The risks highlighted in the book are not limited to addictive behaviours such as internet or gaming addiction, but also include cyberbullying and the increased risk of suicide due to pro-suicide websites and suicide pacts. Cyberbullying is perhaps one of the most common problems linked with the use of technology to date and it is not unusual for me and my team to see children and adolescents who refuse to go to school as a result of cyberbullying. Unlike conventional forms of bullying, cyberbullying implies the use of social networks and internet-based messaging services to harass an individual. This work examines not only the prevalence of the problem, but also the various prevention strategies available, such as having a specific academic curriculum to deal with the issue.

The authors review the existing literature comprehensively – referring also to current evidence – and look at the potential of technology across several areas of mental healthcare, including the provision of psychotherapy and the integration of patients' health records. They also discuss how recent advances – such as virtual reality – could in principle be a powerful tool in exposure therapy. As a team with an interest in e-health, my colleagues and I have been developing smartphone applications for various mental health disorders. The introduction of virtual reality technology means that we could perhaps tap on games and various other sensors and headset devices to create an interactive environment not just for psychotherapy but for other forms of interventions too.

This is a good guide for novices in e-health but equally a useful tool for the more experienced in this area. It would be helpful if a future edition included more detailed coverage of smartphone applications and their inherent risks and benefits – a topic of concern not only for clinicians, but patients at large.

1.7.54 MCQs in Psychiatry for Medical Students

Suzanne Dash¹

date

2017-6

Contents

- *MCQs in Psychiatry for Medical Students*

Love them or loathe them, most medical student written examinations now take the form of multiple choice questions (MCQs). Some medical educators dislike this assessment style, suggesting it encourages students to learn isolated facts in a superficial way. Yet, undeniably, MCQs provide an objective, time-efficient manner of evaluation.

MCQs in Psychiatry for Medical Students is a valuable resource for medical students undertaking their psychiatry rotations. It includes MCQs and extended matching items grouped into chapters concerned either with a type of disorder – for example, psychotic disorders and alcohol and substance misuse disorders – or another important aspect of psychiatry, such as physical health, pharmacological treatments, psychology and psychotherapy.

Each MCQ is accompanied by a paragraph or two explaining the correct answer. More information is provided than is strictly necessary to understand the answer, but this is illuminating rather than turgid. The 400-plus contemporary references encourage the reader to consider issues in more depth than the superficial learning style many associate with MCQs, making the scope of this book potentially greater than is obvious from its title. In contrast, the three extended matching item questions in each chapter are not followed by explanations, making them far less informative.

Writing good MCQ distractor items is a challenge, and in a few places – especially questions on risk factors and protective factors – it is possible to guess the answer by eliminating answers simply based on whether they describe something positive or negative.

This is a must-have title for all medical students; it will pique the interest of many students and may even assist in recruiting future psychiatrists to the profession.

1.7.55 Falls in Scottish homicide: lessons for homicide reduction in mental health patients

Abstract

The sustained fall in Scottish homicide rates follows crime reduction measures informed by the epidemiology of suicide. The violence reduction unit targeted young men carrying knives in public. The restriction of weapons immediately to hand appears to have caused an absolute fall in homicide just as suicide reduction was observed following changes to domestic gas supply. Further homicide reduction may be accomplished in the domestic setting with targeted changes in kitchen knife design in home safety planning for high-risk households. Most commonly homicides involving those in recent contact with mental health services in the UK have domestic characteristics and similar safety planning may be targeted at those with mental disorder and a history of violence.

Contents

- *Falls in Scottish homicide: lessons for homicide reduction in mental health patients*

The sustained fall in Scottish homicide rates to 10.65 per million in 2015–2016 marks a 60% fall in the homicide rate since the peak of 26.3 per million in 2005.^{1,2} The greatest fall in homicide involves encounters between young men in public places. The Violence Reduction Unit, formed in 2005, utilised a public health approach to target young men with educational programmes and stiff penalties aimed at achieving reduction in knife carrying outside the home.³ From 2005 to 2016 police in Scotland recorded a 69% fall in cases of offensive weapon carrying.⁴ From 2008 to 2015, Scottish hospitals saw a 63% fall in admissions and a 50% reduction in deaths arising from assaults with a sharp object.⁵ Limiting the availability of a lethal weapon immediately to hand outside the home has been associated with a dramatic decline in homicide and serious injury.

The targeting of knife carrying in Scotland is an example of situational crime reduction, a highly successful approach inspired by the fall in suicide following changes to domestic gas supply.⁶ The model, aimed at increasing the difficulty of accomplishing a criminal act, arose from observing the marked decline in the UK suicide rate associated with the change from coal gas to natural gas.⁷ A major means of suicide – placing one’s head in an unlit oven and breathing in the gas – abruptly disappeared. Not only was there a dramatic fall in carbon monoxide suicides but a fall in the number of suicides overall. It can be inferred then that there are a group of individuals who, while apparently committed to dying by suicide, can be deviated from a life-ending course of action by a seemingly trivial inconvenience.

Despite the fall in overall Scottish homicides, this has not been observed in homicides associated with those in recent contact with mental health services.⁸ The stereotype of homicides associated with mental disorder involving stranger victims and unusual weapons in public places is false. In a 10-year review of 870 UK homicides carried out by current or recent users of mental health services, the homicide victim was a spouse or ex-spouse in 21% of cases, another family member in 18% and other acquaintances 46%; 15% were stranger victims, as opposed to 24% stranger victims for all homicides.⁸ Similar findings were observed in a 15-year series of 271 homicides carried out by mental health patients in England, where 42% occurred in the shared home of the victim and perpetrator, 25% at the victim’s home and 4% in the perpetrator’s home.⁹ To test the hypothesis that ordinary objects were used in such homicides, this cohort was re-examined: 45% overall involved a knife and of those knives that could be identified 85% were kitchen knives.¹⁰ Homicides associated with mental disorder typically have domestic characteristics, involving family or acquaintances in a domestic setting, not the homicide type targeted in the Scottish campaign.

The evidence would suggest that limiting weapon carrying in public reduces homicides outside the domestic setting, but how can this be achieved within the home where kitchen knives are required? Long sharp-tipped knives have limited specific culinary utility and alternative designs are available.¹¹ One design has an ‘r’ shaped tip and has been

demonstrated as being as effective as wearing an anti-stab vest in a thrust to the torso (details available from the author on request), although similar benefits to safety may be achieved with a rounded or square tips.

Perhaps murder mythology in fiction and in the news media, with its emphasis on the exceptional and planned murder, obscures the possible benefits to changes to knife design, which may reduce the injury of unplanned acts of impulsive violence within the home.¹² Yet there is media bias for reporting the unusual, stranger homicide involving those with mental disorder.¹³ This obscures the role of promoting home safety measures utilised in domestic violence reduction for those with mental disorder and a history of violence and weapon use. Such a public health approach could be criticised for restricting freedom and would not stop a planned act of violence. Conversely, this may provide a way of generalising the benefits observed in Scotland to a domestic situation. The role of simple barriers to immediate weapon use in homicide reduction may also indicate strategies for violence reduction in other contexts.

The author gratefully acknowledges colleagues at The Orchard Clinic, Edinburgh, for their constructive comments and support.

1.7.56 Evaluation of the 13-item Hypomania Checklist and a brief 3-item manic features questionnaire in primary care

Sukhmeet Singh Paul Scouller Daniel J. Smith

Correspondence

Daniel J. Smith

(daniel.smith@glasgow.ac.uk)¹

date

2017-8

Abstract

Aims and method The mean delay for bipolar disorder diagnosis is 10 years. Identification of patients with previous hypomania is challenging, sometimes resulting in misdiagnosis. The aims of this study were: (a) to estimate the proportion of primary care patients with depression currently taking antidepressants who have undiagnosed bipolar disorder and (b) to compare a brief 3-item manic features questionnaire with the Hypomania Checklist (HCL-13). The sample comprised patients with a recorded diagnosis of depression, either on long-term antidepressant therapy or with previous multiple courses of antidepressants.

Results Of 149 participants assessed, 24 (16.1%) satisfied criteria for bipolar disorder. Areas under the curve (AUC) for the 3-item questionnaire and the HCL-13 were similar (0.79 and 0.72, respectively) but positive predictive values (PPV) were low.

Clinical implications Bipolar disorder may be underdiagnosed in primary care. A 3-item questionnaire could be used by general practitioners to screen for bipolar disorder in their patients with depression.

 - * *Clinical implications*

Bipolar disorder affects at least 1–2% of the population and is associated with considerable psychosocial impairment.^{1–4} Accurate diagnosis can be difficult because patients tend initially to present in primary care for help with depression rather than with manic features, and many primary care practitioners do not systematically assess for a history of bipolar disorder.^{5–7} Recently the National Institute for Health and Care Excellence (NICE) recommended that all patients in the UK presenting to primary care with depression should be assessed for a history of manic features, specifically ‘previous periods of overactivity or disinhibited behaviour’.⁸

Recent screening studies of bipolar disorder in UK primary care have identified that between 7 and 10% of individuals with depression may have undiagnosed bipolar disorder, usually bipolar disorder type II.^{9,10} It is also the case that individuals with difficult to treat depression and those with poor response to antidepressants are more likely to have unrecognised bipolar disorder.¹¹

In this context, we aimed to estimate unrecognised bipolar disorder within a sample of primary care patients with depression who were taking antidepressant medications, as well as to evaluate the potential clinical utility of two short screening questionnaires for bipolar disorder: the 13-item Hypomania Checklist (HCL-13)¹² and a brief 3-item manic features questionnaire. Our focus on these brief assessment instruments was stimulated by the need for questionnaires that could be used easily in primary care consultations, which are usually no longer than 10–15 min.

Method

Sample

Practice managers of 9 primary care practices in the west of Scotland identified from their databases 2633 patients who (a) had a recorded diagnosis of depression and (b) were either currently taking long-term antidepressants (more than 12 months) or had had 3 or more courses of antidepressants in the past 5 years. Then, 1860 potentially eligible patients were reviewed by their general practitioner (GP) for eligibility and 1833 written invitations were sent by post, with participant information sheets, on behalf of the research team. There were 204 people who responded to this invitation and 151 were interviewed, giving a response rate of 8.23%. The study was approved by the West of Scotland Research Ethics Committee (reference: 13/WS/0071 18th, approval letter dated April 2013).

Assessment measures

A research nurse completed the Structured Clinical Interview for DMS-IV (SCID-1)¹³ in person in order to obtain a gold-standard diagnosis. An assessment of practice notes was also conducted to corroborate findings from the SCID-1 assessment and to clarify medication regimens. Participants completed the HCL-13 and a brief 3-item bipolar screening questionnaire. This 3-item questionnaire (with a maximum score of 6) was based on the three core diagnostic features for bipolar disorder taken from DSM-5: elevated mood, severe irritability and overactivity.¹⁴ The questions and scoring were as follows: Have you ever had a period of time when you were feeling so good, 'high', excited or 'hyper' that other people thought you were not your normal self or you were so 'hyper' that you got into trouble? (Definitely no (score 0), perhaps yes (score 1), definitely yes (score 2).) What about a period of time when you were so irritable that you found yourself shouting at people or starting fights or arguments? (Definitely no (score 0), perhaps yes (score 1), definitely yes (score 2).) What about a period of time when you were physically much more active than usual, for example, when you had lots of different projects on the go at the same time? (Definitely no (score 0), perhaps yes (score 1), definitely yes (score 2).)

Analyses

Analyses included the Student's *t*-test, chi-squared test and chi-squared test for association, and were conducted using SPSS version 21 for Windows. To assess the likely clinical usefulness of the HCL-13 and 3-item questionnaires, in terms of differentiating between bipolar disorder and major depressive disorder (MDD), we calculated sensitivity, specificity, positive predictive value (PPV) and negative predictive value (NPV) using MedCalc and verified these manually. Positive and negative clinical utility measures were calculated using an online calculator constructed by the developer of the MedCalc test (www.psych-oncology.info/cui.html).¹⁵

Results

Of those who had a full diagnostic assessment, two participants were excluded because their SCID results suggested a primary diagnosis of alcohol-related mood problems. In total, 24 participants from our final sample of $n = 149$ had a DMS-IV diagnosis of bipolar disorder (16.1%; 95% CI 10.8–23.2%) and the remainder had a diagnosis of MDD ($n = 125$, 83.9%).

There were no significant differences between the bipolar disorder group and the MDD group in terms of age, gender distribution and socioeconomic status (assessed using the Scottish Index of Multiple Deprivation, SIMD) (*Table 1*). However, as expected, the bipolar disorder group had higher mean scores on the HCL-13 (9.21 *v.* 6.61, $P = 0.001$) and on the 3-item questionnaire (4.79 *v.* 2.88, $P < 0.001$).

Characteristics of participants with major depressive disorder (MDD) and bipolar disorder

	MDD (<i>n</i> = 125)	Bipolar disorder (<i>n</i> = 24)	<i>P</i>
Age, years: mean (s.d.)	47.50 (10.50)	47.58 (8.79)	0.972 <i>a</i>
Females: <i>n</i> (%)	77 (62.6)	15 (62.5)	0.992 <i>b</i>
SIMD 1: <i>n</i> (%) <i>d</i> (most deprived quintile)	56 (45.5)	14 (58.3)	0.705 <i>c</i>
SIMD 2: <i>n</i> (%)	20 (16.3)	2 (8.3)	
SIMD 3: <i>n</i> (%)	15(12.2)	4(16.7)	
SIMD 4: <i>n</i> (%)	13 (10.6)	1 (4.2)	
SIMD 5: <i>n</i> (%) (most affluent quintile)	18 (14.6)	3 (12.5)	
HCL-13: mean (s.d.)	6.61 (3.36)	9.21 (2.77)	0.001 <i>a</i>
3-item questionnaire: mean (s.d.)	2.88 (1.84)	4.79 (1.56)	<0.001 <i>a</i>

HCL-13, Hypomania Checklist 13; SIMD, Scottish Index of Multiple Deprivation.

Student *t*-test.

Chi-squared test.

Chi-squared test for association.

No SIMD data for 1 participant with MDD.

ROC analyses

The receiver operating characteristics (ROC) curves in *Fig. 1* demonstrate that both the HCL-13 and the 3-item questionnaire performed well in terms of differentiating between MDD (*n* = 125) and bipolar disorder (*n* = 24). For the HCL-13, an area under the curve (AUC) of 0.72 (95% CI 0.61–0.84) demonstrates a ‘fair’ overall ability of the questionnaire to discriminate effectively between the two groups. Similarly, an AUC of 0.79 (95% CI 0.69–0.89) for the 3-item questionnaire also demonstrates a ‘fair’ overall ability. An AUC of over 0.80 is considered to demonstrate a ‘good’ overall ability to discriminate.¹⁶

Table 2 presents the sensitivity, specificity, PPV, NPV and likelihood ratio analyses. For the HCL-13, a threshold score of 8 points had a sensitivity of 75.0% and specificity of 55.28% but PPV was low at 24.66%. At a higher threshold of 9 points, the sensitivity was 70.83%, specificity was 63.41%, PPV was 27.42% and NPV was 91.76%. At the lower threshold of 7 points, the sensitivity was 79.17%, specificity was 52.03%, PPV was 24.36% and NPV was 92.75%. Therefore, a threshold of 4 points was chosen to give the best balance between different statistical parameters.

HCL-13 and 3-item questionnaire screening for bipolar disorder

Questionnaire	Threshold	Sensitivity (%) (95% CI)	Specificity (%) (95% CI)	PPV (95% CI)
HCL-13	13 points	4.17 (0.11–21.12)	99.19 (95.55–99.98)	50.00 (1.26–98.7)
	12 points	12.50 (2.66–32.36)	95.12 (89.68–98.19)	33.33 (7.49–70.07)
	11 points	45.83 (25.55–67.18)	87.80 (80.68–93.01)	42.31 (23.35–63.08)

Table 12 – continued from previous page

Questionnaire	Threshold	Sensitivity (%) (95% CI)	Specificity (%) (95% CI)	PPV (95% CI)
10 points	60.50 (40.59–81.20)	78.05 (69.69–85.01)	35.71 (21.55–51.97)	91.43 (84.35–96.00)
9 points	70.83 (48.91–87.38)	63.41 (54.25–71.91)	27.42 (16.85–40.23)	91.76 (83.77–96.00)
8 points	75.00 (53.39–90.23)	55.28 (46.06–64.25)	24.66 (15.32–36.14)	91.89 (83.18–96.00)
7 points	79.17 (57.85–92.87)	52.03 (42.84–61.12)	24.36 (15.35–35.40)	92.75 (83.89–96.00)
6 points	83.33 (62.62–95.26)	36.59 (28.09–45.75)	20.41 (12.93–29.74)	91.84 (80.40–96.00)
5 points	91.67 (73.00–98.97)	24.39 (17.10–32.95)	19.13 (12.39–27.52)	93.75 (79.19–96.00)
4 points	95.83 (78.88–99.89)	16.26 (10.22–23.99)	18.25 (11.94–26.12)	95.75 (79.19–96.00)
3 points	100.00 (87.75–100.00)	15.45 (9.56–23.07)	18.75 (12.40–26.60)	100.00 (82.35–100.00)
2 points	100.00 (85.75–100.00)	15.45 (9.56–23.07)	18.75 (12.40–26.60)	100.00 (82.35–100.00)
1 point	100.00 (85.75–100.00)	11.11 (6.05–18.25)	18.75 (12.40–26.60)	100.00 (75.29–100.00)
3-item questionnaire	6 points	45.83 (25.55–67.18)	88.62 (81.64–93.64)	44.00 (24.40–65.00)
	5 points	66.67 (44.68–84.37)	78.05 (69.69–85.01)	92.31 (85.40–96.00)
	4 points	83.33 (62.62–95.26)	64.23 (55.09–72.67)	95.18 (88.12–96.00)
	3 points	91.67 (73.00–98.97)	43.09 (34.20–52.32)	96.36 (87.47–96.00)
	2 points	95.83 (78.88–99.89)	28.45 (20.69–37.29)	97.22 (85.47–96.00)
	1 point	95.83 (78.88–99.89)	9.76 (5.14–16.42)	92.31 (63.97–96.00)

HCL-13, 13-item Hypomania Checklist; NPV, negative predictive value; PPV, positive predictive value.

Similarly, a threshold score of 4 on the 3-item questionnaire had a sensitivity of 83.33%, specificity of 64.23% and PPV of only 31.25%. At a higher threshold of 5 points, the sensitivity was 66.67%, specificity was 78.05%, PPV was 37.21% and NPV was 92.31%. At a lower threshold of 3 points, sensitivity was 91.67%, specificity was 43.09%, PPV was 23.91% and NPV was 93.36%. Therefore, a threshold of 4 points was chosen to give the best balance between these different parameters.

The positive clinical utility – the ability of the test to confirm cases of bipolar disorder – was poor for both tests. The negative clinical utility a measure of screening and excluding bipolar disorder, was slightly better for the 3-item questionnaire than the HCL-13 at our threshold values: 0.611 (95% CI 0.541–0.682) compared with 0.582 (0.509–0.655). These thresholds were chosen to give the best balance between sensitivity, specificity, PPV, NPV and positive and negative clinical utility

Discussion

One of the goals of this study was to estimate how common DMS-IV bipolar disorders might be in a sample of primary care patients taking antidepressant medication, specifically those patients who were either taking antidepressant therapy for more than 12 months or who had had multiple courses of antidepressants over the preceding 5 years. We found that 16.1% of our sample had bipolar disorder. This rate is higher than in previous literature from the UK. In samples of primary care patients, Hughes *et al*¹⁰ found a prevalence of 7.3% whereas Smith *et al* found a prevalence of 9.6%. Both studies assessed patients with depressive disorder who had been prescribed antidepressant medication. It is possible that the addition in our study of participants who had previously been prescribed multiple courses of antidepressants led to a higher prevalence estimate for bipolar disorder, because unrecognised bipolar disorder is more common in patients with more severe and enduring depression.¹⁷

We also aimed to compare the HCL-13 and a brief 3-item questionnaire in terms of their ability to differentiate between patients with MDD and bipolar disorder. We found that the AUC for HCL-13 was 0.72, while for the 3-item questionnaire it was slightly higher, at 0.79. For both tests the ability to discriminate between MDD and bipolar disorder in terms of sensitivity and specificity was reasonable, but PPVs were low. This is a function of the low prevalence of bipolar disorder in primary care setting, but represents a potential limitation in terms of the usefulness of these instruments to GPs in everyday clinical practice.¹⁸ In a review of brief screening instruments for depressive disorder in a low-income country, Hanlon *et al*¹⁹ concluded that the low PPV at acceptable sensitivity levels may preclude their use in clinical settings.

Nevertheless, we would argue that there may be some use in primary care for these brief screening instruments alongside additional assessments, for example whether patients have a strong family history of mood disorder. The 3-item questionnaire in particular may be useful to GPs in terms of fulfilling the NICE requirement to assess all patients with depression for a history of manic features. The high NPV of 95% means that clinicians may find this useful for excluding a diagnosis of bipolar disorder in their patients with depression. The NICE guidance states that the ideal instrument should be brief, easy to administer and to score, and should be able to be interpreted without extensive and specialist training.⁸

Strengths and limitations

This was a reasonably large study that took a systematic approach to screening patients in primary care settings. We used definitions of bipolar disorder and MDD based on formal diagnostic classifications by using SCID assessment. The study included a range of people from different social backgrounds, with the majority living in some of the most deprived areas of Scotland. However, it may have been helpful to have more baseline demographic information on patients, such as ethnicity, family history of bipolar disorder and age at onset of depression, and the study may be subject to recall bias because it relied on the patient's recall of prior episodes of manic symptoms rather than a corroborative history. There may also be an issue of selection bias, because GPs were able to exclude certain participants if they felt that they were not suitable for this study. As a result of this, and the fact that only one method of recruitment was used in this study, there was a relatively small final sample given the number of invitations sent, which may have led to ascertainment bias. Moreover, the SCID interviewer was not masked to HCL-13 and 3-item scores, which may also have been a source of bias.

Another potential limitation is that the 3-item questionnaire had no requirement for a minimum duration of symptoms. It is possible that individuals with brief periods of affective instability, such as those with borderline personality disorder, would be inclined to respond positively to these questions. Similarly, we did not take a history of alcohol or drug use, and while we did exclude alcohol or substance-induced mood disorders, the use of psychoactive substances could have led to false positives with the 3-item questionnaire.

Clinical implications

A brief 3-item questionnaire may be clinically useful for GPs who wish to screen for manic features in patients with MDD. This could prompt more detailed assessment, such as an appointment with a relative or friend to obtain a collateral history before assessing the need for a referral to secondary care. Further studies are required in larger samples to assess the clinical usefulness of this test in screening, ideally without the issues of recruitment faced in this study. It may also be helpful to develop the 3-item questionnaire further, perhaps with the addition of other items such as the duration of symptoms. While the addition of items would lead to a more statistically sound test, it would also take longer to administer such a test, which may make it less clinically useful.

A proportion of primary care patients with MDD, perhaps as many as 1 in 5, may have undiagnosed bipolar disorder. For busy clinicians working in a time-restricted environment, we suggest that a brief 3-item questionnaire may be a useful screening tool for bipolar disorder and a first step towards a more comprehensive assessment.

1.7.57 Flexible assertive community treatment (FACT) model in specialist psychosis teams: an evaluation

2017-8

Abstract

Aims and method The impact of flexible assertive community treatment (FACT) has been observed in people previously supported by assertive community treatment (ACT) teams, but its effect on those previously with a community mental health team (CMHT) has not been studied in the UK. An observational study was conducted of 380 people from 3 CMHTs and 95 people from an ACT team, all with a history of psychosis, following service reconfiguration to 3 FACT teams.

Results People previously with a CMHT required less time in hospital when the FACT model was introduced. A smaller reduction was observed in people coming from the ACT team. Both groups required less crisis resolution home treatment (CRHT) team input.

Clinical implications FACT may be a better model than standard CMHT care for people with a history of psychosis, as a result of reduced need for acute (CRHT and in-patient) services.

Recent years have seen a widespread disinvestment from assertive community treatment (ACT), with many teams being merged into generic community mental health teams (CMHTs).^{1,2} Such changes have been criticised for moving away from evidence-based systems, instead adopting untested models of service delivery, with poorer quality care, described in a King's Fund report as 'a leap in the dark'.³ In some cases new services have adopted a flexible ACT (FACT) model, with people able to access intensive support delivered in the community using a team case-load and ACT principles, as and when they require it.^{4,5} In this model, care coordinators manage individual case-loads, but also work together to provide shared care for people at times of increased need, enabling seamless transition between high- and low-intensity care.

