intervention.

Dyadic developmental psychotherapy (DDP) is described as a direct, attachment-based intervention involving the delivery of traditional psychotherapy to both the child and their carer.⁹ Wingfield and Gurney-Smith reported that 12 adoptive parents receiving DDP gained increased curiosity, understanding and empathy for their children, while the children reported fewer behavioural problems, improved control over emotions, better relationships with peers and improved sleep.¹⁰ On the other hand, in spite of progress, a number of parents described the sessions as emotionally exhausting, uncomfortable and upsetting. Feedback from therapists delivering DDP has, however, been very positive. Turner-Halliday and colleagues¹¹ reached out to child and adolescent mental health services (CAMHS) in the UK delivering the treatment. DDP was seen as an effective tool for directly tackling complex profiles of mental illness alongside the root causes of both internalising and externalising problems. The inclusion of parents and carers on such an emotionally stimulating journey was seen to indirectly facilitate secure attachment through an improved mutual understanding.

Multiagency consultation for LAC mental health

In an attempt to better combat the wide range of complex and overlapping symptoms of behavioural, mental, social and cognitive disorders presented by LAC, a small body of research has explored the utility of multi-agency consultation. Upon recounting a number of particularly challenging cases where successful outcomes only emerged in the wake of a concerted effort from all available support, Sprince¹² concludes that child therapists have an obligation to appropriately tailor treatments and advice to the specific network of individuals and organisations responsible for the child's care. The consultation model differs from regular therapeutic interventions in that rather than directly treating the child, their network of carers, teachers, social workers and therapists collaborate to tailor solutions to the child's specific needs, difficulties, history and environment.

Swann and York¹³ refer to this multi-agency intervention as 'THINKSPACE', succinctly illustrating the creation of a space where clinicians, service providers and stakeholders can come together to share their diverse perspectives, knowledge and skills to conjure up a holistic picture and systemic solution. Consultation sessions dedicate around an hour and a half to each child, beginning with the construction of a narrative outlining their development, diagnoses and family history. Attendees then contribute their unique perspectives, theoretical knowledge and practical experience to generate realistic and appropriate solutions. Swann and York emphasise the importance of using everyday language, having only one key interviewer and avoiding giving the primary carer direct instructions.

Qualitative data for evaluation of the consultation model have been collected from social workers and clinicians by Dimaro, Moghaddam and Kyte.¹⁴ Feedback from 138 social workers indicated that a vast majority felt that their goals had been suitably addressed by the collaborative consultation sessions, particularly with regard to assessing concerns, understanding behaviours, understanding relationships and planning next steps. However, 37% of those hoping for effective parenting techniques and 41% of those hoping to work more effectively with staff, agencies and local services felt their goal had not been properly addressed. Subsequent focus groups with 12 of the clinicians illuminated a number of key themes. Primarily, they uniformly felt that the sessions allowed them to provide useful, diverse and practical support. They highlighted the utility of clearly defining roles and objectives and spoke positively about the wider systemic effects their input could achieve.

The sole quantitative trial evaluating the effects of consultation on the mental health of LAC was described by Callaghan et al.¹⁵ Psychiatrists, psychologists and therapists from all three tiers of a UK CAMHS came together to collect collaborative feedback from carers of 45 LAC aged between 4 and 17 years. Outcomes were assessed based on scores on the Health of the Nation Outcome Scales for Children and Adolescents and the SDQ, completed at baseline and 5-month follow-up. Although improvements in total SDQ scores did not quite reach significance, scores on an emotional problems subscale did. This data does rationalise further, more rigorous evaluation of the model but is limited in that it did not include an adequate comparison group, and thus the authors responsible for collecting data were not blinded to experimental procedures. Furthermore, of the 39 carers that completed service satisfaction feedback forms, only 51% felt the intervention offered had been efficacious, and 28% felt their young person had not shown any improvement.

A number of key themes have emerged from the literature exploring mental health presentation and interventions among LAC. Primarily, the formation of secure attachment has consistently been highlighted as a crucial factor mediating mental well-being among this population of particularly vulnerable children. This conclusion emerges from the research contrasting foster care with residential care,^{3,5} the success of treatments targeting child-carer interactions,⁷ and the discrepancy between outcomes for boys and girls,^{3,7} and it is aligned with the apparent predictive power of placement stability and age at entry into care.²

Ethical considerations present a major barrier to quantitative research in that withholding potentially efficacious treatment from a vulnerable child can never be justified. However, uncontrolled quantitative data have pointed towards the efficacy of direct work,^{6,7} as has the more abundant qualitative research.^{10,11} The viability of indirect interventions, on the other hand, is far less well evidenced, with the sole quantitative data-set revealing no significant change in SDQ scores¹⁵ despite promising conclusions drawn from qualitative data.¹⁴

Therefore, in this study, we aim to test the following key hypotheses. Consultation with direct intervention is more efficacious than consultation on its own (H1). Consultation on its own is associated with significant SDQ-rated improvements relative to baseline (H2). A lower total number of address changes and longer time in current placement (H3), younger age at point of referral (H4) and female gender (H5) predict more positive outcomes.

Method

Procedure

In collaboration with a Nottinghamshire-based CAMHS, demographic and treatment-related data for LAC that had accessed the service were collected and analysed ($n = 437$). In pursuit of a suitable outcome measure, only those with both start and end social-worker-rated SDQ scores were included in a subsequent outcome analysis ($n = 104$). Characteristics of the full sample were compared with those of the included sample to determine whether or not it was representative. Permission was then requested and granted to access information regarding presenting problems, diagnoses, address changes and family factors stored on the service's Liquid Logic database for the LAC included in the outcome analysis. Information regarding the nature of treatment for each of these closed cases was also collected, allowing the included sample to be divided into a group receiving just consultation ($n = 69$) and a group receiving both consultation and direct work ($n = 28$).

Sample

Between May 2002 and June 2019, data were available for a total of 443 referrals at the time of collection. Of these, 437 had sufficient data to be included in a preliminary analysis describing the sample, comprising 247 boys (56.5%) and 189 girls (43.2%), with one missing data point. Out of the full sample of 437 LAC, a total of 104 children (23.8%) had both a start and end SDQ score, thus meeting the inclusion criteria for the treatment outcome analysis. Of the 333 LAC not included, 196 (58.9%) were still undergoing treatment, and the remaining 137 (41.1%) were missing either a start SDQ score, end SDQ score or both. Of the 59 boys (56.7%) and 45 girls (43.3%) included in the follow-up outcome analysis ($n = 104$), 69 received cross-domain consultation on its own (66.3%) and 28 received direct work in addition to their consultation (26.9%); intervention details were not available for the remaining seven LAC (6.7%).

Measures

The primary outcome measure was scores on the SDQ, a brief and popular tool used for assessing child psychopathology. It is composed of four subscales evaluating difficulties and one accommodating strengths: emotional symptoms, hyperactivity-inattention, conduct problems, peer problems and prosocial behaviours.¹⁶ Acceptable internal consistency and test-retest stability have been repeatedly demonstrated,¹⁷ and scores have been found to correlate meaningfully with those of other prominent diagnostic tools.¹⁸ Change in SDQ score was calculated as the score reported before treatment commenced subtracted by the score following the treatment's conclusion; positive values therefore reflect improvements in SDQ scores.

Regarding categorical predictors, the included LAC were grouped according to ethnicity, gender, disability and adverse experience. Continuous measures included 'waiting time', calculated as the number of days between initial referral and the date the child was assigned to a treatment programme, and 'treatment duration', operationalised as the number of days between the initial referral and the case closure date. 'Time in current placement' was another continuous measure, calculated as the number of days between the most recent address change and the date that data analysis commenced (1 June 2019). 'Total number of address changes' included short-term placements and returns to previous addresses, in an attempt to best represent placement stability. Start SDQ score and age at point of referral were two additional and more self-explanatory continuous variables also included as potential predictors.

Data analysis

Descriptive and frequency statistics were analysed for both the full cross-sectional data-set and the sample included in the outcome analysis. This was followed by a series of one-way analyses of variance (ANOVAs) and independent-samples *t*-tests in order to identify any significant between-group differences. A parallel analysis contrasted the characteristics of the group receiving just consultation with the group receiving both consultation and direct work. This was followed by an independent-samples *t*-test to determine whether the two treatment groups differed from one another in terms of SDQ score changes. A subsequent single-sample *t*-test was used to determine whether SDQ scores within the consultation group improved significantly relative to a baseline of zero. Finally, a predictor analysis considered the full sample of included LAC, commencing with a series of one-way ANOVAs to identify any categorical protective and risk factors. Pearson's R correlation coefficients were then calculated for the relevant continuous measures, with particular attention paid to the factors associated with changes in SDQ score.

Statement of ethical approval

Ethical approval to conduct this study was not required as the project only involved analysis of existing anonymised data. It was registered in and approved by the Research and Development department of Nottinghamshire Healthcare NHS Foundation Trust.

Results

Demographic and clinical findings

In the full sample ($n = 437$), children waited for a mean of 27.7 days (s.d. = 18.4 days, $n = 317$); they had a mean age at point of referral of 11.3 years (s.d. = 4.2 years, $n = 436$) and mean start SDQ score of 17.2 (s.d. = 8.0, $n = 368$). Start SDQ score did not differ significantly between boys and girls ($t = 0.39$, d.f. = 366, $P = 0.70$). A set of one-way ANOVAs contrasted the group characteristics of those included in the follow-up treatment outcome analysis ($n = 104$) with those that had missing SDQ data or were still open cases (Table 1). No significant between-group difference was found for start SDQ score ($F = 0.512$, d.f. = 1, 366, $P = 0.475$), but significant differences were identified for age at referral ($F = 5.175$, d.f. = 1, 434, $P = 0.023$) and waiting time ($F = 8.366$, d.f. = 1, 315, $P = 0.004$). Subsequent independent-samples *t*-tests revealed that with a mean of 12.1 years (s.d. = 4.0) in comparison to 11.0 years (s.d. = 4.2), children with paired outcome data were significantly older at point of referral than those who were excluded ($t = 2.28$, d.f. = 434, $P = 0.023$). With a mean of 21.7 days (s.d. = 11.3) in comparison with 29.1 (s.d. = 19.5), LAC that met the inclusion criteria were also found to have waited significantly less time between referral and choice than excluded participants ($t = 2.89$, d.f. = 315, $P = 0.004$). Table 1 Descriptive statistics contrasting the included with the excluded sample

	Included ($n = 104$)	Excluded ($n = 333$)
Means	12.1	11.0
d.Rang	4.02–17.10	4.20–17.33
nAge at referral (years)	12.1	11.0
d.Rang	4.02–17.10	4.20–17.33
nWaiting time (days)	21.7	29.1
d.Rang	11.30–48.62	19.50–104.25
nStart SDQ	17.8	17.0
d.Rang	7.31–36.10	4.78–41.00

Fifty-nine boys (56.7%) and 45 girls (43.3%) met the inclusion criteria. For the 100 LAC with data available on the Liquid Logic system, presenting disabilities and adverse experiences are displayed graphically in Figs. 1 and 2. The included sample ($n = 104$) presented with a mean start SDQ score of 17.7 (s.d. = 8.3) and a mean end SDQ score of 14.5 (s.d. = 7.4), equating to a mean improvement of 3.1 points (s.d. = 6.6). The mean age at referral was 12.1 years (s.d. = 4.0), the treatment duration was 248.1 days (s.d. = 259.0), time in current placement was 729.7 days (s.d. = 916.8), the total number of address changes was 8.2 (s.d. = 5.9) and, for the 63 LAC with a recorded choice date, the mean waiting time was 21.7 days (s.d. = 11.2) following referral. Sixty-nine of the included participants received cross-domain consultation on its own (66.3%), 28 received direct work in addition to their consultation (26.9%), and intervention details were not available for the remaining seven (6.7%). Fourteen of the participants receiving direct work completed individual therapy (50.0%), five received DDP (17.9%), four were assigned creative therapy (14.3%), two were assigned Theraplay (7.1%) and one was assigned to each of DBT (Dialectical Behaviour Therapy), EMDR (Eye Movement Desensitisation and Reprocessing) and medical review (3.6% each). The distribution of direct treatment interventions is presented graphically in Fig. 3. Fig. 1 Pie chart graphically illustrating the distribution of presenting

¹ * $P < 0.05$, ** $P < 0.001$.

disabilities for the included sample of LAC. ASD, autism spectrum disorder. Fig. 2Pie chart graphically illustrating the distribution of adversities experienced by the included sample of LAC at the hands of their birth families. Fig. 3Pie chart graphically illustrating the distribution of direct treatments allocated to the subgroup of included LAC receiving both interventions.

Combined and consultation-only treatment (H1 and H2)

The group of LAC receiving only consultation work ($n = 69$) was composed of 38 males (55.1%) and 31 females (44.9%). They had a mean age of 12.2 years (s.d. = 4.2) at point of referral and a waiting time of 23.3 days (s.d. = 12.2), and their treatment lasted for an average of 177 days (s.d. = 216.2) They had changed address a mean of 7.9 times (s.d. = 6.7) and had been in their current placement for 789.1 days (s.d. = 1032.6). The group receiving both consultation and direct work, on the other hand, was composed of 17 males (60.7%) and 11 females (39.3%). They had a mean age of 11.9 years (s.d. = 3.1), a waiting time of 17.7 days (s.d. = 8.5) and a treatment duration of 401.4 days (s.d. = 305.2). They had changed address a mean of 8.4 times (s.d. = 4.0) and had been in their current placement for 629.9 days (s.d. = 653.1). Those receiving both direct work and consultation were found to have significantly longer treatment duration ($t = 4.01$, d.f. = 91, $P < 0.001$) and a higher start SDQ score ($t = 2.26$, d.f. = 95, $P = 0.03$) than those receiving just consultation (Table 2). Table 2 Descriptive statistics for the two treatment groups Consultation ($n = 69$) Consultation and direct work ($n = 28$) Means.d. Ranges Means.d. Ranges Age at referral (years) 12.34.22–17.69 11.93.15–16.28 Time in current placement (days) 789.11032.60–4748 662.9.9653.10–3073 28 Waiting time (days) 23.312.21–48 43 17.78.50–34 28 Start SDQ 16.4*8.41–36 69 20.6*8.26–34 15 Treatment duration (days) 177.1**216.20–850 66 401.4**305.20–1205 28 End SDQ 14.37.52–31 69 15.37.71–29 27 Change in SDQ 2.1*6.315 to 18 69 5.4*7.010 to 18 28²

With a mean change of 5.4 points (s.d. = 7.0) on the SDQ in comparison with 2.1 points (s.d. = 6.3), those receiving both direct and indirect treatment interventions improved significantly more than those receiving just consultation ($t = 2.26$, d.f. = 95, $P = 0.026$). A single-sample t -test indicated that those receiving just consultation nonetheless displayed significant SDQ-score improvements ($t = 2.75$, d.f. = 68, $P = 0.008$). These findings are displayed graphically in Fig. 4. A one-way ANOVA found no significant difference in outcomes for the different direct interventions ($F = 0.65$, d.f. = 6, 21, $P = 0.690$). Parallel one-way ANOVAs identified no significant differences when the included sample was grouped by ethnicity ($F = 0.38$, d.f. = 6, 97, $P = 0.890$), disability ($F = 0.70$, d.f. = 4, 95, $P = 0.593$) or adverse experience ($F = 0.65$, d.f. = 5, 94, $P = 0.662$). Across the paired data, mean change in SDQ score did not differ significantly between boys and girls ($t = 0.41$, d.f. = 102, $P = 0.968$). Fig. 4 Bar chart graphically illustrating the mean SDQ-rated improvements for both treatment groups, with error bars representing standard deviations.

Predictor variables of outcome (H3 and H4)

Correlational analysis for the full sample identified a number of factors predicting SDQ-related improvements, as displayed in Table 3. These were: age at point of referral ($R = 0.22$, $P = 0.027$), treatment duration ($R = 0.20$, $P = 0.049$) and start SDQ score ($R = 0.53$, $P < 0.001$). Start SDQ score was also correlated strongly and positively with total number of address changes ($R = 0.23$, $P = 0.021$) and treatment duration ($R = 0.28$, $P = 0.005$). Finally, a negative correlation was found between number of days waiting and total number of address changes ($R = 0.31$, $P = 0.014$). Table 3 Pearson's correlation coefficients for all continuous variables for the included LAC Age at Referral Address changes Time in current placement Waiting time Start SDQ Treatment duration Change in SDQ Age at referral (years) 0.27 ($P = 0.006$) *0.23 ($P = 0.021$) *0.10 ($P = 0.417$) 0.09 ($P = 0.350$) 0.06 ($P = 0.668$) 0.22 ($P = 0.027$) *Address changes 0.27 ($P = 0.006$) *0.37 ($P < 0.001$) **0.31 ($P = 0.014$) *0.23 ($P = 0.021$) *0.12 ($P = 0.253$) 0.05 ($P = 0.655$) Time in current placement (days) 0.23 ($P = 0.021$) 0.37 ($P < 0.001$) **0.21 ($P = 0.098$) 0.10 ($P = 0.345$) 0.12 ($P = 0.256$) 0.023 ($P = 0.822$) Waiting time (days) 0.10 ($P = 0.417$) 0.31 ($P = 0.014$) *0.21 ($P = 0.098$) 0.02 ($P = 0.885$) 0.06 ($P = 0.668$) 0.08 ($P = 0.512$) Start SDQ 0.09 ($P = 0.350$) 0.23 ($P = 0.021$) *0.10 ($P = 0.345$) 0.02 ($P = 0.885$) 0.28 ($P = 0.005$) *0.53 ($P < 0.001$) **Treatment duration (days) 0.06 ($P = 0.668$) 0.12 ($P = 0.253$) 0.12 ($P = 0.256$) 0.06 ($P = 0.668$) 0.28 ($P = 0.005$) *0.20 ($P = 0.049$) *Change in SDQ 0.22 ($P = 0.027$) *0.05 ($P = 0.655$) 0.023 ($P = 0.822$) 0.08 ($P = 0.512$) 0.53 ($P < 0.001$) **0.20 ($P = 0.049$) *³

Discussion

In summary, the LAC with paired outcome data ($n = 104$) differed significantly from the rest of the sample ($n = 333$) in that they were older at the point of referral (12.1 years *v.* 11.0 years) and waited for less time between referral and appointment to a treatment programme (27.1 days *v.* 29.1 days). It is unclear why children referred to the CAMHS at an older age were more likely to have completed treatment and received both start and end SDQ scores. For the latter discrepancy, on the other hand, it is plausible that shorter waiting times may result in faster recovery, meaning treatment is more likely to be concluded for those that received it quickly.

The children allocated both consultation and direct work ($n = 28$) differed significantly from those receiving just consultation ($n = 69$) in that their treatment lasted longer and they commenced with a higher start SDQ score (20.6 *v.* 16.4). Given that the former group were receiving two forms of treatment as opposed to one, it is understandable that the overall duration would be longer. As for the higher start SDQ score, this discrepancy is likely to reflect the unrandomised group allocation. Treatments were instead allocated based on the needs of the LAC; those with more severe presentations and exposed to more adversity were more likely to receive both forms of treatment. One important strength of the present analysis is that outcomes were assessed and scored by the child's social worker, a third party with no conceivable bias towards observing an improvement.

Despite more severe presentations, the group receiving both treatments displayed significantly greater improvements in SDQ scores than the group receiving just indirect work (5.4 *v.* 2.1), thus confirming the primary hypothesis (H1). As outcomes for the various direct interventions did not differ significantly from one another, this finding can be interpreted as qualitative support for all the included direct treatment programmes. In particular, it extends the findings of Weir et al⁷ in their endorsement of the efficacy of Theraplay, but it contradicts Francis, Bennion and Humrich,⁸ who did not find a significant change in SDQ score. It also provides concrete quantitative data to validate the qualitative findings of DDP research.^{10,11} Furthermore, it forms a preliminary benchmark for future research evaluating the utility of both individual and creative therapy, which is yet to be evidenced in a population of LAC. Conclusions regarding the other three direct interventions are more tentative given that only one child received each of DBT, EMDR and medical review, but the outcomes are nonetheless promising.

Consultation was found to be independently efficacious at moderating SDQ scores relative to a baseline of zero, thus confirming the secondary hypothesis (H2). This finding opposes that of Callaghan and colleagues,¹⁵ who did not find any significant change in SDQ score following consultation, perhaps owing to their smaller sample size or the shorter treatment duration. On the other hand, it aligns more readily with the qualitative data reported by Dimaro, Moghaddam and Kyte.¹⁴ This finding for the consultation-only group, however, should be viewed with some caution. Clinicians appear to have made a judgement that these children did not merit a direct intervention, most likely owing to less severe presentation. Consequently, the finding that CAMHS consultation was of benefit is promising. However, the other finding that this group showed less significant change than the group receiving both treatments may imply that these children required additional therapeutic intervention, which was not necessarily within the specialist CAMHS remit. The findings, therefore, may rekindle the debate on the needs and resource implications of therapeutic services, often offered by other agencies such as social care and the third sector, that have been substantially lost in recent years in the UK.

The ingredients of the consultation model used in the study sample consisted of collaboration and cooperation among a specific network of carers, professionals and organisations to create a thinking space where the complex needs of the LAC could be assessed, understood and managed by mutual support, clarification of roles, common understanding and practical steps. This is compatible with previous work that endeavoured to illustrate the consultation model.^{12,13} Unfortunately, there are no data available on the rationale or indication for offering indirect intervention. Future service-based clinical studies may consider looking into the rationale for choosing consultation as a treatment, for example, data on goal setting and management plans following initial evaluation. Quantifying gradual systemic improvement in general functioning and long-term life trajectories of LAC as a result of indirect intervention remains a challenge to achieve through retrospective or short-term quantitative research.

Contrary to expectations, hypothesis three (H3) was not supported by the present data-set in that greater length of time

in current placement did not predict more substantial SDQ-score improvements, nor was number of address changes found to moderate these improvements. However, in line with the findings of Tarren-Sweeney,² the present analysis did reveal start SDQ score to be positively correlated with number of address changes. The causal directionality of this well-evidenced correlation between mental health presentation severity and frequency of placement breakdown is still unclear.

Hypothesis four (H4) was supported by the present analysis, with age at point of referral negatively correlated with change in SDQ score. This demonstrates the benefits of intervention at a younger age and somewhat aligns with the findings of Tarren-Sweeney² and Guyon-Harris et al.,⁵ both of whom endorse younger age at entry into care as an important protective factor. Probably also driven by an increased propensity to develop secure attachment,^{3,5} it is apparent that parallel to younger age at entry into care, early intervention from CAMHS similarly predicts more substantial improvements. In contrast to previous literature endorsing a gender discrepancy,^{3,8} the present data-set displayed no significant difference in start SDQ score across the full sample, nor did boys and girls included in the outcome analysis differ significantly. This lack of support for hypothesis five (H5) speaks positively towards the efficacy and reliability of both consultation and direct intervention. Similarly, treatment outcomes were equivalent across ethnicity, disability and adverse experience, further endorsing the cross-contextual efficacy of both consultation and direct work.

Limitations

Although the present data-set does provide convincing support for both treatment programmes, conclusions cannot be made regarding their relative efficacy as both groups received consultation. Future experimental research should deliver indirect interventions and direct interventions on their own, to two separate groups. Where in the past the risk of one or both treatments being ineffective may have deemed an investigation of this kind unethical, it can be rationalised by the improvements displayed by both groups in the present study. It is possible for the inclusion criteria to be biased towards including individuals that have responded positively to treatment, who are more likely to have had their case closed and to have completed an end SDQ. However, a noteworthy proportion of the included sample appear to have concluded treatment on turning 18 years of age. This would also explain why the included sample had a mean older age. Although previous research does support the inference that treatment-related improvements are attributable to the facilitation of secure attachment, attachment security was not included as an outcome measure in this study. Given widespread evidence for attachment as a crucial mediating factor,^{5,6} it would be advisable for future research to include attachment security as an outcome measure. This may include considering incorporating the strange situation test⁴ to characterise the attachment between a child and their carer as either secure, avoidant or resistant.

Implications

The literature review that commenced this report isolated the formation of secure attachment as a crucial mediating factor in determining the mental well-being of LAC. It also outlined support for direct work in the promotion of mental health in this population and identified a gap in the LAC literature, with indirect consultation yet to be suitably and quantitatively assessed. This report is the first of its kind to contrast direct and indirect treatment-related outcomes for LAC, and it endorses the efficacy of both. Younger age at entry into care and early treatment are further solidified as key protective factors for mental health of LAC, whereas the previously reported effect of gender is undermined. Despite a number of limitations, these findings provide an important quantitative benchmark to guide treatment decisions and future research exploring the efficacy of interventions for this particularly vulnerable population of children.

We thank the management of the looked after CAMHS service, the IT department and the trust research and development department for providing access and support. We also thank the professionals in CAMHS and children's social care who provided space to conduct the study and helped by reflecting on the clinical implications of the findings.

1.2.47 Extreme ‘gender critical’ views will alienate many gender dysphoric patients

Neil David MacFarlane

date

2021-10

Contents

- *Extreme ‘gender critical’ views will alienate many gender dysphoric patients*

pmc The authors provide a welcome update of evidence and reasoning for the ‘gender critical’ position, and the problems with the ‘gender affirming’ position that the Royal College of Psychiatrists adopted in 2018. Their argument might have been even stronger if it had included an account of recent complaints about pressures against free enquiry and expression in this area.¹ Such pressures may partly account for the paucity of published gender critical clinical and scientific research. Neither did the authors mention the professional misconduct of a ‘gender affirming’ consultant psychiatrist in a London teaching hospital, which was brought to the public’s attention in 2007 by the campaigning journalist Julie Bindel.² Or, specifically, the influence of the pharmaceutical industry, although that was implied in at least one of the references they cited.³ However, some of their reasoning appears to lean towards an extreme gender critical position, which is inconsistent with mainstream psychiatric practice. They write that ‘there is little to no convincing evidence to support fundamental differences between the brains of females and males’. But a lack of reliable neurobiological pathology is true of most psychiatric disorders, for which psychiatrists routinely prescribe drugs and other physical treatments, quite often coercively. Again, ‘As a pure subjective experience, [gender identity] may be overwhelming and powerful but is also unverifiable and unfalsifiable’. Psychiatric disorders are mainly diagnosed on the basis of what patients report about their ‘subjective experience’, so the requirement that transgender patients must provide substantial additional ‘verification’ of their experiences also suggests that the authors have adopted a double standard. Do they propose that patients with depression or post-traumatic stress disorder demonstrate that their problems are ‘falsifiable’ before they can receive treatment? The authors attempt to distance themselves from ‘conversion therapy’, but many gender dysphoric patients will not find their arguments convincing. They claim ‘there is little evidence’ that transgender conversion therapy ‘is taking place in the UK’, but the 2018 National LGBT Survey found that 13% of UK trans respondents ‘had been offered’ conversion therapy, compared with 7% of ‘cisgender’ respondents.⁴ Conversion therapy for homosexuality is closely associated with psychoanalysis.⁵ The American Psychiatric Association removed homosexuality from its list of disorders in 1973, with strong opposition from psychoanalysts. It took nearly three decades for the London-based International Psychoanalytical Association (IPA) to act similarly, in 2002. It seems likely that the IPA continues to tolerate the view that homosexuality is a disorder, treatable by psychoanalysis.^{6,7} The authors allude to ‘complex intrapsychic conflicts’ but fail to explain what they mean by this or provide a reference.

This suggests an undeclared allegiance to psychoanalysis. Some British psychoanalysts appear to see transgender patients as a growth opportunity.⁸ The gender critical views of the ex-Tavistock London psychoanalyst Marcus Evans have been quoted by the BBC⁹ and the *BMJ*,¹⁰ while journalists have failed to scrutinise his implied claim that psychoanalysis can provide valid clinical opinion. Such scrutiny is especially necessary given the problematic relation of psychoanalysis to homosexuality and its wider history of evading scrutiny of its claims to therapeutic efficacy, validity¹¹ and safety.¹² Psychiatry should retain its gatekeeping role for transgender patients seeking physical treatments or legal gender change, but extreme gender critical views, which at present appear to include special pleading for psychoanalysis, would undermine the consent necessary for that role to be effective.

1.2.48 Making the case for the family model in in-patient child and adolescent mental healthcare

Lesley Cousins Joanne Holmes

Correspondence

Lesley Cousins

(lesley.cousins@cpft.nhs.uk)

date

2021-10

Abstract

Within paediatrics, young children experiencing physical and emotional distress are admitted to hospital with their parents as a matter of course, recognising the trauma associated with parting children from their carers. Much of this practice is underpinned by our understanding of attachment theory, which also sits as a fundamental tenet of child psychiatry. Yet the culture in psychiatric in-patient hospitals remains to admit young children without their parents, often to units that are geographically distant from the family home. We argue that the practice of admitting lone children to psychiatric in-patient units is likely to be traumatising as well as less effective. We believe this culture requires challenge and change.

 - *Declaration of interest*

pmc There are currently only seven child and adolescent mental health (CAMH) in-patient units admitting children under the age of 13 in the UK. Of these, just one admits children along with their parent or carer as a matter of course.¹ We believe this standard practice of admitting children without an accompanying parent/carer to be outdated and detrimental to both child and family.

Enter a paediatric ward today and the sight of a parent accompanying their sick child would be commonplace. Indeed, for children of primary school age, and especially those requiring extended treatment over weeks or months, if a parent or carer were not present for much of the admission there would be concerns raised about the adequacy of the care they were receiving from the family. Over the past 60 years, our paediatric colleagues have increasingly recognised the value of parents accompanying their child in order to minimise the child's distress and to improve overall outcomes.² Yet we in CAMH in-patient services continue to admit lone children, often to facilities that are a considerable distance from the family home.

The initial recognition of the trauma caused to children separated from their parents by hospital admission, and the resulting movement to allow parents to stay alongside their children, was significantly led by John Bowlby.³ Bowlby's work in the development of attachment theory has been integral to our understanding of child emotional development and underlies much of our current practice of child psychiatry. Many research studies have confirmed the association between insecure relational family attachment patterns and childhood emotional and behavioural difficulties,⁴ and it is therefore not surprising that we see an increased prevalence of insecure attachment patterns in the clinical population of the children we care for.^{5,6} Given this, it seems illogical that in-patient CAMH practice continues to admit unaccompanied children, placing children at risk of the double trauma of separation from parents and admission to a mental health setting.

Children exist within and respond to the wider system around them, of which the family is the predominant part. Often the journey that brings a child to an in-patient admission involves the breakdown and disruption of this family system.⁷ Any therapeutic intervention must take this into account and address it. The attachment relationship between a parent and child is a dynamic process that we believe can only be really understood by directly observing their interaction. Admitting the parent and child together allows clinicians to assess attachment patterns directly and to establish to what extent disruption in relational security is driving and/or maintaining the child's mental disorder. It is not uncommon for a parent's own emotional difficulties to affect their attachment relationship and we know that a parent's mental health represents the most important correlate for all domains of the child's potential mental health difficulties.⁸ Many parents of children in in-patient CAMH services have significant backgrounds of trauma and it is common to see the effects of intergenerational trauma displayed in a child's behaviour or for a traumatic response to be triggered in the parent by this behaviour. This understandably can make it impossible for any parent to implement any behavioural strategies suggested by professionals. If parents are part of the admission, this helps the team to develop the trust required to undertake the therapeutic work needed and address these issues more readily.

We should not be surprised that some parents understandably find the idea of abandoning their distressed, frightened child with professionals in an institution far from home for a potentially prolonged period unacceptable. This may mean that the family refuse the admission that they need. By preventing parents from accompanying their children are we denying families the potential to get the help they require? Alternatively, some parents, exhausted by the challenge of trying to care for their child, may be eager to accept an admission to hospital, thus gaining respite from the responsibility of care. However, a hospital admission can strengthen the medicalisation of the child's difficulties, and handing over the care of the child to a clinical team may further promote a family's belief that the child needs to be 'fixed' by professionals or disempowers parents if the child's symptoms dissipate once they are in a hospital setting.

Even if a child's mental disorders are not driven by disrupted relationships, it is vital that the parents/carers can be fully involved in their child's care, as they will become the child's care team on discharge. In all cases the parents/carers of a young child need to become part of the solution for that child rather than continuing to fuel the problem or to believe that only professionals can help.

Are we denying children the opportunity to get the help by not routinely admitting parents with them?

Although we strongly believe that the benefits of parents being admitted with their children to in-patient CAMH settings are clear and meaningful, we recognise that, given this is not routine, there are clearly arguments opposing it.

There is evidence that the practice of admitting lone children and focusing on individual work with the child alone is effective.^{7,9} It may therefore be argued that the additional admission of the parent is unnecessary. A study measuring the outcomes of child in-patient admissions in England and Wales demonstrated their effectiveness and calculated the average cost of a child in-patient admission, but it did not compare the units that do not admit parents with the one that does.⁷ We therefore do not know whether this assumption is correct and clear evidence exists that more can be achieved when children are admitted with their parent or carer than when the child is admitted alone.¹⁰

We note that some children with emotional or behavioural difficulties can benefit from time away from the family home, particularly when ongoing stress in the child–parent relationship is the main source of their distress. We would argue that removing the child from the home temporally is unlikely to address the difficulties long term and intensive work is required with parents to make the systemic change that will be required for the child to benefit when discharged. Although this family work can, and does, happen on an out-patient basis, it is often difficult for parents to attend regularly,¹¹ particularly when children are admitted a long way from home.

Finally, we also recognise the considerable financial implications as well as disruption to family life for siblings at home when a parent is admitted with their child.⁷ Again, we would argue that the long-term consequences of having a child with significant behavioural and emotional problems is in itself disruptive and costly, with long-term negative consequences if not addressed. We would, however, also argue that the family's financial needs could be more actively addressed societally and appropriate reimbursement made available.

Clinical implications and future plans

We have argued that a clinical model that promotes parents accompanying their child during an in-patient CAMH admission is beneficial, therapeutic and should be considered normal practice. We believe the current practice of admitting lone children under the age of 13 to be outdated and anti-therapeutic. We recognise that no specific clinical trials have been undertaken to support this model in mental health settings but we note that our paediatric colleagues have not been required to provide such evidence for their culture and the acceptance of parents on their wards to change; common sense has prevailed by itself. Admitting a child to an in-patient ward is a radical treatment option and including parents in this approach significantly adds to the intensity. We argue, however, that the involvement of parents or carers is fundamental to making the most of this period of family upheaval and is in the best interests of both the child and the family.

Lesley Cousins, MB, BChir, MRCPsych, DPhil, is a Year 6 Specialty Trainee (ST6) in child and adolescent mental health (CAMH), currently working at the Croft Child and Family Unit, Fulbourne, Cambridge, UK. **Joanne Holmes**, DM, MRCPsych, PG Cert MedEd, is a consultant CAMH psychiatrist based at the Croft Child and Family Unit, Fulbourne, Cambridge, UK.

Both authors contributed equally to the conceptualisation and writing of this paper.

1.2.49 Freedom to think should not mean freedom from evidence and experience

Peter Swann Timothy Swann Reubs J. Walsh

date

2021-10

Contents

- *Freedom to think should not mean freedom from evidence and experience*
- *Declaration of interest*

pmc Evans made a number of inaccurate statements in his originally published article, which subsequently resulted in the publication of a corrigendum. Some of the inaccurate statements and implications for scholarship and clinical practice are referred to in our letter, which was first submitted on 23 August 2020. Gender identity is a pertinent and timely topic, given the current moral panic around transgender individuals. Evans¹ states several fallacies that risk increasing the stigma towards transgender and non-binary individuals. Throughout, motivated reasoning that seeks to describe transgender individuals as inherently disordered is apparent. This manifests in the very limited selection of evidence cited and in unsupported claims made contrary to the bulk of existing evidence.

It is also important to put the letter in context. The consensus among the World Psychiatric Association,² Royal College of Psychiatrists, American Academy of Child and Adolescent Psychiatry and American Psychiatric Association is that psychological treatments to 'suppress or revert gender diverse behaviours are unscientific and unethical'. The reports from these groups follow detailed review of the current literature.

Evans relies heavily on personal accounts and experiences reported by media organisations. Although each individual story deserves hearing, understanding and respect, there is an inherent danger to highlighting cherry-picked examples from blog posts or newspapers. These sources often have political standpoints or biases. The quoted Christian Institute, for instance, writes on their website that transgender ideology 'seeks to completely destroy the distinction between men and women that God in his wisdom has created', and the Sunday edition of the quoted *Times* has been forced to correct a number of inaccuracies in articles about the Tavistock after intervention from the press regulator.

The existence of a few examples of adverse outcomes does not lend support to the idea that affirming care is harmful. In any area of medicine or psychiatry there are always patients who regret treatment, but provided informed consent is obtained and the proportion remains low, that risk is deemed acceptable. What little legitimate research into detransition exists finds a miniscule rate,³ with the primary cause being lack of social support for the affirmed gender identity. By contrast, trans young people supported in their social transitions show radically reduced rates of internalising disorders compared with those that are unsupported.⁴ The claim that transition is predicated on a 'fantasy that the body can be rapidly sculpted as a way of being rid of profound psychological problems' is spurious; the body need not be altered at all for these effects of affirmation to occur (the Olson study included children receiving no medical interventions; instead,

inclusion criteria were that children should be affirmed in their identity by their families and healthcare professionals), and being trans is not a ‘profound psychological problem’ any more than homosexuality is.

It is also important not to conflate alleged failings of a specific institution or clinicians with that of an entire practice. Psychotherapists or psychiatrists not adhering to professional standards, such as those around informed consent, require a response of upholding good and agreed practices and laws, not stopping provision of care to those who seek it. It is also notable that not all consent violations are presented on an equal basis by Evans and those who share his viewpoint. Withholding access to care because a doctor personally disagrees with the informed choice of a patient for reasons based on speculation or ideology also violates informed consent, particularly where that decision has irreversible consequences for the patient, as in the case of withholding puberty blockade.

There is danger in not involving transgender perspectives on work that affects transgender individuals specifically. Work like this risks contributing to the known stigma and discrimination that the trans community already faces⁵ and allowing the credibility of peer-reviewed science to be misused by transphobic groups to promote a harmful ideology. Journals, editors and reviewers have a responsibility to ensure that published material meets a minimum standard of rigour. Evans makes claims including ‘there is considerable evidence that children are signing up to treatments with long-term implications, with very little real understanding of the consequences’ and ‘There is considerable evidence of children and adolescents changing their minds if given enough time and space to explore things’ without providing references to this ‘considerable’ body of work; we are aware of no such evidence for the former, and the latter claim has been thoroughly debunked.⁶ Similarly, the claim that ‘a new diagnostic category, ‘recent-onset gender dysphoria’ [sic], mak[es] up a substantial proportion’ of Gender Identity Development Service referrals is made without any citations to literature. ‘Rapid-onset gender dysphoria’ is a proposed diagnostic category, based on a single, flawed study.⁷ It is not currently recognised for use in clinical settings.

There are common but false comparisons between gender dysphoria and body dysmorphia or body image disturbance in anorexia. Body dysmorphia is a preoccupation with a perceived flaw in part of the body. Transgender individuals do not falsely perceive their body to be different to how others perceive it, only that it is perceived (by themselves and/or others) in a way that does not reflect their gender identity. We think this is an important distinction and failure to appreciate it could lead to attempts at ineffective or dangerous ‘treatments’, much like the unethical and pseudoscientific conversion therapy targeting homosexuality, which is now widely discredited. It is also a common mistake to try to define these complex issues through our own professional lenses – whether labelling as a psychiatric disorder or as a psychoanalytic defence mechanism that unfairly pathologises gender identities that do not fit our traditional western belief systems. Psychiatry has a history of falling into this trap, and we would hope the profession could learn from its mistakes.

We accept that this was a ‘special article’ rather than original research and not a research article, but we do not think that this excuses it from the high standards of evidence expected in an esteemed publication. We would echo the call for greater research into psychiatry’s role in ensuring transgender youth ‘fulfil their potential in comfort’ (https://www.repsych.ac.uk/pdf/PS02_18.pdf) and would recommend that this begins with the people most affected, listening to their concerns and values, and using scientific rigor rather than anecdote and ideology.

pmc Thank you for publishing our article¹ and facilitating academic debate in this rapidly evolving area of healthcare. It is unsurprising to find disagreement over the interpretation of existing research, and we welcome this opportunity to respond to Ashley and review the many references supplied, including data published after our article was accepted. We happily address Ashley's points and respond to all individual references in Table 1 <https://doi.org/10.6084/m9.figshare.13626380.v3>.

We stated that the College sees the placement of barriers to seeking transition as a form of conversion therapy, and we shortened – but did not substantively change – the position statement quote.² We believe it accurately represents the meaning, and indeed the same abbreviation was used within the body of the position statement itself. If we are wrong about the College's stance, and we agree there is a lack of specificity about barriers, others too may be confused. Given moves to criminalise conversion therapies,³ the College should clarify what constitutes unacceptable practice⁴ and be clear that provision of psychological interventions to address existing mental health needs before referral for cross-sex hormones, or surgery, would not constitute a barrier or conversion therapy. This is of particular importance since the recent UK judicial review, which found that young people are unlikely to be able to provide informed consent for early medical intervention.

We agree we used some non-peer-reviewed literature. It is well established that dissenting voices can go unheard by invested clinicians and reports of harm take much longer to recognise.⁵ In a word-constrained, broad-based discussion, we could not analyse all the existing literature about natural history, persistence of gender incongruence in youth, rising referrals, or the age and sex switches, though these have been covered elsewhere.⁶ Similarly, other authors have noted that gender dysphoria is a common step in the developmental pathway of same-sex attraction.⁷

Proponents of affirmative care often claim that medical transition is well studied, with academic consensus on effectiveness. In reality, the literature is fraught with study design problems, including convenience sampling, lack of controls, small sample sizes, short study lengths and high drop-out rates among participants. Most of the studies cited in Ashley's letter were of cross-sectional observational design (Table 1) <https://doi.org/10.6084/m9.figshare.13626380.v3>. These low quality studies are unable to demonstrate causality and are susceptible to confounders. An important example of the shortcomings of such convenience sampling is the 2020 paper by Turban et al, which claims to demonstrate lower suicidal ideation in adults who had been prescribed GnRHa in adolescence.⁸ There are a number of methodological shortcomings associated with this biased sampling,⁹ the most worrying being the authors' failure to recognise that this single positive finding is inevitable as prescribers would only have offered puberty blockers to adolescents with stable mental health. Those adolescents with severe psychological problems would not have been eligible. Suicidal ideation is almost certainly related to poor mental health (both past and present) in this group rather than any lack of puberty blockade. This same fact also renders any retrospective desire for treatment invalid. The authors' recommendation that 'this treatment [should] be made available to transgender adolescents who want it' is unsupported.

Before-and-after studies and case-note reviews are similarly unreliable. Like first-hand accounts, they are mainly useful for raising, not answering, quantitative questions. Benefits will be bolstered by mutual belief systems, clinician charisma, powerful mood-altering drugs and body modifications, as well as the placebo effect. By their nature, these kinds of evidence are unconvincing to an ethical medical profession with a long history of causing harm.⁵

The problem of missing data distorts routinely quoted high levels of satisfaction and low regret rates in transgender healthcare. It is unknown whether large losses to follow-up in gender dysphoria research, often over 30%,¹⁰ mask

adverse effects, including death by suicide, cardiovascular disease or general morbidity associated with deteriorating mental and physical health. Thus, long-term cohort data, as well as appropriate randomised trials, are essential.¹¹

Publication bias in this area can be demonstrated by a key ‘positive’ published study¹² which was widely reported by media outlets. This population-based study initially reported a ‘longitudinal association between gender-affirming surgery and reduced likelihood of mental health treatment’ and declared that these findings ‘lend support to the decision to provide gender-affirming surgeries to transgender individuals who seek them’. However, when the authors were asked to address significant methodological limitations and reanalyse including a comparator group, any purported benefit disappeared.¹³ The journal editor stated that the original conclusion of the benefits of surgeries ‘was too strong’, and that the data ‘demonstrated no advantage of surgery in relation to subsequent mood or anxiety disorder-related health care visits or prescriptions or hospitalizations following suicide attempts’.¹⁴ The published correction garnered much less media interest than the initial flawed research.

We agree with Ashley that scientific literature must meet the highest standard for publication and that competent care depends on the integrity of the scientific process. We would add that gender healthcare deserves the same rigorous scientific underpinning as all other areas of medicine. However, in the absence of double-blind randomised controlled trials, there can be no analysis of metadata. The often cited ‘What we Know’ project does not meet even the minimum standard of a systematic review.¹⁵ Poor-quality publications are then recycled as ‘evidence’ and can form the basis of poor-quality guidelines,¹⁶ which in turn are cited as further evidence that this ‘treatment’ works.

Ashley calls for love, but this quality resides outside the consultation room and is not a medical intervention. We support the highest-quality compassionate and evidence-based care for all individuals, based on their own values and circumstances, and are only opposed to bad science^{17,18} which supports, promotes or sells medical interventions without reliably quantifying the outcomes. Present and future patients deserve better, unbiased, sound evidence. Higher-quality collaborative research and independent adjudication of the evidence¹⁹ are required to find out exactly what works, for whom, when and for how long.

1.2.51 The article ‘Sex, gender and gender identity’ fails to adequately engage with the extant scientific literature

Florence Ashley

date

2021-10

Contents

- *The article ‘Sex, gender and gender identity’ fails to adequately engage with the extant scientific literature*

The recent paper titled ‘Sex, gender and gender identity: a re-evaluation of the evidence’, which appeared as a Special Article in the *BJPsych Bulletin*, contains concerning misrepresentations of the scholarly literature. The article selectively cites sources to make claims that are contrary to the available literature and best practices, which strongly support access to social, legal and medical transition. Using a direct quote, the authors claim that a Royal College of Psychiatrists position statement includes ‘placing barriers [to] medical transition’ within the meaning of conversion therapy. However, the document actually says ‘place barriers in the way of trans people who seek advice regarding medical and/or social transition’.¹ Raising barriers to transition and raising barriers to people seeking advice are two different things altogether, and the elision misrepresents the Royal College of Psychiatrists’ position statement. Substantively altering quotes in this way is contrary to ethical authorship practices and is difficult to explain. While I would agree that preventing transition is a form of conversion therapy, as expressed in a recent report by UN Independent Expert Victor Madrigal-Borloz,² this is not what the cited position statement says.

Despite discussing these topics, the authors fail to cite available data on the prevalence of anti-trans conversion therapy in the UK;³ fail to acknowledge strong methodological criticisms of studies suggesting that most transgender youth grow up to be cisgender;^{4,5} fail to refer to empirical evidence of the harmfulness of misgendering and deadnaming;⁶⁻⁹ fail to mention that youth referred to gender identity clinics are significantly similar to those in the past despite changes in gender ratios;¹⁰ fail to substantially engage with significant evidence of mental health benefits to transition by brushing it off as immaterial to youth;¹¹ fail to refer to evidence demonstrating that trans youth can be trusted about who they are and do not plausibly transition out of internalised homophobia;¹²⁻¹⁵ and fail to refer to a wealth of data showing transition and gender affirmation to have an important positive impact on mental health.¹⁶⁻²³ Many references used in the article in support of substantial and contentious points are of poor quality and include news reports, non-peer-reviewed blog posts and a Tumblr survey.