An observational study in the UK has not shown negative effects in people previously supported by ACT teams in terms of hospital admissions or need for crisis resolution home treatment team (CRHT) interventions.^{6,7} However, there have been no UK studies assessing whether there could be advantages for people previously supported by a CMHT but now receiving FACT. It might be expected that some people who have not previously had access to periods of more intensive support within the CMHT could benefit from the FACT approach, perhaps with a reduced need to have interventions from a CRHT or hospital admission.

Method

In South Warwickshire there had previously been a single, well-established ACT team, with outcome data over a 10-year period showing a reduced need for time in hospital.⁸ The area was also served by three generic CMHTs and a single early intervention team. The early intervention services were maintained, whereas each of the three CMHTs was divided into a team for people with a history of psychosis (recovery teams) and a team for people with other non-organic mental disorders. At the same time they became 'age-independent', with no upper age limit. The previous ACT team was disbanded and merged into the new recovery teams, which were configured to deliver services using the FACT model. A few months prior to the changes, the ACT team had absorbed a community rehabilitation team and therefore fidelity to the original ACT model had reduced. Characteristics of the ACT, CMHT and FACT teams are shown in *Table 1*.

Characteristics of the different teams

	CMHT	ACT	FACT
Case mix	People with psychotic or non-psychotic disorders	People with history of severe psychosis who have difficulty engaging with traditional services and often with comorbid problems	People with a history of psychosis
Age range, years	17–65 for new referrals, no upper age limit for existing users of the service	17–65 for new referrals, no upper age limit for existing users of the service	17 and upwards for new and existing users of the service
Care planning	Individual case management	Shared care	Individual case management with periods of shared care as needed
Interface with mental health professionals	Referrals made between professionals when needed	All professionals involved in delivery of care without referrals, on a needs-led basis	All professionals involved in delivery of care without referrals, on a needs-led basis
Care coordinator: patient ratio	30	12–15	25

ACT, assertive community treatment; CMHT, community mental health team; FACT, flexible assertive community treatment.

There was no change in acute hospital bed availability during the study period. However, a long-stay rehabilitation ward was closed at about the same time as the other changes took place, with most residents being discharged either to nursing homes or to intensive community placements with 24-hour live-in staff support. This group had been care-coordinated by the ACT team both prior to and following discharge.

The current study was a service evaluation of the new FACT-based recovery teams. It assessed their impact in enabling people to avoid time in hospital, to reduce the use of crisis home treatment support, and to examine how much face-to-face support people received from the new service. There were multiple changes associated with setting up the teams, all of which took place in June 2014. Many people experienced a change in care coordinator and/or consultant, and there were various teething problems with the transition. In order to avoid these becoming confounding variables, we chose to study a 13-month period starting 6 months after the creation of the new services: December 2014 until January 2016. We compared this with a 13-month period in the old services a year earlier (December 2012 until January 2014).

The trust uses a computerised notes system for all staff in the community, which constitutes the sole record of any contacts with clients. It can generate detailed reports on clinical contacts between specified time periods, broken down by team or staff member, and is routinely used for gathering trust performance data. Because people are constantly moving in and out of services, we decided to study only those people who were open to the new FACT service during the 13-month study period, and who had also been in one of the 3 CMHTs or the ACT team during the comparison 13-month period. Because of the closure of the rehabilitation ward, there was potential for a considerable impact on bed use data in the ACT arm of the study – the patients, having spent several years in hospital, were moving to nursing care or 24-hour live-in support. For this reason, we excluded from the bed use analysis those who were being discharged from hospital after several years into nursing or live-in community care.

Results

A total of 475 people who had also been with one of the previous legacy teams the year before were identified as being open to the new service. Of these, 95 had previously been with the ACT team and 380 with one of the CMHTs. Results were analysed separately for these two groups. Tests of significance between the old systems and the new FACT service were carried out using 2-tailed paired *t*-tests or, when data were skewed, using the Wilcoxon signed rank test. A Monte Carlo permutation test, as described by Good⁹ and derived from Fisher,¹⁰ was used when there was no standard statistical method available, such as to compare partially paired data. This type of testing gives a *P*-value directly (much like Fisher's exact test) without an intermediary test statistic such as a *t*-value. To keep the false detection rate (i.e. the overall type 1 error) low at 0.05 on account of multiple testing, we used the Benjamini-Hochberg¹¹ correction, which gave a significance level alpha of 0.0288. This means that *P*-values of less than 0.0288 are significant. Where a significant difference was observed in one group but not in the other, *post hoc* power calculations were carried out in order to check for any potential type 2 errors. Demographic and clinical characteristics of people from the two legacy teams are shown in *Table 2*.

Demographic and clinical characteristics of the cohorts

Previous team	ACT (<i>n</i> = 95)	CMHT (<i>n</i> = 380)
Gender, male: %	66.0	54.2
Age, years: mean	45.3	47.7
Time in services, years: mean	13.7	11.0
ICD-10 diagnosis, %		
Schizophrenia	78.3	53.4
Schizoaffective disorder	16.3	4.7
Bipolar affective disorder	4.3	28.2
Other	1.1	13.8

ACT, assertive community treatment; CMHT, community mental health team.

Face-to-face contacts with the FACT teams

For people previously with the ACT team, the number of face-to-face contacts with a member of the new FACT team reduced from 1.16 to 0.69 per week, with a corresponding reduction in mean duration of contacts from 65 to 38 minutes per person. These differences were statistically significant and are of similar magnitude to the changes observed in the other UK study of FACT.^{6,7} The number of contacts by support workers was not significantly different (0.25 compared with 0.29), but the proportion increased from 22 to 43%. In other words, the reduction of face-to-face contacts in the new FACT system for people previously in the ACT team was a result of less involvement of qualified staff. The number of community-based contacts reduced significantly in the new service, but the proportion was greater, indicating that, overall, more contacts had been lost in clinic settings compared with those in the community. For people previously with a CMHT there was very little difference in number and duration of contacts when the service adopted the FACT model. However, there was greater use of support workers and more contacts were in community settings, consistent with the principles of the FACT model (*Table 3*).

Contacts with FACT team compared with previous service (ACT or CMHT)

Previous team	ACT (<i>n</i> = 95)	CMHT (<i>n</i> = 380)				
Face- to-face c ontacts per week: mean	1.16	0.69	<0 .0001a	0.47	0.45	0 .6018a
Duration, minutes: mean	64.80	38.13	<0 .0001a	26.38	25.33	0 .5544a
By support worker: mean	0.25	0.29	0 .3941a	0.07	0.15	<0 .0001a
By support worker: %	21.45	42.60	<0 .0001b	14.18	33.86	<0 .0001b
In the community: mean	0.74	0.51	0 .0001a	0.25	0.29	0 .0314a

ACT, assertive community treatment; CMHT, community mental health team; FACT, flexible assertive community treatment.

2-tailed paired *t*-test.

Monte Carlo permutation test.

2-tailed Wilcoxon.

P>0.0288 not significant (after Benjamini–Hochberg correction).

Contact with the CRHT and hospital use

The number of face-to-face contacts with the CRHT was compared before and after the changes, and significant reductions were seen in both groups. Similarly, the number of people who required any face-to-face support from the CRHT was significantly lower following the changes.

For people who had previously been with the ACT team there was a 19% reduction in number of days spent in hospital, which failed to reach statistical significance. However, the power calculated *post hoc* was only 4%, which indicates that the numbers were insufficient to conclude there was no difference following the change of model. There was also a reduction in mean number of admissions in this group but numbers were too low for a meaningful comparison to be made. In the CMHT group, reductions in bed use were much greater, with a 36% reduction following the introduction of the FACT model, which reached statistical significance. There was also a non-significant reduction in admissions in this group.

Discussion

People previously with a CMHT

There have been no other UK studies exploring the effect of the FACT model on people who had previously been with a CMHT. We observed that these people experienced less than half the number of face-to-face interventions with the CRHT than when they were with a CMHT, which was statistically significant. This is consistent with the FACT philosophy of enabling people to seamlessly move to a high-intensity team approach at times of increased need.¹² Hence, it is possible that during periods of crisis, people were able to receive intensive community support within the FACT team, reducing the need for transfer to the CRHT. Similarly, the reductions in bed use would be consistent with the ability of the FACT model to support people at times of crisis with less need for admission. There were no changes in background bed availability in the services that would provide an alternative explanation for these reductions.

People previously with the ACT team

The other UK evaluation of FACT considered 112 people who had previously been with an ACT service, comparing their hospital and CRHT use before and after the change,^{6,7} but without an appraisal of the impact of people going to FACT from a CMHT. Our findings for people who had previously been supported by the ACT team were similar, with no evidence of adverse consequences in terms of increased need for admission or increased crisis home treatment team contact in the first year. This was despite a considerable reduction in face-to-face support from mental health services. In fact, bed use was reduced, but not significantly, although this has to be interpreted with caution and may not be clinically meaningful as the number of people admitted during the study period was very low.

A possible explanation for this is that a FACT approach could be a more efficient model than ACT because people only receive high-intensity team-based interventions at times of need, freeing up resources for those who most need them. However, our previous follow-up study of the ACT population in South Warwickshire⁸ showed that most people, once they had been with the service for 5 years, reverted to a relatively low level of bed use. The average time with the ACT team had been over 6 years, and by the time the services changed most of these people were relatively stable. Hence, it might be expected that they would cope well with a move to a less intensive service. Any conclusion that there was no evidence of harm when moving from ACT to FACT would therefore be limited to the context of people who have already received a period of several years of intensive ACT interventions.

Limitations

Because there were a number of changes to services, including moving to an ‘age-independent’ model, caution needs to be exercised in interpreting the findings as being solely attributable to the FACT model. One of the limitations of the observational design is the possibility of regression to the mean or background variations which could contribute to reduced hospital use or less contact with the CRHT. Change point analysis can mitigate against this,^{13–15} particularly if combined with start points staggered in time in order to reduce the effect of wider system changes which might influence results. However, because the time period under study was relatively short and the changes in team structure occurred on the same date it was not possible to use this technique. The most robust method for addressing confounding factors would be a randomised controlled trial, but this was beyond the scope of our pragmatic evaluation. The pragmatic method was limited to routinely collected contact data and did not capture more personally meaningful information about satisfaction, social functioning and engagement with services, which are known benefits of ACT.¹⁶

ACT teams have had varying levels of success in terms of achieving fidelity to the model.¹⁷ Without the use of an objective measure, such as the Dartmouth Assertive Community Treatment Scale (DACTS),¹⁸ it is not possible to know with certainty the degree to which the South Warwickshire team was practising according to the ACT principles. Although previous DACTS measures taken several years earlier had shown high fidelity, this had been eroded with less use of shared case-loads and lower staff to patient ratios. Hence, the observations about the outcome for people who had been with the ACT team cannot be extrapolated with certainty to other ACT teams with higher fidelity. This argument also applies to the Firn studies^{6,7} of dismantling ACT teams, which failed to measure ACT fidelity. Although a FACT fidelity scale is available (from The Netherlands),¹² this has never been validated in a UK setting. As Dutch FACT teams also undertake the role of a 24-hour crisis home treatment service, it would not be meaningful to use this scale with a service in the UK, where this function is provided by separate teams.

Conclusions

This is the first study in the UK which has examined the impact of adopting the FACT model on people previously supported by a CMHT within a generic community psychosis service. Although limited by the observational design, the results are consistent with the hypothesis that FACT may be of benefit to this group, who previously did not have access to ACT. People who had been with the CMHT were able to receive increased support delivered with a team case-load at times of increased need, a key component of the FACT approach, thereby reducing their need for the help of the CRHT. We would argue that there is still a case for maintaining ACT teams, which have been much more rigorously assessed than FACT, and that the benefits to patients justify the investment in these services. However, where mental health providers are planning to disband ACT services, there would be value in configuring new teams according to the FACT model, which appears to be a safe alternative in the short term for people who have been with an ACT team for several years.

1.7.58 Burnout and psychiatric morbidity among doctors in the UK: a systematic literature review of prevalence and associated factors

date

2017-8

Abstract

Aims and method To systematically review the prevalence and associated factors of burnout and stress-related psychiatric disorders among UK doctors. An extensive search was conducted of PubMed, EBSCOhost and British medical journals for studies published over a 20-year span measuring the prevalence of psychiatric morbidity (using the General Health Questionnaire) and burnout (using the Maslach Burnout Inventory).

Results Prevalence of psychiatric morbidity ranged from 17 to 52%. Burnout scores for emotional exhaustion ranged from 31 to 54.3%, depersonalisation 17.4 to 44.5% and low personal accomplishment 6 to 39.6%. General practitioners and consultants had the highest scores. Factors significantly associated with increase in the prevalence of burnout and psychiatric morbidity include low job satisfaction, overload, increased hours worked and neuroticism.

Clinical implications The results indicate a worryingly high rate of burnout and psychiatric morbidity among UK doctors, which could have a huge negative impact on healthcare provision in general. Factors at personal and organisational levels contribute to burnout and psychiatric morbidity, and so efforts made to counter these problems should target both levels.

Doctors have a legal duty broader than that of any other health professional and therefore a responsibility to contribute to the effective running of the organisation in which they work, and to its future direction.¹ In an environment where their health and well-being is not prioritised doctors sometimes become ill, manifesting features of burnout and/or stress-related psychiatric disorders. Such psychiatric morbidity, or ‘caseness’, is detected using self-reported instruments such as the General Health Questionnaire (GHQ).² Doctors also experience ‘burnout’, which is defined as a syndrome of exhaustion, cynicism and low professional efficacy.³ Maslach *et al* described burnout as a prolonged response to chronic emotional and interpersonal stressors on the job, and stated: ‘What started out as important, meaningful, and challenging work becomes unpleasant, unfulfilling, and meaningless. Energy turns into exhaustion, involvement turns into cynicism, and efficacy turns into ineffectiveness’.

Increased prevalence of psychiatric morbidity and burnout has been established in studies from different parts of the

world. A study of Italian physicians found an estimated prevalence of psychiatric morbidity to be 25%, and prevalence of burnout on the emotional exhaustion scale of the Maslach Burnout Inventory (MBI) to be 38.7%.⁵ Other studies have reviewed the factors associated with the development and maintenance of psychiatric illness and burnout among doctors. A survey of Australian doctors found that having medico-legal issues, not taking a holiday in the previous year and working long hours were all significantly associated with psychiatric morbidity.⁶ Self-criticism as a medical student was significantly correlated with psychological stress as a doctor in a cohort followed over 10 years by Firth-Cozens.⁷

Burnout among doctors can lead to self-reported suboptimal patient care,⁸ and to major medical errors.⁹ Psychiatric morbidity increases the likelihood of retirement thoughts and retirement preference.¹⁰ Behavioural responses to burnout established in the literature also include alcohol and drug misuse, physical withdrawal from co-workers, increased absenteeism, arriving for work late and leaving early, and employee turnover.¹¹ An extreme reaction to stress can be suicide, even though the pathway to this is complex and multifactorial. A UK survey of suicides between 1979 and 1983 ranked the medical profession as 10th in the list of high-risk professions.¹²

Mental ill health can be found within every workplace in every country. In the UK the total cost to employers of mental health problems among their staff is estimated at nearly £26 billion each year: £8.4 billion from sickness absences and £15.1 billion from reduced productivity at work.¹³ The National Institute for Health and Care Excellence (NICE) found that promoting the mental well-being of employees can yield economic benefits for the business or organisation, in terms of increased commitment and job satisfaction, staff retention, improved productivity and performance, and reduced staff absenteeism.¹⁴ For the National Health Service (NHS) to reap the benefits described by NICE, priority should be given to employee mental health. However, the constant structural changes to the NHS in England have created instability and lack of job security within the public health workforce.¹⁵ The Health and Social Care Act of 2012 has placed doctors at the centre of clinical commissioning groups in charge of shaping services and made them responsible for £65 billion of the £95 billion NHS commissioning budget.¹⁶ This imposes on doctors, especially general practitioners (GPs), a responsibility unlike any before,¹⁷ one which their training has not prepared them for. The ability to cope with the challenges of working in the NHS and the possibility of stress and burnout were highlighted in the annual meeting of the British Medical Association in 2013,¹⁸ and are the focus of this review.

Numerous research papers document burnout and stress-related psychiatric disorders in doctors worldwide, but none has presented the results in the form of a systematic review showing the prevalence and associated factors among UK doctors. The overall aim of this review was to redress this by assessing the prevalence of burnout and psychiatric morbidity among UK doctors working in different specialties, and to explore the associated identified factors. The objectives were to review the prevalence of the syndrome of burnout and psychiatric morbidity, to explore the nature of the relationship between burnout and psychiatric morbidity, and to identify other factors associated with the development and/or perpetuation of those conditions.

Method

Search strategies

The words 'burnout' and 'doctors' were put into the search field of the EBSCOhost website specifying the following databases: Academic Search Complete, CINAHL Plus, PsycINFO and PsycARTICLES. Limiters activated were: English language, human, apply related words, and a time limit of January 1993 to December 2013. A total of 562 articles resulted from this, reduced to 489 automatically after duplicates were removed; 28 articles were selected for further analysis, and out of these 9 remained based on the study inclusion and exclusion criteria. Using the same parameters but with the words 'psychiatric morbidity' AND 'doctors', a total of 97 articles were generated, reduced to 77 after the removal of duplicates, and from these only 1 was selected as new and appropriate. Again using the same parameters but with the words 'stress' AND 'doctors' NOT 'nurses', 3560 articles came up, reduced to 2259 after duplicates were removed; 23 new articles were reviewed in greater detail, and from these 5 new and appropriate articles were selected.

An advanced search on PubMed with the words 'doctors' OR 'physicians' AND 'stress', with a time limit of 1 January 1980 to 15 December 2013 and other limits (human, English language, clinical trial, journal article, reviews, lectures) generated 5973 articles. After careful analysis of the abstracts 28 new articles were identified for more detailed review, and from these 10 were selected as new and appropriate.

Two searches within the group of British medical journals with the phrases ‘burnout and doctors’ and ‘doctors and stress’ with the time limit of January 1993 to December 2013 yielded two new and appropriate papers.

A review of the reference lists of already-identified papers yielded three relevant papers.

Altogether, this extensive search yielded 30 relevant papers which were included in the units of analysis for this review (*Fig. 1*).

Fig. 10: Flowchart of the study selection process.

Inclusion criteria

Certain criteria had to be met before a study was included in the units of analysis: it had to answer any of the research questions for the measurement of the prevalence of psychiatric morbidity the study had to have used any version of the GHQ, and for the prevalence of burnout syndrome only the MBI was considered population group – only medical doctors in the UK irrespective of which organisation they work in minimum sample size of 50 published between January 1993 and December 2013 published in the English language.

The questionnaires

The GHQ is a well-validated and widely used screening tool for the detection of minor psychiatric disorders (psychiatric morbidity) in the general population.¹⁹ The GHQ-12 is self-administered and only takes about 5min to complete. It enquires about the experience of psychosocial and somatic symptoms in recent weeks. Each of the 12 items is measured on a 4-point Likert scale. Studies validating the GHQ-12 against standardised psychiatric interviews indicate that a cut-off score of 4 or above indicates a high probability that the individual suffers from a clinically significant level of distress (‘caseness’ or psychiatric morbidity).

The MBI is a 22-item self-report questionnaire, which is well recognised and widely used to measure burnout in relation to occupational stress.²⁰ It has three subscales: personal accomplishment (measured by 8 items), depersonalisation (measured by 9 items) and emotional exhaustion (measured by 5 items). Responses are rated for each item according to frequency on a 7-point scale from ‘never’ to ‘every day’. The total score for each subscale is categorised ‘low’, ‘average’ or ‘high’ according to predetermined cut-off scores, based on normative data from a sample of American health professionals. A high degree of burnout is indicated by high scores on the emotional exhaustion and depersonalisation subscales and low scores on the personal accomplishment subscale.

Data extraction

A simple paper data extraction tool was created in Microsoft Word, and the tables from this have been used to portray the results in the results section. Data were extracted by the author over the months of November and December 2013.

Results

A total of 30 papers considered relevant and appropriate based on the study inclusion and exclusion criteria were included in this review. *Table 1* summarises these papers.

Findings on prevalence

Seven studies ^{21,22,24,25,27,30,50} had quantifiable data on the prevalence of both psychiatric morbidity and burnout (an in-depth analysis of studies reviewed in this paper is included in an online data supplement to this article). Altogether 22 studies reported on prevalence of psychiatric morbidity, and the range was 17–52% (average 31%). GPs and consultants had the highest scores. Fourteen studies had burnout scores, with nine reporting scores as percentages and five as mean scores; one study ²⁸ had both percentage and mean burnout scores. For emotional exhaustion the scores ranged from 31 to 54.3% and mean scores ranged from 2.90 to 31.26; for depersonalisation the scores ranged from 17.4 to 44.5% (1.95–15.68) and for low personal accomplishment the range was 6–39.6% (4.36–34.21). GPs, consultants and pre-registration house officers had the highest levels of burnout in the studies.

McManus *et al*, ⁴⁶ in a UK-wide study carried out in 2009, had the largest sample size at 2845 doctors and reported prevalence of psychiatric morbidity at 19.2%. The other two UK-wide studies with samples of over 1000 cutting across specialties and grades ^{23,43} reported psychiatric morbidity prevalence rates of 27.8% and 21.3%, respectively. Taylor *et al* ⁵⁰ reviewed 1308 consultants from different specialties and found the prevalence of psychiatric morbidity to be 32%.

One longitudinal study ³⁰ found no significant increase in the prevalence of psychiatric morbidity over 3 years in a non-specific group of doctors. Another longitudinal study ⁵⁰ found a significant increase in psychiatric morbidity and emotional exhaustion among consultants over 8 years.

The only European Union (EU) study looking at the prevalence of burnout in GPs from 12 EU countries ³⁹ found lower average scores on all burnout scales compared with those of English GPs.

Findings on associated factors

Job satisfaction was found to be protective against the effect of stress on emotional exhaustion. The number of hours worked, job stress and overload were associated with increased psychiatric morbidity in eight studies. Two studies^{22,38} found that women had significantly higher psychiatric morbidity than men, but three studies^{27,34,45} did not find any association with gender. The personality trait of neuroticism was significantly associated with increase in psychiatric morbidity in three studies,^{35,43,47} while conscientiousness was a protective factor. Psychiatric morbidity was also positively associated with taking work home and with the effect of stress on family life.

Job satisfaction was negatively correlated with burnout in three studies.^{21,22,25} Age was an interesting factor; increased depersonalisation was found in younger doctors in five studies,^{21,22,27,29,31} whereas emotional exhaustion increased with age in two studies.^{22,41} Being single was associated with increased burnout scores, and neuroticism increased burnout significantly in two studies.^{43,47} Increased job stress and workload increased burnout in three studies, with significantly lower emotional exhaustion scores in part-time GPs.

Findings on the direct relationship between burnout and psychiatric morbidity

Three studies^{25,30,46} found significant positive correlations between psychiatric morbidity as measured by the GHQ, and burnout syndrome. Using the process of casual modelling, McManus *et al*³⁰ found that when scores were considered in 1997 and later in 2000, emotional exhaustion increased psychiatric morbidity, and *vice versa*. Personal accomplishment increased emotional exhaustion directly, and increased psychiatric morbidity directly but also indirectly through increasing emotional exhaustion. When other mental health problems were considered, anxiety and depression were found to increase psychiatric morbidity in three studies,^{35,37,38} and depression increased depersonalisation.⁴¹

Discussion

The findings indicate that the prevalence of psychiatric morbidity among UK doctors is quite high, ranging from 17 to 52%. This compares unfavourably with the results from a longitudinal survey of people living in private households within the UK, which found an 18-month period prevalence of common mental disorders to be 21%.⁵¹ Only 4 of the 22 studies that reported on psychiatric morbidity found prevalence of less than 21%,^{26,30,32,46} which is slightly better than 27% found in a study of palliative care physicians in Western Australia.⁵² An earlier study of junior house officers in the UK found psychiatric morbidity in 50% of doctors,⁵³ but this was in a period when the working pattern of junior doctors was relatively unregulated. More recent studies of junior doctors contained in this review found the prevalence of psychiatric morbidity to be around 19%.^{26,32} Concern over increasing prevalence of common psychiatric illnesses was borne out by the results from the study which found a 5% increase in morbidity among a cohort of consultants over an 8-year period.⁵⁰

This review also found a high prevalence of burnout among UK doctors measured using the MBI. It lends further support to the growing body of evidence which has found the syndrome of burnout to be prevalent all over the world among health professionals. In a sample of Australian doctors, 24% suffered burnout;⁵² in a New Zealand sample of medical consultants one in five did;⁵⁴ and in a cross-section of Japanese doctors 19% were affected.⁵⁵ This review found even higher rates of burnout, with the prevalence of emotional exhaustion ranging from 31 to 54.3%, which would suggest UK doctors are comparatively more prone to burnout. GPs generally had higher scores for burnout,²⁹ particularly in the study of European family doctors,³⁹ which found that the only countries in which GPs had higher burnout scores than England were Turkey, Italy, Bulgaria and Greece. Emotional exhaustion among a cohort of consultants was shown to have increased over an 8-year period,⁵⁰ with a prevalence of 41% in 2002.