Scientific literature must meet a high standard for publication. The editorial and peer-review process is intended to screen for problems such as these, which gravely threaten the quality of published works and undermine the public’s ability to rely on scholarly publication as an indicium of reliability. Providing competent care for transgender youth depends upon the integrity of the scientific process, of which publication is an important part. The past few years have seen a concerning rise in articles opposing gender-affirming care being published in scientific journals despite failing to engage with the available literature and, at times, being directly contradicted by it. Transgender communities deserve high-quality research and scientific publications.

Gender-affirmative care remains the leading approach to care for transgender youth and is well supported by empirical evidence, clinical experience and ethical reasoning.^{24,25} Contrary to what the article’s authors imply, gender-affirmative care does not foreclose youth’s futures. Quite the contrary.²⁶ Attempts to unduly delay or prevent social, legal or medical transition among youth who desire them should be opposed. Children and adolescents deserve unconditional acceptance and love at all points in their lives, including in their gender.

1.2.52 Effects of diet and fitness apps on eating disorder behaviours: qualitative study

Elizabeth V. Eikey **Correspondence:** Elizabeth V. Eikey. Email: eeikey@ucsd.edu

date

2021-09

Abstract

Background

Diet and fitness apps are often promoted in university and college settings and touted as a means to improve health with little attention given to unanticipated negative effects, especially among those at risk for or with eating disorders.

Aims

Few researchers have studied how these apps affect women with eating disorders in university and college settings. This research investigates the unintended negative consequences of engaging with these tools.

Method

Data collection sessions comprised three components conducted with 24 participants: survey (demographic and eating disorder symptoms), think-aloud exercise and semi-structured interview. Thematic analysis was used to analyse data.

Results

Participants reported that diet and fitness apps trigger and exacerbate symptoms by focusing heavily on quantification, promoting overuse and providing certain types of feedback. Eight themes of negative consequences emerged: fixation on numbers, rigid diet, obsession, app dependency, high sense of achievement, extreme negative emotions, motivation from 'negative' messages, and excess competition. Although these themes were common when users' focus was to lose weight or eat less, they were also prevalent when users wanted to focus explicitly on eating disorder recovery.

Conclusions

Unintended negative consequences are linked to the quantified self movement, conception of appropriate usage, and visual cues and feedback. This paper critically examines diet and fitness app design and discusses implications for designers, educators and clinicians. Ultimately, this research emphasises the need for a fundamental shift in how diet and fitness apps promote health, with mental health at the forefront.

pmc Diet and fitness apps often are touted as a means to improve users' health. Most of these apps consist of nutrition, food, physical activity, weight and even sometimes body measurement tracking tools and connections to a community of users with similar goals. Although these apps are popular^{1,2} and can be helpful to some,³ they can have unintended adverse effects on others, such as university and college students.^{4–7} These apps often overwhelmingly focus on weight loss and normalise weight control methods. Using weight loss as a proxy for health is problematic because it may increase the risk of or exacerbate eating disorder behaviours in already susceptible groups, such as women attending university.⁸ Further, these apps tend to overlook the role of mental health in addressing physical health challenges. The emphasis on weight loss within these apps is consistent with and feeds into Western cultures' obsession with thinness and dieting. Diet and fitness apps also support and encourage dieting behaviours. This is an issue because dieting behaviours and unhealthy weight control methods are also risk factors for eating disorders.^{9,10} Additionally, when compared with, for instance, paper tracking, these apps are always on hand and more discreet because of the prevalence of and norms around smartphone use, making it easier to constantly engage with diet and fitness content. They also often provide users with a set plan based on how much weight they want to lose, and leverage features, such as progress visualisations to influence behaviour, colour choices to denote positive and negative behaviours, and reminders and streaks to encourage consistent tracking. Although disordered eating affects all genders, eating disorders and eating disorder-related behaviours are extremely prevalent among women, especially those in college and university settings.^{8,11–13} In fact, researchers have found that 13.5% of undergraduate women screen positive for eating disorders,⁸ and 40–49% of university women engage in eating disorder behaviours at least once a week.¹³

Only somewhat recently have researchers studied diet and fitness apps in the context of eating disorders.^{4–6} For example, Honary et al⁶ found that almost half of the young people who participated in their study had maladaptive eating and exercise behaviours from using diet and fitness apps. In their study of 493 college students, Simpson and Mazzeo⁴ found that those who reported using diet and fitness apps had higher levels of eating disorder symptoms. Similarly, but focusing on individuals with clinically diagnosed eating disorders, Levinson et al⁵ found that in their cohort, 73% of those who used MyFitnessPal perceived it as contributing to their eating disorder, and these perceptions were correlated with eating disorder symptoms. Although these studies are important to recognise the link between eating disorders and diet and fitness apps, they do not shed light on how these apps may unintentionally affect users and their eating disorder symptoms. To address this gap, a qualitative study was conducted to answer the following research question: what are

the unintended negative consequences of diet and fitness apps among women attending university who exhibit eating disorder-related behaviours? The term ‘unintended consequences’ refers to unforeseen or unpredicted results.⁴² This terminology is common when discussing technological impact, especially related to health information technology. These consequences can be positive, negative or neutral, but often refer to adverse effects.

The research question

This study takes an interpretivist perspective: knowledge is contextual and grounded in participants experiences.¹⁵ This paper reports on one portion of a study on the use, impact and perceptions of diet and fitness apps (and if they are used in conjunction with other technologies, such as social media). Eight themes emerged that highlight the unintended negative consequences of diet and fitness apps. Findings from this study can be used by app designers, educators and clinicians to more carefully consider how these apps affect users, especially young women to whom these apps are often marketed.

Eating disorder behaviours

For the purposes of this research, eating disorder behaviours are behaviours associated with anorexia and bulimia nervosa. These include excessive calorie or food restriction; intense fear of gaining weight; obsession with weight and consistent behaviour to prevent weight gain; self-esteem overly related to body image; bingeing; feeling of being out of control during bingeing; purging; dramatic weight loss; preoccupation with weight, food, calories, fat grams and dieting; refusal to eat certain foods; comments about feeling ‘fat’; hunger denial; excessive exercise regimen and development of food rituals.¹⁶ Because many women do not see a professional for their symptoms and thus never receive a diagnosis,⁸ eating disorder behaviours in this context may or may not indicate full clinical eating disorders or qualify to be categorised as other eating disorders, such as other specified feeding and eating disorder or unspecified feeding and eating disorder. The women in this study self-identify as having an eating disorder. Therefore, in the remainder of this paper, eating disorder behaviours and eating disorders are used interchangeably to emphasise women’s own perspectives and experiences with eating disorders, and the importance of studying eating disorders even in the absence of a clinical diagnosis.

Method

To capture rich information from individuals about how diet and fitness apps may affect eating disorder-related behaviours and perceptions, a primarily qualitative research approach was employed. This methodology allowed for users to share their stories and experiences in their own words and emergent themes unlikely to be discovered when using only quantitative approaches. Three data collection methods were used: surveys (demographic and eating disorder symptoms survey), think-aloud exercises and semi-structured interviews.

Recruitment

In total, 24 participants took part in the study. The focus of this research was university women with eating disorders who use or have used diet and fitness apps in the USA. Participants who were either formally or self-diagnosed were recruited. This was specifically done to include the portion of women who do not seek a professional diagnosis or treatment. Therefore, this study represents users whose needs are largely invisible. This population is important to study because anorexia nervosa, bulimia nervosa and related eating disorder behaviours tend to affect university women,⁸ and diet and fitness app users tend to be younger.¹ To recruit users, on-campus groups were asked to share information on a campus listserv and fliers were posted to social media. Additionally, paper fliers were posted on bulletin boards on and off campus, such as at local gas stations. Because eating disorders are stigmatised conditions, many people may be wary of being seen getting contact information from fliers. Posting paper fliers in discreet locations, such as on the backs of doors in public restroom stalls where participants could covertly obtain information for the study, was the most successful approach.

Measures

Demographic and eating disorder symptoms survey

The survey contained questions about age, gender, and race/ethnicity, as well as eating disorders and app use. A combination of three well-known measures for assessing the severity of disordered eating and exercise behaviours and attitudes was used, which is similar to Tan et al¹⁷ and described in *Table 1*: the Eating Attitudes Test (EAT-26),¹⁸ the Eating Disorder Examination Questionnaire (EDE-Q 6.0)¹⁹ and the Clinical Impairment Assessment Questionnaire (CIA 3.0).²³

Measure	Description	Interpretation
EAT-26	The EAT-26 is a 26-item self-report questionnaire that assesses symptoms and concerns characteristic of eating disorders on a six-point scale (always to never), using behavioural questions regarding the past 6 months. ¹⁸ It is often used as a first step in a multi-stage screening process and has been useful as a screening tool to assess eating disorder risk. It consists of three subscales – diet, bulimia and food preoccupation, and oral control – that make up an overall score. As part of the EAT-26, participants are also asked to self-report their height, current weight, ideal weight, lowest adult weight and highest adult weight. For those who score >19 and/or qualify for one or more of the behavioural questions, the recommendation is to see a qualified professional because they are exhibiting symptoms characteristic of eating disorders. Even without the cut-off score, this measurement can be used as a continuous measure of eating disorder symptoms.	
EDE-Q 6.0	The EDE-Q 6.0 is a 28-item self-report questionnaire that measures frequency and impact of eating disorder behaviours in the past 28 days that reflect severity of aspects of the psychopathology of eating disorders, using seven-point scales (no days to every day; not at all to markedly), and questions where respondents report the number of times or days they engaged in particular behaviours. ¹⁹ A highly reliable and validated tool, the EDE-Q 6.0 is the most commonly used assessment for eating disorders. ^{17,20} It consists of four subscales – restraint, eating concern, shape concern and weight concern – which make up the global score. Higher scores indicate greater levels of symptoms. Suggested cut-offs range from 2.30 with the occurrence of binge eating and/or excessive exercise in community samples of young women to indicate ‘probable’ eating disorders, ²¹ to 2.80 for clinical samples. ²²	
CIA 3.0	The CIA 3.0 measures the severity of psychosocial impairment from eating disorder features in the past 28 days, on a four-point scale (not at all to a lot). ²³ It is a 16-item measure that focuses on mood, self-perception, cognitive functioning and work performance, which is intended to be taken after a measurement of current eating disorder behaviours (such as the EDE-Q 6.0). It then provides values to assess the severity of psychosocial impairment secondary to eating disorders. Higher scores indicate greater psychosocial impairment. A score of 16 is suggested as a cut-point for predicting eating disorder case status. ¹	

Think-aloud exercise

The think-aloud is a method in which participants speak out loud thoughts that come to mind as they go through a task.²⁴ The objective with the think-aloud exercise was to explore participants’ perceptions linked to specific aspects of the app. Participants went through three tasks: setting goals, viewing progress visualisations and using social and community features of the app. As users went through these tasks, they were asked to speak aloud what they were thinking and feeling as they interacted with the app.

The Authors own the copyrights to the individual articles.

Semi-structured interview

The purpose of the interviews was to understand participants' general experience with and perceptions of diet and fitness apps. Participants answered questions regarding why they used diet and fitness apps, the role the app played in their eating disorder behaviours (both positive and negative), unanticipated effects and their reflection on their use over time. At approximately 14 interviews, repetitive themes in the participant responses were apparent and converged into the same points (i.e. data saturation).

Procedure

Although there were distinct methods of data collection, they occurred during the same session. All sessions began with the demographic and eating disorder symptoms survey. All participants took the demographic survey; five opted not to take the eating disorder symptom survey. Current app users ($n = 17$) then participated in the think-aloud followed by the interview. Former app users ($n = 7$), on the other hand, only participated in the interview after taking the survey. In those cases, participants discussed how they used the app and were asked to recall specific features. Participants were compensated \$25 each for approximately 1 h of their time. All but one data collection session took place in person (one was conducted via telephone).

Ethics

All procedures contributing to this work comply with the ethical standards of the relevant national and institutional committees (Institutional Review Board approval number: STUDY00004634) on working with human participants. Institutional review board approval was obtained from Pennsylvania State University, and written informed consent was obtained from all participants. Materials were reviewed by a mental health professional. Resources were provided to every participant. Participants who currently did not use diet and fitness apps were not asked to interact with apps to avoid potential triggers. A plan was in place to work with participants in seeking support should they need it during or after a session; participants were reminded they could cease the session at any point. Because participants were students at one university, the university's Center for Counseling and Psychological Services was available to participants.

Data analysis

Excel for MacOS and JASP for MacOS (JASP Team, University of Amsterdam, the Netherlands; see <https://jasp-stats.org/>) were used to organise and analyse the quantitative data from the demographic survey and eating disorder symptoms measures. Body mass index (BMI) was derived from height and weight data. For those aged 20 years, BMI was computed with the United States National Institute of Health calculator (https://www.nhlbi.nih.gov/health/educational/lose_wt/BMI/bmicalc.htm), and for those aged <20 years, BMI was calculated with the Centers for Disease Control and Prevention calculator (<https://nccd.cdc.gov/dnpabmi/calculator.aspx>). Think-aloud exercises were video and audio recorded, and interviews were audio recorded. In total, the think-aloud exercises and semi-structured interviews were 21 h and 36 min. The think-aloud exercises and interviews were transcribed for a total of 436 pages, and analysed together. The data were analysed by the author, using Braun and Clark's thematic analysis approach,²⁵ which included becoming familiar with the data, systematically identifying codes and themes, and defining and naming the common themes found across the entire data-set. Similar discussions and answers were grouped together, and initial codes related to unintended negative consequences were developed. During data collection, the analysis was iteratively performed to refine the themes as more data was collected. The videos and still images were used to better understand specific app content and features to which participants were referring.

Results

Participant demographics

Participants were aged 18–23 years, with a mean of 20.63 years. The majority of participants identified as White (non-Hispanic) ($n = 18$), with one from Israel; three identified as Asian, Asian American or Pacific Islander; two identified as multi-racial and one identified as Native American or American Indian. Most participants had not been professionally diagnosed with an eating disorder ($n = 17$), and most reported being in recovery or recovered ($n = 20$). Participants estimated they had an eating disorder anywhere from 2 months to 7 years (mean 34.93 months, s.d. 26.78 months), and most ($n = 20$) felt that their eating disorder began before using diet and fitness apps. The most used app was MyFitnessPal ($n = 21$); however, many of the other apps used had similar features to MyFitnessPal. Participants reported using diet and fitness apps anywhere from 2 months to 8 years (mean 30.21 months, s.d. 30.05).

Participants reported current (mean 22.90, s.d. 3.58), high (mean 24.71, s.d. 3.84), low (mean 19.54, s.d. 3.40) and ideal BMI (mean 21.13, s.d. 2.26). At the time of data collection, most participants were in the healthy range ($n = 16$), followed by overweight ($n = 2$) and obese ($n = 1$). Highest reported BMI for participants was most often in the healthy range ($n = 14$), followed by overweight ($n = 3$) and obese ($n = 1$). Lowest reported BMI most often fell in the underweight ($n = 8$) or healthy range ($n = 8$), followed by overweight ($n = 2$). Most participants reported an ideal weight in the healthy range ($n = 17$), followed by underweight ($n = 1$) and overweight ($n = 1$). Seventeen out of nineteen participants reported their ideal weight as less than their current weight, and only two reported their ideal weight as higher or the same as their current weight.

Sixteen out of nineteen participants answered one or more of the eating disorder questionnaires in a way that suggested eating disorder symptoms. For the EAT-26, the overall mean score was 21.32 (s.d. 10.63), and 15 out of 19 participants exceeded the cut-off point. For the CIA 3.0, the overall mean of all 19 participants did not reach the cut-off point of 16 (mean 14.84, s.d. 10.39); however, nine participants exceeded this threshold. For the EDE-Q 6.0 global score, the overall mean of 2.70 (s.d. 1.04) was between suggested cut-off points.^{21,22} Scores were also compared with the norms of university women, which was computed by taking the norm mean (1.65) and adding 1 s.d. (1.30), to equal 2.95;²⁶ ten participants exceeded this threshold. Additional information can be found in Supplementary Table 1 available at <https://doi.org/10.1192/bjo.2021.1011>.

Themes

Eight types of unintended negative consequences from using diet and fitness apps emerged, which can be seen in *Table 2*. These themes focus on the interaction between the user, context and app, and how the design of apps affects attitudes and behaviours. These themes include fixation on numbers, rigid diet, obsession, app dependency, high sense of achievement, extreme negative emotions, motivation from ‘negative’ messages, and excess competition. Although these were common when users’ focus was to lose weight or eat less, these adverse effects were also prevalent when users wanted to gain weight, eat more or focus explicitly on eating disorder recovery. As a result of these unintended negative consequences, some participants reported secondary effects, such as interference with personal relationships, social outings, school and work, as well as increased health issues. *Table 2* Emergent themes, definitions and example quotations

Theme	Definition	Example quotations
Fixation on numbers	Developing a fixation on numbers associated with food and exercise, an acute awareness of calories, an altered relationship with food and/or a need for exactness from the quantifications within the app	‘I think it’s [logging food and exercise everyday] definitely very triggering because you look at food differently. Like now when I look at food, I see like that’s protein, that’s fat, that’s carbs instead of like that’s a chicken breast, that’s peanut butter, that’s a piece of bread... it’s definitely very, very triggering to be tracking it all the time. And especially back then [during my eating disorder], it was like, “Well, that’s 100 calories right there, like I need to eat broccoli instead, that’s like 35 calories”... It’s a number game basically...’ [U06] ‘I try to get exactly on [the number]... I like having it exactly on... It [the app] made me more OCD [obsessive compulsive disorder] ‘cause I’m like, “I have to hit this number”, basically... making sure I hit those numbers... There was one time my parents wanted to go out to dinner... So, I called the [restaurant] so I could already track it and have it as close as possible. And then my parents get here, and they’re like, “Oh, we’re going go to [this other restaurant] instead”. And I was literally having anxiety about going. I didn’t want to go to dinner. I was like, “No. I already had everything perfectly planned for my day”, and that was probably a bad moment... I feel like eating disorders stem from people

trying to be perfect, and with this, you're hitting numbers trying to be perfect, so I think that could be kind of bad' [U14]Rigid dietDeveloping a strict and rigid diet, including eating the same foods every day and/or developing safe and fear foods through the use of the app's food database, personalised prior meals or the barcode scanner'I think another kind of bad thing about it is I eat the same thing almost every single day except for dinner, but I think like just because in my head, I can kind of keep track of the points, and I think that's probably part of it. I'm not going to eat like a lot of new stuff if I have to like kind of go and do the work for it and see how much it is, so I think that kind of makes me eat the same thing every day' [U08]'I love how it could scan a label... That was my favourite thing in the world... It got to the point where I would never buy something that didn't have a label on it 'cause I couldn't track it... And I would be very secretive about just having a picture and being able to successfully find it on the app. If I couldn't find it on the app, I wasn't going to eat it 'cause... It wouldn't have been correct... You start to eat the same things... '[U17]ObsessionBecoming obsessed with logging and tracking, which can lead to the development of obsessive thoughts around food and exercise'I just think the entire app in general is harmful... For someone like me, it's extremely dangerous. Just everything. Being able to log your calories, 'cause you become obsessive over taking pictures of labels, you're measuring things, and getting the correct amounts becomes impulsive and just like obsessive. Exercise then, plays a same role in that... I got to be honest: before I started using the app, I felt like my logging wasn't that dangerous. It wasn't that compulsive or that obsessive, I should say...' [U17]'...I remember, I had that year at least five, six anxiety attacks because I was so anxious about what I'm eating, and I was so nervous about it. And the app said one thing and then the computer said something else, and I just lost my mind... So for me, it emotionally was a bad thing, the app... That's when I was really obsessing, and I would make sure everything is measured to the centimetre, to the ounce... I think it [the app] makes us overthink food, which can lead to obsessing about it... So I think the focus should be way more on health and way less of numbers... I think this [the app] just reinforces the wrong thing' [U12]App dependencyFeeling that one needs the app, feeling safe and in control with the app, developing anxiety when not using the app and/or not wanting to cease app use'In the moment, I didn't care. I knew it [the app] was harming my brain because I knew it was messing with my head mentally, but I just wanted to keep it because I felt like that was the one thing I could control. Because when you have an eating disorder, that's the one thing you want, is control. And I knew this app gave me control over what my parents wanted me to eat, just in that sense. I never really told them 'cause I didn't want to lose that control I had. Because being forced to eat a sandwich or being forced to eat, to go see a therapist, I had no control over those, but with the app, I felt like I had control over one part of my life that I really wanted to change' [U21]'Last summer, I had to delete it [the app]. I deleted it and had to get it back 'cause I was like, "Oh, my gosh, I need to know what I'm eating"... I literally got anxiety, so I had to get it back... I was like, "Maybe I should just stop tracking and just eat intuitively". So, that's why I tried deleting it. And then like a few days later, I had to get it back...' [U14]High sense of achievementFeeling extremely rewarded for eating under calorie and nutrient budget, engaging in compensatory behaviours and inputting them on the app, and losing weight; often occurs when receiving positive feedback on the app, such as via green visualisations'I definitely would say that if I got to the end of the day... like if on Tuesday, I was a little bit more in the green [on] Wednesday, I'd feel better about it. So it was almost like an accomplishment *per se*... Sustaining it [my eating disorder] would absolutely be seeing that when you're low or you're in the green... You don't even think about green being a good thing but just the colour cues that you associate with rewards... when you're starting to reinforce eating less, eating less, eating less... So I think it's [the app's] very much targeted towards the weight loss rather than fitness, *per se*' [U19]'I obviously like to be in the green for the calories remaining... This thing, progress bar, I mean, I kind of like, I mean, I used to like to see it really close to that like goal line or even like below, which sounds bad. But because that looked better to me if the bar's lower. So I mean, I guess, maybe that's kind of a problem, but I mean, it kind of made me feel that I was kind of like successful for the week if it was like mostly under the bar, obviously [laughs] even though that's under your calorie thing, which is probably not good... I just kind of wanted to see where I was in my calories for the day, and if I was like under what they allotted me, then I was happy... If I went to this bar and I saw everything was like below the goal, then that would kind of make feel like all right, that was good' [U04]Extreme negative emotionsFeeling extreme negative emotions, such as guilt, embarrassment and shame, especially when exceeding one's calorie or nutrient budget or gaining weight; often occurs when receiving negative feedback on the app, such as via red visualisations'At the end of the day, if I was still very hungry and I didn't have any calories left, that whole red number... That red number would scare me a lot because I'd be like, "Well, now I can't eat anything, and I'm really hungry, and I can't sleep with an empty stomach". Then if I ended up eating, I would wake up feeling guilt for going over my intake because I felt like it would get in the way of my goal of losing weight... Once it hit 200 or more, I would get really stressed out, even panic because... I would be ashamed because I felt like I wasted my whole day of when I was fasting 'cause when I was fasting, it would be a really low goal of calories... So it was just very stressful to deal with the red numbers... The red number would

come, and I'd be over my calories, and it just freaks me out all the time. I wouldn't even want to go to school if I knew I ate too much that night or that day before... I feel guilt for what I ate that day 'cause it's usually something that was high in calories, like a cookie or something. And then that caused that to become a fear food, like dietitians like to call it, a fear food that I try to exclude from my diet because that leads to a red number that embarrasses me' [U21]'I don't like the colour red. I feel like it's bad, and it would always be like a frowny face, like bad, like you didn't do what you're supposed to today, and I was like, "I know, I know I didn't"... I think they definitely need to be not as like strongly represented. Like if you're 1 calorie over, it's like, "Ok, like no big deal". It should be like a range, you know what I'm saying? One calorie over is different than being like 400 calories over, and I think it definitely gave me the wrong perception and made me kind of go like the other way especially like when all my things were red in [my] app, I was like, "Ok, well, then this makes me definitely not want to eat for like 3 days after seeing that" [U05]Motivation from 'negative' messagesFeeling motivated by 'warning' messages usually intended to curb unhealthy behaviours, such as feedback that states low weight or low calorie intake'...I was under-eating, so they [the app] would show me, you would be 90 pounds in a month or something if you kept on eating like this... I would just under-eat more to make that happen faster... So, I used to exercise 400 calories, then I would just skip lunch, I would eat dinner... Over here it would be 500 remaining or something. And at that point it would be, "Ok, so you're going to be 95 pounds if you kept on eating like this in 2 weeks". So that was more of a motivation, I think... Because you're trying to lose so much weight, and you're like, "If you keep on under-eating, you're going to be 98 pounds", which is exactly what you want to be at that point... It's not a warning...' [U22]'If you click this "Complete Diary"... So it tells you, "If every day were like today, you would weigh this amount", which [laughs] it's like I have such mixed feelings about it because like it can be motivating, but also it can be really triggering... like someone with an eating disorder is like, "Yeah, yeah, you're right; oh my god, I can weigh less than that in 5 weeks if I eat less"... When you're in the middle of your eating disorder, you think this is motivational, but when you look back on it, it's like, that's horrible [laughs], like that's really horrible' [U06]Excess competitionMaking calorie consumption, expenditure and weight loss a game by trying to beat the app or self; often achieved by netting fewer calories each day and/or being under budget'It was kind of like a game to beat the calories, kind of. So one day I had a 0, maybe it was like a negative calorie. I was like, "Oh, wow, like look at me, like that's cool!"... Just because like you can visualise what you're eating, so the more you don't eat, it's like, "Oh, I beat the app!"... I definitely wanted to beat the calories they gave me. I feel like that kind of does start an eating behaviour where you don't want to eat anything... Like especially 'cause they give you a calorie limit. I know when I was under the calorie limit, I was like, "Ok, I won today"... I was like, wait a second, the app kind of like made it a game for me to like not eat much' [U07]'It just became this weird competition thing with it [the app]... I would just be like, "I need to be lower than what it was before". [laughs] I don't know... It just always had to be less than the day before in the food and the weight and everything... Because then, if I wasn't, then I was like a failure 'cause that was what the eating disorder thoughts were telling me' [U13]

Participants discussed developing a fixation on numbers, fuelled heavily by the app's quantification, which worsened their eating disorder behaviours and changed their relationship with food. Having used the apps so much, many participants reported already knowing the calorie content of every food they ate before logging it. Participants also explained that they tended to eat the same foods each day because they knew the calorie content and could mitigate any unknowns about what they were consuming (even if they abandoned the app). The app also fed into the concept of fear foods and safe foods, where users would only buy and track foods if they were aware of their calorie content (e.g. in their personal app database or foods that had a barcode).

They described becoming obsessed with logging their food intake, and developing obsessive thoughts around food and exercise that sometimes interfered with schoolwork. For example, some participants used the app to log all their meals in advance, which acted to strictly control their consumption. Some also described developing a dependency on these apps. Many participants discussed how they needed the app and became very anxious when they stopped using it; they sometimes redownloaded the app to relieve their anxiety. One participant described how uncomfortable she was when she went to a clinician who wanted her to explore the idea of not using her physical activity tracker (Fitbit).

A number of participants described the role of green progress visualisations, which users see when they have remaining calories on MyFitnessPal and similar apps. Many expressed feeling rewarded when viewing this feedback, as it signalled they were consuming less than their allotted calories. On the other hand, participants felt guilt, embarrassment and shame over exceeding their calorie budget and being shown red visualisations in response. The extent to which they exceeded their budget affected participants differently. Some expressed that they felt badly regardless of how much they went over their budget, whereas others explained how they felt worse the higher their calorie number exceeded

their budget. Many participants also described being in an unhealthy competition with themselves and with the app to eat less and less each day, because the app ‘gamified’ eating, exercise and tracking.

Although there are some features in diet and fitness apps that attempt to curb maladaptive eating and exercise behaviours, participants explained that these did not work as intended. For example, MyFitnessPal has a feature called ‘Complete Diary,’ which is a button that allows users to tell the app they are finished logging food, exercise and weight for the day. Once clicked, either a warning message or weight projection appears. Many participants found both types of messages to be motivating to continue to lose weight regardless of the content or context of the message.

Discussion

Unintended negative consequences are prominent regardless of where users are in their journey (e.g. recovery or not). This is a result of the design of diet and fitness apps, the individual and their context. This section first discusses implications for educators and clinicians, and then critically examines the design of diet and fitness apps and offers suggestions for improvement.

Implications for clinicians and educators

Understanding the unintended consequences can be useful for psychiatrists, psychologists and other mental health experts, as well as general practice clinicians, to aid in the diagnosis and treatment of eating disorders. Especially in college and university settings, healthcare professionals should be aware of and engage in discussions about the use and potential downsides of diet and fitness apps. Educators should also be privy to possible unintended negative effects to prevent triggering or exacerbating maladaptive eating and exercise behaviours. By encouraging or even requiring the use of digital food and physical activity tracking as part of nutrition courses and ‘healthy’ university initiatives (e.g. <https://www.usatoday.com/story/college/2016/01/19/oklahoma-college-tracks-students-fitness-with-fitbits/37410983/>), educators may unknowingly exacerbate eating disorder-related issues, especially among university women. Therefore, great caution should be exercised when considering promoting diet and fitness apps, especially in these settings. As always, it is important to remember that app users and app use exist in a larger context, where societal norms and external pressures influence the effects of these tools.

Rethinking diet and fitness app design

The design of diet and fitness apps may partially contribute to unintended negative consequences, which are related to three major areas: the quantified self movement, our conception of appropriate usage, and visual cues and feedback.

Table 3 outlines how these findings relate to app design, to help us understand where we can make improvements to minimise unintended negative consequences and focus more on promoting healthy behaviours. However, it is important to note that although small changes may have some positive impact, this work highlights the need to change how we think about health promotion in digital tools by focusing on the mental health needs of users and the interplay between mental and physical health. A more holistic and personalised approach is consistent with prior literature on supporting the needs of people with eating disorders.²⁷ *Table 3* Summary of suggestions to address diet and fitness app issues

Area	Problem	Related unintended negative consequences	Suggestions
Quantified self movement	Overabundance of quantification despite the fact that not all aspects of health can easily be quantified	Some quantifications are not good health indicators	
	Too much of a number focus can trigger and exacerbate eating disorder behaviours	Fixation on numbers	
	Rigid diet		
	Obsession		
	App dependency		
	High sense of achievement		
	Extreme negative emotions		
	Motivation from negative messages		

Excess competition Work meaningfully with people with eating disorders during all phases of designing these tools
 Find new ways to acquire user needs and non-numeric yet quick and easy methods for tracking behaviours
 Consult expert recommendations about healthy eating and exercise during design process
 Support healthy eating patterns, food variety, portion control, shifting to better food choices and various eating contexts
 Change exercise tracking to focus on performance and enjoyment rather than calorie expenditure
 Incorporate qualitative components to assess other aspects of health Conception of appropriate usage Push users to log consistently over long periods of time
 Tend to view breaks and abandonment as negative
 Encouraging overuse can trigger and exacerbate eating disorder behaviours Obsession
 App dependency Reduce reminders to log daily
 Encourage breaks
 Rethink what app engagement is and reward users for engagement that is not actively logging or viewing numbers
 Visual cues and feedback Try to use visualisations to motivate users but do not fully understand their effects
 Visual cues do not always match users' goals
 Warnings have opposite of intended effect or are avoided
 Visualisations and messages can trigger and exacerbate eating disorder behaviours High sense of achievement
 Extreme negative emotions
 Motivation from negative messages
 Excess competition Study effects of design and warnings more thoroughly and on different users at different times
 Develop more nuanced design visualisations that better coincide with intended messages and users' goals
 Rethink unhealthy eating and exercise pattern thresholds for showing feedback

Quantified self movement: moving beyond numbers

The quantified self is reflected in diet and fitness apps' heavy focus on numbers. Although self-tracking numeric data has benefits,^{28–30} findings cast light on issues with the quantification and tracking of behaviours related to diet and exercise, especially for those with a history of eating disorders, which has been supported by other literature.^{6,31} Users with eating disorder behaviours develop a fixation on numbers and a rigid diet partly because of diet and fitness apps' heavy focus on numbers, as well as features such as barcode scanners, which are aimed at reducing user burden but actually encourage eating pre-packaged and fast foods,³² which often are not the healthiest options. Because food, exercise and weight are quantified and goals are numerically driven, users become overly preoccupied with numbers, and food begins to be viewed as its caloric and macronutrient content.

Although the quantified self movement has its merits, it is clear that using numbers as indicators of health has its limitations and feeds into the need for control, which is a hallmark of eating disorders. To begin to reduce unintended negative consequences, designers, developers and researchers need to focus less attention on quantifying food, weight and exercise. Instead, understanding what a healthy lifestyle is and finding ways to promote that with technology is imperative. For example, rather than focus mostly on calories, apps should be designed to help users develop a positive relationship with food and their body, as well as healthy eating patterns that include fruits, vegetables, protein, dairy, grains and oils; focus on food variety, nutrient density and amount/portion sizes; help limit added sugars and saturated fats, and reduce sodium intake; find ways to help people shift to healthier options and assist healthy eating in various settings (home, work, school, restaurants, etc).

For physical activity, the focus should be less on exercise's relationship to calories and more on how much exercise, what types, ability to perform, enjoyment and its relationship to positive mental health. Studies have shown that exercising for enjoyment rather than appearance is correlated with low self-objectification, low body dissatisfaction and less disordered eating.³³ By focusing on exercise as something enjoyable and healthy, the focus will be less on exercise as a means to lose weight or look 'better', and thus improve overall mental health. Apps should also adapt to users' personal contexts and needs around physical activity and healthy eating, as well as acknowledge systemic barriers and the role of trauma. Because customisation may be crucial for supporting users' needs, more sensor-based and passive

tracking are being explored.³⁴ However, caution must be exercised, as automated detection often reproduces biases and existing norms, exacerbating inequities, which can worsen mental health.

Other important aspects of health not easily captured in many current diet and fitness apps include positive body image, mental health and bodily functioning. For example, does a user feel good in their clothes? How is their self-esteem, emotion regulation, concentration, etc? Are they depressed, anxious, etc? Are they experiencing any pain or discomfort? Are they less tired throughout the day, and do they have improved sleep? All these things are important aspects of health. Even for users whose weight loss is a healthy goal, these factors may influence their needs and ability to lose weight, which means supporting these needs can positively affect all users.

Conception of appropriate usage: encouraging less logging (in some cases)

The quantified self movement coupled with our conception of appropriate app usage can lead to an obsession (about logging, food, weight and exercise) and the development of an app dependency, which is partly fuelled by how much and how often designers, developers and researchers think people should use these types of digital tools. To promote consistent and long-term use, many apps contain reminders to log and gamified aspects (e.g. streaks). This, coupled with the quantification, leads to users becoming obsessed with logging, which is in line with prior research.^{6,32} However, contrary to some research,³² users with eating disorder behaviours do not really ‘lose the habit’ of logging, because they feel the need to have control over their food and body. Despite numerous studies aiming to reduce app abandonment,^{32,35,36} abandonment is not always negative. In fact, for users with eating disorder behaviours, taking a break from apps can be beneficial.⁷ Taking time off from apps can help users learn to listen to their body’s signals of hunger and fullness and decrease their dependency on apps, which is important if we wish to promote health. Therefore, reducing logging reminders and encouraging breaks may be beneficial. Ways to reward users for engaging with apps without viewing quantified behaviours or actively logging (e.g. providing an alternative app view during break periods) could be explored.

Moreover, we need to ask ourselves: what role should these apps play in users’ lives? Are they meant to be used every day throughout a person’s life or are there more finite periods? How do we determine a success versus a failure (and should we impose a viewpoint of ‘success’ or allow users to choose)? We have to stop pushing an ideal, universal use and start understanding how people actually use these technologies ‘in the wild’, and how their needs change over time. Then we can design around their natural patterns of use, be more adaptive and flexible, and acknowledge different situations and contexts. Although app vendors want users to use their technology long term, we also must understand that this is not appropriate for all users and may even be harmful for some.

Visual cues and feedback: investigating effects more thoroughly

Findings show that app visualisations and feedback, such as coloured visualisations and messages, can unintentionally contribute to unhealthy behaviours. Instead of promoting healthy behaviour change, red and green visualisations in combination with the focus on numbers often result in users feeling a high sense of achievement when being under their calorie budget and extreme negative emotions when being over their budget, which has been seen in other research.⁶ These colours were likely chosen because of the connotations they already have in some societal contexts. However, these effects in the context of diet and fitness apps are not well studied. Studying these effects is crucial, given that the effects of colour choice can vary from context to context.^{37–39} Thus, we need to examine the effects of colours on users, and find ways to balance emotion response and behaviour change strategies.

The rewards and punishments users get from diet and fitness apps through these visualisations and the focus on the quantified self often promote excess competition. Although many apps want to encourage competition, users with eating disorder behaviours often develop unhealthy competitive behaviours. Not only do these visualisations instil a sense of reward in punishment in users, but they also tend to be very limited. For instance, at the time of this study, in MyFitnessPal, users see the red number regardless of whether they exceed their daily allotment by 1 or 1000 calories, which does not make sense if the focus of these apps is promoting health. Therefore, we need to develop more nuanced visualisations to motivate users without negatively affecting them.

Users also felt motivation from (what are intended to be) ‘negative’ messages and visual cues. For example, the ‘Complete Diary’ function in MyFitnessPal is meant to motivate users in the appropriate context and provide a warning to deter unhealthy habits. In many instances, users felt both messages motivated them to continue unhealthy behaviours regardless of the content, suggesting that more research is needed to understand how warnings and other feedback messages influence user perceptions and behaviours. One of the issues lies in the threshold that is used to determine with what feedback is presented. Although these algorithms are proprietary to MyFitnessPal, at the time of this study, MyFitnessPal seems to use a baseline of 1000 calories consumed to determine which message the app shows. If users do not hit this threshold, then they are shown the ‘Based on your total calories consumed for today, you are likely not eating enough’ message. If users consume over 1000 calories, then the app presents ‘If every day were like today, you would weigh X pounds in X weeks’ message. This occurs regardless of how many calories users have remaining. Thus, more research is needed to understand the appropriate thresholds to use to provide different feedback based on users’ needs.

Further, precautions such as warnings should not focus on taking away someone’s agency or labelling someone or their behaviours as ‘bad.’ There is a tendency to do this with eating disorder-related behaviours, which can increase stigma and reinforce negative emotions. Rather than adding these types of features, users and potential users from a variety of backgrounds should be more meaningfully involved in all aspects of the design process in a way that honours their lived experiences as expertise, and have the power to inform design decisions within these apps.

Limitations

First, the sample comprised a small subset of rather homogenous users. Thus, it is likely that not all consequences and perceptions are represented in this work. Future research should include more users from a variety of races, ethnicities, cultures, genders, ages and types of conditions. Second, BMI has a number of problems and limitations. It was used in this study as way to provide additional information only, not to advocate for its blanket use to denote health or diagnose/treat eating disorders. Third, unfortunately, normative clinical data that have similar contexts and participants are not easily available for all measures. In general, the means reported in clinical samples for the EDE-Q 6.0 and CIA 3.0, (e.g. Dahlgren et al⁴⁰) are higher than the present study; however, it is important to note that participants in this study were often recollecting past experiences with eating disorder behaviours, and many reported being in recovery currently. Thus, it is possible that eating disorder symptom scores at the time of the study were lower than they would have been if the study had occurred during what participants described as the worst points of their eating disorders. The findings suggest that specific design choices are problematic for some users. However, these design features and choices themselves were not tested. Research could benefit from experimental testing of these designs, as well as participatory and community-driven design of diet and fitness apps.

In conclusion, the use of diet and fitness apps by women with eating disorder behaviours is likely more common than many realise, given the rates of dieting and weight loss among healthy weight and underweight women.^{41,42} This work identifies problematic aspects of design and design suggestions, as well as implications for clinicians and educators. Although this study focuses on users with a history of eating disorders, redesigning apps to focus on health is beneficial to all users. Ultimately, this research emphasises the need for a fundamental shift toward a more holistic, personalised approach to health and how it is represented in digital tools.

I would like to thank participants for sharing their experiences and expertise. This research would not be possible without them.

- *Mr Sluggish Schizophrenia*
 - *Declaration of interest*

pmc r.t.l. Anatoly Smulevich, unknown, Marat Vartanyan, Aleksandre Tiganov. Photo Credit: Robert Van Voren

On 15 April 2021, the World Psychiatric Association (WPA) congratulated the Russian professor Anatoly Smulevich on his 90th birthday on its website. It wrote that ‘his work is highly regarded both in Russia and around the world . . . the WPA would like to wish Prof. A.B. Smulevich the happiest of birthdays and thank him for his long-standing contribution to the world of psychiatry’.

To most, the name Smulevich rings no bells. I have been involved in the fight against the political abuse of psychiatry for almost 45 years and know full well that he was one of the main researchers in the field of ‘sluggish schizophrenia’, the main diagnosis used against dissidents in the Soviet Union. He belonged to the small group of ‘nomenklatura psychiatrists’ who monopolised all contacts with the outside world and dominated psychiatry in the USSR. Their actions caused the forced hospitalisation of thousands of dissenters, who were subjected to torturous ‘treatment’, and established a repressive and abusive psychiatry that affected millions of people and disabled many for the rest of their lives. Like the Nazi euthanasia programme, this Soviet political abuse of psychiatry is among the worst violations of medical ethics. Professor Smulevich not only contributed significantly to the ‘scientific basis’ of this perversion of medicine, he also actively defended the position that criticism against Soviet psychiatry was a matter of politically inspired slanderous allegations. He was considered by the KGB to be a ‘trusted psychiatrist’.

In an interview on 29 September 1986, he claimed that in the USSR ‘a sane person cannot be sent to a psychiatric hospital’. In March 1989, during a meeting with an American delegation, he explained that 38.1% of all schizophrenics suffered from sluggish schizophrenia and described the symptoms, which included ‘anti-Soviet thinking’ and ‘delusions

of reformism'. He then argued that all dissidents could be diagnosed as suffering from sluggish schizophrenia. During the discussion of the case of an alleged victim, Smulevich continued: 'In the Soviet system this is a person who has overvalued ideas. Yes, one can fight for freedom in a thousand and one ways but it should not be to the neglect of other areas of his life. [He] fought for freedom and even wrote books about freedom, neglecting all other ideas in his life. His life became unbalanced, all of his interests were expressed in one area'. In the same year, he published an article in the *British Journal of Psychiatry*, actively defending the concept of sluggish schizophrenia.

In most of the biographies of Professor Smulevich that one can now find on the internet, most of his work on sluggish schizophrenia and his activities during the Soviet period are omitted, but those who were sent to psychiatric hospitals because of their convictions very well remember the man nicknamed 'Mr Sluggish Schizophrenia'.

1.2.54 The need for biodiversity champions in psychiatry: the entwined crises of climate change and ecological collapse

Jacob Krzanowski

date

2021-08

Abstract

The past 20 years have seen the disappearance and degradation of biodiversity on earth at unprecedented rates. This phenomenon shares similar drivers to those behind climate change yet requires its own solutions. The twin catastrophes of climate change and biodiversity loss demonstrate how our health is bound up in the vitality of this planet. There has been an increasing effort on the part of healthcare professionals to appreciate this relationship, as evidenced by the growing influence of planetary health as a discipline. However, the health impacts of biodiversity loss have been less focused on than those brought on by climate change. Psychiatry's appreciation of the interface between environments and our health, alongside the evidence for the connection between nature and mental health specifically, prompt psychiatrists to ensure that the institution of healthcare throws its influence equally behind solutions to climate change as well as biodiversity loss.

pmc This article is both a provocation and a call to action for psychiatry to champion biodiversity while raising awareness of the risk of ecological collapse. Although the connection may not at first be intuitive, our influence as healthcare professionals, appreciation for health as a concept defined by wellness rather than an absence of disease and understanding of how sick environments create illness, both seen and unseen, place responsibility firmly at our table to advance the cause of all life on earth.¹

These arguments are underscored as international organisations such as the World Health Organization (WHO) increasingly recognise the causal links between our health and biodiversity loss.² This is particularly important because framing the crisis through the lens of health may prove to be instrumental in shifting the tide towards the unified action needed.

In fact, new evidence is rapidly verifying that the loss of biodiversity in both quantity and quality has real impacts on our health, both mental and physical.^{2,3} This evidence is finally catching up with associations between nature and healthfulness that exist across many cultures, and the knowledge central to many indigenous cultures.⁴ While this is an important development we should respect that gaps in our knowledge and apprehension regarding specific correlations should not preclude action.

We have been slow to respond to climate change and must bear this in mind. At the same time, in the face of uncertainty we should allow ourselves to be compelled by a change to life on earth described as the sixth planetary extinction, marked by a rate of extinction nearly 1000 times pre-human levels.^{5,6} It therefore falls to healthcare professionals to mitigate not only the consequences of climate change but also the equally concerning trend of ecological destruction.

Climate change: one driver of biodiversity loss among many

The planetary crisis we are facing is more complicated and worse than was first imagined. For decades, scientists have understood that the planet is getting hotter.⁷ As the temperature rises, we are facing changes to the climate that are difficult to predict and harder to control. Climate change looks like rising water levels, protracted and intensified heat waves, changes to water composition and the degradation of ecosystems.⁷ These changes to the ‘weather’ are directly tied to increasing food and water scarcity, which in turn lead to displacement through forced migration and armed conflict.⁸

The consensus among those studying this phenomenon is that climate change is a product of changes to human behaviour since the industrial revolution.⁹ Through unregulated extraction and consumption of carbon-based fuels, the global temperature has steadily increased, long after this association was first suspected in 1896 by Swedish scientist Svante Arrhenius. The establishment of the Intergovernmental Panel on Climate Change (IPCC) by the United Nations in 1988 cemented a global commitment to better understand the development and implications of climate change.

As we grapple with the scale of the crisis, the need to unify climate change with social justice is increasingly underscored. People who have experienced and will continue to experience the greatest impacts of climate change on health are the least responsible for greenhouse gas emissions.¹⁰ To date, the vast proportion of total historical emissions has been produced by a proportionally small number of wealthy countries.¹⁰ However, in the past 20 years we are now coming to the sobering fact that climate change and its injustices are not all we must confront.