This review has been able to pool together different studies which report on factors associated with the development and perpetuation of psychiatric morbidity and burnout. Neuroticism was positively and significantly correlated with psychological distress and burnout in three studies.^{35,43,47} Neuroticism refers to a lack of psychological adjustment and instability leading to a tendency to be stress-prone, anxious, depressed and insecure, and it has been shown to negatively predict extrinsic career success.⁵⁶ McManus *et al*,⁴³ in a 12-year longitudinal study on a cohort of students who started studying medicine in 1990, found that doctors who are more stressed and emotionally exhausted showed

higher levels of neuroticism all through their careers. Neuroticism was also positively associated with perceived high workload. The researchers concluded that neuroticism was not only a correlate but a cause of work-related stress and burnout. Similar findings were noted by Clarke & Singh⁵⁷ in a study looking at the pessimistic explanatory style of processing information, which is a manifestation of neuroticism. In that study neuroticism was shown to positively predict psychological distress in doctors, and the authors recommended that susceptible doctors should be offered cognitive-behavioural therapy (CBT) to alter their explanatory style.

In an editorial titled ‘Why are doctors so unhappy?’ Richard Smith stated that the most obvious cause of doctors’ unhappiness was that they feel overworked and under-supported.⁵⁸ Job stress, feeling overloaded and the number of hours worked were positively linked to psychiatric ‘caseness’ and burnout in many of the studies in the present review, and this cut across specialties and grades. A General Medical Council (GMQ survey⁵⁹ of doctors in training found that 22% felt their working pattern leaves them short of sleep at work, and 59% said they regularly worked beyond their rostered hours. Increasing job stress without a commensurate increase in job satisfaction was associated with the presence of psychiatric morbidity, and job satisfaction was also positively correlated with illness in six of the reviewed studies^{21,22,25,34–36}. Another significant finding was the correlation between psychiatric disorders and burnout, with the two feeding off each other, leading to worsening outcomes.

The public health importance of these findings cannot be overemphasised. GPs are at the frontline of healthcare delivery in the UK, and around 90% of all NHS contacts take place in primary care, with nearly 300 million GP consultations a year.⁶⁰ The estimated total number of GP consultations in England rose from 217.3 million in 1995 to 300.4 million in 2008, with a trebling of telephone consultations, and with the highest consultation rates among the growing population of elderly individuals.⁶¹ Increased live births of over 110 000 over the past 10 years,⁶² and an ageing population⁶³ have contributed to the pressure felt by services in general. However, in spite of the increased demand on primary care services, the proportion of the NHS budget that is spent on general practice has slumped to record levels, and GPs report that this has compromised the quality of care they can provide.⁶⁴ Under these circumstances, the added expectation from the UK Department of Health that GP surgeries should open for longer hours and should expand patient choice will undoubtedly lead to even more psychological distress and burnout among GPs.

A government-driven emphasis in the NHS on performance management and targets increases job demands and stress among managers,⁶⁵ and increases psychiatric morbidity among doctors. The current climate of austerity in the UK, and the expectation that doctors should continue to provide high-quality care to patients within an NHS intending to make £20 billion worth of savings,⁶⁶ further expose doctors to burnout and stress. Psychiatrists are already having to deal with the expected increase in demand for mental health services stemming from the economic downturn,⁶⁷ and the increase in suicide rates⁶⁸ among the working-age population. Psychiatrists are particularly vulnerable to burnout, and patient suicide is a factor significantly associated with stress and burnout in this group⁶⁹.

Burnout among doctors can affect the entire public health workforce because as a syndrome it is considered ‘contagious’.⁴ With the push for doctors to take up leadership positions at every level within the NHS a burnt-out doctor can negatively affect the entire healthcare delivery system. Unhealthy coping strategies in response to burnout and stress were identified in this review: these include retiring early, taking work home, taking it out on family, mixing less with friends, and avoidance, all of which work against the development of a healthy work-life balance.

Limitations

Some key limitations are worth highlighting. First, all the studies were cross-sectional surveys using questionnaires sent to the participants online or by post. Response rates varied, with some as low as 17%, and only in half of the studies was effort made to increase the response rate by sending reminders or repeat questionnaires. Non-response bias could have affected the results. Second, although the MBI was used in all the studies examining burnout, different versions of the MBI were utilised. With the GHQ some studies used the 28-item version but most used the 12-item version. The cut-off for ‘caseness’ using the GHQ also differed between studies and ranged between 3 and 5. However, these differences may not have significantly affected the overall findings given that a study to validate the two versions of the GHQ found no difference between them, and also established that the different cut-off for ‘caseness’ did not affect the questionnaire’s validity.²

The cross-sectional method used for the surveys makes it difficult to draw a firm conclusion on the outcomes from

a cause and effect perspective. Also, the number of potential confounders for the presence of burnout and common psychiatric disorders is vast and cannot be controlled for in surveys alone.

The fact that this literature review ends in 2013 may be considered a limitation, but the hope is that this paper will trigger more research in this area, and the author's intention is to update the literature review by 2023.

Recommendations

Doctors are ultimately responsible for the quality of care they provide at any time, and they need to be aware of their own vulnerability to burnout and psychiatric illness, and of their impact on patient care. Traditionally, doctors take pride in working a lot of hours,⁷⁰ and are 3 to 4 times less likely to take days off sick compared with other health professionals;⁷¹ this combination is a recipe for burnout. A whole list of support networks is available on the GMC website,⁷² and doctors should be encouraged to utilise these. However, there is a 'culture of fear' among doctors regarding the GMC, and 96 doctors, a lot of whom had mental health problems, have died by suicide since 2004 while being investigated by the GMC.⁷³ A lot more work is therefore needed to make the most vulnerable doctors feel supported.

At an organisational level, approaches designed to reduce the workload of doctors should be prioritised. Changes to doctors' contract of service should reflect an understanding of the impact of work-related factors on the health and well-being of doctors, and any such contract should contain the necessary protections to reduce the experience of psychiatric illness and burnout. The benefits of a healthy workforce on the quality of care provided in the NHS cannot be overstated.

1.7.59 The impact of transforming care on the care and safety of patients with intellectual disabilities and forensic needs

John L. Taylor Iain McKinnon Ian Thorpe Bruce T. Gillmer

2017-8

Abstract

NHS England recently published a national plan to develop community services for people with intellectual disabilities and autism who display challenging behaviour by using resources from the closure of a large number of hospital beds. An ambitious timescale has been set to implement this plan. The bed closure programme is moving ahead rapidly, but there has been little progress in developing community services to support it. This paper discusses the impact of the gap between policy and practice on the care and safety of patients with intellectual disabilities and forensic needs who form a distinct subgroup of the target population and are being disproportionately affected by this government policy.

The policy context

Building the Right Support, a national plan to develop community services and close hospital beds for people with intellectual disabilities and autism who ‘display behaviour that challenges’ (p. 4), was published last October by NHS England and its local authority partners.¹ The genesis of this plan was the Winterbourne View scandal in 2011, which involved the systematic abuse of people with intellectual disabilities in an independent sector hospital unit run by Castlebeck Care in Bristol, England.² This led to a concordat that committed the Department of Health to a rapid reduction in the number of people with intellectual disabilities and challenging behaviour in hospital beds by mid-2014.³ Under pressure from politicians and stakeholder groups, who claimed that the government had failed to deliver on its concordat promises and that the situation had worsened,⁴ the chief executive of the National Health Service (NHS) committed to a 2-year intellectual disability hospital closure programme during a parliamentary select committee hearing on services for people with intellectual disabilities and challenging behaviour in early 2015.⁵

The ensuing national plan includes the closure of 45–65% of local clinical commissioning group (CCG)-commissioned and 25–40% of NHS England national specialist-commissioned in-patient beds by 2018. This is a ‘starting point’ and commissioners are encouraged to be ‘ambitious in thinking about how much further they can go’ (p. 6; unless stated otherwise, all quotations in this commentary are from *Building the Right Support* document¹). The rationale for these numbers and timescale is unclear beyond what NHS commissioners and local authorities have told the plan’s authors ‘they believe is possible’, which was then ‘sense-checked’ against geographical variations in current in-patient service usage (p. 27). The money saved from these bed closures is to be reinvested in the development of community services (p. 6). The national plan is clear that this transition will involve significant costs. It is stated that commissioners ‘will need to invest in new community support *before* closing inpatient provision’ (p. 7, italics added). Also required is the ‘temporary double running of services as inpatient facilities continue to be funded whilst new community services are established’ (p. 44). Local Transforming Care partnerships were tasked with drawing up implementation plans to support a new model of care and to start delivering against these plans by 1 April 2016.

Lack of investment in community services

Unfortunately, little progress appears to have been made in agreeing, let alone implementing, new community service models to support the bed closure plans as envisaged in the national plan. The current authors work clinically with patients with intellectual and developmental disabilities who display offending and offending-type behaviours in inpatient and community services across six CCG areas in the north-east of England. As a group we have been closely involved in initiatives to increase hospital discharge rates and reduce readmissions, bed numbers and lengths of stay as well as to support and strengthen community services for people with intellectual disabilities who are at risk of offending. These innovations pre-date the Transforming Care programme and have already led to the closure of two inpatient units and a number of satellite beds in our services (40 beds in total). Despite our engagement and commitment to this transformation process we are concerned about the impact of the national plan, and the manner in which it is being implemented locally on patient care, patient safety and the safety of others.

The North East and Cumbria is one of six ‘fast-track areas’ in the national plan, set up with £2.06 million support from the NHS England Transforming Care programme to ‘help fund transitional costs and speed up implementation’

(p. 12). Fast-track areas aim to reduce in-patient bed usage by around 50% within 3 years, thereby ‘freeing up tens of millions of pounds which will be invested in community-based support to prevent hospital admissions’ (p. 13). The North East and Cumbria service model, which aims to deliver a 50% reduction in in-patient admissions, is currently in draft form and the ‘new community model’ embedded within the overall service model is not due to be considered by the North East and Cumbria Transforming Care Board until September 2016 at the earliest. Once the model is agreed, implementation plans will need to be developed, and resources including people and funds will need to be identified to enable it to be initiated. Judging by the pace of progress to date, this is likely to take considerable time. In the meantime, plans for in-patient bed closures are progressing rapidly, with 31 out of 112 beds (35%) across our medium- and low-secure and locked rehabilitation services currently empty as part of the closure programme.

The effects of Transforming Care

The impact on patient care and safety of the drive to close in-patient beds without first having developed or strengthened community services is already beginning to show locally. The population served by these in-patient services, in contrast to the intended target population, is relatively high functioning intellectually (that is, mild/borderline in intellectual disability terms),⁶ shows high levels of psychiatric comorbidity⁷ and personality disorder characteristics,⁸ and generally does not display ‘behaviour that challenges’, but outwardly directed high-impact offending behaviour that has resulted in criminal convictions and/or detention under the Mental Health Act 1983 on the basis of ‘abnormally aggressive’ and/or ‘seriously irresponsible’ behaviour. Chief among the behaviours that bring these patients into these services are serious violence and aggression, sex offences, damage to property and firesetting.⁹ The most recent national census data reflect this offending behaviour profile, in that 33% of patients with intellectual disabilities detained under the Mental Health Act in England are subject to Part III criminal sections, and 21% of that group are subject to Ministry of Justice restrictions, meaning that they cannot be discharged without the approval of the Secretary of State or a mental health tribunal.¹⁰ Just 17% of in-patients with intellectual disabilities in the census were informal – that is, not detained under the Act.

The imperative to empty and then close in-patient beds has resulted in pressure being applied on clinical teams through commissioner-led ‘care and treatment reviews’¹¹ to provide discharge dates for some forensic patients who continue to present levels of risk that local service providers and community teams are not adequately resourced to manage, or to consider transfers from NHS to independent hospital beds. Some evidence for the movement of patients around the in-patient system – possibly to create the illusion of progress – comes from a recent update from the NHS England Director of Transformation – Learning Disabilities,¹² who reported that in April 2016, 20 of the net 100 recorded discharges were in fact transfers to other hospitals, and the destination of a further 20 discharged patients was unknown.

There is also concern that owing to the pressure to discharge as quickly as possible to meet the national plan targets, patients’ rehabilitation is being hurried and/or truncated, resulting in some people being discharged before they are ready to take on the challenges of living in the wider community, or without the receiving community services being properly prepared to manage the risks these patients continue to present. The high level of clinical complexity and associated forensic risk in this population can require a significant period of assessment, formulation and specialist treatment to help patients develop thinking styles and attitudes, emotional control strategies and lifestyles less compatible with offending behaviour. A carefully considered and planned period of pre-discharge preparation is an important component of the treatment pathway and is essential to facilitating a successful transition from hospital to community care.

Another consequence of the current rapid bed closure policy is that people with intellectual disabilities and forensic needs who require urgent hospital treatment are being admitted to generic psychiatric services. This includes patients who have been previously detained in hospital under the Mental Health Act 1983 and discharged on community treatment orders, and who have been subsequently formally recalled to hospital owing to escalating risks of harm to themselves or others. Admission to acute psychiatry units can result in these patients being targeted and exploited by more able patients. In addition, they are unable to access appropriate assessment and treatment as the staff teams in these services have little or no experience of working with this population and lack the specialist skills required.¹³ This will result in longer periods of in-patient admission for these patients as access to suitable interventions aimed at reducing forensic risks is delayed.

One aim of the Transforming Care programme is to prevent people with intellectual disabilities and challenging

behaviours from undergoing unnecessary admissions to intellectual disability and mental health in-patient services. Whether an admission is necessary or not is inevitably a matter of judgement. With the requirement for commissioner agreement to admission, there is a real risk of the judgement of clinicians being circumvented. Efforts to prevent admission to hospital by increasing supervision and support to people in community settings to manage emerging risks have paradoxically resulted in situations amounting to *de facto* deprivation of liberty in some cases, where a short informal hospital admission to allow the risks to be assessed and required amendments made to care plans would have been a less restrictive and more clinically effective option.

Discussion and conclusions

People with intellectual disabilities who require treatment in hospital for behavioural, psychiatric and forensic problems should have access to the best evidence-based interventions available, delivered by caring staff with positive attitudes and person-centred values, in good-quality, safe environments. It is clear that a disproportionate number of people with intellectual disabilities are detained in hospital under the Mental Health Act ¹⁴ and, once detained, they have on average longer lengths of stay than detained patients who do not have intellectual disability. ¹⁵ The *Building the Right Support* national plan aims to address these inequities, albeit based on uncertain evidence and questionable assumptions.

There is no credible evidence or analysis presented to support the proposed bed reduction numbers. Between 1988 and 2015 the number of intellectual disability beds in the NHS reduced dramatically, from approximately 33 000 to about 2500. ¹ It is debatable whether this 90%-plus reduction over the past 30 years has been caused by centrally driven government policy initiatives, for example *Valuing People*, ¹⁶ or the impact of human services theories, such as social role valorisation, ¹⁷ on the deinstitutionalisation and community care movements in the 1980s and 90s. ¹⁸ Either way, looking at the most recent census of in-patient services for people with intellectual disabilities in England, ¹⁰ 83% were legally detained under the Mental Health Act 1983, with all of the scrutiny and protections this affords via mental health tribunals, hospital managers' hearings and Care Quality Commission inspections. It could be argued therefore that the majority of the remaining intellectual disability in-patient beds represent equipoise in the system and, as such, the current huge diversion of resources into forcing the closure of these remaining beds is unlikely to be successful in the long term.

The national plan starts from the supposition that all people with intellectual disabilities 'should have a home within their community' (p. 4). Seemingly underpinning this position is a belief that families and the community are always better for people with intellectual disabilities and that hospital services do not provide safety and sanctuary for some people. For many of our patients with forensic needs, their histories indicate that families and the community can be part of the problem rather than the solution. Putting to one side the fact that communities are generally not keen to embrace people who might have violently or sexually assaulted people in their midst, or set fire to their buildings, people with disabilities frequently experience abuse, aggression and violence in and by the community. ¹⁹ There are many examples of people like Brent Martin, who was brutally murdered in 2007 by his more able 'friends' in Sunderland 3 months after being discharged from hospital. ²⁰

A further assumption underpinning the national plan is that hospital admissions should be as short as possible. There is an apparent lack of understanding that the population managed and treated by in-patient forensic intellectual disability services is distinct from the population envisaged within the Transforming Care programme. Patients with significant forensic histories have frequently experienced high levels of abuse, neglect and deprivation. They require time to develop insight into their difficulties in relating to others, acquire skills in regulating their emotions and acknowledge their future support needs. The application of a bed closure policy and as yet unclear community service model that is designed for a very different population carries significant risks of harm for patients with intellectual disabilities and forensic needs, as well as for others. The implementation of that policy without the required and promised investment in and development of community services is especially concerning. Some of the unintended consequences of this approach might include more vulnerable offenders with intellectual disabilities being sent to prison rather than diverted to hospital for appropriate treatment as recommended in the Bradley Report ²¹ While imprisoned, such offenders will likely be targeted by other prisoners because of their disabilities and will remain at risk of re-offending, as they will be unable to access prison offending behaviour programmes ²² Finally, it is perhaps ironic that this policy will possibly lead to an increase in the use of independent sector hospital beds for people with intellectual disabilities – exactly where this all started.

1.7.60 Prevent: what is pre-criminal space?

David Goldberg Sushrut Jadhav Tarek Younis

Sushrut Jadhav (s.jadhav@ucl.ac.uk)¹

date

2017-8

Abstract

Prevent is a UK-wide programme within the government's anti-terrorism strategy aimed at stopping individuals from supporting or taking part in terrorist activities. NHS England's Prevent Training and Competencies Framework requires health professionals to understand the concept of pre-criminal space. This article examines pre-criminal space, a new term which refers to a period of time during which a person is referred to a specific Prevent-related safeguarding panel, Channel. It is unclear what the concept of pre-criminal space adds to the Prevent programme. The term should be either clarified or removed from the Framework.

 - *Coining of 'pre-criminal space'*
 - *Denotation and connotation*
 - *The derivation of pre-criminal space*
 - *Rhetoric*
 - *Opinion*

The Prevent Training and Competencies Framework¹ begins thus: “Prevent is part of the Government's counter-terrorism strategy CONTEST and aims to stop people becoming terrorists or supporting terrorism; as such it is described as the only long term solution to the threat we face from terrorism. Prevent focuses on all forms of terrorism and operates in a pre-criminal space, providing support and redirection to vulnerable individuals at risk of being groomed in to terrorist activity before any crimes are committed. Radicalisation is comparable to other forms of exploitation; it is therefore a safeguarding issue staff working in the health sector must be aware of. [...] Staff must be able to recognise signs of radicalisation and be confident in referring individuals who can then receive support in the pre-criminal space.” (p. 5) The Framework is cascaded down the National Health Service (NHS) hierarchies in England to ensure that all front-line staff in the NHS receive mandatory training in the Prevent process. NHS staff refer patients considered vulnerable to radicalisation to local Prevent leads and onward to Prevent case managers and the Channel panel. The Channel acts as a multi-agency panel along the lines of other safeguarding panels in England.

This Training and Competency Framework follows from the *Prevent Duty Guidance*,² the *Channel Duty Guidance*³ and the *Channel: Vulnerability Assessment Framework*⁴ produced by the government following *CONTEST: The United Kingdom's Strategy for Countering Terrorism*⁵ and the Counter-Terrorism and Security Act 2015. The Framework does not name these documents but mentions two other documents which focus on multi-agency working. The first, *Safeguarding Children and Young People*,⁶ details the roles and competencies for healthcare staff when working with other professionals to safeguard children and young people. The second, *Building Partnerships, Staying Safe*,⁷ stresses the importance of effective interprofessional working.

The focus of the Framework is on training. Among the competencies listed within is to understand the concept of pre-criminal space. This article examines this term using publicly accessible government documents and internet searches performed on Google and Google Scholar. It is a textual analysis, read in the context of other government documents,⁸ which presumes that what is read may not necessarily be what the authors initially intended. Meanings applied to words, particularly new compound words, gain significance over time and use.⁹ One of the presumptions of this method is that textual analysis may not relate directly to what is happening in practice.

Pre-criminal space in the NHS England Framework

'Pre-criminal space' appears four times in the Framework document, including twice in the introduction: 'Prevent focuses on all forms of terrorism and operates in a pre-criminal space' (p. 5) '... individuals [...] can then receive support in the pre-criminal space' (p. 5) '... aware[ness that] [...] the health sector contribution operates in pre-criminal space' (p. 8) 'Understand [...] the concept of pre-criminal space' (p. 10). The meaning of 'pre-criminal space' can be deduced from these quotes. 'Prevent focuses on all forms of terrorism and operates in a pre-criminal space' suggests that pre-criminal space may relate to specific physical spaces and times where professionals 'operate' or act within the aims of the Prevent programme. The statement that 'individuals [...] can then receive support in the pre-criminal space' suggests that the professional activity involved is 'support'. What constitutes 'support' is detailed in the *Channel Duty Guidance*.³ The fact that 'the health sector contribution operates in pre-criminal space' implies that other health sector activities may not operate in the pre-criminal space. In what way NHS activity in this 'space' is different from that in other space is not stated anywhere. The need for health professionals to understand 'the concept of pre-criminal space' suggests that there is an important difference between what pre-criminal space is and what it is not. Read in the context of Prevent² and *Channel Duty Guidance*,³ pre-criminal space is likely to start on acceptance of a referral of a person within the Channel panel, or perhaps on referral or discussion of the possibility of referral by NHS staff to Channel personnel. Thus, pre-criminal space has temporal and spatial aspects. As the time and space is decided by negotiation with and between professionals, the term also has inter-professional dimensions. This is supported by Framework naming documents that focus on effective multidisciplinary work rather than the Prevent and Channel Duty guidelines.^{6,7}

The Framework document views the Prevent programme as part of the wider safeguarding agenda. However, there is one important difference compared with other safeguarding panels: the coordinator of the Channel process, the Channel Police Practitioner (CPP), is a police officer or is employed by the police (ref. 3, para. 30). Thus, unlike other safeguarding procedures, the police have a central coordinating function.

Coining of 'pre-criminal space'

The term pre-criminal space is new. It was introduced by this Framework and cascaded to all trusts by NHS England. The term does not occur in non-NHS Prevent documents or in CONTEST. References to pre-criminal space since the term was introduced are largely found in trust documentation and NHS PowerPoint presentations, together with some journalist reports and blogs. For instance, the *Telegraph* comments on the police use of the term and possible repercussions on state-Muslim relations.¹⁰

All NHS trusts in England are mandated to enact the Framework document and produce policy or guidance documents. None of these documents define pre-criminal space any further. Many use pre-criminal space with quotation marks, a few prefacing the term with 'so-called'. The usual statement is a reiteration of 'Prevent operates in the pre-criminal space'. Occasionally the hyphen is replaced by a space between 'pre' and 'criminal' but the words are never placed directly together. The most detailed definition we have found comes from a glossary in a Prevent document from

Mersey Care NHS Trust, beginning with a precautionary note: ‘These definitions relate to PREVENT and are not always authoritative in any wider context.’ ‘Pre-Criminal Activity/Space’ is explained by focusing on ‘multi-agency working to ensure that individuals are diverted away before any crime is committed’.¹¹ This definition merges ‘space’ with multi-agency activity.

Denotation and connotation

So far we have argued that pre-criminal space refers to the time when a person is engaged by the Channel panel and related professionals. It denotes the time, space and interprofessional activity involved in planning, coordinating support and possibly monitoring in the NHS England Prevent programme. What is unclear is whether the Channel process and panel meetings are in any way different from other multi-agency activities. This may be deduced by examining possible connotations of the term based on participants’ understanding of language use in its social context.

Pre-criminal space consists of three terms: ‘pre’ meaning before, ‘criminal’ as a person who has committed a crime or repeated crimes, and ‘space’ as a continuous physical area. ‘Pre’ appears to modify the second term, ‘criminal’, rather than space. Hyphens are not usually used after prefixes such as ‘pre’, unless the resulting meaning becomes ambiguous, for example ‘pre-order’ rather than ‘preorder’. Thus, the use of the hyphen both gives a separation between pre-crime and crime and creates the link. The term implies that the ‘space’ is pre-criminal, not the individual. While the use of the term ‘space’ suggests a physical space, such as a meeting room, there are no references to where the vulnerable person is to be supported. ‘Space’ in this context is used as a relational concept, common in expressions such as ‘I need space to think’, meaning ‘I need a place for myself, away from certain social relationships’.

The derivation of pre-criminal space

The etymology of the term is significant to the discussion. ‘Pre-crime’ and ‘space’, as separate words, suggest they are potentially independent concepts. The term ‘precrime’ was said to be coined by science fiction writer Philip K. Dick in his short story *Minority Report*.¹² The drama is based on the concept that crime has not occurred yet but will occur in future unless measures are taken. The belief that crime can be prevented by identification and intervention has a long history. In the 19th century, Lombroso’s theory of criminal atavism famously purported to identify future criminals by their abnormal physical appearance. In recent years, criminologists use the term pre-crime to criticise the move to criminalise people prior to the committing of crime.¹³ More recently, the term ‘pre-criminal space’ has been used in the US security industry in relation to Islamic fundamentalist terrorism.¹⁴ We find no evidence that the concept of ‘space’ in pre-criminal space derives from academic theorising about space. Depending on context, however, space connotes elements of time as well as physical or abstract forms of space. Space in pre-criminal space can thus gain different metaphoric associations depending on the immediate social context. Pre-criminal space may describe the physical space where ‘support’ is planned, ‘operated’ or monitored. It may also relate to the time that the person is subject to the Channel panel process, or to differences in the social rules of interprofessional interaction, as compared with different safeguarding panel discussions. Finally, it may refer to differing social identities of the person referred to the Channel panel and the professionals involved.

Rhetoric

The Framework provides an abbreviated and reasoned argument in support of the Prevent programme and the involvement of health professionals. Like all arguments, it persuades through the use of the metaphoric qualities which words gain in use. There are two sets of metaphors within the Framework, one pertinent to NHS professionals and the other to the police. The health metaphors are borrowed from structural engineering, with vulnerability and support suggesting the diathesis-stress model. The person is weakened from external assault or internal deficiency; structural support is provided from outside so the individual can withstand potential assaults or threats. Even the WRAP acronym (Workshops to Raise Awareness of Prevent) suggests physical bodily protection against external threat. The criminal justice terms (i.e. radicalisation, extremism, CONTEST, counter-terrorism, strategy) suggest a heightened spatial metaphor, polarisation and direction of movement. The creation of the term pre-criminal space may be an attempt to bridge the health and police use of metaphor: the health metaphor aiming for stability and predictability, while the criminal justice

metaphor focuses on adaptability. The lack of effective definition of pre-criminal space allows for evolving inter-agency norms during the Channel process to vary with context.

If new concepts emerge by visual analogy,¹⁵ pre-criminal space can be seen as an extension of crime prevention. It can be visualised as a system of continuous and contained passages. Prior to the vent (derived from the Latin root, as in *prevent*), professionals direct radicals, people who have an attractive or repulsive charge or energy, past the vent and into the channel. As the radicals pass along the vent their charge or energy becomes less strong and the radical no longer moves towards the extreme.

If the term pre-criminal space mobilises healthcare professionals and Channel partners towards a crime prevention role of health intervention, pre-criminal space has the potential to act as a form of ‘excitable speech’ to alert listeners to the threat of terrorism.¹⁶ The rhetorical use of the term pre-criminal space during the Channel process could be perceived as an attempt to persuade professionals to disclose information or make decisions they would otherwise not make in other safeguarding forums and in comparable circumstances.

Opinion

The Training and Competency Framework is an action plan, laying out who does what, when and with whom. For the implementation of Prevent, terms need to be defined to such a degree that the participants can understand the concepts involved. Indeed, the Framework itself asks NHS staff to understand the concept of pre-criminal space (p. 10). Pre-criminal space clearly denotes a period of time in the Prevent process without adding further meaning and keeping open the opportunity for the term’s possible rhetorical use in Channel meetings.

One synonym for pre-criminal space is crime prevention. This raises the possibility of changing the wording of the Framework to replace this obscure and newly coined term with ‘crime prevention’. Alternatively, discussion and clarification of the concept of pre-criminal space would allow it to define the participants’ relationships as the crime prevention activity proceeds. Further multidisciplinary research linking NHS documents to practice may enable the Prevent guidance and framework to be linked with practice. When the time comes for the Prevent framework to be updated (although no such date is given in the document), we recommend that the term should be clarified or removed.

We thank the Newton International Fellowship, supported by the Royal Society, the British Academy, and the Academy of Medical Sciences.

1.7.61 Drug information update. Atypical antipsychotics and neuroleptic malignant syndrome: nuances and pragmatics of the association

Abstract

Neuroleptic malignant syndrome (NMS) is a rare but potentially fatal adverse event associated with the use of antipsychotics. Although atypical antipsychotics were initially considered to carry no risk of NMS, reports have accumulated over time implicating them in NMS causation. Almost all atypical antipsychotics have been reported to be associated with NMS. The clinical profile of NMS caused by certain atypical antipsychotics such as clozapine has been reported to be considerably different from the NMS produced by typical antipsychotics, with diaphoresis encountered more commonly, and rigidity and tremor encountered less frequently. This article briefly discusses the evidence relating to the occurrence, presentation and management of NMS induced by atypical antipsychotics.

Neuroleptic malignant syndrome (NMS) refers to an idiosyncratic severe adverse reaction associated with the use of antipsychotics. It is a rare and unpredictable side-effect that has been associated with both first- and second-generation antipsychotics.^{1,2} It occurs in about 0.02–3% of individuals who are prescribed antipsychotics.³ NMS is generally characterised by rigidity fever, autonomic dysregulation, tremor, elevated creatine phosphokinase (CPK) levels and leucocytosis (*Box 1*).⁴ NMS is a potentially fatal adverse event. It can lead to permanent neurological impairment in survivors in the form of parkinsonian symptoms and cognitive deficits, which could be primarily ascribed to the raised core body temperature and ischaemia following rhabdomyolysis.^{5–7}

Atypical (second-generation) antipsychotics were initially considered to have negligible risk of inducing NMS due to their distinctive pharmacodynamic characteristics.⁸ In fact, side-effect profile has been one of the important distinguishing features between typical (first-generation) and atypical antipsychotics. However, considerable research evidence has accumulated to suggest that atypical antipsychotics are also associated with NMS.^{9,10} Clozapine was one of the earliest atypical antipsychotics implicated in the causation of NMS.¹¹ Subsequently, almost all of the atypical

antipsychotics have been associated with the occurrence of NMS. The clinical features of NMS induced by atypical antipsychotics have been reported to be somewhat different from those induced by typical antipsychotics.¹⁰

Atypical antipsychotics are among the most commonly prescribed antipsychotics.^{12,13} They are utilised for the treatment of a range of psychiatric disorders including schizophrenia, mania, depression with psychotic symptoms and personality disorders, and for behavioural symptoms in dementia and intellectual disability.^{14,15} Hence, understanding the clinical presentation and occurrence of NMS associated with atypical antipsychotics is of clinical relevance. This article discusses the evidence relating to the occurrence of NMS with atypical antipsychotics and various aspects of management for this condition. The authors reckon that the definition of ‘atypical’ antipsychotics itself may not have clear margins,¹⁶ yet the term ‘atypical’ remains in clinical usage to refer to those medications that have comparably smaller chances of causing extrapyramidal symptoms. We do not aim to present a systematic review of the topic, but rather a pragmatic review of the literature on NMS with atypical antipsychotics.

Reports of atypical antipsychotics causing NMS

Risperidone

Risperidone has been associated with probably the largest number of cases of atypical antipsychotic-induced NMS.^{9,17} It has been noted more frequently in the younger age group who had been antipsychotic naive. A severe clinical picture of typical NMS has been encountered, marked by rigidity, extrapyramidal symptoms, fever and highly elevated CPK levels. Tachycardia was more common than diaphoresis and autonomic dysregulation occurred frequently.⁹

Clozapine

Cases of clozapine-induced NMS, reported since the 1980s, typically occurred with rapid dose increases. Also, many patients who developed clozapine-induced NMS had a history of NMS with other antipsychotics. Tachycardia, tachypnoea, diaphoresis and autonomic lability were encountered frequently, possibly due to clozapine acting on adrenergic and muscarinic receptors.¹⁸ Rigidity and extrapyramidal symptoms were rare, possibly due to the lower affinity of clozapine to the D₂ receptor. The increases in CPK were lower and delayed when compared with other antipsychotics. The occurrence of fever and autonomic instability in patients receiving clozapine in the absence of rigidity may necessitate ruling out the diagnosis of clozapine-related agranulocytosis before a diagnosis of NMS.¹⁹ The clinical severity of clozapine-induced NMS has been described to be lower than with other antipsychotics, and hence such cases have infrequently required intensive care unit admissions. The infrequent occurrence of rigidity and extrapyramidal symptoms in patients with clozapine-induced NMS require a high degree of suspicion for this diagnosis. However, certain researchers have suggested that clozapine-induced NMS should not be considered as a diagnosis in the absence of typical features of NMS.²⁰

Box 1 Symptoms and signs commonly encountered in neuroleptic malignant syndrome

- Fever
- Rigidity
- Elevated creatine phosphokinase (CPK) levels
- Tachycardia
- Tachypnoea
- Altered mental state
- Fluctuating blood pressure
- Diaphoresis
- Leukocytosis

Olanzapine

Although olanzapine has been reported to present with the typical features of NMS, extrapyramidal symptoms and fever were absent in a small proportion of patients. Autonomic imbalances and diaphoresis are frequent, and are often the first signs to appear in patients with olanzapine-induced NMS. Nausea was infrequent, probably due to the antiemetic purported properties of olanzapine,²¹ but neurological impairments such as hemiplegia, ataxia and seizures have been reported.⁹ Several cases have been reported in patients receiving other medications apart from antipsychotics, for example mood stabilisers and antidepressants, and the clinical picture of NMS has been more severe in such patients.⁹

Amisulpride

Several cases of amisulpride-induced NMS have been described in the literature,^{22,23} many reported in elderly males. The clinical profile primarily involves an altered mental state, frequent rigidity and high levels of CPK, whereas high fever, tremor and other autonomic symptoms have been reported less frequently. The lower propensity to cause autonomic symptoms is probably due to low affinity in amisulpride for muscarinic, adrenergic, serotonergic and histamine receptors than in other antipsychotics.²⁴

Quetiapine

Quetiapine-induced NMS has been primarily reported in the elderly, although it has also been described in children.²⁵ Clinically, it presents with extrapyramidal symptoms and prominent autonomic symptoms such as tachycardia, blood pressure fluctuations, tachypnoea and diaphoresis. These prominent autonomic symptoms may be consequent to norepinephrine reuptake inhibition, histaminergic antagonism and serotonin toxicity associated with the use of quetiapine.²³ The outcome of quetiapine-induced NMS has been relatively poor, probably due to the older age of patients in whom it has been reported.⁹

Aripiprazole

Several case reports and case series have accumulated on the occurrence of NMS in patients receiving aripiprazole.^{26,27} Rigidity and altered mental state seem to be present frequently in such patients, while fever, diaphoresis and tachypnoea are less frequent. NMS has been reported to occur more commonly with fast upward titration of dosages of aripiprazole. The severity and duration of NMS seem lower than in other antipsychotic medications, probably due to the partial dopamine agonist activity of aripiprazole. Aripiprazole has also been implicated in combination antipsychotic regimens, when used alongside other atypical antipsychotics such as clozapine.²⁷

Ziprasidone

Few cases of ziprasidone-induced NMS have been described.^{28,29} The onset of NMS in these patients has been generally abrupt, with most displaying typical features such as alterations of mental state, fever, diaphoresis, tachycardia, blood pressure alterations, leukocytosis, tremor, and other extrapyramidal symptoms with high CPK. No fatality has been reported with ziprasidone to date, and recovery is usually achieved in about 10 days.

Paliperidone

Paliperidone has a similar pharmacodynamic profile to risperidone, but it has a lower affinity for dopamine receptors and higher serotonin antagonist activity. Paliperidone-induced NMS has been described mainly in patients who have been previously treated with other atypical antipsychotics and have had a recent dose increase or cross-titrations.^{30,31} Paliperidone-induced NMS presents with a typical clinical profile with mental state alteration, rigidity, diaphoresis, hyperpyrexia, tremor and other extrapyramidal symptoms, and the outcome is favourable, with resolution achieved in all cases.

Zotepine

Several cases of zotepine-induced NMS have been described in the literature.^{22,32} Rapid dose escalation was reported in one case, although NMS has also developed with the usual titration pattern. Zotepine-associated NMS presents with alterations of mental state, rigidity, diaphoresis, fever, tachycardia and leukocytosis, with less frequent occurrence of tremor, tachypnoea and alterations in blood pressure.

Other atypical antipsychotics and summary

At present, there is a single case report of iloperidone being considered as a cause of NMS.³³ The patient, who had schizophrenia, developed mutism, diaphoresis, diffuse lead pipe rigidity and tachycardia without fever or marked increase in CPK levels. The outcome was favourable, but the patient also required anticoagulation therapy for the management of comorbid pulmonary embolism.

Blonanserin was reported as a cause of NMS in a 30-year-old female with intellectual impairment.³⁴ The patient presented with fever, tachycardia, rigidity, extrapyramidal symptoms and leukocytosis after the initiation of blonanserin. Symptomatic improvement was seen after discontinuation.

Although different atypical antipsychotics have different NMS clinical symptom profiles, rigidity, tremor and fever are encountered less frequently with atypical antipsychotics, whereas diaphoresis is quite common. Clozapine is particularly associated with atypical presentations of NMS with infrequent CPK level elevations. Risperidone, on the other hand, produces a clinical picture more similar to the NMS induced by typical antipsychotics. Some of the atypical antipsychotics have also been associated with serious features such as myoglobinuria and acute renal failure.^{35,36}

Risk factors for atypical antipsychotic-induced NMS

A few significant risk factors for atypical antipsychotic-induced NMS have been identified. They have been reported in one study as male gender, confusion, dehydration and delirium.²⁵ Another study reported Black and minority ethnic background, antipsychotic polypharmacy, use of aripiprazole, and increasing dosing patterns.³⁷ More recently, it has been suggested that rapid dose escalation of the antipsychotic may be a risk factor for NMS.² The demographic profile of patients who developed NMS with atypical antipsychotics does not seem to differ substantially from that of patients with NMS induced by typical antipsychotics.

Management

Diagnostic uncertainty

The clinical picture and features of NMS with atypical antipsychotics seem to be different from those of typical antipsychotics. This had led to uncertainty over the diagnosis of NMS in patients on atypical antipsychotics who manifest only few of the NMS symptoms.³⁸ Among the core symptoms of NMS, fever is often encountered less frequently in patients with atypical antipsychotic-induced NMS.³⁸ The issue is further complicated by the various operational definitions of NMS.³⁸ The DSM-IV-TR defines NMS as the presence of severe muscle rigidity and elevated temperature after antipsychotic initiation along with two or more of: diaphoresis, dysphagia, tremor, incontinence, changes in level of consciousness, mutism, tachycardia, elevated or labile blood pressure, leukocytosis, or laboratory evidence of muscle injury (elevated CPK level). Various other criteria for NMS have been postulated, each with varying emphasis on the individual symptoms and signs.³⁹ Another set of criteria defines NMS in patients with either three major symptoms (hyperthermia, rigidity, elevated CPK level) or two major and four minor symptoms (diaphoresis, tachycardia, tachypnoea, abnormal blood pressure, leukocytosis, altered consciousness).⁴⁰ Yet another diagnostic system defines NMS through the presence of extrapyramidal symptoms and fever (37°C) alongside three minor symptoms within a 48-hour period.⁴¹ This may potentially mean that a case fulfilling the diagnosis of NMS according to one set of criteria may not do so with another set. The DSM-5 has taken a pragmatic approach of not explicitly stating the number of criteria required for the diagnosis of NMS.

It has been proposed that with the growing awareness of NMS, those in the early course of its development may benefit from early identification and immediate treatment. This may lead to an abortive course of NMS development, with an incomplete picture and only few of the criteria being met. Hence, some authors have proposed a dimensional concept of NMS, which takes into consideration the minor and subthreshold forms of NMS.^{38,42} This is likely to further our knowledge about NMS pathophysiology, clinical profile subtypes and appropriate management strategies.

Furthermore, various other medical and neurological conditions may present with a clinical picture similar to NMS (briefly mentioned in *Box 2*). Patient condition may require expedient decisions so that a rational line of management can be instituted. Hence, the clinician may need to take a brief and focused history for being reasonably sure about the diagnosis. Neuroimaging and electroencephalogram may be helpful for ruling out neurological pathologies mimicking NMS. For example, in patients with psychosis, catatonia may be considered as a differential diagnosis, especially when the patient is mute and exhibits staring. It may not be possible to exhaustively rule out all differential diagnoses, and at times management may need to be started on an empirical basis.

Treatment strategies for NMS

The management of NMS caused by atypical antipsychotics would not be substantially different from the management of NMS induced by typical antipsychotics (*Box 3*). NMS is a medical emergency and requires immediate attention for clinical management. Clinical diagnosis should be supplemented by laboratory tests, particularly CPK levels and total leukocyte counts. Once the diagnosis is suspected, the offending antipsychotic agent must be immediately stopped. Regular monitoring of the vitals should be carried out. The patient should be moved to the intensive care unit based on the severity of their medical condition. Intensive care would typically focus on monitoring of cardiorespiratory and renal status. Serial monitoring of serum electrolytes should be performed and corrected as required. In extreme hyperthermia, physical cooling measures may be instituted.

Several pharmacological options are available for the treatment of NMS.^{43,44} Dopaminergic agents such as amantadine and bromocriptine have been demonstrated to decrease the duration of and mortality associated with NMS. Amantadine 200 mg to 400 mg per day in divided doses is administered either through a nasogastric tube or orally. Bromocriptine is started at the dose of 2.5 mg three times a day and can be titrated upwards to 45 mg per day. Benzodiazepines, particularly lorazepam, can be given when underlying catatonia is suspected and where agitation is encountered in the patient. Lorazepam challenge can be done with 1 to 2 mg lorazepam administered parenterally, and may be continued in cases which show some response. Dantrolene is a muscle relaxant that can be applied in cases presenting with severe rigidity and hyperthermia. It is initiated at doses of 1–2.5 mg/kg body weight and can be repeated 6 hourly if improvement is seen. It can be administered orally after improvement with the parenteral preparation.

Box 2 Differential diagnosis of neuroleptic malignant syndrome

- Amphetamine toxicity
- Anticholinergic delirium
- Benign extrapyramidal side-effects
- Brain abscess
- Catatonia
- Heat stroke
- Malignant catatonia
- Malignant hyperthermia
- Meningitis or encephalitis
- Mid-brain structural lesions
- Non-convulsive status epilepticus
- Sepsis
- Serotonin syndrome
- Thyrotoxicosis

The altered mental state encountered during NMS also needs attention. If sedation is required, benzodiazepines may be a preferred choice. The medical management of the patient takes precedence over the underlying psychiatric disorder. As the patient's condition improves, discussion about further treatment options may be initiated.

Re-challenge with antipsychotics after NMS

One of the important considerations for a clinician is to whether to start another antipsychotic after a patient develops NMS. If the antipsychotic had been started for the control of psychotic symptoms, then the risk of psychosis without the cover of antipsychotics is high. The clinician may have to weigh the pros and cons of re-starting antipsychotic medication: the advantage of making the patient more manageable against the risk of inducing NMS.

Box 3 Treatment of neuroleptic malignant syndrome

- Consider shifting to intensive care unit
- Regular monitoring of vitals
- Monitoring of electrolytes and correction if required
- Management of medical comorbidity
- Physical cooling measures if required
- Dopaminergic medications: amantadine and bromocriptine
- Muscle relaxant: dantrolene
- Benzodiazepines: for management of agitation, when clinical suspicion of catatonia is present

Several reports of post-NMS antipsychotic re-challenge have been published.⁴⁵⁻⁴⁸ Indications for a re-challenge need to be clearly documented and other options of management (including electroconvulsive therapy) should be explored. Taking informed consent from the patient and/or family members/carers becomes necessary in such circumstances. Re-challenge should be done with an atypical antipsychotic with low propensity to cause NMS and dose titration should be gradual. Careful monitoring should be instituted, watching the evolution of symptoms of NMS. The re-challenge strategies thus adopted are in no way different from those post-NMS due to typical antipsychotics.

Conclusions

As psychiatrists, we are likely to encounter NMS induced by atypical antipsychotics during clinical practice. Although it is an uncommon adverse event of antipsychotic use, the potential fatality requires the clinician to take cognisance of this, and institute treatment immediately. The presentation of NMS induced by atypical antipsychotics, especially clozapine, may be quite different from NMS induced by typical antipsychotics – rigidity and tremor are encountered less frequently, while diaphoresis is probably encountered more frequently. Hence, a high degree of clinical suspicion may be required. Overall, the management of NMS induced by atypical antipsychotics is not broadly different to the management of that induced by typical antipsychotics. Additionally, an episode of resolved NMS does not preclude the subsequent initiation of antipsychotics, although due caution needs to be exercised while re-challenging antipsychotics in patients with a history of NMS induced by atypical antipsychotics.

1.7.62 Drug information update. Lithium and chronic kidney disease: debates and dilemmas

Sumeet Gupta Udayan Khastgir

Correspondence

Sumeet Gupta (sumeet.gupta@nhs.net)¹

2017-8

Abstract

Lithium is an established treatment for bipolar disorder and an augmenting agent for treatment-resistant depression. Despite awareness of renal adverse effects, including chronic kidney disease, for the past five decades, there has been a lack of research evidence. This has led to debates around the existence and magnitude of the risk. This article discusses the current evidence base regarding the link between lithium and chronic kidney disease, monitoring of renal functions and its clinical implications.

– Conclusions

Lithium is one of the oldest psychotropic medications. It remains the gold standard treatment for bipolar disorder and an augmenting agent for treating depression. Over the past few decades, additional benefits of lithium have also come to light, most importantly its role in preventing suicide and Alzheimer's disease.^{1,2} As it is often used as a maintenance treatment for lifelong disorders, concerns have been raised about its potential long-term organ toxicity, mainly the effect on glomerular function leading to chronic kidney disease (CKD).^{3–5}

Debate 1: does lithium cause CKD?

The association between CKD and lithium has been known for a long time, and monitoring renal function in patients receiving lithium therapy has been the norm for many decades. Despite this, there has been little research into the renal adverse effects of lithium so far. A link between lithium therapy and CKD has received increasing recognition, and there are several explanations for this. First, glomerular function decreases gradually as a normal part of the ageing process; increased life expectancy has led to increasing numbers of lithium patients being diagnosed with CKD. Second, there has been a resurgence of interest in lithium and its safe use, owing to its proven effectiveness in bipolar disorder in comparison with other mood stabiliser drugs and its anti-suicide effect. Last, more effective monitoring of renal function and the use of more sensitive measures to diagnose CKD, such as the estimated glomerular filtration rate (eGFR) rather than serum urea and creatinine levels, have led to the early identification of affected patients.

Despite significant progress over the past two decades, doubts still remain about the existence and magnitude of the risk.^{3–5} Unlike its tubular adverse effects, which more commonly present with polyuria and polydipsia, the glomerular adverse effects of lithium therapy appear after long-term use and might not normalise or improve after its discontinuation. It has therefore been difficult to attribute causality for this adverse effect.

The debate about lithium nephrotoxicity started in 1977, with reported abnormalities in renal biopsies from a small group of patients treated with lithium.⁶ Initial cross-sectional, case-control and small cohort studies with short-term follow-ups reported contradictory findings on the toxicity risk.^{7–10} In 1994, Bendz *et al* published a study of 142 patients who had been taking lithium for more than 15 years. The authors measured the glomerular filtration rate (GFR) by chromium-51-labelled ethylene diamine tetra-acetic acid (⁵¹Cr]EDTA) clearance and found that in 21% of patients the GFR was lower than in the demographic-matched population control group.¹¹ Two meta-analyses of these diverse studies failed to produce conclusive evidence for or against lithium nephrotoxicity. Although they showed that patients on lithium therapy had worse renal function than controls (as measured by serum creatinine levels or the eGFR), they reported that the clinical significance was questionable. Both meta-analyses highlighted poor quality data and significant heterogeneity among studies.^{12,13}

Recent epidemiological studies utilising large databases have consistently shown that CKD (defined as an eGFR of < 60 ml/min/1.73 m²) is common among lithium patients but that lithium therapy increases the risk of CKD. In addition, renal failure in patients with end-stage renal disease (ESRD) is not as rare as previously thought.^{14–17} In a retrospective cohort study using the General Practice Research Database, Close *et al* reported that patients taking lithium for bipolar disorder had a twofold increased risk of developing renal failure and a two-and-a-half-fold increased risk of developing CKD of any stage compared with lithium-naïve patients.¹⁴

The relationship between lithium therapy and renal failure or ESRD has been investigated in many other studies that mainly use data from databases of patients undergoing renal replacement therapy (dialysis or renal transplant). A Swedish study found that 0.81% of renal replacement therapy patients had kidney disease attributable to lithium-induced nephropathy. Moreover, the risk of ESRD in lithium-treated patients was nearly sixfold greater than in the general population.¹⁷ Another recent retrospective cohort study, of renal replacement therapy patients in Australia, reported that the incidence rate of ESRD due to lithium therapy had increased significantly from 0.14 cases per million population per year (95% CI 0.06–0.22) in 1992–1996 to 0.78 cases per million population per year (95% CI 0.67–0.90) in 2007–2011. This report emphasised that lithium-induced nephropathy is not a rare cause of ESRD, and is becoming more common.¹⁸ However, the debate is far from over and contradictory findings continue to be published. For example, in a review of patients with ESRD in Sweden, Aiff *et al* found 32 cases of ESRD in patients who had started taking lithium before 1980 but none in those who had started taking lithium after 1980. Hence, the authors suggested that the opposite was true: renal failure might not be a problem with the current practice of maintaining lower serum lithium levels along with

better monitoring of renal function.¹⁹ In a recent population-based retrospective cohort study in Denmark, Kessing *et al* also failed to identify any patients with lithium-induced ESRD. However, their findings indicated that bipolar disorder is independently associated with CKD.²⁰ Therefore, uncertainties about the magnitude of the CKD risk are yet to be resolved.