The year 2020 marked the end of a 10-year period designated the ‘UN decade on biodiversity’. The stated aim of the effort was to live in harmony with nature. This commitment was in part brought on by alarming reports such as the Millennium Ecosystem Assessment in 2005, which noted that humans had changed ecosystems more rapidly in the previous 50 years than at any point before.¹¹

Biodiversity is a contraction of biological diversity and simply put is the stuff of life itself. The 2005 report defines biodiversity as variability among living organisms from all sources, including terrestrial, marine and other aquatic ecosystems, and the ecological complexes of which they are part.¹¹ Biodiversity itself is the basis of the complex of plants, animals and microorganisms that make up an ecosystem.¹¹ The accumulation of all of our planet’s ecosystems is encapsulated by the biosphere.¹²

To help us understand our dependence on these systems the concept of ecosystem services was created. This model looks to explain all the ways in which we are connected in the web of life and outlines that ecosystems: (a) provide resources such as food, water, timber, medicines and fibre, (b) regulate climate, foods, disease, waste and water quality, (c) contribute to cultural experiences such as recreation, aesthetic enjoyment and spiritual fulfilment and (d) support soil formation, photosynthesis and nutrient cycling.¹¹ The truth has been plainly described by the environmental activist Satish Kumar in the following stark terms: ‘We are nature. What we do to nature, we do to ourselves’.¹³

Since the mid-2000s, global efforts to address the collapse of biodiversity have emerged, most notably with the establishment of the Intergovernmental Science-Policy Platform on Biodiversity and Ecosystem Services (IPBES). Its 2019 Global Assessment Report describes a biosphere transformed and degraded by human activity, whereby ‘seventy-five per cent of the land surface is significantly altered, 66 per cent of the ocean area is experiencing increasing cumulative impacts, and over 85 per cent of wetlands (area) has been lost’.¹⁴ It identifies climate change as just one among several drivers – albeit one with a multiplying effect – that have an impact on both nature and human well-being, alongside habitat change, invasive alien species, overexploitation and pollution.^{11,14} The thing that cannot be forgotten is that many of these losses, in particular of species and biodiversity, are irreversible.¹⁵

The pivotal importance of attending to the loss of biodiversity is reflected in its inclusion within the UN’s sustainable development goals and the UN’s choice to designate the 2020s as the ‘decade for eco-system restoration’.^{16,17} Biodiversity loss and climate change share human behaviour as their root cause, but while their solutions are mutually beneficial, they demand distinct strategies. The centrality of biodiversity to the survival of all life, coupled with its demand for solutions apart from ones that address sustainability or climate change per se, is why biodiversity loss specifically requires champions among healthcare professionals.

Planetary health: an opportunity for healthcare’s growing role

Why has change been so slow to come? Resistance has been in large part cultivated by corporations, politicians and the interests of the wealth that entwines them.¹⁸ In our own community, David Pencheon, a former head of the NHS Sustainable Development Unit, has referenced a kind of ‘moral offset’ that means health professionals feel less motivated to act on the climate crisis because their work already improves lives.¹⁹ Health services also prioritise acute illness over prevention, discounting future risk in favour of short-term medical responsibility.¹⁹

At the start of the millennium, the importance of an interdisciplinary approach to health and climate change was recognised. Institutions such as the *Lancet* sounded the need to frame the crisis in terms of its effects on health. Although not a new term at the time, the concept of planetary health was fully endorsed in 2015 by a joint effort between the *Lancet* and the Rockefeller Foundation, a sign that healthcare as an institution had begun to throw its weight behind a response to the planetary crisis.²⁰

Planetary health in the simplest sense makes the assertion that human health is inextricably linked to the health of the planet. It can be understood as a discipline that borrows from public and environmental health but is bold and explicitly

political. Richard Horton, editor-in-chief of the *Lancet*, described planetary health in 2018 as ‘an inquiry into our total world. The unity of life and the forces that shape those lives’.²¹

At the heart of planetary health lies a paradox that many of the gains to health have come from an untold exploitation of the environment.²² The field does not shy away from this uncomfortable fact and indeed is based on the belief that a more balanced relationship wherein both humans and the planet thrive is possible and essential. It suggests that acting as stewards of the biosphere, humans can move from an exploitive to a nurturing role.²² As a whole, the discipline and its advocates seek to bring the influence of healthcare, as an institution, into the centre of discussions and campaigning around the climate and ecological crises. Such aspirations are in line with the increasing anticipation that casting planetary change through the lens of our own health may be instrumental in helping to inspire the type of action urgently needed.²³

Alongside this developing approach, in October 2020 the National Health Service (NHS) made the impressive commitment to become the first carbon-neutral national health service.²⁴ Yet the report leaves the issue of biodiversity loss behind. This trend towards focusing on climate change is similarly reflected in the *Lancet*’s countdown on health and climate change,²⁵ and as of February 2021 four NHS trusts have declared climate emergencies since Newcastle upon Tyne Hospitals NHS Foundation Trust first did so in July 2019.

Although the field of planetary health is premised on a connection between health and nature, clinicians are only beginning to grapple with its implications. This may reflect the fact that the impacts of biodiversity loss on humans are dizzying in their scope but also, with respect to mental health particularly, can be harder to understand and therefore measure. Moreover, although the emphasis on climate change has created a focus point for action, it unintentionally creates a conceptual blind spot whereby the broader threat of ecological collapse can feel like an ‘add-on’ and therefore harder to address or even a distraction.

Biodiversity and human health

The concept of ecosystem services underlines how essential biodiversity is to life on earth. Without pollinators many plants cannot reproduce and without plants no oxygen is made. Links between health and biodiversity have been clearly drawn and are now continuously emerging in greater breadth and resolution.² In 2020, the COVID-19 pandemic highlighted the connection between biodiversity loss and infectious disease, while research elsewhere highlighted the role of ecosystems in sequestering carbon.^{26,27} Moreover, a growing evidence base recognises that our well-being and mental health are tied to the health of our ecosystems. Similarly, the destruction and loss of natural spaces is increasingly shown to affect our mental, emotional and spiritual health.

Carbon capture

The links between climate change and biodiversity are increasingly clear. Rising global temperatures degrade our richest ecosystems, yet these also represent essential storages of carbon. A recent paper by Dinerstein et al states that nearly all of the remaining native ecosystems will require preservation to keep the global average temperature rise below 1.5°C.²⁷ The paper brings together startling facts, including that intact forests sequester twice as much carbon as planted monocultures, and highlights that diverse systems from peatlands to mangroves are also important carbon storehouses. They make clear that it is the rich biodiversity of these natural spaces that allows carbon to be stored in such amounts. This understanding motions at the need to consider climate change and biodiversity loss in the same breath with efforts to ‘pair nature and climate deals which are mutually reinforcing’.²⁷ We are in a race against time where every piece of the puzzle is connected for better and worse.

Pandemics

Pandemics act on our physical and mental health through both direct and indirect mechanisms resulting in immediate but also far-reaching changes to individuals and societies. The origins of COVID-19 and its development into a global pandemic are closely tied to ecological destruction.²⁶ It is a double tragedy that the experience of lock-downs and quarantine have highlighted the importance of natural spaces for many.²⁸ Concerns about the impact of biodiversity loss were made as early as 2005, when Paul Epstein noted that ‘widening social inequalities and changes in biodiversity have apparently contributed to the resurgence of infectious diseases.’²⁹ The 2020 IPBES workshop on biodiversity and pandemics is clear about the drivers behind COVID-19, stating that ‘pandemics have their origins in diverse microbes carried by animal reservoirs, but their emergence is entirely driven by human activity [...] The underlying causes of pandemics are the same global environmental changes that drive biodiversity loss and climate change’.²⁶

More sobering is the warning that, without changing these underlying drivers, we can expect more frequent pandemics. Indeed, there are an estimated 1.7 million undiscovered viruses, 631 000–827 000 of which could have the ability to infect humans. Averting further pandemics rests on a reversal of the unsustainable exploitation of the environment driven by demand from wealthier countries and emerging economies.²⁶

Nature and well-being

There is a growing recognition of the impact of nature on well-being.³⁰ Exactly how exposure to nature benefits humans is not entirely clear. Theories such as that proposed by Kaplan & Kaplan in 1989 suggest that exposure to nature acts on well-being by modulating stress through restoration of our attention.³¹ Nature is also believed to enhance our well-being by supporting health-promoting activities such as physical activity and social interaction.^{30,32} Astonishingly, from the view of public health, green spaces have also been found to be equigenic, a term referring to interventions that disrupt the normal health disparities arising from socioeconomic inequality.³³ In urban environments, such spaces provide further mental health benefits as they mitigate heat islands, improve air quality and prevent floods, leading to longer-term and more holistic health benefits.³⁴

Crucially for psychiatrists, links have also been made between natural spaces of high value and improved mental well-being.^{3,32,34} A 2014 literature review by Lovell et al, however, offers caution about drawing definitive associations between increased biodiversity and health and encourages further research on this relationship.³⁵ Recently, a study of the impact of biodiversity across Europe added the finding that the diversity of birds in an ecosystem improved people’s life satisfaction.³⁶ Irvine et al, in a review of spirituality and biodiversity, offer that ‘there is suggestive evidence that biodiversity appears to contribute to spiritual outcomes’.³⁷ They note that these sorts of observation are critical in making clearer links between conservation of biodiversity and human well-being.

Eco-distress and solastalgia

During the 2019–2020 Australian bushfire season, it was estimated that 3 billion animals were affected.³⁸ This is an unspeakable tragedy for the life lost and those living in the areas affected by the fires. However, it was also witnessed by many abroad, eliciting feelings of helplessness, confusion, guilt, grief and anxiety. Much like the loss of these ecosystems, it is unclear how the growing presence of such emotions will affect people. An increasing interest in such questions has been seen with the emergence of concepts such as eco-distress and solastalgia.³⁹ For the moment, these constructs do not describe mental illness but rather proportional reactions to traumatic ecological events. The term solastalgia specifically describes the distress resulting from the transformation and degradation of one’s home environment. Although such concepts are relatively new, they underscore the role that mental health professionals play in raising awareness about ecological collapse and its psychological toll.

How to respond?

Recognising biodiversity loss, and ecological collapse more broadly, does not necessarily mean dividing attention from climate change. Indeed, one of the best ways healthcare systems can address ecological collapse is by mitigating their greenhouse gas output: if they were a nation, healthcare systems globally would constitute the fifth largest greenhouse gas emitter.⁴⁰ What is key is understanding the crisis holistically, so that psychiatrists work against the conceptual fragmentation that prevents bold systemic solutions.

Within mental health services, pharmaceuticals contribute around 20% of our total carbon footprint.⁴¹ The development and adoption of sustainably informed prescribing practices provide a concrete way for institutions and individual clinicians to play their part.⁴² Sustainable prescribing would need to take into account the environmental implications of common prescribing practices, including polypharmacy, unclear durations of treatment and exceeding recommended dose ranges.⁴³ Such considerations would create greater space to offer non-medication-based complementary therapies, including those that are nature-based.

Beyond the ethics of accurately representing the broader ecological crisis, this holistic approach also makes it more likely that policies that tackle greenhouse gas emissions alongside other drivers of ecological collapse will be found and implemented. For example, a green rooftop developed by a hospital to reduce air conditioning could also then be cultivated with plants favoured by local pollinating insects. If tended or enjoyed by psychiatric in-patients, this becomes an intervention in which climate change, biodiversity and therapeutic impacts are married.

Part of the difficulty in knowing how psychiatrists should most effectively lend their voices to the crisis of biodiversity loss is the immensity that the term implies. How do we go about saving the biosphere? The Global Deal for Nature proposes a firm target of protecting 30% of the earth by 2030, which lays the ground for global action.²⁷ This clearly stated goal, much like the limit of 1.5°C warming for climate change, helps us to believe that, in spite of overwhelming complexity, conceptually simple strategies such as conservation can work.

With this as a foundation, psychiatrists could focus on two kinds of strategic action. First, psychiatrists should support and initiate further research into the relationship between mental health and the natural world. In the UK, this effort could be advanced by innovative collaborations between mental health institutions and wildlife organisations such as Natural England and the Wildlife Trusts. Psychiatrists should also engage with knowledge and practices developed by colleagues in the field of ecopsychology, including giving consideration to concepts such as nature connectedness.⁴⁴ Supported by a more robust evidence base, psychiatrists will better identify ecology-related causal factors in mental illness, as well as potential avenues of support. This sensitivity, in turn, will increase patient awareness of how mental health is entwined with natural spaces.

In adopting the cause of biodiversity, new research would be complemented by expanded clinical experiences and opportunities for first-hand observation of the nature–mental health interface. Psychiatrists, for example, can help make more immediate changes to the environments of our health services. This includes championing public green spaces and supporting trusts and hospitals to tend their own natural spaces. NHS Forest, for example, is a programme that has promoted planting trees on NHS grounds.⁴⁵ The conservation of areas close to health services more easily allows for the integration of sustainable green care options within mental healthcare. A project such the Green Walking initiative, which has seen eight trusts introduce green walking programmes for psychiatric in-patients, shows how easily local green spaces can be integrated into clinical care and generates insights into best practice that complement ongoing research.⁴⁶

The second kind of action would see psychiatrists advocate, campaign and highlight the mental health implications of ecological collapse in their organisations and communities in a way that bridges people’s lived experiences with the aspirational scale of planetary health.

The American Psychological Association has made recommendations for how mental health professionals can highlight the relationship between health and climate change, identifying education, awareness, communication and motivating climate solutions as important areas of action.⁴⁷

Although these areas are humble it should be remembered that healthcare’s involvement in campaigning against climate change began with the premise that simply sharing information can lead to a change in perspective. Developments such as the NHS net-zero plan, the establishment of planetary health institutes around the world, publications focused on

planetary health, the *Lancet* countdown and the UK Health Alliance on Climate Change (UKHACC) all emerged as a result of passionate voices calling for action.

Speaking eloquently and listening carefully are skills that mental health professionals use every day. As leaders within mental health, psychiatrists should speak to the government and the health sector broadly to ensure that the relationship between biodiversity and health is heard. Advocating for the inclusion of instruments that take into consideration the impact on mental health of developments and changes to land usage, for example, would be a clear and effective demand. In summary, all of these suggested actions offer important steps in conceiving of a sustainable mental health service that champions a more preventive style of patient care.

Conclusions

At the heart of psychiatry is the appreciation that our health and experience are influenced by a complex web of interactions. Carrying this knowledge has allowed psychiatrists to make bold observations on the very real impact of social inequality on people's mental health.⁴⁸ This ability to understand how influenced people are by their environments is also why psychiatrists should see the growing threat to nature as entwined with climate change and ultimately with mental and physical well-being for everyone.

I thank Daniel Maughan, Phil Davison, Alan Kellas, Lisa Page, Katherine Kennet and the entirety of the RCPsych Sustainability Committee for their knowledge, inspiration, energy and clarity of vision. Thanks also to Frances Mortimer, Rachel Stancliffe and Benjamin Whittaker at the Centre for Sustainable Healthcare. Thank you also to my partner Baillie Card for her generosity and wisdom.

Jacob Krzanowski is a specialist registrar in general adult psychiatry with South London and Maudsley NHS Foundation Trust, an Associate Registrar in Sustainability for the Royal College of Psychiatrists, London, and an Associate of the Centre for Sustainable Healthcare, Oxford, UK.

- *W. Alwyn Lishman, MD, FRCP, FRCPsych (Hon)*

pmc Emeritus Professor of Neuropsychiatry, Institute of Psychiatry, Psychology and Neuroscience, King's College, London, UK

Alwyn Lishman, who died on 24 January 2021, aged 89, was the first Professor of Neuropsychiatry to be appointed in the UK. He was the co-founder and Honorary Life President of the British Neuropsychiatry Association (BNPA). In 2016, when addressing the BNPA, Alwyn said that he wanted to be remembered for what he did, in terms 'expressed concisely', thus setting a challenge for those of us who now wish to celebrate his exceptional contribution to psychiatry. His famous book *Organic Psychiatry: The Psychological Consequences of Cerebral Disorder*,¹ first published in 1978, set an example of conciseness and clarity in medical writing while at the same time single-handedly defining the discipline of neuropsychiatry. Alwyn considered this book to be his most important legacy; two further single author editions followed in 1987 and 1997. At the time this book was published, neuropsychiatry was a small specialist interest. Now, thanks considerably to his influence, it is a major component of psychiatric research and practice.

Alwyn saw neuropsychiatry as much more than an admixture of neurology and psychiatry, as involving the understanding of brain mechanisms in relation to mental disorder, and benefiting from advances in neuropsychology, biochemistry, genetics, imaging and many other disciplines. For him, neuropsychiatry could equally apply to the study of schizophrenia, affective disorders or traumatic brain injury, in fact to the whole of psychiatry. By defining neuropsychiatry in this way, he was redressing the balance between brain and mind that had been polarised by the influence of psychoanalytic theory.²

His research was wide-ranging. Memory was one of his early interests. In what he called 'a crude approximation to testing Freud's theory of repression', he explored the effect of the hedonic tone of the material to be remembered, finding that, while normal people recalled pleasant material better, the pattern was reversed in depressed patients. Later his emphasis was to exploit brain imaging in relation to psychiatry, and studies of brain damage in alcoholism and psychosis of epilepsy followed.

Alwyn Lishman was born in Houghton-le-Spring, County Durham, on the 16 May 1931. His father, George Lishman, had been a prisoner during the First World War and, when his poor health prevented him from becoming a doctor, he ran the family business, a tallow chandlery that supplied candles for mining and shipbuilding. His mother Madge (née Young) was a teacher, described by Lishman as something of a dragon who locked him up with his sister Valerie until they finished their homework without any mistakes. Alwyn's innate perseverance and attention to detail must have been greatly enhanced by this strict upbringing.

For somebody who was a master of words it is perhaps surprising to know that he could read music before he could read words. He assiduously played the piano from the age of 5 and wanted to be a musician but pressure from his father finally persuaded him to go to Birmingham University to study medicine. His interest in the relationship between brain and behaviour was sparked by his time working with Solly Zuckerman while doing an intercalated degree in Anatomy and Physiology. He qualified in 1956.

After his house jobs, he spent his National Service practising neurology. He was posted to the Army head injury hospital outside Oxford, where he was mentored by Ritchie Russell. Neurology attracted Lishman for its clinical precision, but the lack of effective treatments and his wish to help his patients made him consider other options and he followed Bob Cawley, his great friend from medical school, to the Maudsley Hospital in London in 1960. He said that it took a certain degree of unworldliness to make the move to a much less prestigious discipline.

He described the Maudsley in the 1960s as extremely social and great fun and he built lifelong friendships there. Jim Birley, Griffith Edwards and Mike Rutter were contemporaries. He thrived under the abrasive but kind influence of Aubrey Lewis and his doubts about psychiatry quickly evaporated when he realised that thinking at the Maudsley was as rigorous as any. He wrote his doctoral thesis on 'Psychiatric disability in soldiers with penetrating head injuries', using the Oxford register set up by Ritchie Russell. At a time when there was little interest in brain injury, Lishman's insights into the behavioural and psychiatric consequences of frontal and left temporal injuries were stunning.

He was appointed to his first consultant job at the National Hospital (Queen Square) in London in 1966. His clinical work there fuelled his interest in neuropsychiatry, and he cherished his interactions with neuropsychologists such as Oliver Zangwill and Elizabeth Warrington, but the dismissive attitude of some neurologists towards psychiatry prompted him to return to the Maudsley in 1967 as consultant psychiatrist. In 1979 he was appointed to the first Chair of Neuropsychiatry in the UK, at the Institute of Psychiatry. In 1987, with Jonathan Bird, he co-founded the BNPA, the first, but not the last, neuropsychiatric association in the world and still a thriving forum that welcomes people from different disciplines. He was made an Honorary Fellow of the Royal College of Psychiatrists in 1999.

Alwyn was an exceptional mentor, and he was proud that several of his trainees went on to hold chairs of neuropsychiatry. For me, the debt of gratitude is immense. When I arrived at the Maudsley in 1971 we were assigned a 'moral tutor' and Alwyn Lishman was mine. This led to fruitful years of research and, more importantly, we became close friends and I became part of his family. Alwyn, an accomplished musician, was generous enough to be my accompanist when I, a tone-deaf late starter, misguidedly attempted to take my clarinet grades. To my surprise he was even more nervous than I was. We tacitly agreed not to repeat the experience.

In 1966 he married Marjorie Loud, a psychiatric social worker he met while training at the Maudsley, and they had two children, Victoria and William. He continued to play the piano and the organ and built his own harpsichord. He retired early in 1993 to look after Marjorie, who had developed a brain tumour. Marjorie died in 2000. Alwyn's last few years were marred by the ravages of dementia. He is survived by his two children and two grandchildren.

- *Anthony Ng: the kids are alright*

Dr Anthony ‘Tony’ Ng is a general psychiatrist and medical director of community services at Northern Light Acadia Hospital in Bangor, Maine, USA. He has a long interest in disaster emergency psychiatry and climate psychiatry and in 2019 took up a year-long role as the first chair of the American Psychiatric Association’s (APA’s) Caucus on Climate Change and Mental Health. He is the former chair of the APA’s Committee on Psychiatric Dimensions of Disaster, with which he is still involved. In addition, he is a member of the Climate Psychiatry Alliance, an independent organisation (with members in the USA and UK), which works to lobby government and raise awareness of the links between climate change and mental health. Dr Ng is also a proud member of the Royal College of Psychiatrists.

Dr Ng has aided the psychological response to victims of disasters around the world and led a disaster response coalition, the New York City chapter of National Voluntary Organizations Active in Disaster (NYCVOAD), between 2001 and 2003. His work has involved him in atrocities such as the 9/11 terrorist attack in New York in 2001 and the Sandy Hook school shooting in Connecticut in 2012, as well as natural disasters such as Hurricane Katrina in 2005, among many others.

This interview took place via Zoom in September 2020 and has been edited for length and clarity.

How did you come to be interested in the area of disaster relief and, more recently, climate psychiatry?

Well, it began with an interest in trauma, because I realised so many of my patients in community mental health had some sort of trauma-related issues. I then became interested in humanitarian assistance for refugees and so forth. It was the 1990s and I think Bosnia, Croatia and Cambodia were pretty up there in the news. And I was mostly focused on the psychiatric piece, PTSD and so forth. As I’m doing this stuff, I realise that you can’t really appreciate it until you can look beyond just the trauma – you need to look at how these things happened in the first place. And that got me interested in things such as socioeconomic factors, political strife and also climate issues. Climate became a big issue for me about 5 years ago, but it was brewing before that because I responded to [Hurricane] Katrina and I saw the aftermath of it all. When you start looking at it, it is climate change that leads to some of the severe weather that we’ve seen.

In the past few years, the APA started to take a lot more interest in the relationship between climate change and natural disasters and that led to the connection I have with the Climate Psychiatry Alliance. We wanted to explore what climate change is doing to our patients and what are the long-term effects it could have on psychiatric well-being in terms of population-based models, as well as the individual-based model.

How have people in the USA been affected by disasters, both natural and man-made?

Almost every year we’re seeing increasing preparation for some sort of weather issue, whether its tornadoes or hurricanes or wildfires. Ice storms can also be a big problem in the winter, which take out a fair bit of the country if they happen.

What has been challenging is that disasters based on terrorist attacks are the media-driven events; they don’t happen often but they have high emotional content. And I think that’s what draws a lot of the attention. But every year, every US state is struggling with some sort of weather-related event – they’ve kind of gotten used to it. But what people are not seeing is how often these hurricanes are coming, how intense they’re coming and also why the risk of these events is going up. More people are migrating to the coasts for whatever reason. In essence, it puts them more at risk for trauma from natural disasters, which may be stemming from climate change. And so it’s kind of a ripple effect. But it’s a slow pain. People don’t appreciate the impact as much.

I wanted to hear a little bit more about your past work in disaster relief. Was there anything that stands out as a particular learning experience for you?

I honestly think the best learning experience was the work that I did for 3 years in New York City after 9/11. Now, granted, it wasn’t climate related, but what it really educated me on was the strong interface between disasters and mental health, along with the human service side. You really can’t appreciate disaster mental health until you really develop a good understanding of human service response to disasters.

As a psychiatrist you think about the PTSD, depression, anxiety and all those things. Certainly, you can work with those. But when you look at it more deeply – people are worrying about food, shelter, job stability, legal issues – those become bigger issues for them. So, it is not as much about the diagnostic arena, but how do people in distress behave? However, the focus in psychiatry has always been on that small diagnostic corner and the research money goes into that area.

The majority of people don't go on to develop PTSD, but they certainly have a lot of distress behaviours that can affect their overall well-being. For example, after a disaster, how do I find my loved ones? How do I get information about what's going on? How do I seek care? I just lost my job, so who will assist me with resources? How we intervene in these areas early on has an impact much later.

One of the pieces of feedback we often hear from people is that it's not the disaster that created the stress, it's the disaster *after* the disaster.