It is clear that not all patients taking lithium experience glomerular adverse effects. Most likely, only a select group of patients develop CKD and only a small proportion of these progress to ESRD.²¹ Moreover, the association between lithium therapy and CKD is unlikely to be entirely explained by coincidence or confounding variables (such as age, other psychotropic drugs or comorbid medical/psychiatric illnesses). Discrepancies among studies were largely due to methodological differences such as varied parameters to assess renal function and definitions of renal impairment, short-term follow-up, a lack of patients on long-term lithium therapy, combining high-risk and low-risk groups, choice of control group (healthy *v.* psychiatric patients), and an inability to control the confounding variables. Definitive data on the magnitude of the risk are still lacking. Moreover, in the absence of any pathognomonic histological or biochemical changes, lithium-associated CKD remains a diagnosis of exclusion.

Debate 2: is there any relationship between the tubular and glomerular adverse effects of lithium?

It was previously assumed that CKD is preceded by tubular adverse effects of lithium. However, differences in the prevalence of tubular and glomerular adverse effects and a lack of correlation between reduced glomerular function and tubular abnormalities on renal biopsy (in the form of tubular dilation and microcysts) argue against this assumption.^{22,23} Despite this, the presence of tubular adverse effects is suggested to increase the risk of CKD, hence the suggestion that treating or preventing tubular adverse effects might help to prevent deterioration of glomerular function.²¹

Debate 3: is it possible to identify patients at high risk of developing CKD/ESRD and to predict the prognosis of these adverse effects?

As only a small proportion of patients on lithium therapy experience CKD, early identification of these high-risk patients might help to prevent and manage this adverse effect. Over the years, researchers have tried to identify both susceptibility and treatment-related factors such as associations with ageing, comorbid physical/psychiatric health problems, cumulative lithium dose or treatment duration, dosing frequency, and number of toxicity episodes.

Acute lithium toxicity is known to cause acute renal failure, and many patients suffer renal impairment even after recovering from an acute episode. There is consistent evidence that acute nephrotoxicity episodes can lead to CKD.^{6,9,24} Recently, Clos *et al* suggested that lithium-associated CKD is primarily mediated by acute lithium toxicity, and that avoiding lithium toxicity can prevent renal impairment.²⁵ Studies suggest a relationship between impaired renal function and either persistent high serum lithium levels (>0.6mmol/L *v.* <0.6mmol/L) or a single serum lithium measure of > 1.0 mmol/L. As these were not prospective studies, it is difficult to establish a causal relationship, especially as reduced renal function can also increase serum lithium levels.^{26,27} On the other hand, a recent randomised placebo controlled trial of low-dose lithium therapy (serum lithium levels of 0.25–0.50 mmol/L) in elderly patients with mild cognitive impairment did not show a significant difference in eGFR over a 4-year follow-up period.²⁸ The study suggests that lower therapeutic levels of lithium might not impair renal function.²⁸ In contrast, other studies have failed to show a relationship between CKD risk and lithium dose or serum lithium levels.^{17,24} It is well established that higher serum lithium levels provide better protection against another affective episode (especially a manic episode). Therefore, the debate about what serum lithium level represents a balance between safety and effectiveness is likely to continue until more definitive data become available.

Once-daily dose is thought to be associated with less renal impairment than multiple daily doses.²¹ Although a few studies do not support this, none have so far reported disadvantages for once-daily dosing.²⁹ Therefore, although a definitive answer is lacking, it makes sense to adopt a once-daily dosing strategy. Comorbid physical health conditions such as diabetes or hypertension can independently cause CKD, but CKD is also commonly seen in lithium-treated patients, even in the absence of a comorbid physical illness. Therefore, comorbidity is unlikely to entirely explain the association between lithium and CKD.

So far, evidence about CKD risk factors is limited and somewhat contradictory. However, it indicates that lower therapeutic lithium doses might have a reduced detrimental effect on renal function and that acute lithium toxicity should

be avoided to prevent renal dysfunction. Furthermore, once-daily dosing might be safer than multiple daily doses.

Debate 4: how can we effectively monitor glomerular adverse effects?

Monitoring renal function in patients on lithium therapy has been the norm for many years, but there are significant discrepancies among the different guidelines on the parameters that should be used and the frequency of monitoring.^{30–32} The UK National Institute for Health and Care Excellence (NICE) recommends 6-monthly monitoring; the British Association for Psychopharmacology recommends annual monitoring; and the American Psychiatric Association recommends monitoring every 2–3 months for the first 6 months, followed by 6-monthly to annual measurements.^{30–32} However, they do not give specific guidance about the parameters for measuring renal function and continue to recommend measuring serum urea and creatinine levels, although recent guidelines have started to recommend measuring the eGFR. In other medical areas, measuring serum urea and creatinine levels is no longer a preferred option for monitoring renal function: standard practice is to monitor the eGFR. Many equations can be used to calculate the eGFR from serum creatinine concentration, with differing accuracies. Recent NICE guidelines on managing CKD suggest using the CKD Epidemiology Collaboration (CKD-EPI) equation. They also suggest using the CKD-EPI equation based on cystatin C levels if accurate GFR estimates are necessary.³³ Psychiatry guidelines do not recommend any particular method for calculating the eGFR.

The importance of measuring proteinuria to monitor renal function in CKD patients is now firmly established. Proteinuria is an independent predictor of CKD progression, cardiovascular disorders and all-cause mortality.³³ However, a role for estimating and monitoring proteinuria in lithium-related renal impairment is yet to be established. The evidence so far is sparse and contradictory: some reports suggest that proteinuria is linked to lithium-associated CKD and indicates a poor prognosis, while others suggest that lithium-associated CKD is not associated with proteinuria and that in the presence of proteinuria one should rule out other causes.^{5,10,21} However, recent publications have highlighted the importance of monitoring proteinuria in patients with lithium-associated CKD.^{21,34}

Unfortunately, psychiatric guidelines have not kept up with advances in nephrology, and we need guidelines for evidence-based monitoring of renal function. Recent publications suggest that renal function should be monitored regularly via the eGFR and that the degree of proteinuria should be measured in patients with a declining eGFR or an eGFR of <60 ml/min/1.73 m.^{221,34} However, these recommendations are developed for CKD associated with other aetiological factors, and more specific evidence-based monitoring guidelines need to be developed to screen and monitor lithium-associated CKD.

Dilemma 1: should lithium be stopped if a patient develops CKD?

The most common dilemma clinicians face is what to do if a patient on lithium therapy develops CKD. In this scenario, the clinician must decide whether to continue or discontinue lithium. Advice in the literature is contradictory, ranging from discontinuing lithium as soon as renal function starts to deteriorate (as evidenced by two consecutive tests) to continuing lithium even in the presence of CKD.^{18,35} The decision to discontinue lithium is based on the assumption that lithium is a causative factor for CKD and that its discontinuation would improve renal function or at least slow down deterioration. However, neither of these assumptions is completely supported by current evidence.^{4,5,36} Moreover, we still do not know whether lithium-associated CKD is reversible or irreversible. It has been suggested that this adverse effect might be reversible at the initial stages, only becoming irreversible after a certain threshold is reached.^{4,21} Presne *et al* suggested that the threshold might be somewhere between a GFR of 25 and 40 ml/min/1.73 m.²² Thus, the advantages of discontinuing lithium are uncertain.^{4,5,35,36} On the other hand, there is enough evidence to suggest that lithium discontinuation is associated with high risk of relapse for patients with mood disorders, especially those with bipolar disorder. Moreover, the illness might become treatment refractory.²¹ One of the advantages of lithium is its anti-suicide effect: the risk of suicide is known to increase after lithium discontinuation.³⁷ The decision to continue or discontinue lithium treatment should thus only be taken after careful assessment of the benefits and risks, and because of uncertainties surrounding these, it is essential that the decision-making process should include patients and all of the professionals involved, including nephrologists. Our experience agrees with a documented report that many psychiatric patients prefer to maintain their mental stability against the unknown risk of further deterioration in renal function.³⁸ In clinical practice, it is not unusual to request that a nephrologist makes this treatment decision. However, it is important that psychiatrists should not abdicate responsibility, because nephrologists might not be fully aware of

the risks associated with the psychiatric illness.^{5,21,34,35} Another option would be to continue lithium treatment while closely monitoring renal function. Many authors have suggested trying to keep the lithium level at the lower end of the therapeutic range, although there is not much evidence that this prevents further deterioration in renal function. However, as CKD patients are particularly prone to lithium toxicity, this strategy appears prudent.

Dilemma 2: should we consider lithium therapy for patients already diagnosed with CKD?

There is not much research evidence to support or dispute this decision. Lithium treatment may lead to further deterioration in renal function, which could be clinically important because the renal reserve is already low in patients with CKD. A study of elderly patients suggested that individuals with pre-existing CKD were more susceptible to a lithium-associated decline in renal function³⁶ On the other hand, we should not deprive such patients of an effective therapy because of unproven adverse consequences. In 2012, Werneke *et al* designed a mathematical model based on the existing, but limited, evidence to analyse the risks and benefits of continuing or discontinuing lithium therapy for CKD patients. They concluded that most patients should continue lithium treatment even if long-term renal adverse effects develop. They also recommended prescribing lithium to CKD patients because treatment benefits outweighed the risks.³⁵ However, at present there is not enough evidence to support any decision.

Conclusions

Limited knowledge of its renal (especially glomerular) adverse effects has led clinicians to either avoid or prematurely discontinue lithium therapy because of the perceived risk of a negative renal outcome. Over the past decade, a few large database studies have confirmed the existence of lithium-associated CKD, but uncertainty remains about the magnitude and determinants of the risks. Lithium therapy is here to stay and we should learn to optimise its efficacy and safety. There is a need for large-scale prospective studies focused on the early identification of high-risk patients and for developing evidence-based guidelines to monitor renal function in patients treated with lithium.

1.7.63 Shared decision-making in medication management: development of a training intervention

shared decision-making in medication management in mental health as part of the Shared Involvement in Medication Management Education (ShIMME) project. Three stakeholder groups (service users, care coordinators and psychiatrists) received training in shared decision-making, and their feedback was evaluated. The programme was mostly well received, with all groups rating interaction with peers as the best aspect of the training. This small-scale pilot shows that it is feasible to deliver training in shared decision-making to several key stakeholders. Larger studies will be required to assess the effectiveness of such training.

Shared decision-making is a collaborative process in which clinicians and patients make treatment decisions in partnership. Both partners bring valuable contributions to this process: patients share their experiences, values and preferences, and clinicians support patients in clarifying these, as well as providing clinical expertise and evidence-based information about treatment options. Jointly, they aim to reach an agreement on the best way to proceed.^{1–3}

Shared decision-making is considered particularly relevant for preference-sensitive decisions, where there are several reasonable treatment options and evidence does not support a clear best choice. Different options require the balancing of possible benefits against potentially significant adverse or as yet unknown effects.^{3–5} Most medication decisions in mental health fall into this category, which makes psychiatric medication management an important area for shared decision-making.⁶

There are good reasons for encouraging adoption of shared decision-making in mental health. Many patients wish for greater participation in treatment decisions.⁷ In chronic conditions, where long-term healthcare decisions are required, studies have shown that shared decision-making improves satisfaction, adherence and well-being.⁸ Shared decision-making is at the core of recovery principles which promote autonomy and self-management skills, as well as being considered essential for delivering patient-centred care.⁹ National and international government initiatives,^{1,10–13} such as the UK Health and Social Care Act 2012 and the US Patient Protection and Affordable Care Act 2010, endorse shared decision-making, as do professional bodies^{14–16} and practice guidelines.^{17–21} Shared decision-making is an expected element of all NHS care (Health and Social Care Act 2012, s. 23, 26). Although there is evidence of its benefits, and many patients want greater involvement,⁷ the adoption of shared decision-making into routine clinical practice continues to be slow,^{22,23} especially in mental health.²⁴

A range of interventions has been developed to promote implementation of shared decision-making, predominantly in physical health.^{25–28} Although this is an evolving area, relatively few interventions focus specifically on treatment decisions in mental health.^{6,29–33} Evidence is sparse regarding the effectiveness of such interventions in general,^{23,25} and in mental health settings in particular,³³ although some promising results have been reported. These include a study of in-patients with schizophrenia or schizoaffective disorder who received five sessions of shared decision-making training;²⁹ a multifaceted programme based on shared decision-making concepts for primary care physicians treating patients with depression;³⁰ a peer-run Decision Support Centre in the waiting area of a psychiatric medication clinic;³¹ and online resources supporting shared decision-making.³² The limited evidence available points towards interventions being more effective when involving healthcare professionals and patients together, rather than only targeting one group.²³

The Shared Involvement in Medication Management Education (ShIMME) project was set up to promote shared decision-making of service users (the term ‘service users’ was used in the ShIMME project and has been retained here) in medication decisions by delivering a specially developed training programme to three key stakeholder groups: service users, care coordinators and psychiatrists. (In the context of the ShIMME project ‘care coordinator’ refers to psychiatric nurses, social workers, occupational therapists, psychologists, support workers, peer workers and students training in these disciplines.) To our knowledge this is the first UK-based project to deliver and evaluate such an intervention that targets multiple stakeholders simultaneously.

The project was a partnership between Cambridgeshire and Peterborough NHS Foundation Trust (CPFT) and Anglia Ruskin University. Reflecting the strong collaborative ethos, service users were active team members jointly with academic researchers, mental health practitioners and other professionals working within CPFT.

This paper describes the stages of the ShIMME project: consultations about shared decision-making, development and implementation of a pilot intervention, and evaluation of feedback. It is one of several articles relating to the project.^{34–36}

Method

Consultation phase

The initial phase of the project involved a literature review and consultation with local stakeholders about the process of shared decision-making. Data were collected via focus groups with practitioners and users of adult mental health services in CPFT. Four focus groups were conducted with service users ($n = 27$), two with psychiatrists ($n = 4$), one with community psychiatric nurses (CPNs, $n = 10$), and one with care coordinators other than CPNs ($n = 8$). Four individual telephone interviews were also conducted with psychiatrists. Discussion was generated in response to open questions about current practice in medication management, how decisions should ideally be made, perceived barriers to and facilitators of shared decision-making, and how shared decision-making training should be conducted. Consultation groups lasted around 90 min and were audio recorded. The anonymised transcripts were analysed using thematic analysis,³⁷ conducted with NVivo software (www.qsrinternational.com). This involved a detailed exploration of transcript texts by two team members who worked in collaboration to iteratively develop themes.

The following themes about shared decision-making in medication management, which are presented in more detail elsewhere,³⁴ emerged from this analysis and fed into the development of the training programmes.

1. Ongoing respectful, trusting, open and honest relationships are paramount – service users’ concerns and experiences need to be heard and taken seriously.
2. Differences of power in the consultation can be complex and a barrier to shared decision-making – clinicians can underestimate the effect this has.
3. Access to reliable, user-friendly information is essential, including information about reducing or coming off medication and adverse effects of medication.
4. All available treatment options should be considered, including non-pharmacological treatments.
5. The process of shared decision-making needs to be flexible, taking into account preferences and situations which may change over time. Acute stages of illness or crisis situations were identified as times when shared decision-making would be likely to be more problematic.
6. Broader stakeholders (beyond service user and prescribe!¹) have important roles in the shared decision-making process (e.g. other professionals, carers).
7. There is currently significant variation in medication management and the extent to which this involves shared decision-making.

Training intervention: design

A multidisciplinary working group including service users, academic researchers, psychiatrists, a mental health nurse and a pharmacist met regularly to develop the training intervention. The results of the consultations, literature review and examples of existing practice fed into the development.

Training was designed to be delivered to service users, care coordinators and psychiatrists in parallel but separate groups. The aim was to optimise the impact of the intervention by delivering it simultaneously to key stakeholders who are actively involved in medication management, while addressing the specific training needs and concerns of each group. Each group was facilitated by a service user trainer, and either a psychiatrist (for service user and psychiatrist groups) or a mental health nurse (for care coordinator groups), allowing participants to learn from two relevant perspectives.

The programme employed a range of interactive learning methods. These included specially commissioned video material showing different clinical scenarios, small group exercises, general group discussions, use of testimonials and role plays. The resource materials and hand-outs covered a diverse range of views and approaches, to raise awareness and stimulate discussion. All participants had access to the public section of the project website (www.shimme.arcusglobal.com) as well as a secure discussion forum for their group.

The training programmes for the three stakeholder groups covered the same core content: background to the project key components of shared decision-making in the clinical encounter and rationale for promoting shared decision-making barriers to and facilitators of shared decision-making awareness of the effects of power imbalances in psychiatric consultations developing collaborative relationships importance of clarifying personal preferences, values and experiences in shared decision-making the concept of a ‘meeting of two experts’ in the clinical encounter, with personal experience and clinical expertise complementing each other³⁸ accessing and appraising information about medication, including examples of decision aids raising awareness of adjuncts or alternatives to medication addressing issues around coming off or reducing medication trialling of versions of three paper-based tools developed for supporting and recording the shared decision-making process information about useful websites.

In addition to the core content, the service user groups focused on: practising setting personal goals and identifying preferences making use of a personal well-being plan and self-help resources looking beyond medication to enhance well-being, drawing on Deegan’s work on ‘personal medicine’³⁹ introduction to assertiveness how to access information about medication, including a talk by a National Health Service (NHS) trust mental health pharmacist, who was available for further discussion afterward supported ‘hands-on’ experience exploring relevant websites.

Besides the core content, the care coordinator training focused on adopting the role of a ‘shared decision-making coach’, supporting service users to play a more active part in the shared decision-making process³⁵ The programme for psychiatrists focused on competencies and resources that support embedding shared decision-making into routine clinical practice while acknowledging real-life challenges.

Training intervention: delivery

All training group participants were recruited from CPFT community mental health services: service users from the rehabilitation and recovery pathways; and professionals from these services and from assertive outreach teams. Service users were invited to participate by their care coordinators and psychiatrists and care coordinators were approached by team managers. In total, 47 service users, 12 psychiatrists and 35 care coordinators took part in the training.

Training was held in three different locations to reduce travelling for participants. Service users were reimbursed for travelling costs and received a fee (£40) for completing an evaluation before and after the programme.

The training was delivered in small group settings (2–12 participants), with each cohort completing their course of training together. An atmosphere of trust, acceptance and respect was encouraged. Participants had the opportunity for informal interaction before and after sessions as well as during breaks. Facilitators and project team members could be contacted between sessions for additional support.

Service user training groups were structured into four 2h sessions, meeting fortnightly After the training, two follow-up sessions were offered for ongoing support. Care coordinators met three times, at monthly intervals, for 1.5 h.

Psychiatrists had two 2 h sessions, one month apart, with an online self-study component. For organisational reasons one multidisciplinary team of clinicians received their training together in a single day.

Evaluation

The experience and impact of the training intervention was evaluated by collecting quantitative and qualitative data anonymously from participants at different stages of the project.

After providing baseline data, participants and facilitators completed a short questionnaire after each session, and participants completed a longer one immediately after the final training session. The questionnaires explored what the participants had hoped to learn from the programme, their views on its content and impact, and feedback on particular sessions, practical aspects, teaching methods and support materials.

Analysis of quantitative and qualitative data examining the impact of the intervention at a 12-month follow-up, as well as an economic analysis, will be reported on separately.

Results

Although care coordinators and psychiatrists were mostly trained in separate groups, their demographic and feedback data are reported as one group of clinicians. Demographic and attendance data for service users and clinicians are shown in *Table 1* and *Table 2*.

Demographic characteristics of participants

	Service users (<i>n</i> = 47) <i>n</i> (%)	Clinicians (<i>n</i> = 47) <i>n</i> (%)

Attendance	37 (79%) attended at least 3 sessions of 4	20 of 21 (95%) attended at least 2 sessions of 3 14 attended team training day	6 of 10 (60%) attended both training sessions 2 attended team training day

The mean length of contact with mental health services for service users was 17 years. The most common reported diagnoses were schizophrenia, schizoaffective disorder or psychosis (*n* = 28, 60%), followed by depression (*n* = 12, 26%), bipolar affective disorder (*n* = 9, 19%), personality disorder (*n* = 5, 11%), anxiety (*n* = 4, 9%) and post-traumatic stress disorder (*n* = 4, 9%). Some participants reported multiple diagnoses. The majority of service users received state benefits (*n* = 43, 92%), with *n* = 39 (83%) on a disability living allowance.

Immediate post-programme feedback was given by 61 (65%) participants: 33 (70%) service users and 28 (60%) clinicians, including 22 (63%) care coordinators and 6 (50%) psychiatrists. Before starting the programme, service users mostly hoped to learn about ways to cope with their symptoms not solely focused on medication, to understand their medication better and to negotiate decisions. Clinicians were particularly interested in improving their practice, learning about the model and process of shared decision-making, availability of support materials, and sharing experiences with colleagues.

Expectations of the programme were largely met in both groups, with the majority of participants expressing a positive view about its content. In all groups, the opportunity for discussion and exchange of views with peers was highlighted as the best aspect of the programme. In addition, service users valued the clarity of the information conveyed, access to resources and the prospect of greater collaboration in consultations. Clinicians also appreciated access to resources and the information given, as well as the opportunity to reflect on their own practice, particularly in the case of psychiatrists.

There was little negative feedback. Just over half of service users (*n* = 17, 52%) and the majority of clinicians (*n* = 20, 71%) did not identify any aspects of the programme as being 'least satisfactory'. Some service users mentioned dissatisfaction with practical aspects or teaching methods, and a few referred to difficulties reading all the paperwork/understanding everything. A small number of psychiatrists expressed concerns about a perceived bias against their profession. Most participants felt the training was pitched at the right level. Use of the project website was variable, with about half of service users visiting it outside sessions. Most psychiatrists visited the website, but only a few

care coordinators did. The online forum was not used by any of the groups.

Most clinicians rated the training programme as relevant to their clinical practice, but fewer expected that what they had learned would shape their future practice. Over half of service users expected or were at least hopeful that the programme would affect future practice.

A summary of the post-programme feedback is given in *Table 3*.

Summary of feedback

	Service users (<i>n</i> = 33)	Clinicians (<i>n</i> = 28)
Most important things participants hoped to learn	Lifestyle changes/coping with symptoms/alternatives to medication Understanding medication management/SDM/negotiating decisions Sharing experiences Understanding side-effects of medication Assertiveness/confidence with professionals Info about project/research Reducing/coming off medication	Improving practice Learning about SDM model and process Support materials/tools for SDM Sharing ideas and practice Information about medication, including side-effects and coming off Learning about the project Gaining confidence in discussions with service users Understanding service user perspective
Views on content of the programme	Positive views 28 (85%): interesting, helpful, informative, empowering, encouraging, learned a lot Other comments 4 (12%): SDM needs to be implemented from consultant psychiatrist downwards/did not learn that much concrete	Positive views 21 (75%) 18 (82%) care coordinators, 3 (50%) psychiatrists: very good, good, interesting, informative, well-balanced Other comments 4 (14%): repetitive, some prejudice against psychiatrists
Best aspects of programme	Meeting others, exchanging views and experiences, supportive environment Information conveyed, new ideas and access to resources Learning to be involved in my medication management, feeling confident my views will be listened to	Interaction with others, chance to discuss implementation of SDM Direction regarding resources/tools to support SDM, information Concept of SDM Gaining confidence in promoting SDM/putting SDM into practice Reflecting on own practice Getting service user perspective
Least satisfactory aspects	Practical aspects, teaching methods Not understanding everything, not able to read all paperwork Parts boring, same	Practical aspects, teaching methods Perceived bias against psychiatrists Did not improve personal knowledge of medication Content
Training pitch at right level	32 (97%)	20 (71%): 17 (77%) care coordinators, 3 (50%) psychiatrists
Use of project website	17 (52%)	11 (39%): 6 (27%) care coordinators, 5 (83%) psychiatrists
Relevance of training programme and impact on future practice	Expecting impact: 12 (36%) Hopeful of impact: 7 (21%) Doubtful/unsure: 5 (15%) Relevant for others: 2 (6%)	Relevant: 23 (82%) Impact on own practice in future: yes 16 (57%), no 1 (4%), hopeful/probably 2 (7%)

SDM, shared decision-making.

Listed in order of frequency.

Discussion

The ShIMME project was a small-scale exploratory project with an emphasis on service users co-leading in all aspects, while aiming to ensure the views of all key stakeholders were integrated into the development and delivery of the training intervention.

The training programme was well received overall, demonstrating the feasibility of providing group-based training in shared decision-making to service users and practitioners in NHS community settings. In this case, service user participants were drawn from the rehabilitation and recovery pathways which serve people with chronic and often severe mental health problems. Demographic data from participants indicated high levels of chronicity and disability. The positive feedback, good attendance and engagement from this group suggest that taking part in shared decision-making training is possible and worthwhile for people experiencing a range of mental health challenges.

Feedback indicated that service user participants were interested in being actively involved in managing their mental health, including gaining a better understanding of medication and exploring a range of other strategies to foster well-being. Clinicians showed an interest in improving their practice by learning about shared decision-making.

Members of all the stakeholder groups gave positive feedback about the group-based training, allowing for the exchange of ideas and experiences with peers. This was also reflected in facilitator comments about the supportive atmosphere and participants' enjoyment of meeting with each other in the service user groups. Interaction with peers seemed to be an important aspect of the whole programme.

There may also be advantages in service users and clinicians attending joint training groups, allowing participants from different backgrounds to work together on an equal basis and to gain a better understanding of others' perspectives without the pressures and structures of the clinical encounter. The involvement of carers and important others might bring further benefits.

The feedback about the content, approach and pitch of the teaching within the group of psychiatrists was not quite as positive as in the other groups. The reasons for this are likely to be multifaceted and would warrant further exploration, with possible adjustments of the programme. Away to enhance acceptability and engagement would be to encourage more psychiatrists to become involved in shared decision-making training and development of tools.²⁸ Use of the project website was limited, in particular by care coordinators and service users. Technical difficulties with the website might have contributed to this, but comments during sessions indicated that some participants, particularly service users, had low IT confidence and limited internet access outside the training sessions. Future training programmes will need to provide non-digital resources, as well as supporting access and use of IT resources.

The project team developed three paper-based tools to support the process of shared decision-making, which were trialled in training groups and repeatedly revised. Although useful, these would need to be integrated into the existing electronic records system to be truly effective in promoting, supporting and documenting the process of shared decision-making without significantly affecting consultation time. At present this remains a challenge, but there have been some promising recent developments.⁴⁰

Both groups of clinicians considered the training relevant to their clinical practice, although they appeared uncertain whether the programme would influence their future practice. This might be due to concerns about additional barriers to implementation or aspects of the training itself. Despite their positive feedback about the programme, service users were also cautious about its impact. This might reflect the perception that they have little influence in making significant changes to their healthcare delivery or doubts about positive initiatives being translated into clinical practice.

While this pilot programme had the limitations of a modest number of participants, not all of whom provided feedback, the consultation data from local stakeholders, the development of the training programme and the feedback from participants were all encouraging. Drawing on experiences from this project, CPFT has been working towards implementing shared decision-making across the trust by embedding shared decision-making into its procedures, raising awareness and offering training to practitioners across the trust (www.promise.global/sdm.html). The associated Recovery College (www.cpft.nhs.uk/about-us/recovery-college-east.htm), which is open to service users, family, friends and staff,

also included training in shared decision-making. The pilot project benefitted from a supportive environment within the trust, and the success of implementation in other organisations would depend on their own local conditions.

The complexity and difficulty of implementing shared decision-making in a mental health setting should not be underestimated.^{36,41} For it to truly become a routine part of clinical practice, changes in attitudes and behaviours are necessary among all parties involved, as well as the wider society.^{36,42} Psychiatrists are well placed to take on a leadership role in promoting shared decision-making within health services and should also be pivotal in explaining the benefits of increased patient autonomy and responsibility to the general community.

We thank all ShIMME project team members, service users and practitioners, as well as Dr Fiona Blake, Sheena Mooney, Mary Jane O'Sullivan and others for critically reviewing the manuscript. We are grateful to Prof. Matthew Large for his contributions as part of the *BJPsych Bulletin* Author Mentoring Scheme.

1.7.64 Trainee experiences of intellectual disability psychiatry and an innovative leaderless support group: a qualitative study

Abstract

Aims and method There is very little research into the challenges of training in intellectual disability psychiatry or into interventions which may address these challenges. Using focus groups, we explored the experiences of intellectual disability psychiatry trainees, and evaluated a leaderless trainee support group developed in Bristol.

Results Five distinct themes were identified via framework analysis: that trainees felt unprepared for the difference from previous posts; the need for support; the value of the group; that trainees were concerned about judgement in supervision; that the group structure was valued.

Clinical implications Our findings highlight the support needs specific to intellectual disability psychiatry trainees. Leaderless peer support groups may be a valued resource to address such issues, and may be a useful model to be considered by other training schemes.

Intellectual disability psychiatry (also known as learning disability psychiatry particularly in UK healthcare services) is a specialty in the UK involving the assessment and management of mental health problems in individuals with intellectual disability and other developmental disabilities. Trainees in intellectual disability psychiatry face specific challenges, including the need to acquire enhanced communication skills, understand a range of genetic, neuropsychiatric and neurodevelopmental conditions, and utilise knowledge of complex psychopharmacology.¹ They may also have to confront substantial existential and societal issues associated with caring for vulnerable individuals who face exclusion and disadvantage in many aspects of their lives.²

Although there is little published literature, one study exploring the experiences of intellectual disability psychiatry trainees described strong feelings of isolation, alienation, lack of skills and impotence, not unlike the feelings experienced by the patient groups the trainees worked with.² Prompted by these findings, trainees on the Bristol intellectual disability psychiatry training scheme developed an innovative, leaderless trainee support group (*Box 1*) after taking advice from a consultant psychotherapist. The group aimed to provide a forum for reflective peer support for core and advanced intellectual disability psychiatry trainees (doctors specialising in psychiatry, previously termed senior house officers and specialist registrars). It has continued since 2005, with individual membership varying from 6 months (core trainees) to 3 years (advanced trainees).

Here we report the findings of a qualitative study exploring the experiences of trainees in intellectual disability psychiatry who participated in this support group. The aims were to explore doctors' experiences of training in intellectual disability psychiatry, in particular the positive and negative aspects of working in this specialty, and the role of support and supervision; and to evaluate the model of a leaderless peer support group from the perspective of its participants.

Box 1 Trainee support group

- **Who:** All core and advanced trainees in intellectual disability psychiatry placements are invited. Typical attendance is 3–6 participants, dependent on need, leave or competing priorities. The group does not have a facilitator or leader, and was set up with an egalitarian structure.
- **When:** Fortnightly before the academic programme.
- **Where:** On the site of the academic meeting, central in the area between the different placements.
- **How long:** 90 min.
- **Structure:** 10 min of chat as people arrive, 70 min of focused support group. No fixed agenda, time used between trainees depending on needs that day.
- **Boundaries:** start and end time, confidentiality, respect.

Method

We approached this project using a qualitative design, as we were interested in exploring a variety of individuals' interpretations of their experiences.³ Although one-on-one interviews were an alternative, focus groups provided a time-efficient way to gather data, allowed discussion of the issues raised, and enabled researchers to gain a sense of whether the individuals identified with each other's experiences.⁴

Procedure

Two focus groups were held, one for each cohort, each lasting 90 min. Focus groups were facilitated by two of the researchers (J.N. and J.K. for the first cohort, and J.K. and D.R. for the second), who used a topic guide and encouraged free-floating discussion. The facilitators sought clarification when needed, and prompted the participants to move on to new areas when they started to repeat previously discussed issues, or after periods of prolonged silence. They also encouraged participants to share examples from their own work wherever possible. Recordings were transcribed, including spoken words, speech fillers and dysfluencies, by a medical secretary.⁵

The topic guide comprised four sections: experiences of working with people with intellectual disability; the role of support and supervision in training in intellectual disability psychiatry; reflections on the value and usefulness of the trainee support groups; specific consideration of the leaderless, egalitarian model of the trainee support group. The list was generated from data gathered via a previous semi-quantitative survey investigating perceptions of the trainee support group held by trainees and trainers in 2007.

Participants

All doctors who had been members of the trainee support group during the preceding year were invited to participate in each of the study's two focus groups. This process was performed twice, 4 years apart, sampling two non-overlapping cohorts. This was to allow exploration of whether experiences were cohort specific. Each focus group comprised five participants. The first included three core and two advanced trainees and the second two core and three advanced trainees. Each group was mixed gender and had trainees from different community learning disability teams (CLDTs) in the scheme. The ages of the participants were between 25 and 40 years.

Participation was voluntary, without incentive and occurred during work time. All participants consented to their comments being recorded and transcribed for analysis, with individual identities removed.

Ethical considerations

The regional training programme director reviewed the proposal, considered relevant ethical issues and gave approval for the study.

Analysis

Framework analysis was the most appropriate analytic method, given its relative simplicity and ease of use, and served the intended aims of seeking themes rather than generating explanations or new theories or concepts. A process similar to the framework analysis described in detail in Rabiee was followed.⁵

Stage 1

Two authors (J.K. and D.R. in the first and R.S. and H.T. in the second focus group) independently immersed themselves in the focus group transcript as a whole. The transcript was manually coded on paper, thus developing a 'thematic framework'.

Stage 2

Following this, quotes were highlighted, pasted into a separate document and arranged by broad themes.

Stage 3

The interpretation stage of the analysis was done jointly between each pair of authors and involved refining and condensing the themed quotations using suggested criteria of: attention to frequency; emotion/intensity; specificity (attention to actual personal experience over hypotheticals); and extensiveness. Internal consistency (reduced attention to views subsequently contradicted or changed) could not be reviewed as suggested by Rabiee,⁵ as individuals could not be consistently tracked throughout the transcript.

Stage 4

The final stage involved a review of the analysed and interpreted data to see whether they had resulted in significantly overlapping themes suggestive of an overarching or superordinate theme. Themes were named by a process of abstraction as described by Fade.⁶ A requirement for reflexivity was acknowledged from the outset. Thus, researchers' influence was viewed as a necessity for making sense of the richness of the data generated by group participants rather than as bias to be eliminated.⁷

Results**Results of thematic analysis**

Five distinct themes evident in both focus groups were identified. Owing to the anonymisation of participants during transcription, it was not possible to attribute quotes to specific participants. However, the quoted contributions incorporated a broad range of views arising in themes evident in both focus groups. Furthermore, it was evident in the transcript that they did not represent any one dominant voice.

Theme 1: unprepared for difference

Both groups perceived placements in intellectual disability psychiatry as being quite different to other psychiatry posts. This was viewed as having both positive and negative facets. Positive aspects included having more time allocated to conduct detailed assessments, and the potential to work jointly with colleagues from other professional groups. These were seen as enabling the doctor to assess the patient in a holistic manner and the overall experience was described as 'rewarding' by several trainees: "You don't just see the person in one dimension; you are seeing a holistic view. Working with people with disabilities ... can be very rewarding." A variety of negative issues were discussed, including problems associated with reliance on suboptimal collateral histories and doctors questioning their own abilities to provide adequate care to this patient group, particularly with respect to specialist skills such as epilepsy management: 'Suddenly you are asked to treat something you've probably not had a great deal of training for [epilepsy]... suddenly you are expected to already know about it.' Some trainees appeared to be aware of such differences prior to starting posts, which was sometimes a source of apprehension. However, for others it was more of a surprise: 'I think it is very

different to what one gets in general psychiatry and I think that is not clear at the outset and sometimes can come as a surprise.’

A sense of isolation while working in these posts was part of the discourse in both groups. The change from being in large mental health teams to smaller CLDTs, where the other professionals have limited psychiatry training, was noted. The low number of medical colleagues in the CLDTs also generated feelings of isolation, as did the geographical spread of posts: “The posts can be quite isolating ... there might be you and another doctor within the team. We are quite isolated, we are far and few. There is that huge geographical spread which means that you don’t tend to see people informally.”

Theme 2: need for support

The trainees described the need for help and support in coping with aspects of their work. For example, there were accounts of doctors struggling with the emotions evoked by working with a patient group with disabilities: “I think it is quite difficult to work with people with [intellectual disabilities]; especially people who are severely ... physically and mentally disabled, it can make [you] feel quite low if you see those people who are completely dependent on carers. If you work with someone who has so much pain and trouble, if you work with them and you don’t get any support, I think I would personally get depressed, just thinking about it. If you don’t actually discuss your feelings with someone else who understands where you are coming from, I think that can pile on and on and can actually start affecting you in your personal life too.” Some trainees also described being overwhelmed by the additive effect of numerous emotionally challenging encounters: ‘In a week you collect things in your head. If there were deaths you would have a formal debrief, but these things are not deaths. They are things that keep on happening, small things.’

Many of the participants also expressed feelings of impotence to ‘fix’ the underlying conditions of their patients with intellectual disability: ‘I’ve always been taught to diagnose a disorder and treat it... I felt powerless.’

The trainees described the trainee support group and consultant supervision as addressing different support needs: “I think they are quite separate things... they do quite different things. I think... supervision is about supporting your work and this [trainee support group] is a place that supports you.”

The trainee support group was also highlighted by several trainees as a useful place to talk about difficulties related to training and difficulties experienced within CLDTs.

Being a doctor who is newly working in learning disability and the emotions that generates and the challenges of training, I think you get more out of discussing that with a group of people who are going through the same thing.

Theme 3: value of the group

The trainees described finding the group a source of: “Genuine support and encouragement and reassurance. We talk, and when you talk it comes out, and you are able to share, and it is not so ... painful anymore.” Some participants also recalled specific clinical and nonclinical issues where the group had been helpful to them: ‘I was struggling ... the support was phenomenal.’ Trainees also stated that the group had a positive impact on their clinical work: ‘I think it does help us to become better clinicians in terms of how to deal with our emotions ... we do learn from each other a lot.’

Positive aspects to the structure of the group included: permission to discuss anything, the group being confidential, and the opportunity to be with peers who are experiencing similar challenges: “The openness and the fact that you feel a bit equal ... you can pretty much bring anything there. I can speak and no one will judge me.” Sessions that had been of most value were reported to be those that were best attended, and setting ground rules was considered helpful to the group. If the group discussion was solely focused on an informal chat or issues such as rota swaps, it then lost its supportive benefits: ‘Incredibly valuable [sessions] have been the ones where people, lots of people, have come and come on time, and other times they definitely have felt like a missed opportunity.’

Theme 4: judgement in supervision

Participants described finding it easier to talk about their feelings with peers in the group than in consultant supervision. In particular, worries were expressed regarding looking incompetent during supervision, as the consultant would need to sign off the trainee at the end of the placement.

I don't want to say something [in consultant supervision] that will make me look bad, that will go on my file.

I would probably be worried in supervision that I don't want to say that I felt unsure about myself.

I find the trainee support group is more about me and about how I am coping, whereas clinical supervision is everything about the client and getting my assessments and appraisal.

Part of the issue might be your unhappiness with your interaction with other members of the team or with your consultant, which ... you would find difficult to discuss in supervision.

However, consultant supervision sessions were deemed more appropriate for some other issues, which trainees said they would not discuss in a group setting: 'Certain personal and professional issues that you may want to discuss in a supervision environment I wouldn't do in a Balint group or here.'

Theme 5: group structure

The egalitarian model was described as enabling core and advanced trainees to express their opinions knowing trainees were viewed as of equal value to the group: 'My views were valued and ... I could also give advice to my senior colleagues, which is not always respected everywhere, so this was a major strength.'

It also allowed all members to talk about what they felt was important to them rather than to a facilitator. However, some noted a downside that a less confident member might not highlight their desire to bring a new topic to a session, and the group could be dominated by particular individuals: "There is a freedom in the group that comes from the fact that it's unstructured and doesn't particularly have an agenda. I think a chairman would be useful [...] in asking if particular quiet members would [...] like to say anything because there are some people who have attended and I haven't heard speak in 6 months." The lack of a leader was thought to promote a more lax view on attendance and punctuality, and some trainees and consultants were reported as giving the group a lower priority than other aspects of the trainees' work. Group members arriving late or leaving early was disruptive and disturbing: 'We value the group, we see it as valuable or we wouldn't come at all, but we don't value it as highly as other things in our timetable so it tends to be the first thing that gets bumped.'

Discussion

This study adds substantially to the very limited literature detailing the peculiarities and challenges of training in intellectual disability psychiatry.^{1,2} One strong theme that emerged from our results was how trainees considered training in intellectual disability to be different from other psychiatric posts and the degree to which they were prepared for this. The reasons cited were related to both the specifics of the work and the structure of teams. It is well known that psychiatric disorders in intellectual disability may be more complex to diagnose, particularly owing to difficulties in effective communication. A further contrast with many other areas of psychiatry is the degree to which healing or restoration to full function or participation is possible. In intellectual disability psychiatry, the primary disability is often the intellectual impairment or associated developmental disorder, thus treatment of any mental illness may restore the patient's previous level of functioning and quality of life, but no further. Despite epilepsy management being a common role for the intellectual disability psychiatrist,⁸ our findings suggest that many trainees felt apprehensive about their skills and confidence in this area.

Feelings of isolation were also highlighted. CLDTs in the area of the study are geographically spread out and based away from their mainstream psychiatric colleagues. Separation from peers has been noted as off-putting to foundation doctors,⁹ but few studies explore feelings of isolation among psychiatry trainees² It has been noted previously that

individuals who work with people with disabilities can feel stigmatised and isolated.^{10–12} Stigma by association is the process by which relatives, support staff, friends and associates feel stigmatised owing to their contact with a stigmatised group.^{13,14} This may also affect trainees working in this area and contribute to their feelings of isolation. We think that one reason the group was valued could be its ability both to reduce the feeling of isolation by bringing trainees together, and to mitigate some of the stigma felt by enabling the trainees to share difficult experiences. One could speculate that the group may have not just attenuated some potential negatives of the subspecialty training, but also contributed to the enjoyment and reward of it. If this were to be true, it would be interesting to study whether training schemes in areas with specialty-specific support or educational groups do better in relation to trainee retention or satisfaction than those without such structures.

It should be noted that despite the challenges, there was also a strong and pervasive feeling of positivity about training and working in intellectual disability psychiatry. Such experiences were startlingly absent in previous work,² but are important to note to reassure future recruits in the specialty. In particular, the trainees mentioned the term ‘rewarding’, a varied and complex concept.¹⁵ The view that community-based intellectual disability psychiatry would be rewarding was predicted some 30 years ago,¹⁶ although this is the first study as far as we are aware that affirms this view. Intellectual disability requires a particularly holistic approach, often not dissimilar to the approach of general practitioners (GPs). While there is an absence of published surveys or qualitative studies on what psychiatrists find rewarding, interpersonal relationships between doctor and patient have been found to be particularly satisfying for GPs.¹⁷ However, we are unaware of similar studies among psychiatrists.¹⁸

Both focus groups discussed how consultant supervision and the support group were different, but mutually supportive and compatible. When surveyed, UK trainees report they are mostly happy with supervision and find it useful.¹⁹ The Royal College of Psychiatrists recommends that supervision should enable ‘the development and assessment of clinical and personal skills under direct one-to-one supervision by an expert’ and should be ‘focused on discussion of individual training matters’.²⁰ The hierarchical nature of consultant supervision is both valued by trainees²¹ and necessary for valid competency assessments, but this can be a potential barrier to seeking support in some areas, particularly revealing vulnerabilities to a supervisor who is also an assessor. Personal upset and secondary grief relating to patients is considered by some supervisors and supervisees to be a boundary breach in supervision.²² The trainee support group is set up without hierarchy and this may have contributed to reducing boundaries around discussing vulnerabilities. Honest discussion about how trainees were ‘coping’ was easier in the trainee support group than supervision, despite the College suggesting consultant supervision should include this.²⁰ This study adds to previous work suggesting some mismatch between intent and what trainees feel comfortable discussing.²³ This space for honesty is a value of the group but it would be a concern if the availability of the trainee support group and its support acted as a colluder or barrier to honesty in consultant supervision.

Group peer support may be more beneficial than alternatives such as paired peer support. Several of the benefits described in both focus groups suggested similarities to Yalom’s therapeutic factors: universality, altruism, guidance, imparting of information, cohesion, and existential factors.²⁴ That senior trainees stayed in the group for up to 3 years may reinforce some of these factors, and their relative maturity and existing trust following a longer involvement in the group may provide additional support.²⁵ It also provides senior opinions, which have been found to be supportive when shared in other contexts.²⁶ A common concern when leaderless groups are used for supervision is a loss of focus on the task and drifting into support and advice-giving.^{27,28} As the model presented here is primarily for support, and advice is part of that, the lack of leader is not a concern in this context, although the results did suggest that some participants would have liked a facilitator role in encouraging quieter members to contribute.

As this is an analysis of a single group and the findings have not been replicated elsewhere, it is difficult to generalise the utility of such groups to other areas. However, we think similar models of egalitarian peer support that require limited resources for setting up may have the potential to benefit trainees in other, smaller or more challenging, specialties.

Strengths and limitations

The qualitative design and use of focus groups is appropriate to investigate attitudes and experiences of trainees. The training rotation is relatively small, with 7–9 core and advanced trainees available to attend the trainee support group in each 6-month period. ‘Group think and the articulation of group norms may have introduced a positive bias. However, the anonymity of participants in the transcript is likely to have mitigated self-censorship and there was evidence of a diversity of opinion, particularly illustrated by both praise and criticism of the trainee support group and highlighting a range of experiences in training. The anonymisation happened at transcription rather than at analysis stage. This precluded the ability of the authors analysing the data from tracking individuals’ comments or reviewing whether they were linked to particular posts or trainers. Generalisability is a concern in qualitative studies, and was also a concern in this particular training scheme. First, at the time of the focus groups, the Bristol scheme was performing above average on trainee satisfaction in GMC surveys.²⁹ Second, many of the CLDTs may be unusually isolating for trainees compared with elsewhere in the country by virtue of their geographic spread and relatively rural setting. Finally, in several CLDTs within the scheme, most team members, except psychiatrists, are employed by a different organisation and may have few psychiatric skills.

In conclusion, we have highlighted some of the challenges and rewards of training in intellectual disability psychiatry. Our evaluation of an egalitarian, trainee-led peer support group suggests that the model could be useful for other intellectual disability psychiatry training schemes. Whether this could be a support structure suitable for other specialties remains to be studied.

We thank Dr Andrew Clark, consultant psychotherapist, for help with setting up the group; Dr Kristina Bennert for recording equipment; Gill Wetherall for transcription of the tapes; Dr Helen Sharrard, training programme director, and all consultant trainers for supporting the groups; and importantly, all trainees who enthusiastically participated in them over the years.

1.7.65 Scottish independence: the view of psychiatry from Edinburgh

woman whose research work had wrenched the pendulum radically in the direction of biological psychiatry, with her landmark *Lancet* paper¹ showing anatomical differences on CT scans between the brains of those with and without schizophrenia. I feared that she ate psychotherapists for breakfast, although she had sounded kind and friendly on the telephone. My anxiety was misplaced, since the person who emerged was a woman of fierce intelligence, with rigorous, idealistic, uncompromising and wholly admirable moral standards; compassionate and committed to patients and science, without any personal vanity, unless you include intellectual certainty.

Professor Johnstone is not a postmodern relativist: her life has indeed been a life scientific. For her this is seamless: the scientific truth is what leads to effective and therefore optimal treatment. She has never given interviews before, owing to a self-deprecating Scottish horror of self-publicity, but agreed to speak now as a retired professor.

Eve Cordelia Johnstone, ‘Scottish neuroscientist’, is the eighth generation of Glaswegian Presbyterian doctors, but the first woman doctor in her family. She laughed gently at my southern ignorance in asking about Catholicism in Glasgow: of course the Catholics were often of Irish origin, poor, poorly educated and discriminated against. No chance of eight generations of doctors then. (In fact, her father was a dentist because his serious deafness made medicine impossible.)

She remembered vividly the poverty and overcrowding in Glasgow, the worst in the UK at the time. One of her first patients on medical take was an exhausted woman presenting with open tuberculosis, a urinary tract infection and a haemoglobin of 8, who arrived late at night, after three jobs that day: scrubbing steps, cleaning offices, then washing dishes. ‘Had she ever been to the hospital before?’ I ask. ‘Yes, to be sterilised after having 13 children.’ The woman was 35 and looked 20 years older. Infant mortality was 28/1000 in Glasgow at this time, compared with about 6/1000 now.