The Climate Psychiatry Alliance website alludes to the impact of climate change on 'the theoretical foundations and research priorities of psychiatry'. Can you elaborate a little bit on how you think climate change might have an on impact those areas?

With climate change, we have not had the investment to really look specifically at what some of the markers or correlations are that might impact on people's mental health. So, I think this is one of the charges of the Climate Psychiatry Alliance – to increase people's awareness of the need to fund research.

One of the biggest achievements it [the CPA] was able to do is to create a Climate Change Caucus within the American Psychiatric Association, which sits under the Disaster Committee. They were able to advocate for it to become a standing entity. The other thing about the entity is that it falls under the Council of Research within the APA, so that means it also gives them a little bit more face time in terms of encouraging a focus on further research. Certainly, we need a better research base for climate change and mental health. And people are slowly doing it.

But the challenge, of course, is that the return isn't as fast as some of the other psychiatric research. Climate change in general is a creeping disaster. It's a death by a thousand cuts kind of thing if you don't do anything about it. And the healing process also takes a long time. So, though your results may not be earth shattering within a year or two, certainly over time they could add to the overall resources we have to deal with climate change and better understand the resources that we need to help people with it.

So, you were the first chair of the Caucus on Climate Change?

I was very honoured to be asked to chair the first year to really kind of get it going a little bit. It's only about 3 years old now. And the other nice thing about it is that, because of the work of the Caucus, the disaster course which the APA gives to its members (basically teaching about basic principles of disaster psychiatry) has added a section on climate change impact and disaster psychiatry.

So, you can point to some tangible gains. It seems that you see the functions of the Caucus as raising the profile of climate change psychiatry and influencing research priorities. Are there any other areas you think are important for the Caucus or for the Climate Psychiatry Alliance?

We also worked on areas such as lobbying. One of our members, for example, she lives in DC [Washington DC] and she has significant knowledge about advocacy to legislators on climate change issues. She has become a resource for local politicians because Congress is right there.

One nice thing about the Climate Psychiatry Alliance that's different from the Climate Caucus is that the Climate Caucus sits with the APA. So, you kind of have to do things within what the APA can do within its lane. But the Climate Psychiatry Alliance allows many more opportunities to engage without representing official positions.

Do you think it's important for us as psychiatrists to take an interest in climate change?

I believe it is important to appreciate its impact. I think to be a better psychiatrist you do have to have some appreciation of climate change, especially perhaps climate change where you're working.

It may be a big task to try to understand climate change globally. But I think for every psychiatrist, I think there's some impact within our areas. So, if you work in a rural area, you should know what climate change is doing to your rural population, for example if there's a change to the crop cycle, if there's a change to the drought season. If you're in the

city as a psychiatrist, how does it affect your patients there? Does it increase the risk of allergies by affecting air quality for example?

In a city environment, you may have more people in the population who may appreciate climate change. Outside that, they may not have the same feeling, but your farmer may have just lost a job because of severe drought in your area. It's not that you're blatantly up front saying 'I want to talk about climate change', but you're saying 'I could see in the back of my mind how climate change may be impacting your life and what stresses you go through'.

One of the problems with addressing climate change is that it's sometimes hard to see the wood for the trees, so your suggestion that we focus on the small area that we can make a difference in sounds helpful. Do you have any advice for psychiatrists generally about what they could do on an individual level and at a system level to combat the climate crisis?

It's helpful if you can identify what local resources are available for you where you're living. Let's say, for example, using my wife's island (she is originally from the Isle of Man), you need to know what the Isle of Man initiatives are. One of the areas they're looking at is a reduction in the use of peat for heating.

The use of peat creates a significant amount of carbon emissions. How is that impacting your local community? And these are very easy things to look up. I think then you can appreciate the impact because, for example, yeah you can reduce peat use, but how does it affect your patient who is trying to get heat? Because peat may be the cheapest thing right now for them. You can help to at least frame the discussion with your patients.

And also, I think certainly it's helpful to encourage more like-minded advocacy. For example, could we have a similar Caucus on Climate Change in the UK for psychiatrists?

Would that be a good idea, do you think?

I think we should work closely. I think, first of all, such a group can encourage the Royal College [of Psychiatrists] to put more on the climate change agenda that will trickle down to what individual psychiatrists do, but that also can ripple down to the research that you and I were just talking about earlier. There's a lot on for the leadership and because there are so many things going on, they may not see this as a big priority for them.

And maybe the *local* psychiatric association can get together and say, 'OK, what is the impact of climate change in Northern Ireland?'. I know that by me doing something, I feel like I'm contributing to a solution rather than sitting there on the sideline.

Do you think climate change has a disproportionate effect on people with mental disorders?

I believe so for many reasons. For people who have mental illness in general, they are often already disadvantaged socioeconomically. I can move away to an area that's nicer so that it can be less impactful on me in terms of climate change. People with mental illness are often stuck. Their coping mechanisms are challenged because of mental illness. Whatever anxiety and stress they may deal with from other ripple effects, whether it is just higher heating bills and other related stresses, they don't have as many resources to help them navigate through those challenges. We might have the option to say, 'I do my part because I buy organic meat and can buy socially responsible groceries'. But if you live in a neighbourhood where organic options are not available you don't have that choice.

One of the things we're seeing is a spike in climate-related anxiety, particularly among children. Do you have any thoughts about how we can talk to kids about climate change without making them really anxious about it?

As much as we adults try to think about this, kids are much more concerned. They're much more savvy about what's going on than we are. And I think they are a very good barometer for us. In terms of talking to kids, I think it's a conversation that needs to happen. And it's OK if you don't have all the answers. I don't think kids expect you to have all the answers. I think the piece I would really instil in them is to understand what science is and what facts are. If I can ask my kids to do some critical thinking, I'm setting them up so that in 10, 15 years time, they would ask these same questions in the same way that we would like them to.

That brings us to 'alternative facts'! A lot of us in the UK have watched with dismay as Trump reneged on the Paris climate agreement, et cetera. Are you more pessimistic now than you were about the chances of the USA addressing climate change in a meaningful way?

I think, first of all, it is very hard for some folks to appreciate what climate change is. They live in, let's say, a small village. If you talk about corals, they never see corals. It doesn't affect them. It doesn't mean anything to them. I think one thing we fail at in terms of having those discussions about climate change is how climate change affects you *there*, where you are, versus climate change in general. And when people can't relate to it, it becomes harder for them to empathise and say, 'I have to do something about it'.

But this is not just us. I think everywhere is struggling with that, too. One interesting thing about the model of government we have here in the US is that there's a lot of state government versus federal government. So, yes, while the federal government pulled out of the Paris Agreement, there are a lot of governors who basically said, 'We're not – that's going to be our benchmark'. For example, in the state of Maine, the governor has created a task force on climate change. She wants to reduce emissions, wants to improve climate change and she wants to aim for the goals of the Paris Agreement. So, I think that's the little bit of hope that we have.

Which leads me neatly on to my final question. There is sometimes a lot of pessimism around climate change for people who do believe in it, that actually we're not moving fast enough to make meaningful change. How hopeful in general are you about whether humanity can turn away from climate disaster?

Maybe I'm too optimistic, but I think as the human race, we will move toward a better place. Are we going to have bumps along the way? I can guarantee you we will but I do think folks are increasingly seeing some of these critical issues. I think for a lot of reasons, economics will drive it. I mean, you can look at history. Climate change, yes, it's not easy, but I can still remember when I was growing up in the 1970s seeing Environmental Protection Agency commercials of people dumping toxic waste and trash in rivers and now we have made significant progress in those areas. So, I think it's going to happen slowly.

You clearly are an optimist.

Yes and no. To some degree, I am pragmatic. I think what really helped me personally is having a 10-year-old son. I tell him that sometimes he's the best teacher for me. He reminds me of certain things, because you know, we rationalise all kinds of reasons for why we do certain things, but the kids bring it down to core values. So, I think this is what we need to do.

As much as people feel frustrated that we can't make big changes right now, 5 years ago I didn't know about Greta [Thunberg], I didn't know about those kids. Now, I hear about kids taking legal action, asking for injunctions on certain initiatives that they feel may be damaging to the climate. That's a big deal. And as I said, over time, these kids vote. Over time these kids become leaders in whatever field they're going to and will have an impact. To change the culture, you need a couple of generations before you can move it through.

Climate change, it's unfortunate, but it's going to be a marathon, not a sprint, so we've got to be prepared for it.

1.2.57 Is climate change a mental health crisis?

Abstract

The Earth's climate is in a complex state of change as a result of human activity. The interface between climate change and physical health has received significant attention, but its effects on mental health and illness are less understood. This article provides an insight into the psychiatric sequelae of climate change, suggests strategies that psychiatrists can use to take action, and argues that it is their responsibility to do so.

Contents

- *Is climate change a mental health crisis?*
 - *Declaration of interest*

pmc Anthropogenic climate change is irrefutable and has become increasingly difficult to ignore. It is currently considered by experts to represent the largest existential threat to humanity, endangering life itself through environmental degradation, rising ambient temperatures and extreme weather events, among other mechanisms. Efforts to tackle this complex and unpredictable issue have assumed national and international priority, exemplified by the introduction of the 2008 Climate Change Act and the International Paris Agreement, respectively. A global youth movement calling for action on this matter has also received widespread media attention.

The World Health Organization regards climate change as this century's defining issue for health systems. The body of research connecting climate change with health has primarily focused on physical health. Of the literature investigating mental health, the majority either describes effects on vulnerable localities or presents qualitative data,¹ limiting the universal generalisability of such findings. Individuals with mental disorders are particularly susceptible to the effects of climate change. This is hardly surprising, given its widespread influence on physical, social and economic systems, all of which are key determinants of psychological well-being. It is already apparent that climate change is contributing to an impending and inevitable global mental health crisis.

There is a growing wealth of research examining extreme weather events, including hurricanes, floods and wildfires, in the context of mental health.¹ Climate experts anticipate an increased periodicity and intensity of such events in a collage of unfolding disasters, rendering these crises harder to predict and respond to. The Australian bushfires and Hurricane Eta are just two examples that caused mass devastation in 2020.

It is helpful to divide the mental health consequences of extreme weather events into direct and indirect.² Such events are associated with mass destruction, and expose the population to direct danger, physical injury and death. Immediate psychological responses include acute stress and grief reactions. The long-term psychopathological patterns that occur following trauma are well understood, and it is recognised that extreme weather events increase the prevalence of post-traumatic stress disorder, depression, anxiety, substance misuse and stress-related relationship difficulties.³

We must also consider the destructive impact of extreme weather events on infrastructure, specifically properties, transport services, social support networks and employment. They place additional strain on already overstretched health-care resources such as community and in-patient mental healthcare systems. In 2005, Hurricane Katrina resulted in a surge in neurotic and affective disorders that disproportionately affected women, young people and those of lower socioeconomic status.⁴ The identification of at-risk groups is essential in ensuring effective prevention and treatment of weather-related mental illness.

Associated with climate change are destructive, enduring and largely irreversible long-term environmental changes – desertification, deglaciation, thawing permafrost, rising sea levels, loss of biodiversity and species extinction, to name a few. Sadness, hopelessness, anxiety and grief reactions are recognised individual psychological responses to environmental degradation.² Societal sequelae include scarcity of resources and involuntary climate-related migration, both of which are likely to result in increased armed conflict and exacerbation of mental health issues. Much of the existing evidence of these responses to climate change come from vulnerable areas, such as coastal and circumpolar regions, which should be regarded as predictions of the future globally.

Global warming is an already demonstrable facet of climate change, and rising temperatures are known to have adverse effects on mental health outcomes. Associations between warmer temperatures and mania in older people, transient affective disorders, substance misuse and psychiatric hospital admissions have all been established empirically.⁵ Furthermore, those affected by mental illness are up to three times more likely to die from a heatwave than those unaffected.⁶ Factors that may explain this vulnerability include poorer baseline physical health, increased isolation and institutionalisation, maladaptive behaviours and the effects of psychotropic medications. Rates of suicide have consistently been found to rise during heatwaves.¹ Global warming thus represents a key factor influencing psychiatric morbidity and mortality.

Climate change has been shown to increase the risk, frequency and distribution of foodborne, waterborne, vector-borne

and zoonotic infectious diseases.² This is likely to be compounded by an uncontrollable surge in global antimicrobial resistance. The profound psychological burden of infectious diseases is plainly exemplified by the COVID-19 pandemic. Restrictive measures, including quarantine, isolation and social distancing, superimposed on vast economic setbacks and a widespread unemployment crisis, have undeniably contributed to a mental health emergency whose full extent is yet to be determined.

Individual psychological responses to COVID-19 are wide-ranging, from anxiety and low mood to insomnia, denial, fear and even anger. The phenomenon of ‘headline stress disorder’, a heightened emotional reaction to seemingly endless news reports that can induce somatic symptoms of anxiety, has been observed throughout the pandemic.⁷ Frontline healthcare workers were particularly susceptible to psychological symptoms during the initial stages of the outbreak,⁷ and this disproportionate impact on our future healthcare workforce will only inflate the magnitude of the crisis. It is probable that ongoing climate change will bring about further pandemics, and COVID-19 provides a means of predicting and mitigating the psychiatric ramifications of new infectious diseases.

The above phenomena are already influencing diagnostic frameworks in psychiatry. There is an advent of integrating new terminology for climate-specific mental disorders into the lexicon, highlighting the growing awareness of climate-driven psychological experiences. ‘Ecoanxiety’ relates to fears about environmental doom and uncertainty, and ‘solastalgia’, a contraction of nostalgia and solace, conceptualises psychological distress secondary to environmental degradation. A range of ‘psychoterratic’ syndromes have since been described, in an attempt to capture the diverse emotional disorders seen in response to climate change.⁸

At present, the DSM-5 and ICD-11 offer no specific references to mental disorders related to climate change, but it is likely that such phenomena will soon be incorporated. Psychiatric phenomenology has historically adapted to contemporary cultural issues, and climate change should be no exception. In 2008, Wolf and Salo described the first patient diagnosed with a putative ‘climate change delusion’.⁹ The patient in question was a 17-year-old boy with a depressive illness, who refused to drink and compulsively checked taps based on the belief that he would deprive others of water. Seasonal affective disorder, now widely regarded as valid and common just 40 years after its first description, is a further example of the evolution of psychiatric frameworks in response to environmental factors.

We have a moral and professional duty as mental healthcare professionals to act on the impending climate-driven health crisis. Every-Palmer et al identify the ‘CARM’ approach – collaborate, advocate, research and mitigate – as a useful tool for conceptualising our opportunities to do so.³

Interdisciplinary collaboration with policy makers, healthcare organisations and other stakeholders represents the most comprehensive and effective means of raising awareness of this emerging issue. The *BMJ*, *Lancet* and *PLOS Medicine* have conveyed the responsibility of mental health experts to provide clear information detailing the mental health sequelae of climate change.³

It is best practice to treat patients holistically by considering the environmental, social and economic determinants of health and illness. Climate change and its associated complications are a prominent example of such determinants. The literature consistently report a disproportionate impact of climate-related psychological consequences for those with pre-existing mental health issues. We must identify and advocate for vulnerable populations, to ensure equity of resource allocation.

Our understanding of the complex interactions within and between climate change and mental health is in its infancy. Future research in the field should be prioritised to attain a more concrete understanding of these interactions, and to inform the development of effective interventions for both prevention and treatment of climate-related mental health issues. It is crucial that mental healthcare professionals anticipate the inevitable psychological and psychiatric burden of climate change.

The future of global mental health and the planet is in our hands. We should therefore strive to reduce the environmental impact of our institutions and practices. As doctors, our carbon footprint from clinical practice is ten times greater than that from our personal lives.¹⁰ The Royal College of Psychiatrists’ Sustainability Committee has generated a summary of ten ways to reduce one’s footprint in the professional setting¹⁰ – a good starting point for those willing to make a difference. Mental health professionals take pride in providing individualised care, but we must acknowledge that continuing clinical practice that ignores this issue will contribute to an international mental health crisis. Our decisions will not be forgotten by the patients and psychiatrists of tomorrow.

pmc Malawi, a south-eastern African country of approximately 20 million people, has only three consultant psychiatrists. As grim as this ratio is, it is not unique to Malawi; rather, it is a tendency within Africa that begs interventions.

The Malawi Quick Guide to Mental Health, by the Scotland–Malawi Mental Health Education project, is one such intervention. With Donncha S. Mullin and Robert C. Stewart as lead editors, this is a seven-part practical resource material adapted mostly from World Health Organization’s *mhGAP Intervention Guide Version 2.0* (2016) and the Royal College of Psychiatrists’ *Where There is No Psychiatrist* (2018).

The target reader is ‘the busy primary care provider working at first- and second-level healthcare facilities in Malawi’ and the 90-page guide is adapted to the practical realities of working in mental health, paying attention to the country’s official national language (Chichewa), social mores, current mental health legislation and local support institutions.

Written in accessible language and formatted in bullet-point presentation style, the first three parts provide guidance about mental health and the ongoing COVID-19 pandemic, mental health emergencies and the principles of assessment and management of mental illnesses. The other sections offer guidance about specific psychiatric disorders, including epilepsy, which is identified within the neurologist’s remit but may present to mental health services.

A chapter is dedicated to special populations (pregnant women, older adults, children and adolescents) and a final part contains information leaflets on specific mental disorders written in English and Chichewa, adapted from existing leaflets of the Royal College of Psychiatrists, Mind and National Centre for Mental Health.

This guide fulfils its aim in providing support for the non-specialist mental health worker in landlocked Malawi and neighbouring Anglophone countries, by virtue of its being written in English. Always signposting to other resource materials for additional information, this guide is a primer for the curious non-specialist health worker.

The curious specialist reader will be furnished with aspects of the Malawian world-view about mental illness and the country’s mental health legislation, the Malawi Mental Health Treatment Act 1948, a functional colonial relic, which is also not unique to Malawi. *The Malawi Quick Guide to Mental Health* is a pragmatic intervention addressing the dearth of mental health specialists in Malawi but this resource material will also serve other Anglophone low- and middle-income countries in similar predicaments.

- *Klaus Bergmann, MD, FRCPsych*

pmc Formerly Consultant Old Age Psychiatrist at the Bethlem Royal and Maudsley Joint Hospital, London, UK

Klaus Bergmann, who died following a stroke on 5 December 2020, was one of the towering figures in British old age psychiatry in its early years, playing a major role in bringing the specialty to maturity. In the 1960s and 1970s, he was based in the Department of Psychiatry at Newcastle University, headed by Martin Roth. Mentored by David Kay and in collaboration with Gary Blessed and Bernard Tomlinson, Klaus was deeply involved in one of the first community cohort studies of the prevalence and outcomes of old age mental disorders outside hospitals. The important findings of these studies have dictated policy ever since.^{1,2}

Although involved in research, Klaus was a superb clinician who cared more about his patients than he did about anything else at his work. His acumen in diagnosis and treatment was second to none. He was the reason many of his trainees went into old age psychiatry, some of those now occupying the highest levels in the profession.

He was born in 1930 in Dresden, younger brother to two older sisters, to Fritz and Alice Bergmann. Fritz owned a millinery firm that he was able to re-establish in Luton after emigration from Germany. In 1937, before the Second World War, his Jewish family moved via Palestine to England. He would often recount his childhood disappointment that he had not been allowed to wear the uniform and carry the dagger of the Hitler Youth, which he coveted.

Klaus was educated first at St George's School, Harpenden, following which he studied medicine at Sheffield University, where he met his wife Marie, a fellow student reading German. After National Service, he returned to Sheffield for psychiatric training under Erwin Stengel, also a refugee from the Nazis. This gave him a broad outlook based both on rigorous history-taking and mental state examination, but with psychoanalytic insights. He always maintained an affectionate respect for Stengel but, as was the case with others among his senior colleagues, he could never resist telling humorous stories about them. This characteristic betrayed both immense respect for those Klaus deemed worthy, combined with a refusal to adopt blinkered hero worship.

In 1964, Klaus moved from Sheffield to Newcastle, where the Department of Psychiatry was headed by Martin Roth, and it was here that he entered old age psychiatry. Klaus often said that he regarded Roth as the Kraepelin of old age psychiatry, i.e. a founding father in terms of classification and phenomenology. Once again, Klaus enjoyed poking fun at him without ever losing respect for his important contributions to the specialty. In 1966, Klaus took up a consultant post at St Francis Hospital, Haywards Heath, Sussex, where he was overworked and grossly under-resourced. So, in 1969, he returned to Newcastle, continuing to carry out research in the community.

At heart, Klaus was a clinician and a teacher and, in 1979, at the invitation of Raymond Levy, he moved down to London to the Bethlem Royal and Maudsley Hospital as a consultant old age psychiatrist, replacing Felix Post, who had retired. With typically wry humour he asked Raymond: 'Do you think they'll mind that I'm not a gentleman?'. As a matter of fact, they did not mind, and he settled in there very well. At the Maudsley he worked alongside Raymond Levy, who became Professor of Old Age Psychiatry. Later, they were joined by Robin Jacoby and Marisa Silverman (now Parrish).

Klaus inspired loyalty through his clinical skills and his courage. He was not frightened to offend people in defence of his patients. For example, if he saw something that he regarded as shocking, he would, himself, shock the perpetrator. One day, he arrived at a care home to be led into the day-room, where all the residents were sitting round the walls except for one old lady who was on a commode in the middle of the room, incompletely shielded by one or two movable screens. Klaus turned to the care-home manager and said: 'Oh, do you sh** in your sitting-room?'

He was often incredibly funny. Never completely shaking off his adolescent schoolboy personality, he was a fount of good and very non-PC jokes, designed on occasions to shock some of the more prudish people at the Maudsley. His office was a chaotic mess, with journals and committee papers all over the desk and the floor. His colleagues used to joke that he would not be able to retire but would have to be removed as a hoarder under a section of the Public Health Act. This delighted him, and he often boasted about it. In the end, he retired without recourse to the Public Health Act. Early on in his retirement he wrote reports for the General Nursing Council in connection with disciplinary action. He was rather fond of what he called his 'naughty nurses'.

Klaus enjoyed a long and happy marriage to Marie, who survives him with their son George, their daughter Caroline, and three grandchildren. Vicky, their elder daughter, died of cancer in 2014.

Abstract

Climate change is already having unequal effects on the mental health of individuals and communities and will increasingly compound pre-existing mental health inequalities globally. Psychiatrists have a vital part to play in improving both awareness and scientific understanding of structural mechanisms that perpetuate these inequalities, and in responding to global calls for action to promote climate justice and resilience, which are central foundations for good mental and physical health.

pmc Climate change is affecting the physical and mental health of human populations through direct and indirect mechanisms including population displacement, forced migration, and economic and food system instability.¹ Global action and ‘a robust response [to climate change] ... will improve human health and wellbeing’² and reduce associated psychological consequences.³

We suggest that by addressing mental health inequalities, psychiatrists can contribute to addressing climate change and its health effects. We highlight the interconnectedness of inequality, climate and ecological destruction, and adverse mental health outcomes. We go on to propose a model for mental health practice and research that promotes climate justice and resilience in the context of increasingly complex geographical, economic and sociocultural factors.