Born in 1944, the young Eve was sent to an academic private Presbyterian girls’ school and was an obvious high flyer. This remained the case: she qualified in medicine in Glasgow in 1967. As a woman medical student, she was one of a 20% maximum quota. Most of her female contemporaries ended up doing a bit of part-time practice rather than working ‘in a serious capacity’, as she put it.

As a clinical researcher who looked after patients with scrupulous care, she is proud of having been supported by the Medical Research Council (MRC) continuously for 33 years, which is almost unprecedented. She did research at Northwick Park in Harrow from 1974 until 1989, and was Professor and Head of Department of Psychiatry at the University of Edinburgh from 1989 until 2010. She has a reputation in Edinburgh for supporting younger psychiatrists, although she has no time for slacking (or striking, as a doctor): ‘I worked 12 hours a day, it was what I expected’.

The struggle for schizophrenia

In 2016 it may be hard to remember the climate in which the 1976 *Lancet* paper landed.¹ Debate on the origin and meaning of mental illness was in the international public domain. The flamboyant R. D. Laing, a fellow Scot, was describing psychosis as a sane response to an insane society, chiming perfectly with the other social and sexual revolutions in progress.² Thomas Szasz published *The Myth of Mental Illness* in the same year, depicting psychiatrists (and all other doctors) as agents of social control.³ In 1975 Miloš Forman’s *One Flew over the Cuckoo’s Nest* portrayed the excesses of medicalisation, incarceration and psychosurgery.⁴ A famous study emerged in the USA in 1973, showing how journalists going to the emergency room complaining of ‘hearing’ three words in their heads attracted the diagnosis of schizophrenia.⁵ This massively discredited conventional psychiatric diagnosis. In the UK, David Cooper published *The Death of the Family* (1971), describing the family as the crucible of mental illness, and coined the term ‘anti-psychiatry’.⁶ The now discredited and mother-blaming notion of the ‘schizophrenogenic mother’ was widely held.

So just imagine the hostile reaction that a paper showing anatomical changes in schizophrenia would receive. As Professor Johnstone remembers: ‘There was all this anti-psychiatry stuff [...] People were saying schizophrenia didn’t exist [...] I had to prove my opponents wrong.’ As she reminisces today, it is not difficult to detect her contrarian relish for the battle: Professor Johnstone had no time for these theories. ‘There were 200 000 people in hospital with schizophrenia [...] what did they think they were there for?’ she asks incredulously. It was also the time that John Wing had written about the phenomenon of institutionalisation,^{7,8} although she points out ‘he never claimed that the institutions were the cause of the illness’.

In her own mind, Professor Johnstone was crystal clear: “‘I felt it had to be that this was a disease, but I couldn’t prove it [...] and then the non-invasive method of CT scanning came in. I was lucky. Before that people had to do

pneumoencephalography (injecting air into the ventricles and X-raying them, resulting in terrible headaches and worse), so there were no controls because of the dangers of the technique. The papers were all in Japanese or German.” This is a chilling moment: we are talking the Third Reich. ‘It sounds awful to admit’, she says ‘but the best papers [in support of the notion of schizophrenia as a disease originated in] the Third Reich. The Nazis wanted proof that schizophrenia was an inherited degenerative condition.’ When the 1976 study was published, even other neuroscientists objected, suggesting that the anatomical change could be secondary to drug treatment or encephalitis. ‘But I knew something was wrong with these people [...] When I was 21, I saw a 21-year-old woman, terribly distressed by paranoid delusions, who had been working in a bank 3 weeks earlier. It was ridiculous to say this was due to imperfect interpersonal reactions at home [...] just stupid.’

With iron determination, she then went on to refute all the challenges to the original paper with a study of 600 people with schizophrenia in Shenley hospital.⁹ They were followed up until death, and their brains at autopsy showed larger ventricles and smaller brains. However, there was no gliosis, suggesting that the pathology may be neurodevelopmental. Professor Johnstone, for all her modesty, cannot suppress an element of glee in having pipped to the post her American research competitors. Daniel Weinberger, backed by the enormous funds of the National Institute for Mental Health, confirmed her findings 2.5 years later.¹⁰ Not shirking controversy, she then ran a placebo-controlled trial of electroconvulsive therapy (ECT), which demonstrated ECT to be effective, albeit only for about 8 weeks, particularly in those depressed patients who experienced delusions and had intellectual disability.

Her next project, the Edinburgh High Risk Study,¹¹ was a prospective study of 16- to 22-year-olds, carefully comparing the incidence of developing schizophrenia in a cohort of people whose relatives had schizophrenia, the controls having no family history. Twenty-one of the high-risk group who then developed schizophrenia in fact had some anatomical differences in the brain when they were still well. The changes include smaller amygdala and hippocampus and hyperfolded gyration. Of course, this finding raises a host of ethical issues in relation to premorbid diagnosis and its implications.

I asked Professor Johnstone what she thought of the recovery model, and she was sceptical: “‘Seems to me a bit of a semantic issue [...] if it’s a dreadful illness, very hard for families, specially if you knew the people before they became ill [...] and people don’t want to say how bad it’s going to be. I don’t think the [Royal College of Psychiatrists] has emphasised psychopharmacology enough. We need much more individually tailored treatments, taking account of distinct side-effect profiles, not general algorithms. Unfortunately, it’s not true that the drugs we have now are vastly better, although it is better to have a wider range.’” She sees non-pharmacological treatment as ‘a bit better than nothing, if [the patient] will engage’, but her scrupulous honesty demands that we acknowledge that ‘a terrible thing has happened to them.’ Talking to her it was clear that she personally provided intensive clinical care to her patients and their families, and we could easily agree that continuity of care is crucial and dangerously eroded in many overstretched contemporary psychiatric services. She is unconvinced of the benefits of the newer antipsychotics: ‘It’s true the side-effects are different, but they hammer weight on to you, which is very distressing for young people.’ As for clozapine, the benefits have been ‘greatly exaggerated’.

Her academic success has been recognised. She received a CBE in 2002 for services to medicine, and a Lifetime Achievement Award of the European Psychiatric Association in 2009. She also had many senior roles in the MRC, including the chairing of the highly publicised inquiry into the disastrous linking of the MMR (measles, mumps and rubella) vaccine and autism. With the distressed parents of autistic children leading a class action against the government on the basis of the Wakefield paper,¹² she was truly in the eye of the storm. ‘I had to carry the parents with me.’ The disgraced Wakefield ‘got what he deserved’, she says.

In retirement Professor Johnstone has remained actively interested in the link between schizophrenia and cognitive impairment. She reminds me that there is a 3% point prevalence of schizophrenia in people with mild intellectual disability, three times higher than in the general population. The focus of understanding is in the area of overlap of schizotypal cognitions, molecular genetics and anomalies of brain structure, where ‘we are seeing a final common pathway that leads to schizophrenia.’ The large data-sets she has in this area fit well with the work of the Patrick Wild Centre, a charitable trust in Edinburgh set up for research into autism, fragile X syndrome and intellectual disability. Politically savvy and persuasive, she raised the funds for the centre, named after a person with severe autism.

Future hopes

In terms of the future, she told me about some hopeful developments in Edinburgh, which have potential for a personalised preventive psychiatry. Starting with a simple skin biopsy fibroblast, stem cells and then neurones can be grown, giving an opportunity to ‘develop drug treatments which basically work on an individual patient’s brain which has been developed in a dish’, as Professor Stephen Lawrie, her successor at the University of Edinburgh, put it. Roll on the day.

1.7.66 Handbook on Obsessive-Compulsive and Related Disorders

Lynne M. Drummond¹

date

2017-8

Contents

- *Handbook on Obsessive-Compulsive and Related Disorders*

This multi-author book examines the disorders categorised in DSM-5 as obsessive-compulsive and related disorders (OCaRDs) and also covers two other related disorders: illness anxiety and obsessive-compulsive personality disorders. The text is written by experts in the field, many of whom were instrumental in developing the concept of OCaRDs in DSM-5. Unlike many multi-author publications, this is brief and to the point. Each of the chapters is arranged in a structured format which includes a general introduction; diagnostic criteria and symptomatology; epidemiology; comorbidity; course and prognosis; psychosocial impairment; developmental considerations; gender-related issues; cultural aspects of phenomenology; assessment and differential diagnosis; aetiology and pathophysiology; treatment (somatic as well as cognitive and behavioural) and a summary of key points at the end. Most chapters also contain illustrative case vignettes which demonstrate the disorders and their potential severity.

This excellent title should be on the bookshelf of every psychiatrist, whether working with adults or children. Mental health workers, managers and commissioners often overlook common conditions such as obsessive-compulsive disorder and body dysmorphic disorder, regarding them as less severe and important than conditions such as schizophrenia. This work describes the hugely detrimental effects these conditions can have on the individual’s mortality, morbidity and social functioning. It also considers newly defined disorders, such as hoarding and skin-picking disorders. These conditions are poorly understood and have generally not been researched extensively. They do, however, appear to be widespread and often have extreme consequences on the individual’s mental and physical well-being. For example, hoarding disorder, which was previously often classified as obsessive-compulsive disorder or else obsessive-compulsive personality disorder, may affect up to 6% of the adult population. Excessive hoarding can lead to death due to fire risk or the falling of large numbers of possessions resulting in an avalanche. It also frequently coexists with self-neglect and – owing to the extreme shame – social isolation. Nevertheless, few community mental health teams in the UK offer comprehensive treatment for hoarding disorders. Some enlightened councils have developed hoarding protocols incorporating housing agencies, social services, and mental and physical health services but overall these are patchy and rare.

Hopefully, heightened awareness will lead to systematic research and a better understanding of the disorders and their treatment, as well as the development of effective services. This handbook would be a perfect introduction to these areas for a busy practitioner seeking brief but authoritative information.

1.7.67 Shrink Wrapped: Tales from Psychiatrists

Gary Cooney¹

date

2017-8

Contents

- *Shrink Wrapped: Tales from Psychiatrists*

There is something that feels a little otherworldly about *Shrink Wrapped*. As readers, we are invited to find our way into the psychiatrist's mind, to take our bearings from this anonymous collection of short anecdotes and reflections, written by psychiatrists, as a point of departure into understanding what it might mean to be a modern-day 'shrink'. We find warm, affectionate and humorous musings that are abruptly punctured by sharper observations, memories painful to revisit, self-doubt, recrimination and a sense of ever-questioned legitimacy. It is an honest, undiluted look into the experiences of eight psychiatrists, the whispered, confessional moments that blurred the boundaries of their personal and professional lives.

There is a strength of variety to the collection and, at its best, it draws us into questioning ourselves: what kind of a psychiatrist have I become and how did I get here? Does the voice I'm reading remind me of my own thoughts or my own journey? There are, however, one or two weaker moments alongside: in its editorial efforts to be snapshot-succinct, it can sometimes feel frustratingly whimsical and underdeveloped, like a string of highly promising film trailers. There are also passages that veer a little close to what might be found in the reflective practice section of an online portfolio.

Shrink Wrapped is as intimate and conversational as a cup of tea with a close colleague. It considers our own professional self-consciousness, 'the navel-gazing and self-doubt' that besiege our specialty, and takes a frank, unabashed look at the inevitable cross-pollination of our work and life experiences. The collection provides the reader with moments of piercing honesty, such as this summation from one particularly candid contributor, reflecting on what she, as a psychiatrist, might represent: 'I am very clearly a middle class professional White woman who is sitting here telling [the patient] what is happening.'

But who was this woman? Indeed, who were any of these interviewees? Their names are listed in the acknowledgements but not alongside any of their own contributions, an editorial device which purports to leave us free to explore the book in our own way. I found this troubling, untethering, as if I were experiencing these voices in an alternative space. It felt more in service to the interviewees, in defining the boundaries of the reader-writer relationship. It reminded me a little of the dynamic in clinic: you might be able to learn something about a psychiatrist, but not on your own terms. A lot will also be held back.

1.7.68 Service user perspectives on coercion and restraint in mental health

Diana Rose Emma Perry Sarah Rae Naomi Good

date

2017-8-01

Abstract

Coercion remains a central aspect of many people's mental healthcare. It can include the use of legislation to restrict freedoms, the use of physical restraint, the restriction of freedom of movement and/or association, and the forced or covert administration of medication. There is good evidence that the use of such measures can traumatise service users. This article reports the findings of a survey of service users regarding their experiences of coercion and restraint and embeds this in the wider international and institutional environment.

Contents

- *Service user perspectives on coercion and restraint in mental health*
 - *The CRPD*
 - *Global South*
 - *Industrialised West*
 - *Conclusion: minimising coercion and restraint*

Most jurisdictions in the industrialised West promulgate mental health legislation which permits infringement of liberty and treatment against the will of the person detained. Increasingly, coercion in the community is also allowed. Partly at the behest of the World Health Organization, other countries are developing similar legislation. This ability to compel and coerce is unique in medicine and, from within psychiatry, has been called discriminatory (Dawson & Szmukler, 2006) and criticised for the focus on risk.

Dealing first with the United Nations' 2006 Convention on the Rights of Persons with Disabilities (CRPD) and its implications for coercion and compulsion globally, this article summarises what is known about service users' responses to coercion and compulsion, which includes chemical, physical and mechanical restraint. Responding to the paucity of studies focusing specifically on physical restraint (which is commonly followed by chemical restraint), this article reports on recent experiences of people subject to this practice in the UK while situating this in more general concerns.

The CRPD

The CRPD appears to be top of the agenda for service user movements everywhere except the UK. The European Network for (ex) Users and Survivors of Psychiatry (ENUSP) has provided a point-by-point explanation of how European human rights legislation is in breach of the CRPD and the World Network (WNUSP) was involved in drawing up the Convention itself. It is important as it is the first time that people 'with psychosocial disabilities' have been recognised as equal in law to other citizens in terms of rights.

But the Convention is controversial, particularly since the publication of the General Comment on Article 12, which states that all persons with disabilities must be deemed to have legal capacity all of the time. This intensifies the commitment in Article 14 to abolish compulsory detention and treatment by doing away with the last criterion on which it could be justified. The General Comment has drawn the ire of leading Western psychiatrists (Freeman *et al*, 2015). The debate is also not settled within service user circles, as shown by the different positions of Tina Minkowitz and Anne Plumb (see Spandler *et al*, 2015).

Global South

The CRPD language of ‘persons with psychosocial disabilities’ has also had important implications in the Global South. There is a move from the terms ‘user/survivor’ to ‘persons with psychosocial disabilities’. For example, the Pan African Network of Users and Survivors of Psychiatry is now the Pan African Network of Persons with Psychosocial Disabilities. A similar move has been counselled in India (Davar, 2013). This is not simply a change in language but a political position that states ‘we don’t have psychiatry and don’t want it’.

An Indonesian government programme, Aceh Free Pasung, intends to protect the human rights of people with severe mental illness by eliminating the practice of *pasung* from the province. *Pasung* means restraint by shackles, rope, wooden stocks and cages, and can cause death. Since the alternative was the building of a mental health hospital, the initiative has enabled access to free hospital treatment (Minas *et al*, 2011). Its replacement with neuroleptics, restraint and hospital confinement is nevertheless problematic.

Industrialised West

Decisions about coercion often hinge on the concept of risk. Recent evidence suggests that risk assessments exclude service users from the discussion and render invisible the fact that the assessments are more or less fictions in actuarial terms (Coffey *et al*, 2017).

How risk of harm within mental health settings is perceived and managed has received attention. However, harm in the context of restraint is mostly not recognised. Nonetheless, restraint-related deaths have been reported throughout the Western world, including in the UK, where 38 deaths have been recorded since 1988, 15 of people from Black and Minority Ethnic (BME) communities (Aiken *et al*, 2011). A qualitative study of in-patients showed that nurses and patients had very different accounts of both the determinants of and appropriate responses to violence and aggression (Rose *et al*, 2015).

Reviewing evidence of the effects of restraint, Cusack *et al* (2016) concluded that ‘restraint can be a form of abuse, its inappropriate use often being a consequence of fear, neglect and lack of using de-escalation techniques’.

A small pilot study by the National Survivor User Network (NSUN), as yet unpublished, surveyed 65 people about their experiences of restraint and recruited respondents mainly through the weekly e-bulletin. The findings align with Strout’s (2010) integrative review of the international qualitative literature on patient perspectives on the use of restraint. Strout identifies four categories: negative psychological impact, re-traumatisation, perceptions of unethical practices, and the broken spirit. Of the respondents surveyed in the NSUN study, 43% ($n = 28$) stated that their most recent experience of restraint had felt like an act of aggression ‘a great deal’, 12% ($n = 8$) ‘a lot’ and 15% ($n = 10$) ‘somewhat’. Although the number was small, all respondents from BME communities ($n = 5$) stated that their experience had felt like an act of aggression ‘a great deal’ or ‘a lot’. Respondents frequently cited the unnecessary use of physical force and the number of staff members who were involved in each incident of restraint. The most frequent reason for restraint given by respondents was the refusal to take medication, and physical restraint was routinely followed by a rapid tranquillising injection. This was often experienced as shaming and humiliating:

When I become agitated it is very obviously extreme fear and terror. On each occasion it is ALWAYS male staff pinning me down – always face down so [I] can’t breathe or move and who pull my underwear off/down to inject. They know the abuse history – it has been a police case. They never have talked to me afterwards. It is like being raped again.

One clear theme was the link between instances of physical restraint and tranquillisation with re-traumatisation. Consistent with studies of women’s experience of restraint representing an event that re-enacts the experience of trauma and sexual abuse, Gallop *et al* (1999) found that restraint and associated feelings of humiliation, punishment and powerlessness engendered traumatic emotional reactions such as fear, anxiety and rage.

Half of the respondents stated that experiencing physical restraint had affected their engagement with services ‘a great deal’. The majority reported a loss of trust in staff, and increased fear, suspicion and wariness. Others reported that they avoided services because of their experiences.

The Promise study (Wilson *et al.*, 2015), which informs the development of a proactive care framework to reduce the need for physical intervention, involved interviews with both staff and patients. The most dominant theme to emerge centred on staff–patient communication and relationships, with 11 patients and 19 staff members providing suggestions:

if you wish to reduce the number of restraints a high level of communication is needed whatever the issues of a particular patient, whatever their predisposition to violence or hatred of psychiatric staff, or factions within the resident group, or dislikes of a particular patient. In an ideal world there must be more verbal communication ... the culture is to encourage what Winston Churchill used to say was a 'jaw jaw rather than war war', to counsel and support a person onto a different state of thinking. (Wilson *et al.*, 2015)

Conclusion: minimising coercion and restraint

In the NSUN study, 94% ($n = 50$) of respondents reported that restraint could have been managed very differently, emphasising that if staff had taken the time to listen and to speak to them addressing fears, frustrations and concerns, the situation could have been avoided. Respondents said that staff needed better training and that service users should be involved in this.

No differences were found in the experiences of restraint occurring within the past 10 years compared with the past 2 years. Of the NSUN respondents, 40% ($n = 23$) reported incidents of restraint that occurred within the past 2 years, suggesting no recent improvement in experiences of restraint. These findings signal that the 2-year UK government programme 'Positive and Safe', launched in 2014 with the goal of reducing the need for physical restraint (Department of Health, 2014), has had no impact to date and that a fundamental culture change is needed. This directive was followed by an investigation involving the facedown restraint of a woman eight and a half months pregnant in July 2016 (*Mental Health Today*, 2016).

There are various arguments for reducing coercion and restraint and many different approaches that service users say they find more beneficial. Since 2007 the Mental Health Act in England has made it mandatory for advocacy to be practised by professionals alone, although the service user voice is not completely absent (Newbigging *et al.*, 2015). It will be important to regain and strengthen the user voice within peer and self-advocacy, as has happened in Africa (Kleintjes *et al.*, 2013).

Joint crisis plans or advance directives are counselled by many as a means of reducing incidents of restraint and of listening to the needs of service users (Papageorgiou *et al.*, 2002; Amering *et al.*, 2005). Approaches that include peer facilitators and improvements to the frequency and quality of communications are crucial. Some existing institutional systems make good communication a practical impossibility.

From the perspective of service users, coercion and restraint are mostly harmful and must stop being legitimised. There is an urgent need to challenge and address these practices as they represent gross human rights violations according to the stipulations of the CRPD. UK compliance with the legislation is due to be monitored in the next 2 years.

Conflict of interest. No authors have any conflicts of interest to declare.

1.7.69 Patient safety and quality of care in mental health: a world of its own?

Danielle D’Lima Mike J. Crawford Ara Darzi Stephanie Archer

Correspondence

Danielle D’Lima (d.d’lima@ucl.ac.uk)¹

date

2017-10

Abstract

Quality and safety in healthcare, as an academic discipline, has made significant progress over recent decades, and there is now an active and established community of researchers and practitioners. However, work has predominantly focused on physical health, despite broader controversy regarding the attention paid to, and significance attributed to, mental health. Work from both communities is required in order to ensure that quality and safety is actively embedded within mental health research and practice and that the academic discipline of quality and safety accurately represents the scientific knowledge that has been accumulated within the mental health community.

Contents

- *Patient safety and quality of care in mental health: a world of its own?*

With repeated examples of failure across the healthcare system,^{1,2} there has long been a need to understand how we can better uphold and improve on the quality and safety of care that is being provided to our patients. There is a gap between the policy and guidelines generated from research evidence and the practice of medical, nursing and allied health professionals. This gap is at risk of increasing, owing to an under-appreciation of heterogeneity in local context³⁻⁵ and the ever-growing demands on the healthcare system, with fewer resources provided to manage them. As a result, quality and safety in healthcare, a discipline which aims to integrate scientific understanding with applied practice, has made significant progress over recent decades and is now regarded as an active and established community of researchers and practitioners alongside the fields of improvement and implementation science.⁶⁻⁸

Such growth has been reflected in the establishment of discipline-specific journals. For example, the BMJ launched *BMJ Quality and Safety* in 1992, and in 2006 a journal devoted purely to implementation science was introduced – *Implementation Science*. The evolution of the discipline has also included the development and refinement of a number of methodological tools, such as Plan, Do, Study, Act (PDSA) cycles and Driver Diagrams, which draw on the manufacturing industry to support individuals in applying continuous quality improvement (CQI) principles in healthcare practice.⁹

Despite the growing international interest in quality and safety in healthcare, its application to a mental health context has not been explored.¹⁰ It cannot be assumed that findings based on physical health in acute care hospitals can be automatically applied to mental health. This is because of the different challenges presented by patients and settings in this specialised area of care, including a greater emphasis on community-based care, greater use of Mental Health Act legislation and increased risk of self-harm.¹⁰ Mental health in general has been viewed as a neglected area and one in which patients may be less likely to have a voice when it comes to their care and safety.¹¹ It has also been suggested that

the stigma surrounding mental health issues has the potential in itself to contribute to staff neglecting patient safety and quality of care.¹⁰ In order to deliver high-quality care to patients, it is essential that a firmer understanding of patient safety and quality of care in mental health is not only developed, but also disseminated appropriately to ensure that it has the greatest impact.

Key literature searches of high-profile quality and safety journals reveal that there is a lack of published literature under the umbrella term of mental health. For example, a high-level search conducted in *BMJ Quality and Safety* in July 2016 based on the search term 'mental health' appearing in the title or abstract returns just 56 hits across all archives. When restricted to 'mental health' appearing in the title only (and therefore indicating that it is the primary focus of the article), the search returns just 17 results. This is disappointing, especially when compared with similar searches on key search terms for other medical specialties, for example paediatrics (94 hits for title and abstract) and surgery (237 hits for title and abstract). These findings are also reflected in other notable quality and safety journals such as *Implementation Science* (30 hits for 'mental health' in a title-only search) and the *International Journal for Quality in Health Care* (15 hits for 'mental health' in a title-only search). We recognise that there are inherent challenges in these comparisons, including selection of terminology and disciplines; however, these searches are intended to be illustrative rather than exhaustive.

Even the small number of studies that are returned from these searches do not consistently focus on mental health as the primary setting of interest. Instead, mental health tends to form one component of a system-level study often associated with high-level quality improvement and quality of care structures in the healthcare system.¹²⁻¹⁴ In other instances, mental health is positioned as just one example or context alongside physical health settings and is therefore not the sole focus of the article or its key messages.¹⁵⁻¹⁷ Generally, the work being published in these quality and safety journals does not focus on aspects of safe care that may be of specific importance to a mental health setting or explore how established quality and safety metrics apply and translate to this unique context. However, searches do identify a systematic review on medication errors in mental health¹⁸ and some work around continuity of care and communication between in-patient and out-patient mental health settings, for example.¹⁹

Contrary to these findings, searches run across the broader medical and social science literature reveal that much has been published on the topic of quality and safety in mental health in other, more specialty-specific areas (e.g. psychiatric nursing journals). For example, academic teams in mental health led by Louis Appleby, Len Bowers and Joy Duxbury contributed a significant amount of work. Therefore, it seems that the issue is not necessarily a lack of work on quality and safety within a mental health context, but instead a lack of its representation as part of the stand-alone quality and safety discipline.