Climate change and mental health: unequal effects, but not by chance

The COVID-19 pandemic has shown that minoritised and indigenous communities are at heightened risk from combined social and ecological shocks, including adverse weather events and pandemics, owing to vulnerability resulting from pre-existing factors such as discrimination, exclusion, poverty, land dispossession and malnutrition.⁴ There are also inequalities in exposure to ecological hazards. A study on associations between air pollution and neighbourhood characteristics in England and The Netherlands found higher concentrations in the most deprived 20% of neighbourhoods in England, with higher concentrations in both countries in neighbourhoods with >20% non-White populations, after adjustment for urbanisation and other variables.⁵

On a global scale, there is increasing recognition that climate change is compounding many health inequities and undermining pre-existing support structures which protect against poor mental health.⁶ The climate crisis has been called a racist crisis, reflecting both its disproportionate effects on Black communities and people of colour globally, as well as its evident unequal effects within countries.^{7,8} Following Hurricane Katrina, for example, Black New Orleanians faced greater stress than their White counterparts, even after adjustment for demographics, parental status, evacuation timing, home damage and job status; income had no clear effect.⁹ There was a similar pattern for post-traumatic stress disorder, which was partly but not fully explained by greater baseline mental distress.¹⁰

In recent years, campaigns for international action on climate change have highlighted how unjust social and economic systems, including legacies of colonialism, structural racism, and other exclusionary forces such as sexism and ableism at all levels shape vulnerability to the effects of climate change on mental and physical health. We contend, as argued by Leon Sealey-Huggins and colleagues (2018), that ‘we can only properly understand the harm being wrought by weather events and climate change by directly connecting it to broader social and political processes, of which structural racism is a central part’.⁷

Future research must further clarify the mechanisms as a result of which people with severe mental illness are more vulnerable to the adverse effects of climate change. This should include a recognition of closely interwoven vulnerabilities due to social exclusion, stigma and direct consequences of their illness or medications, as well as the effects of unequal distribution of resources at local, national and international levels, all of which affect people’s and communities’ capacities to cope and adapt.

Intersections between urban health inequalities and climate change effects

Cities are the places where most people live globally – 56% of the global population as of 2018¹¹ – and are the places where people are most exposed to the adverse effects of climate change. For example, the urban heat island effect means that higher temperatures are experienced in urban areas than in more rural ones nearby, and access to places for people to cool off in, such as shady green spaces or waterways, is often more limited. The health effects of rising exposure to high temperatures are not only physical but have also been associated with increased risks of mental ill health¹² and with suicide.¹³

Cities are also a key focus for research into mental health inequalities, particularly in relation to differences in urban versus rural rates of schizophrenia. The spatial distributions of other mental health outcomes such as suicide and self-injury are less clear cut, suggesting a greater need to further understand the influence of sociocultural and environmental characteristics of particular neighbourhoods.¹⁴ One example of this is how qualitative methods have begun to unpack the paradoxically low rates of direct self-harm in highly deprived areas in London.¹⁵

People in cities often experience the greatest exposure to some of the key contributors to climate change, including air pollution from fossil fuels and degradation of green space. Further, increased exposure to poor-quality air and green spaces often mirrors and compounds pre-existing socioeconomic inequalities. Evidence on the lifelong effects of air pollution on mental health outcomes such as depression continues to emerge.^{16,17} Exposure to air pollution and traffic noise are similarly unequal for different neighbourhoods with regard to both socioeconomic status and ethnicity, with those least likely to own a car often most likely to live in traffic-clogged and polluted areas.¹⁸ At the same time, good access to urban nature can help to partially mitigate the harmful effects of socioeconomic inequalities.¹⁹

Further, there has been greater awareness of the urgent need for more urban green space²⁰ and a recognition of strong disparities in access to green space in European cities.²¹ Access to green space has been linked with reduced depression risk,^{22,23} and there is increasing recognition that social factors affecting both availability²⁴ and levels of use²⁵ seem to mediate the mental health effects of green and blue spaces such as parks, forests, rivers and beaches.

There is increasing evidence of biologically plausible explanations of associations between urban environmental exposures and mental health. These include the effects of traffic and air pollution exposure on neurodevelopmental pathways in children,²⁶ neuroinflammation across the life course,¹⁷ and changes in arousal and stress responses associated with time spent in green space.²⁷ Proposed mechanisms through which the green space's benefits may be manifest include a shift in attention, promoting curiosity, social networks, group cooperation and physical activity. However, methodological and interpretation challenges remain, for example, in understanding the importance of confounding factors such as noise pollution and general neighbourhood deprivation.¹⁷ Limited studies have translated these observations into robust evidence for improved mental health.²⁸

There is also a lack of research from low- and middle-income countries (LMICs) on the effects of climate change on mental health. This is urgently needed to inform policy action in these contexts. In LMIC contexts, forced migration due to climate change – with the destination locations often being cities – is a significant challenge, and studies have highlighted that dislocation from one's home compromises emotional well-being related to happiness, life satisfaction, optimism for the future and spiritual contentment, even despite well-intentioned relocation programmes focused on material compensation and livelihood re-establishment.²⁹

Challenges in conceptualising complexity

For mental health, 'the risks and impacts of climate change ... are already rapidly accelerating, resulting in a number of direct, indirect, and overarching effects that disproportionately affect those who are most marginalised'.³⁰ Our ability to fully appreciate and act on these vulnerabilities has been constrained by complexity on multiple levels, from the geographic scale to the interrelated nature of the underlying causal mechanisms.

These constraints have limited research into the effects of climate change on mental health, to date. Quantitative approaches have tended to focus mostly on proximate causes, which can obscure important structural and political drivers of the distribution of mental health effects of climate-related heatwaves, floods, wildfires and droughts.³¹ Studies which have found associations between heat and mental health outcomes such as suicide have also cautioned about the difficulties of ascertaining causal effects using an ecological study design.¹³

Berry et al (2018) proposed that a systems approach that accounts for interrelated and interdependent factors, forming a complex whole, is important for future research thinking and leadership around climate change and mental health.³² We argue that this approach should also accommodate a structural and intersectional understanding of pre-existing inequalities in mental health. This may come from approaches which address broader inter-penetrative global socio-economic processes such as globalisation,³³ and the syndemics model of health that focuses on ‘interacting, co-present or sequential diseases and the social and environmental factors that promote and enhance the negative effects of disease interaction’.³⁴

The role of psychiatry in understanding and addressing climate change

In 2015, our Australasian colleagues³⁵ proposed the ‘CARM’ approach – to collaborate, advocate, research (and educate) and mitigate – as a framework for psychiatrists to join with a growing number of medical entities to act on climate change. We have proposed our recommendations within this same framework (*Box 1*), and with the emphasis that interventions need to be ‘coordinated and rooted in active hope’ to tackle the problem in a holistic and effective way.³⁰ Alongside growing recognition that we should practice psychiatry more sustainably,³⁶ we should acknowledge it as our professional and ethical responsibility to address the environmental, social and economic determinants of mental illness.³⁵ *Box 1* Framework for psychiatrists to act on climate change (adapted from the ‘CARM’ approach³²). Collaborate Work with disadvantaged communities so that their voices and priorities are better heard, and help them influence policy decisions Build on existing multidisciplinary work across specialties, and with patients and the public, to drive meaningful change on key issues relevant to climate and mental health Advocate For patients and communities’ mental health and well-being For actions that strengthen local community resilience and tackle global injustice For policies and funding for appropriate and evidence-based interventions to support and protect mental health following climate-related extreme events Research (and educate) To improve understanding of mental health in relation to the causes of inequalities, climate vulnerability and resilience Continue to build the evidence base for action, including through participatory and action research methods, and using mixed methods and systems approaches that recognise the interconnectedness and complexity of these subjects Advocate for increased funding for research to improve understanding of how both structural inequalities and climate change affect mental health, including when they intersect and how we can address them in tandem Mitigate Prioritise primary prevention for mental health across the life course Strengthen mental health systems and links between healthcare services and local communities Improve equity of access to quality care Act within local services to reduce carbon and improve mental healthcare

Collaborate

Psychiatry should work with disadvantaged communities to help them influence policies that may be linked to climate change, including empowering indigenous communities, implementing processes for equitable access to resources and ensuring inclusivity in long-term sustainable development policies. We should build on our multidisciplinary work with colleagues across specialties, with patients and the public, and with other health organisations. For example, psychiatrists can make use of the Royal College of Psychiatrists’ membership of the UK Climate and Health Alliance to collaboratively communicate the urgency of the situation and the case for action, and to influence policy makers, community organisations and other stakeholders to deliver meaningful change.

Advocate

Climate change is a global problem which needs global cooperation and local action. As advocates for patients’ and communities’ mental health and well-being, psychiatrists can help to drive these objectives forwards. There is already strong evidence that the psychiatric community can use in advocating for policies and interventions which can build local community resilience and tackle global injustice. These could include but are not limited to urban planning and regeneration; increased green space; cleaner air; community food growing; liveable streets; and high-quality, low-carbon housing. Importantly, they should also include national and international policies for urgent action on climate change and protection for those harmed or displaced by it, which may further exacerbate pre-existing mental health inequalities. With an already increasing frequency of adverse weather events, there is also an important role for the

psychiatric community in advocating for policies and funding support for appropriate mental health interventions in the wake of climate-driven events such as floods, major storms and wildfires, and to strengthen resilience to them.

Research (and educate)

A better understanding of the causes of inequalities, vulnerability and climate resilience as they relate to mental health is clearly needed, requiring changes to both research and education. Alongside more established quantitative epidemiological approaches, this is likely to benefit from qualitative and narrative methods, as well as systems approaches that recognise the complexity of these interlinked causal relationships and policy challenges.³² We should continue to build the evidence base for action, including through participatory and action research methods that emphasise the voices, needs and priorities of those who are most climate vulnerable and which seek to tackle structural injustices. We should also advocate for increased funding for research focused on understanding and addressing the effects of structural inequalities and climate change on mental health.

Mitigate

There are a number of areas where we can intervene early in addressing unequal climate change effects, for example, through prioritising primary prevention for mental health disorders across the life course and working upstream to address drivers of mental ill health and intervene early; strengthening mental health systems, particularly in areas of high deprivation; and strengthening links between clinical services and local communities. Against a backdrop of both national health service and governmental carbon reduction initiatives, psychiatric services must also both reduce their own emissions and improve mental healthcare, to avoid contributing further to the root causes of climate-related mental distress.

Conclusion

The time is now for concerted action to better understand and intervene in the structures and policies that create and perpetuate social and ethnic inequalities globally and harm planetary health. Working together to create the conditions for good mental health, such as enabling equitable access to resources, services and healthy environments, will also strengthen climate resilience and health equality across society. We can no longer overlook the interconnected ecological and social crises, and psychiatrists can play a critical part in defining the fairer and healthier society of tomorrow.

Abstract

Aims and method

In the context of increasing recognition of the role of nature in well-being, but limited evidence for specific patient groups, we describe a mixed-methods evaluation of a 10-week green care intervention (a woodland group) for 18- to 30-year-olds who had experienced a first episode of psychosis. Data were collected using the Questionnaire on the Process of Recovery (QPR), semi-structured service evaluation questionnaires, the NHS Friends and Family Test (FFT), and focus group analysis.

Results

All participants present at week 10 ($n = 5$) would recommend this group to others; 4/8 participants showed reliable improvement on QPR outcome measures. Thematic analysis identified themes of connection with nature and others, development of a sense of well-being and ‘peacefulness’ and new perspectives on psychotic experience.

Clinical implications

This small retrospective evaluation describes patient-reported benefits, feasibility and acceptability of green care interventions within early intervention in psychosis services (EIS).

– Declaration of interest

pmc Early intervention services (EIS) aim to reduce symptomatic periods and improve developmental and social trajectories for those who have experienced a first episode of psychosis (FEP).¹ Full recovery and therapeutic engagement may be difficult to achieve.^{2–4} Green care uses natural environments to facilitate improvements in well-being, with growing evidence to support effectiveness in the general population.^{5,6} Evaluations suggest that people with mental health problems may benefit proportionally more from such nature-based care.⁷ Accessing green space may mitigate health inequalities closely tied to severe and enduring mental illness (SMI),^{8,9} including for young people, among whom nature ‘connectedness’ is low.¹⁰ Groups in natural spaces may also confer potential advantages for therapeutic engagement and work.^{11–13} However, there is limited evidence for green care for those with SMI^{14,15} and, to our knowledge, none in FEP. Green care is a ‘complex intervention’, combining psychological work, physical activity and social interactions,¹⁶ so our study used a mixed-methods approach, as recommended by the Medical Research Council.¹⁷ This mixed-methods evaluation considers potential benefits and barriers encountered in a green care programme delivered in an EIS.

The intervention

The woodland group was facilitated by Circle of Life Rediscovery (CLR), commissioned by Sussex Partnership NHS Foundation Trust for 10 weekly half-day sessions. Two CLR staff prepared and attended groups, collaborating with EIS staff who facilitated transport and supported individuals (up to 15), with an overall staff:participant ratio of at least 1:3.

The group included a short walk, refreshments, contemplative time and activities such as learning about plants and habitats, maintaining the woodland area and cooking.

All participants were aged between 18–30 and had experienced FEP, some demonstrating active psychotic symptoms. Target problems included isolation, anxiety and depression.

Ethics and consent

This study was conducted as a service evaluation and did not require research ethics approval. All participants gave written consent for data to be collected and used within evaluations of the service.

Data collection and analysis

Participants completed the 15-item Questionnaire about the Process of Recovery (QPR) at weeks 1, 3, 6 and 10. The QPR has good internal consistency, high test–retest reliability and convergent validity.^{18,19} ‘Reliable change’, an estimate of statistical significance of change in outcome scores, was calculated using the Jacobson–Truax formula with published Cronbach’s alpha and standard deviation.^{20,21} Participants in the final session also completed a semi-structured service evaluation questionnaire and the NHS Friends and Family Test (FFT).²²

Qualitative data were invited through free-text portions of the evaluation questionnaire and through intervention summaries completed by participants and staff. A 20 min focus group ($n = 7$) was convened in the final session, facilitated by the group leader and transcribed by the first author. All three authors independently performed thematic analysis of the data.

Results

The QPR 5-point Likert scale ranges from 1 (disagree strongly) to 5 (agree strongly). Mean QPR scores increased from 3.4 ($n = 3$) at week 1 to 3.8 at week 10 ($n = 8$). Four patients showed reliable improvement and one showed reliable deterioration for those with data at two time points ($n = 8$).

All participants present at week 10 ($n = 5$) recommended the group on the FFT.²²

Results of the evaluation questionnaire (at week 10) are shown in *Table 1*. Table 1 Participants' ($n = 8$) scores on the service evaluation questionnaire (at week 10) Mean (median) *a*

Statement	Mean	Median
I feel more connected to the world around me	4.4	4
My emotional and psychological well-being has improved	4.3	4
My recovery has been helped	4.1	4
I have found ways to manage difficult emotions	3.5	3.5
I have found things that can help me in a crisis	3.8	4
I have connected with other people in a positive way	4.8	5
I have had some difficult social encounters	3.4	3
I have been more worried about the world around me	2.5	2.5
I feel more hopeful	3.9	4
I have felt more confident about going to new places	3.4	4
I have learnt new skills	4.3	4
I have felt more confident about meeting people	4	4
I have made friendships which may continue	4.1	4

All authors were concordant on two higher-order themes from the qualitative data. The first was connection with others and nature. Participants described reduced isolation and improved relationships: “‘It’s therapeutic to sit round a fire with other people [...] it’s nice to feel connected.’ ‘The difference [...] I’m not isolated [...] I can feel normal. You go to doctor’s appointments, you’re not part of the 9–5 but we are still here.’ ‘I feel [...] awe/curiosity for the natural world.’”

A second overarching theme was of positive change in self, including skills development and emotional change. This was expressed as feeling ‘confident to do things’ or ‘I enjoyed the cooking [...] it helped distract me more, and it’s skills I have used at home’. Participants appreciated creativity and the chance to ‘take something away’ – including physical objects, memories and new skills. They described feelings of calmness: ‘100% impact. I feel better about myself [...] I feel supported, I feel able. I have found stillness, calmness [...]. It is very healing’. Staff noted that participants appeared more relaxed in the woodland group than in other settings.

Particularly relevant to this group were repeated suggestions that the group enabled changed perspectives on psychosis. One participant wrote ‘[it] showed me what’s real in my [...] psychotic state’ and another ‘[it] helps me understand other people’s perception of psychosis’.

Barriers to participation included short sessions and poor weather. No adverse events, near misses or concerns regarding risky behaviour were reported.

1

Scores are on a 5-point Likert scale: 1, ‘strongly disagree’, 5 ‘strongly agree’.

Discussion and conclusions

This evaluation offers promise for green care as an intervention in FEP. Unusually, group attendance improved over time and all participants recommended it. Sequential QPR measures showed positive trends across all recovery domains; additionally, attendees described increased insight and contextualisation of difficulties, alongside distraction from problematic symptoms. Participants spontaneously discussing their beliefs and experiences, potentially enabled by the attention-restoring and stress-reducing properties of the woodland environment, seems to have encouraged reflection and reality testing. The group was therapeutic, with features of universality, development of socialising skills and interpersonal learning.²³

Feedback for improvement was sparse. The location, with associated travelling costs, and the intensive EIS staff involvement were cited as barriers to re-commissioning. CLR staff reported that the 'scaffolding' provided by NHS support enabled them to facilitate the group. Without this early input, successful engagement of this patient group seems less likely. Full economic (and carbon) costings, including staff resource, should be part of future evaluations and commissioning for such groups, as within the wider social prescribing context.²⁴

The findings are limited by small sample size, areas of incomplete data and use of patient-reported outcome scales only. We have no data from those who chose not to attend the intervention. Although qualitative analysis allows themes to emerge from the data, defining components and aspects of the intervention which may be poorly understood,²⁵ thematic saturation was likely not reached, and participants may have felt constrained by facilitator presence in the focus group. Further exploration of the increased reflective ability on personal psychotic experiences that participants reported feeling within the grounding and supported woodland setting would be particularly helpful.

Initiatives to boost green prescribing are expanding.²⁶ This is a preliminary report, indicating promising features for green care as a sustainable intervention in EIS. As a community-based intervention it is empowering and there is potential benefit from developing nature connectedness, which is associated with increased conservation behaviours.²⁷ Although further exploration of the benefits of green care, including its influence on psychotic experience and longer-term outcomes, is needed, the experiences this group describe suggest that nurturing opportunities for patients to access nature could promote recovery and rebalance relationships with the environment.

Data availability

The data that support the findings of this study are available on request from the corresponding author. The data are not publicly available owing to potential compromise of the privacy of those who contributed.

S.C. gathered and analysed evaluation and focus group data and produced the first draft. H.S. and C.B. contributed to qualitative analysis and contributed to subsequent drafts. All authors meet ICJME criteria for authorship.

This research received no specific grant from any funding agency, commercial or not-for-profit sectors.

Declaration of interest

None.

pmc Psychiatrists are now interesting to the general public. It was not always so. After years of meeting them only as cardboard cut-out figures in crime novels there is now curiosity about who they are and what they do. I have just finished reading Joanna Cannon's book *Breaking and Mending*, about the effect of psychiatry on the person. Written by someone exquisitely sensitive to every nuance in professional life, Joanna's book was an eye-opener for me with my more hardened exterior. Brian Barraclough's autobiography is very different. It satisfies the voyeur in the reader – what are the people psychiatrists treat really like and what do they get up to?

And there is much for the voyeur here. But this independently published book has a misleading title. Brian Barraclough does not come over as 'partly Anglicised'; he is a Kiwi through and through, and although his assiduous English wife Jennifer, also a well-known psychiatrist, has done some, possibly a great deal of, editing she cannot hide its craggy authenticity. Despite spending 38 years of his life in the soft underbelly of Sussex and Hampshire, Dr Barraclough has not acquired the veneer of many English sophisticates, who might write more smoothly. He has always lived in the marvellous upside down map of the world where New Zealand is securely on the top.

Here we read about the recent history of psychiatry. It is so odd that it is hard to believe it is recent and not ancient history. Barraclough fosters the old by giving an oral testimony, almost mediaeval in its bluntness, unapologetic and unadorned, thinking primarily not of the reader but of the need for accurate report. So, we are taken back to characters and experiences that some younger psychiatrists might find unbelievable. Dr Barraclough's mentor, Harold Bourne, bluntly tells a female medical student 'your vivid red lipstick represents a penis', and also, while maintaining he is primarily a psychoanalyst, practises long-term 'ECT maintenance' (i.e. giving courses of electroconvulsive therapy at intervals of a few weeks 'to avoid relapse'). We read about a woman who broke her teeth after unmodified ECT (she had osteogenesis imperfecta), another woman, a devout member of the Church of England who had severe obsessional disorder, who, after much deliberation, was recommended for a leucotomy. Afterwards she is observed by Barraclough to squat and defecate on the floor. She looks up and says, 'That is my shit, clean it up'. He also describes working for a psychiatrist who carried out 'behaviour change treatment' for homosexual men in a closed ward for 9 days, topped up with aversion therapy for others; there is no discussion of outcome.

You might think that these experiences might all come from New Zealand. No, half come from the Mecca of psychiatry in the 1960s, the Maudsley Hospital in London. This was the 'only decent place to study', according to Harold Bourne, where once trained, the inspired joined the diaspora to spread enlightenment to the hungry elsewhere. But this was a time when opinion, not evidence, guided clinical practice, even at the Maudsley. After all these experiences, it is not surprising that Dr Barraclough turned his attention to the dead, to the subject of suicide, where his contribution is widely praised and may be described more fully in a forthcoming volume.

1.2.62 The psychology of climate anxiety

Joseph Dodds¹

Correspondence

Dr Joseph Dodds

(jdodds@faculty.unyp.cz)

date

2021-08

Abstract

This paper focuses on climate anxiety and its role in the psychology of climate change, compared with responses to the COVID-19 global pandemic. Four psychological hypotheses for why we do not act on climate change will be reviewed, and the role of anxiety for each, as well as potential solutions. Different types of climate anxiety both inside and outside the clinic will be explored, along with associated defence mechanisms and treatment.

Climate psychology and climate anxiety

The past decade has seen the important development of climate psychology.^{1–7} Ursano and colleagues² describe climate change as one of the top threats to global health in the 21st century, and psychology has begun to respond. The American Psychological Association's 2010 report into climate change¹ identified six key areas for psychology, including risk perception, psychological and behavioural causes of climate change, psychosocial impacts of climate change, adaptation and coping strategies, psychosocial barriers to action and the role of psychologists. At the same time, psychotherapists and clinical psychologists are coming to terms with ecological loss, anxiety and guilt in their patients, and also among themselves, as they come to grips with the faltering biosphere.^{8,9}

This article focuses on climate anxiety and its role in climate psychology, while recognising that anxiety interacts with a range of other emotions such as grief and rage. The American Psychological Association¹⁰ refers to ecoanxiety as 'a chronic fear of environmental doom', ranging from mild stress to clinical disorders like depression, anxiety, post-traumatic stress disorder and suicide,^{11–13} and maladaptive coping strategies such as intimate partner violence^{14,15} and substance misuse.^{16–20} Cianconi et al²¹ found complex types of climate anxiety and trauma, including intergenerational effects, especially where environmental damage involves loss of a way of life or culture.

It is essential to differentiate between pathological and adaptive forms.²² *The Handbook of Climate Psychology*⁴ defines climate anxiety as a 'heightened emotional, mental or somatic distress in response to dangerous changes in the climate system', but suggests that 'paying heed to what is happening... is a healthier response than turning away in denial or disavowal'. Climate anxiety can lead to symptoms such as panic attacks, loss of appetite, irritability, weakness and sleeplessness,¹ yet given the increasing evidence about the impact of climate change on health, psychological professionals might ask if their patients feel too much anxiety, or whether they themselves feel too little. Climate anxiety is being felt much more powerfully among the young,^{23,24} by first responders to climate-related natural disasters^{25,26} and climate scientists and activists, who are exposed to information about the threat more than most and therefore may need psychological support.

When considering the effects of climate anxiety, it is necessary to focus on at-risk populations, including children, the elderly, the chronically ill, those with mental illnesses and those with mobility impairments.² Those from lower socioeconomic groups are disproportionately affected by climate change because of disparities in infrastructure and health resources. Severe weather events can also damage social support systems and mental health infrastructure, further isolating the most vulnerable.^{27–29} Clayton^{30,31} reports that anxiety, fatalism, hopelessness and fear have been increasing globally, and offers a clinical approach to understanding, measuring and treating climate anxiety, while emphasising the distinction between adaptive and maladaptive types, and the need to keep the society-level response required to combat climate change in mind.

Given our need to effectively mobilise in response to climate change, the Climate Psychology Alliance⁴ suggests that psychologists and psychotherapists should not aim to get rid of climate anxiety, but instead 'support individuals and communities to build strong containers that allow the expression and exploration of their emotions without collapsing under it or turning away'. Climate change is a psychological problem but that does not mean that it should be individualised or medicalised. As Lawton writes,³² if ecoanxiety is treated as pathology, 'the forces of denial will have won... what we are witnessing isn't a tsunami of mental illness, but a long-overdue outbreak of sanity'.

Why do we not act? Four psychological hypotheses

Climate anxiety is heightened in those that are aware of and *feel* the existential threat of climate change, by the fact that most of us, most of the time, act as if it does not exist. The poverty of collective responses to climate change is in stark contrast to its threat. Why do we not act? This section explores four psychological hypotheses, the role of anxiety for each, and comparisons with psychosocial responses to COVID-19.³³

Faulty alarm hypothesis: cognitive bias in our evolved risk detection system

This explanation suggests humans have evolved the ability to respond to certain types of threats optimally, especially those that are immediate, visible, fast (something happens so slowly that it slips our notice), with historical precedent, simple causality, clear and direct personal impacts or caused by an 'enemy' tribe or group.^{1,34,35} From this perspective, the problem with climate change is that we do not feel enough anxiety as it slips our notice by missing all of the characteristics above. The answer is to help us feel the anxiety, to motivate us to act, turning up the volume on the threat and our response. The lack of effective risk perception leads to behaviours that worsen climate change.³⁶ According to the 2018 American Psychological Association report, 'the perception of risk regarding climate change, belief in the ability to effect change, and the etiology attributed to extreme weather events are important factors impacting the decisions people make regarding climate change related behaviors'.²

Comparison with COVID-19

Both climate change and COVID-19 are environmental crises where human behaviour and psychology are important factors, yet the latter happens much faster, with clearer links between behaviour and consequence, leading to much more dramatic responses. International efforts to respond to COVID-19 may have the unintended benefit of shaking people out of climate lethargy, by showing that the global mobilisation required to confront climate change is possible, and allowing the public to see (and feel) that invisible environmental dangers are very real.³³ However, as with climate change, with the COVID-19 pandemic we also see huge levels of denial, anger and despair.

Social dilemma: bystander effect

Social dilemmas (or commons dilemmas) involve conflict between individual and collective self-interest.³⁷ For example, it is in every fisherman's interest for other fishermen to adopt quotas on how much fish can be caught every year to ensure fish stocks recover, but simultaneously, each would like to take what they can. Climate change is the ultimate commons dilemma.³⁸ How do we escape from this 'rational-disaster' model of human extinction? Games theory³⁹ studies such conflicts, most famously with the prisoners' dilemma. Anxiety here refers to not only the 'costs' of the game when played badly, but of predicting the behaviour of others. How can I trust that you will do the right thing? And how can I trust that you trust that I will do the right thing? Research in human and animal behaviour^{40,41} shows cooperative strategies can flourish in a wide range of contexts. The key is to focus on the structure of the game, to allow cooperative behaviour to flourish.

Comparison with COVID-19

Responses to both involve social dilemmas. When reviewing how successful different countries were/are in tackling the viral pandemic, it seems that a crucial factor was not the wealth of the nation, but its social cohesion and a collectivist versus individualistic orientation.⁴²⁻⁴⁴ To the extent that the measures were clearly enunciated, seemed fair and received widespread social support, systems of trust were established and each could play their part in the collective effort. Climate change is another order of complexity beyond COVID-19, but important lessons can be learned.

Ecopsychology: the problem of disconnection from nature

Since the 1990s, ecopsychology has emerged as a particular response within psychology to environmental problems, emphasising a holistic approach,⁴⁵⁻⁴⁸ suggesting that our modern lives are so disconnected from nature that we do not care enough to want to protect it, and fail to realise that we are threatened by damage to the natural world. Ecopsychology views disconnection from nature as also central to the current mental health epidemic.^{18,49} Reconnecting to nature is seen as a requirement for mental health that also provides the emotional link that will drive us to act (out of love, not just fear). Ecopsychologists emphasise that the anxiety, guilt, grief and anger we feel concerning collapsing ecosystems, our 'pain for the World', are appropriate and, although difficult, provides the starting point for action and a renewed relation to Earth.⁵⁰

Comparison with COVID-19

COVID-19 forces us to recognise that the 'split' between ourselves and nature is not real, and shows that our social systems are all too fragile in the face of environmental danger. On the other hand, ecopsychology tends to downplay that nature does at times try to kill us, and is not only a beneficial force that nurtures. For some, COVID-19 is a natural response of Earth to human degradation, as Gaia retaliates against a human civilisation getting too close to remaining wild spaces. In a sense, it has partially worked. COVID-19 has arguably done more than any climate treaty to reduce carbon emissions,³³ perhaps buying us a little more time. Some hope this is a moment for 'waking up', to take stock and give us a chance to change our futures.

Psychoanalysis: climate denial and apathy as a defence against anxiety

The psychoanalytic model of environmental problems^{5-7,51,52} focuses on the complex way humans deal with anxiety (see also terror management theory⁵³). In contrast to the faulty alarm hypothesis, the anxiety of climate change is seen as not too little, but too much, defended against through individual and socially structured defences.^{9,54} Defence mechanisms are strategies the ego uses to defend against anxiety, conflict and threats to self-esteem. From this perspective, as with the Faulty Alarm hypothesis, we need to be able to feel the anxiety (and other feelings) produced by climate change. However, merely amplifying messages of fear and guilt can backfire, by strengthening and rigidifying defences. Climate anxiety is therefore, in part, a realistic but painful response to our situation, and difficult to hold onto, especially in a social context of generalised denial.

Comparison with COVID-19

The psychoanalytic perspective helps explain certain factors the faulty alarm theory cannot account for, in particular, why responses to climate change include a substantial amount of anger and hostility. Climate scientists have been the recipients of death threats and abuse, and negative reactions in the context of COVID-19 are even more pronounced.

Types of climate anxiety and defence

Melanie Klein⁵⁵ identified two groups of anxieties. Paranoid–schizoid anxiety involves feelings of persecution and fears of annihilation and fragmentation, and is defended against by psychotic defences (denial of reality), projective identification and splitting. Depressive anxieties relate more to loss, guilt and fears of dependency, dealt with by neurotic defences. We can relate these to the findings of affective neuroscience,⁵⁶ which differentiates the FEAR system (involving the amygdala, medial and anterior hypothalamus, and the periaqueductal gray), which generates anxiety in response to external threats; and the PANIC system (centred on the anterior cingulate gyrus, with connections to thalamic, hypothalamic and other nuclei, such as ventral tegmental areas), which generates anxiety in response to the loss of attachment figures.

The psychoanalytic model suggests that the threat of climate change leads to two types of climate anxiety: first, the ‘apocalyptic’ fears (fears of death, annihilation and extinction); and second, complex feelings around loss, grief, dependency and guilt^{52,57} for losses that have already occurred and those that are to come (‘pre-traumatic stress’, ‘anticipatory mourning’, ‘solastalgia’^{58,59}). Responses to climate anxiety include proximal defences (pseudo-rational, threat-focused and more conscious), distal defences (functioning unconsciously and taking a symbolic form) and facing difficult feelings and generating adaptive responses.⁶⁰ Anxiety, guilt and loss become more manageable as they become more shared,⁶¹ and can be reflected upon in a safe space where realistic possibilities for action open up. All major defence mechanisms⁶² are clearly visible in relation to climate change, focused on the two emotional threats: denying the reality of climate change (it does not exist, it is a conspiracy), or denying our losses, dependency or responsibility (nature might die but we will be fine; it is caused by other humans or natural causes, the Chinese or the sun, not me).

There are many shades of variation: not only outright denial, but minimising the threat (it will not be that bad, it will happen in the future, or to other species or countries), by finding scapegoats through projection; intellectualisation (taking courses on climate change without allowing emotional responses or behavioural change); idealising charismatic leaders that support denial, repressing and suppressing awareness; reaction formation (denying the reality or the impulse while simultaneously giving expression to its opposite, e.g. those who ‘burn a tire for Earth day’ or participate in ‘coal-rolling’, becoming environmentally destructive to prove to themselves they either do not believe in climate change or do not care, as an attack against perceived group enemies, and a means of evacuating bad internal states); hopelessness (it is too late anyway); apocalypticism (the end of the world is exciting and allows for fantasies of the ‘bad’ being punished for their behaviours, and we can start again and better⁶³); or manic defence behaviours, such as seeking distraction through increasing addictive behaviours and consumption,^{18,19} to avoid thinking about the problem. A certain amount of climate activism is also of a manic reparation type, which can quickly lead to disillusion and burnout if the movement’s goals are not quickly met. These are just a few of the responses/defences that climate change evokes, with many reactions comparable with the COVID-19 pandemic.

Working with climate anxiety

Adams⁶⁴ asserts that treating climate anxiety needs to address the underlying dangers, and therefore requires meaningful collective responses, including ‘acknowledging loss collectively and publicly’ as ‘an important step in facing up to the reality of the Anthropocene and the impossibility of carrying on “as normal”’. Randall^{57,59} has emphasised the importance of experiencing and articulating difficult emotions, such as loss, grief and fear, in a shared context as a way of developing forms of mutual support. In addition to dealing with anxiety in their clinical practice, therapists can help support the development of social containers to express, contain and mobilise climate anxiety into positive social change.⁴ Ultimately, the results need to be measured in reduced carbon dioxide emissions rather than necessarily reduced expressions of fear.

By allowing feelings and thoughts we usually avoid to be brought into awareness, we can avoid more pathological unconscious acting-out. Bednarek⁶⁵ agrees that climate anxiety should not be seen ‘as a problem to be solved or a condition to be medicated’, but rather ‘an important encounter with our awareness of our impact on the world’. All of us need to wake up to climate anxiety, including mental health professionals. Those who are most informed about the current danger, such as scientists, journalists, students or activists, often express the most intense fears – an anxiety heightened by feeling isolated in a culture in denial.^{66,67} Instead of pathologizing their anxiety, which only worsens mental health, we can ask ‘what support do we collectively need in order not to freeze and anaesthetise ourselves against this context of so much loss?’⁶⁵

The answer lies not only from work in individual psychotherapy, but in developing strong social networks of supportive relationships, and a living relationship with the natural world.⁶⁸ Community is crucial for collective resilience, as we are seeing in the COVID-19 pandemic. Nature itself can function as one of these containing spaces.^{8,46,69} To conclude, the symptoms of climate anxiety are not necessarily feelings to be got rid of, but lessons to be learned, although only if they can be felt in a safe way, through developing meaningful action and positive social, psychological and ecological change.

Joseph Dodds (PhD) is a psychoanalyst (IPA) in private practice with the Czech Psychoanalytical Society, a psychotherapist (UKCP), Chartered Psychologist (BPS) and psychology lecturer with the University of New York in Prague, and the Anglo-American University..

Abstract

This editorial is co-written by a developmental psychologist and a young climate activist. We start by showing how the climate crisis is imposing a heavy psychological burden on children and youth, both from experiencing climate-related disasters and from the knowledge that worse is to come. We then describe the global movement of youth demanding urgent climate action. We conclude that health professionals can support young people in many ways, but particularly by supporting their capacity to take action, raising awareness about the impact of the climate crisis on youth mental and physical health, and taking action themselves to work for a secure climate future.

pmc .. _sec1:

The climate crisis poses an existential threat

Climate change is well underway and poses a critical threat to the future. Although the Earth is currently only about 1.1°C above preindustrial levels,¹ it is clearly already too hot.

The Global South (also referred to as low- and middle-income countries or the majority world) is currently bearing the brunt of climate change effects, but they are rapidly becoming more common globally; for example, unprecedented wildfires in the Amazon, Australia and California, record-breaking hurricanes in North America and record-breaking heatwaves in the UK and Europe. Glaciers and icecaps are melting faster than predicted, rising sea levels have already forced coastal and island populations to relocate, and droughts and resource shortages have already contributed to conflict and refugee crises.² Global warming is contributing to the Earth's sixth mass extinction, with about 1 million animal and plant species under threat.³ All these serve to heighten young people's awareness of the reality of the climate crisis.

We are fast approaching irreversible tipping points and, without moving speedily to net zero emissions and draw down the excess greenhouse gases already in the atmosphere, we face an existential threat to the global ecosystem and human civilisation.⁴ The well-being and even survival of today's children are at risk. As Aran Cosentino (Italy, aged 18 years) said, 'I am worried about climate change because the future of us young people is in danger. If governments do not act quickly, we will not have a future where we can live in peace with our children'.

Impact of climate change on child and youth physical and mental health

Both the causes and consequences of climate change are inequitably distributed. It has been disproportionately caused by the Global North, also referred to as high-income countries, the minority world or the WEIRD nations (Western, educated, industrialised, rich democracies), comprising 12% of the world's population,⁵ However, it will most severely affect the Global South,⁶ where 85% of children live⁷ but the institutional capacity to respond is weaker.^{8,9} Further, although predominantly caused by the current generation of adults, the worst consequences will occur during the lifetimes of today's children and young people,¹⁰ as reflected by Emma Demarchi (Australia, aged 17 years): 'Young people are facing climate related inter-generational theft and its effects on us are astounding'. Also, climate change will also reinforce societal inequalities based on income, ethnicity, race and class. For example, the United Nations International Children's Emergency Fund (UNICEF)¹¹ vividly illustrates how climate change exacerbates pre-existing socioeconomic inequalities. When confronted with an extreme weather event, like a drought, a child from a wealthier family may experience temporary hardship, but can recover relatively fast – their family can safely relocate and stay together, purchase food even when prices escalate, access clean water even when scarce, access healthcare even when services are overstretched, and maintain the child's education and reduce other social stressors. None of these may apply for a child in poorer circumstances, who may find themselves on an escalating downward pathway through the accumulation of negative repercussions, to result in long-term, and sometimes lifelong, deprivation.

Climate change has both direct and indirect effects on the physical and mental health of children and youth. Because of their immature physiological systems, reliance on adults and likely repeated exposure to climate events over time, children are more vulnerable to the negative effects of climate change than adults.^{12,13} Both sudden extreme weather events and slower, longer-lasting climate effects (e.g. rising sea levels, droughts) are increasing in frequency and ferocity. These, in turn, directly cause deaths and injuries, physical ill health (e.g. through malnutrition, lack of clean water, infectious diseases) and mental health problems, including post-traumatic stress disorder, anxiety and depression, phobias and panic, sleep disorders, cognitive deficits and intellectual disabilities.^{14–16} As one example, after floods in Pakistan, 73% of 10- to 19-year-olds displayed high levels of post-traumatic stress disorder symptoms, with displaced girls affected most seriously.¹⁶ Reactions to climate disasters also include distress, grief, anger, feelings of helplessness and hopelessness, and increased aggression and violence.¹⁷

More broadly, climate change threatens the underlying social, economic and environmental determinants of children's health.¹⁸ By disrupting families and communities, climate change can have an indirect impact on children; for example by increases in rates of domestic violence and child abuse after hurricanes and wildfires.¹⁹ Climate change causes and exacerbates conflict²⁰, being described as a 'threat multiplier' for intra- and interstate conflict.²¹ There are already millions of so-called 'climate refugees', forced to seek new homes, where they are often met with hostility and

resistance.²² The resultant disrupted parenting, education and social connections all have long-term sequelae for children and youth.^{16,23} Particularly for Indigenous youth, breaking their connection with the land can lead to mental health problems, including depression, despair and suicide.²⁴

Emotional responses to the climate crisis

Although adults may wish to protect children from knowledge of the climate crisis, this is neither possible nor right: the United Nations Convention on the Rights of the Child²⁵ confirms their right to know about, and be involved in, issues that will affect their future. Research around the world shows that most children and youth know about the climate crisis and are worried about it. A 2013 survey of British 11- to 16-year-olds found that 74% were worried about its impact on their future.²⁶ A more recent study of Australians aged 7–24 years indicated that 96% considered climate change a serious problem, and 89% were worried about its effects.²⁷ Even more recently, 16 young people summarised the results of a survey of 1477 young Australians (aged 10–24 years) as thus: ‘We are aware of climate change, and we are worried about climate change. We are concerned about the repercussions of climate change globally, regionally and here at home. We are concerned about experiencing climate-related disasters due to a lack of action by those in power, and we are worried about what that means for us, our families, and our friends, in the present, and in the future’.²⁸ A recent survey by the Royal College of Psychiatrists²⁹ found that 57% of child and adolescent psychiatrists reported seeing children and young people distressed about the climate crisis and the state of the environment.

The emotional impact of knowing about the climate crisis is not limited to ‘worry’. Children and youth also experience anger, frustration, depression, sadness, grief, anxiety and a sense of powerlessness about its impact on their lives.^{26,30} Interviews with 10–12-year-olds in the USA found that strong feelings of fear, sadness and anger were expressed by 82% of the children.³¹ In a 2019 survey of over 15 000 Australians aged 14–23 years, one in five reported planning to have no children, or fewer children, because of their concerns about climate change,³² as illustrated by Alice Hardinge (Australia, aged 23 years): ‘My future feels dire, and my decision to have children has been impacted by the fear of food shortages, droughts, fires and floods’.

Burgeoning rates of ecoanxiety (severe and debilitating worry) and ecological grief (grief related to current or anticipated ecological loss) are commonly described.³³ However, despite these emotional reactions being uncomfortable and, in extreme cases, debilitating, it should be recognised that they are based on a rational understanding of the climate science, and hence should not be regarded as unreasonable, illogical or pathological.

Children and youth taking action

For decades, children and youth have been responding to their knowledge of, and fears about, the climate crisis by demanding climate action from older generations and those in power. In the past 2 years, Greta Thunberg has been the face for the millions who have mobilised across the world, but back in 1992, 12-year-old Severn Cullis-Suzuki gave a speech at the United Nations Rio de Janeiro Earth Summit that ‘silenced the world for 5 minutes’. Severn said to world leaders, ‘You grown-ups say you love us. But I challenge you, please, make your actions reflect your words’.³⁴ Almost three decades later, in 2018, Greta Thunberg made a very similar speech to world leaders at the 24th United Nations Framework Convention on Climate Change (COP24) in Katowice, Poland: ‘You say you love your children above all else, and yet you are stealing their future in front of their very eyes’.³⁵ The similarities between the two speeches, almost three decades apart, starkly show how little has changed and how children and young people are right to feel frustrated.

Greta Thunberg began striking from school on 20 August 2018, vowing to stay until the Swedish election 3 weeks later. Initially it was just Greta and her sign ‘Skolstrejk för klimatet’ (‘school strike for the climate’), but from the second day others started joining her. After this first strike, Greta began boycotting class every Friday, announcing the strikes as ‘Fridays For Future’, which quickly gained international attention.

Showing how her actions resonated with children around the world, just a few months after Greta’s first day of striking, school students across the world had coordinated national school strikes involving thousands of children and youth, such as in Australia, where over 150 000 students took action in November 2018. The first global day of action followed on 15 March 2019, with strikes in over 100 countries, and by 20 September, just 13 months from the first climate strike, an estimated 4–6 million people participated in >2500 events in over 163 countries. This is estimated to be the largest climate mobilisation in world history.³⁶

Despite these massive displays of child and youth fear, anger, frustration and determination, their demands have ‘not translated into action’ and emissions have continued to rise whilst ‘the changes required are still nowhere in sight’, as Greta Thunberg said to world leaders at 25th United Nations Framework Convention on Climate Change (COP25) in Madrid, Spain, on 11 December 2019.³⁷ Now, in a time of global unrest, with concurrent crises facing young people, they continue to organise mobilisations with demands centred in an understanding of the fundamental ways in which social and economic issues are interlinked with the climate catastrophe.

Action is the antidote to despair

Conversations with students who have engaged in school strikes or other forms of activism show how their activism has helped them manage their anxiety about the future and channel it into determination, courage and optimism. As Alice Hardinge said, ‘Climate despair is real and dangerous, the best cure is action ... [taking action] creates a sense of solidarity, of cooperation and productivity in the face of despair’. This idea that ‘the best antidote to anxiety and despair is action’ suggests that an important way to build young people’s resilience, self-efficacy and agency is by encouraging and supporting their involvement in activities to both mitigate and adapt to climate change.³⁸

Young people involved in climate activism appear to have learned many valuable positive skills and attributes through their involvement. The Melbourne School Strike organiser and volunteer for the Australian Youth Climate Coalition, Andeli Zuz (Australia, aged 20 years), said: ‘Without the skills I learned in activism I simply would not have been able to do this job, as simple as that. It has taught me far more about community organising and event management than school ever could’. Another Melbourne school strike organizer, Emma Demarchi said: ‘Taking action on climate change can be incredibly rewarding and fulfilling and has certainly built many of my skills up’.

It is interesting to note that these skills and capacities which young people report developing through taking action on the climate crisis match well with those describing positive youth and young adult development,^{39,40} including self-regulation of behaviour and emotions, ‘bigger-than-self’ values such as social justice, conflict resolution skills, teamwork skills and social and civic engagement skills. As Alice Hardinge said: ‘I’ve learnt how to ... talk to authority figures, recognise my rights, speak confidently in public ... not let keyboard warriors impact my self-worth ... communicate non-violently and how to work effectively in a non-hierarchical and consensus based collective’. These skills will stand them in good stead throughout their lives.

Yet, although taking climate action is highly rewarding and beneficial for young people, the burden and scale of the climate crisis is often overwhelming. For example, Emma Demarchi said: ‘Climate action can also very often feel just as lonely and full of despair and anxiety. Young people often feel like they are fighting a battle they need to win but know they might never and the impacts on mental health can be great’. Andeli Zuz commented: ‘Sometimes it [climate action/advocacy] makes me feel empowered, like I have some control, other times deflated as I feel like no matter what I do it won’t work’.

Young people who feel immense pressure and responsibility to do all they can to protect the future are thus at risk of burnout and mental strain. To sustain their mental health, engagement and empowerment, strong communities and support networks that are honest and hold space for their feelings are vital. Mental health professionals have an important role in validating such feelings, helping young people manage them and supporting their activism. It is encouraging to see some resources to support such work now being developed. For example, the Royal College of Psychiatrists has recently produced a resource to help young people cope with ecodistress.⁴¹ However, equally critical is to demonstrate to young people that they are not being asked to take the whole burden themselves; this entails mental health professionals themselves taking action, and using their influence and expertise to work for speedy and effective policy change to help secure a habitable planet and a safe future for the next generation.

There are other important roles for mental health professionals. For example, in response to the confusion that many parents express about how to talk to, and support, their children in the context of the climate crisis, parent-focused resources were developed by the Australian Psychological Society,^{42,43} and can be used in community workshops. Not all children and young people, nor all mental health professionals, are aware of the implications of the climate crisis for the next generation, creating an ongoing need for education in work places, practice and through written material. It also needs to be acknowledged that facing up to the reality of the climate crisis is challenging for mental health professionals themselves. In Australia, Psychology for a Safe Climate (<https://www.psychologyforasafeclimate.org>) has developed resources and methodologies for supporting activists, including health professionals, to manage their

climate grief. In advocating for policy change, strong position statements from our professional organisations can be a valuable tool.

Concluding comments

The climate crisis is already placing significant psychological burdens on children and young people, from both direct experience and simply knowing the dangers it poses for their future. Yet until recently, children's voices have been neglected in discussions of the climate crisis. But the courage and determination of Greta Thunberg acted as a catalyst for children in their millions to raise their voices and demand to be taken seriously, and to demand action.