The specialty-specific literature succeeds at providing a significant amount of research into patient safety incidents that are more precisely related to a mental health setting. These include violence and aggression, patient victimisation, suicide and self-harm, seclusion and restraint, and absconding and missing patients.¹⁰ Other key areas that apply more broadly across all settings are falls and other patient accidents, adverse medication events and adverse diagnostic events such as misdiagnosis. This literature is not without its faults, however, as there is a tendency for it to focus on areas of safety that may be of greatest concern to the public rather than areas of quality that may contribute most to patient experience and clinical outcome effectiveness. It may also not be fully reflective of the vast developments that have been made in understanding quality and safety in healthcare more broadly.

There is a clear disparity between the two bodies of literature (i.e. work around mental health within the established quality and safety discipline and work around quality and safety of care within the broader and less defined mental health discipline). In recent years there has been a call for 'parity of esteem' between physical and mental health (i.e. recognition of mental health as an equally important discipline within medicine).^{20,21} The data that we have presented certainly suggest that there is no parity in the attention being paid to quality and safety, and this is an area that requires attention. The structure of the National Health Service (NHS) is guilty of fostering this separation, to some extent, through commissioning different organisations to provide physical and mental healthcare.²² However, Academic Health Science Networks are aiming to help break down historical barriers between acute care and mental health trusts.

Furthermore, the two bodies of literature appear to exist in silos and do not explicitly refer to or build on one another as a matter of course. Therefore, the core integration of the quality and safety discipline with the mental health setting is currently lacking and not fully reflective of the scientific understanding that has been incrementally built up via the specialty-specific journals. The opportunity has also been missed for the two bodies of work to effectively communicate, learn from each other's limitations and strengthen one another. For example, a more thorough integration could ensure

that quality and safety is explored across the board within the mental health setting in a way that is appropriately sensitive to the local context without being restrictive. This approach is likely to have the greatest direct benefit to mental health patients when such research translates into clinical practice.

It is important to discuss and reflect on the potential reasons for this disparity in order to understand how it might be rectified in the future. It is possible that academics focusing specifically on quality and safety as a research area (i.e. not wedded to any particular specialty) are not conducting a sufficient amount of research in a mental health context. Assuming that academics of this type are more likely to submit to quality and safety rather than specialty-specific journals, it is possible that the issue centres on a lack of work being completed in these settings by patient safety and quality improvement researchers.

A recent independent report into the quality of in-patient mental health services highlighted the need for further training and use of quality improvement in mental health services.²³ The Royal College of Psychiatrists also recognise this issue and have set up a working group to steer progress. The Institute for Healthcare Improvement (IHI) is working with a number of mental health trusts in the UK to build capacity and capability to implement quality improvement programming at scale. It is important to recognise the challenges in applying improvement science in different healthcare delivery models, targeting different health conditions that follow very different courses. For example, the challenge of adapting quality improvement methodology for long-term conditions (which is often the case in a mental health setting) as opposed to interventional healthcare where it is simpler to measure impact and change pre- and post-implementation.

We must also consider what drives authors to publish in specialty-specific rather than quality and safety journals. It may be the case that mental health professionals and academics are more motivated to do so. For example, they may have concerns about ensuring that their work has the greatest impact or be unaware of the alternative journals that are appropriate. If this is the case, then raising awareness across the scientific community will be vital for ensuring that authors submit their work to the most suitable outlet in terms of target audience and opportunities for translation. On a separate note, it is possible that work is already being submitted to quality and safety journals but is not being accepted. There may be factors around quality of work and acceptance processes that need to be considered. This could be due to differences in academic approach and levels of rigour across the disciplines.

These dilemmas have a number of potential implications for both research and practice, and recommendations for the future are required in order to increase and support integration between the two bodies of work. Both the quality and safety and mental health disciplines should be concerned by the clear disparities between their bodies of work. Existing in silos automatically forms a barrier to effective quality improvement and safer patient care. Mental health should form a core part of the quality and safety agenda and influence the ways in which it grows and develops as a discipline over time. The disparity may also prevent the academic expansion of the discipline as a science owing to a lack of incremental growth that is fully reflective of all relevant research on this complex topic area. It is also likely that the mental health community will miss out on full access to the knowledge that has been accumulated within the quality and safety discipline, which will therefore prevent optimal patient care.

Quality and safety journals should explicitly invite submissions from the mental health community in order to demonstrate their openness to work based in this setting. Simultaneously, mental health professionals and academics should be made aware of the different disciplines with which they could be integrating their work, and should not be penalised for publishing their work in quality and safety rather than specialty-specific journals. The long-term goal should be to normalise that quality and safety journals are a viable option for mental health professionals' academic work. This would involve incorporating and building on the present understanding of quality and safety that has already been developed more broadly, rather than scoping out a separate area of quality and safety that applies solely to the mental health setting. Patient safety and quality of care in mental health should not be existing in a world of its own but instead be a fully integrated component of the broader scientific discipline. It is the responsibility of members of both communities to ensure that this happens.

1.7.70 A Devil's dictionary for mental health

Philip Timms

Correspondence

Philip Timms (philip.timms@slam.nhs.uk)¹

date

2017-10

Abstract

Clinical psychiatry, for all its emphasis on scientific rigour, is mediated mainly by words rather than by numbers. As with other professional areas, it has developed its own set of jargon words and phrases. Many of these are not the technical terms traditionally seen as jargon, but standard English words and phrases used in an idiosyncratic way. They therefore go unnoticed as jargon, while enfeebling our communications. I have used the template of Ambrose Bierce's *The Devil's Dictionary* to highlight some examples, with the aim of helping us all to talk, write and, perhaps, think more clearly.

Contents

- *A Devil's dictionary for mental health*
 - *What is jargon?*
 - *My Devil's Dictionary*
 - *Casting out demons*

A review of health literacy suggests that patients often do not understand what doctors are trying to tell them – and, rather obviously, tells us that we should be more straightforward.¹ But it is not just us. The US boss of Pfizer has exasperated a British parliamentary committee with his obscure business jargon.² Farrington has highlighted the chasm between clinical and managerial language.³ Brian Lask pilloried the 'infestation' of family therapy publications with jargon, pomposity and impenetrability.⁴ And, although they were mainly addressing technical obfuscation, a pair of psychologists have trenchantly characterised much of the research communication in their field as 'bullshit'.⁵ They recommend translating 'others' procedures and outcomes in(to) ordinary language' to separate out any discernible content from the chaff of jargon.

But I am not here going to consider how we talk to patients or managers – or even researchers and academics. I have been thinking about how we talk to each other. It can be said that technical jargon does not matter inside a profession because each participant understands the words involved. It only becomes a problem when a professional tries to communicate with outsiders.⁶ But I think we may have a problem in day-to-day communication between those of us involved in mental health services. Over the past few years I have noticed the appearance of words and phrases which, because of their novelty and lack of definition, create real problems with communication. Many of these can be seen as 'weasel' words or phrases. They carry a covert meaning or overtones of meaning – or, sometimes, no meaning at all. They can be defined as 'something that someone says either to avoid answering a question clearly or to make someone believe something that is not true' (<http://dictionary.cambridge.org/dictionary/english/weasel-words>). Some are more technical, but all can be seen as forms of jargon owing to their characteristic use in medicine and psychiatry.

What is jargon?

But what is jargon? The current version of the online Oxford Dictionary defines it as ‘Special words or expressions used by a profession or group that are difficult for others to understand’. It also tells us that it been with us for nearly 400 years, being derived from Late Middle English, originally in the sense of ‘twittering, chattering’, later ‘gibberish’ (www.oxforddictionaries.com/definition/english/jargon). Earlier dictionaries are more robust: ‘Barbarous or debased language: gibberish: speech full of technical terms etc’.⁷ Synonyms include slang, cant, idiom, argot, patter and gobbledegook (www.thesaurus.com/browse/jargon). Nobody much likes jargon, even though we all seem driven to use it.

At first hearing, such language may not sound at all technical. The words or phrases are drawn from day-to-day English, but, as we use them, their meaning starts to dissolve. They become the aforementioned weasel words because they are either novel or of broad, inclusive meaning. Those inside a profession find that they can use such language in an idiosyncratic way to preserve professional authority and power.⁸ If you cannot understand a discussion, you cannot participate. The young may feel that they have to use this language to be an authentic part of professional life. The old, consciously or unconsciously, realise that it can be used to conceal, confuse, stonewall and neuter objections or criticism. Moreover, jargon is mostly categorical and conceptual, not concrete and specific. It can present an intimidating facade behind which, if one takes the trouble to look, there is little of substance. Although unsavoury, is it not a victimless crime? Not according to the House of Commons Public Administration Select Committee. They felt that ‘the use of inaccurate, confusing or misleading official language which results in tangible harm, such as preventing individuals from receiving benefits or public services, should be regarded as maladministration’ (p. 16).⁶ Perhaps, then, we should take this issue more seriously.

One might, in an uncharitable moment, single out managers as the main offenders. However, I have heard colleagues from our sister professions talking impenetrably, as well as my fellow psychiatrists and, regrettably, myself. We are all guilty. So, I decided to round up some words and phrases that seem, to me, to be misused in this way. Some of these are specific to psychiatry and mental health, some are used across medicine. Some remain a local coinage, others have attained a more universal currency. We hear some in the front line, in wards and community teams, and others in committee rooms and consultation papers. Ambrose Bierce was a 19th-century journalist who was similarly intrigued by the ways in which language can be misused. I have used the template of his *The Devil’s Dictionary*⁹ to produce my own, somewhat scattershot, rogue’s gallery.

My Devil’s Dictionary

Acting out: an analytical term provoked by extravagant behaviour. Example: ‘the patient acted out by shouting in the lounge’. We are thereby relieved from the burden of considering the matter further.

Adherence (to medication, advice, etc.): a delusion, held by all doctors, most strongly by enthusiastic pharmacologists. For us, a mainstay of treatment. For our patients, an irritation best neglected. They are reluctant to reveal their disinterest, not wishing to distress their psychiatrist.

Acuity: a snappy euphemism which removes to arms-length the stress and risk of our under-resourced and risky services. Essential to reduce the anxiety felt in higher echelons of management.

Behavioural: a term used by those of us with no behavioural training, to describe behaviour of which we disapprove (*see* ‘Acting out’). Commonly combined with ‘just’ – ‘It’s just behavioural’. Usually paired with the helpful conclusion: ‘he/she is not for our service’.

Best evidence: the cracked and misty lens with which the one-eyed man navigates the country of the blind.

Care pathway: a sequence of ideal interventions (*see* ‘Best evidence’) for a model patient. Lengthy and complicated, so best illustrated on a sheet of A3 paper. The dogged patient may be said to trudge, march or run the gauntlet on such a trek.

Challenge: the presentation of the impossible and implausible as a bold plan. Example: the NHS Challenge – save £20 billion in the next 3 years while improving quality. You can then, subsequent to the inevitable failure of the plan, pillory those involved as being old-fashioned, inflexible, not trying hard enough ... according to taste.

Clinician: a drone, a harmless drudge who sees patients. They can apparently perform audit, supervision and research simultaneously (*see* ‘Job description’). Their ability to be in two places at once (*see* ‘Job description’) suggests that they would have been burned as witches in less scrupulously rational times.

Consultation: the practice of gathering views about a proposed change in a service. To complain that such views are subsequently ignored would be both harsh and naive (*see* ‘Listening event’ and ‘Efficiency saving’).

Cover: an illusion of doubles. It suggests that an overworked colleague will also do your work in your absence. Essential to maintain the appearance of an adequately staffed service.

Cut: the Voldemort word that must never, ever, be uttered (*see* ‘Efficiency saving’). Sometimes linked with ‘Transformation’.

Distress: a catch-all for every experience from mild anxiety to raging psychosis. As one gently minimises the more extreme and intractable varieties of experience, one can slyly insinuate that psychiatry is just a way to medicalise normal experience.

Efficiency saving: as the wolf to Red Riding Hood’s grandmother. Cloaked in two benign words with which none can take issue, it stalks our services – and suddenly they disappear. *See also* ‘Challenge’ and ‘Cut’.

Evidence: the single academic paper that supports one’s proposed course of action.

Holistic: a synonym for comprehensive, originating from the word ‘whole’. But where did the ‘W’ go? The spelling generates a spurious overtone of spirituality. Clearly not intentional; evidence of unconscious processes at work.

Hypothesis: a simple idea that leaves port to the sound of marching bands, but then founders on the rocks of bureaucracy or upon the craggy island of sober reflection.

Integration: the unicorn of service provision. Often spoken of but rarely seen. Some say they have seen it in Birmingham. Others say it is a mirage, glimpsed by the desperate.

Innovation: a novelty that attracts money.

Inappropriate (behaviour): rational behaviour of which we disapprove. Studiously neutral, it is commonly used in close proximity to an emphatic font. Example: ‘patients must *not* use our accident and emergency department inappropriately’.

Job description: a work of fantasy that masquerades as a workaday agenda. As nectar to the bee, it attracts naive applicants to your service while obscuring the inquisitive gaze of our College. Any subsequent disaffection can be met with the phrase ‘caveat emptor’.

Just: an excellent way to deny complexity. One can avoid the trouble of biopsychosocial formulation without admitting to idleness, ignorance or indifference. Example: ‘It’s just... behavioural/social/drug-induced...’.

Liaison: the assurance that someone will, at some time, communicate something to someone. Example: ‘Community mental health team to liaise with primary care’. A common parasite of care plans and strategy documents. The phrase ‘liaison psychiatry’ can be honourably exempted.

Listening event: a talking shop.

Metric: a swaggering and self-confident synonym for ‘number’, ‘figure’ or ‘statistic’. It ballasts with false weight the inadequate and corrupted data that leak out of our struggling services.

Medical model: a synonym for the crudely biological. Essential if one has a sketchy acquaintance with medicine but a sincere desire to damn psychiatry. Best bolstered by a quote from an antique textbook which few have ever read – or even heard of.

Mission statement: a haiku of the obvious. A way for those remote from the front line to sincerely avow the commitments of an organisation. Only misfits and malcontents could assert that such statements are banal and platitudinous.

New ways of working: the promise that clinical drones (see above) can become queen bees. The admirable and novel element is that psychiatrists should, as far as possible, steer well clear of patients.

Ongoing: a way to communicate to the naive reader an impression of dogged and ceaseless activity.

Paradigm shift: a bit of a change. It proclaims how different (and how much better) your pet idea (*see* ‘Hypothesis’) is from everything that has gone before. Such shifts promise seismic change but most, mysteriously, register zero on the Richter scale of life.

Prioritisation: cutting one service to provide another. One service dies and another is born. Disney’s circle of life.

Quality indicator: an easily measurable irrelevance.

Quality improvement: an unarguable good. It marvellously exempts management from any responsibility for the lack of armaments or ammunition and ‘empowers’ frontline platoons to sort out the subsequent carnage.

Research: the selection of an unrepresentative group of people, the provision of an unsustainable intervention and the careful selection of a rating cut-off point to show your intervention to its best advantage.

Recovery: a two-edged sword. To Tweedledum, an essential reorientation of services to patient priorities. To Tweedledee, a pretext for culling rehabilitation services.

Reconfiguration: another attempt to rearrange the chairs on the deck of the Titanic (*see* ‘Transformation’).

Significance (statistical) (*see also* ‘Research’): a simple number that lends colossal weight to negligible differences.

Signposting: a respectable way to rebuff those seeking help from our service. We direct the patient towards another step on their therapeutic pilgrimage (*see* ‘Care pathway’), braced by the pious assurance that another will meet their need. Much loved by hard-pressed commissioners for whom distance from our services is by far the best medicine.

Target: a worthy aim, applauded by all. The resources marshalled to meet it hyperperfuse privileged parts of the organisation but induce gangrene and necrosis elsewhere.

Triage: a battlefield technique to sift the doomed from the salvageable. Applied to civilians in peacetime when the money runs out.

Transformation: an ‘abracadabra’ word, the promise to turn an ugly duckling into a swan. This powerful spell can reduce resistance to modish technology or to shedding staff. Memories mysteriously fail when the new swan proves to be just another maladroit fowl.

Vision(s): in a patient, evidence of brain dysfunction. In ourselves, evidence of foresight, imagination and understanding.

Work-life balance (*see* ‘Job description’): an excellent way to communicate an uncomfortable truth. Example: ‘We know you need to work X+1 sessions to do the job, but we will only pay you for X sessions’. Dissimulation is charmingly paired with an expression of concern for one’s welfare.

Casting out demons

The American edition of the online Oxford Dictionary, somewhat uncharitably, states that weasel words are ‘intentionally ambiguous or misleading’.⁷ I am less judgemental and would suggest that they have a less deceitful function. They help us to feel more at ease with difficult truths we have both to confront ourselves and to present to others. However, although we may feel more comfortable, we will not be communicating as well as we could – and not thinking as clearly as we should. I would not go as far as the Local Government Association which was widely reported to have published, for its members, a list of banned words and phrases.¹⁰ After all, context is everything and, in spite of my accusations, some of these words may be used quite helpfully from time to time. But an awareness of them can serve us as the canary once served the coal miner: as a sign that something may not be quite right, and that we need to keep our wits about us. To the charge that I am a cynic, I confess that I do not have the stomach for it. I still shrink from the uncomfortable and cling to desperate and unreasonable hopes. I have been unable to yet become that paragon described inimitably by Bierce⁹ (p. 34) as ‘A blackguard whose faulty vision sees things as they are, not as they ought to be’.

This list is not comprehensive and is certainly not static. New weasel words will emerge as others wither and perish. Each of us can identify our own offenders. To pay attention to how we talk (and write) is not self-indulgent. It can help us to think more clearly, to communicate more meaningfully and to engage with reality rather than self-serving fantasy.

1.7.71 Personality disorder services in England: findings from a national survey

Abstract

Aims and method We aimed to evaluate the availability and nature of services for people affected by personality disorder in England by conducting a survey of English National Health Service (NHS) mental health trusts and independent organisations.

Results In England, 84% of organisations reported having at least one dedicated personality disorder service. This represents a fivefold increase compared with a 2002 survey. However, only 55% of organisations reported that patients had equal access across localities to these dedicated services. Dedicated services commonly had good levels of service use and carer involvement, and engagement in education, research and training. However, a wider multidisciplinary team and a greater number of biopsychosocial interventions were available through generic services.

Clinical implications There has been a substantial increase in service provision for people affected by personality disorder, but continued variability in the availability of services is apparent and it remains unclear whether quality of care has improved.

Personality disorder is a serious mental health condition affecting up to 52% of psychiatric out-patients and 70% of in-patients and forensic patients.¹⁻⁴ Given the significant public health implications associated with the disorder – including extensive use of healthcare resources, high rates of suicide and reduced life expectancy – effective treatment is a priority.⁵⁻⁸

In 2003, the National Institute for Mental Health England (NIMHE) published *Personality Disorder: No Longer a Diagnosis of Exclusion*, challenging the healthcare community to address shortcomings in the treatment of people with personality disorders.⁹ Citing a survey of English mental health trusts conducted in 2002, the paper brought to attention the variability in practice and highlighted institutionalised stigmatisation which explicitly barred patients with personality disorder from mainstream services. At that time, only 17% of trusts had a dedicated personality disorder service, 40% provided some level of service, 28% had no identified service, and 25% did not respond.⁹

The 2003 NIMHE publication⁹ set out broad principles for how personality disorder services should be developed, stipulating that they should be multidisciplinary, follow a hub-and-spoke model, accept the management of risk, use the care programme approach (CPA),¹⁰ offer specialist biopsychosocial interventions, deliver training and consultation, and support the development of patient networks. Similarly, the 2009 guidance on borderline personality disorder from the National Institute for Health and Care Excellence (NICE) specified that mental health trusts should develop specialist multidisciplinary teams and/or services for people with personality disorders.^{11,12} In 2011, a preliminary investigation at a regional level found that specialist service capacity for those with personality disorder was inadequate.¹³ There have been no systematic attempts at a national scale aimed at understanding how the evidence for the management of personality disorder is being applied or whether service availability has become more uniform.

In 2014, the National Personality Disorder Service Review Group was formed to evaluate the extent to which variable service availability affects those with personality disorder. The group used the vision of *Personality Disorder: No Longer a Diagnosis of Exclusion* as its benchmark. Through this lens, we sought to map the availability and nature of dedicated personality disorder services, and to compare these to the care for clients with personality disorder available through generic services. The group drew on a wide range of evidence to define the concept of a ‘dedicated personality disorder service’. This included the Delphi study of the 11 pilot personality disorder projects within the National Personality Disorder Programme.¹⁴ We considered a dedicated service as one which is explicitly designed to manage the care of individuals affected by personality disorder, as opposed to a generic service which might be considered a typical community mental health service. *Table 1* displays the characteristics hypothesised by the group to distinguish dedicated from generic services.

Summary of service characteristics

Dedicated personality disorder services	Generic services
Personality disorder inclusion	No diagnostic inclusion/exclusion criteria
Variable service availability	Ubiquitous
Personality disorder-specific interventions	Offer range of biopsychosocial interventions
Specialist team	Mainstream multidisciplinary team
Local, regional and national catchment	Local catchment
Variable tiers (T1 to T6)	Locally focused tiers (T2 to T3)
Target complexity	Range of complexity
Treatment, consultation and training	Treatment orientation
Variable framework (includes CPA)	Operate under CPA framework

CPA, care programme approach.

Aims

The primary aim of this study was to describe a number of organisations which provided care for those affected by personality disorder and whether this care was delivered through dedicated personality disorder services, generic services or both.

The secondary aim was to evaluate the provision of services for personality disorder along key quality indicators outlined by NICE and NIMHE,^{9,11,12} and explore any differences between dedicated and generic services. The quality indicators evaluated were: Is there a multidisciplinary team available? Is care managed under the CPA process? Are patients offered specific interventions for personality disorder within a biopsychosocial approach? Are services involved in education, training and research? What level of patient and carer involvement do services employ? What exclusion criteria, if any, are applied by services?

Method

Survey design

We conducted a cross-sectional survey of mental health organisations in England using a questionnaire designed for this study. Data were collected between January and June 2015 using an online survey tool (www.surveymonkey.com).

Sample

The sample included any English mental health National Health Service (NHS) trust or independent provider of mental healthcare to adults or young people. In 2015 there were 57 relevant English mental health NHS trusts and 10 independent service providers, all of whom were approached to participate in the survey.

Procedure

Letters were sent to the medical directors of each NHS mental health trust and the CEOs of the independent providers informing them of the survey and requesting the name of the individual who they considered to have the requisite knowledge to complete the survey. Once details of these individuals were obtained, letters were sent inviting them to take part. Non-responders were followed up at least twice where necessary, offering further information or support to complete the survey questionnaire.

Survey questionnaire

Following an analysis of available literature, the electronic survey was structured to address the primary and secondary aims of the project. Participants were asked to briefly describe their organisation (e.g. NHS or independent provider, geographical remit) and their own professional role. They were then given a brief definition of a dedicated personality disorder service and of a generic service and asked to indicate whether their organisation had services of each type and detailed questions about its characteristics. We requested details of a maximum of five dedicated personality disorder services per organisation.

Questions relating to service characteristics included service leadership, team make-up, service access, inclusion and exclusion criteria, care management framework, intervention availability, patient and carer involvement, and training, education and research activity. The survey took up to 45 minutes to complete and could be conducted electronically or with telephone support.

Data analysis

Data were downloaded from Survey Monkey and entered initially into Excel for checking and data cleaning, and transferred to STATA (version 11) for statistical analysis. To address the primary aim of the survey, the characteristics of services were summarised descriptively in order to build a picture of service availability and characteristics. The availability of biopsychosocial interventions was assessed by generating a score ranging from 0 to 100 based on the number of available interventions of each type, weighted to give equal consideration to each of the three domains. The availability of personality disorder-specific interventions was assessed by determining whether services offered psychological therapies developed specifically for personality disorder.¹⁵ The level of perceived patient and carer involvement was similarly analysed and scored from 0 to 100 based on the number of involvement activities for each service, with paid involvement double weighted.

To address the secondary aims of the survey, logistic and linear regression was used to evaluate the effect of service type (dedicated or generic) on professional diversity, exclusion criteria, CPA usage, biopsychosocial provision, patient and carer involvement, and training, education and research activity. Multilevel models, with a random effect for organisation, were used to adjust for the potential higher similarity between services within the same organisation than between services from different organisations. Robust standard errors were used for linear variables that did not conform to a normal distribution. Where significant differences between dedicated and generic services were found, multivariate models were used to adjust for the influence of potentially confounding service characteristics.

Results

Respondents

Of the 57 relevant English mental health NHS trusts, 52 responded (response rate 91%) and of the 10 independent service providers approached 4 responded (response rate 40%).

Primary study aim: availability of services for people with personality disorder

Of the 56 organisations that responded to the survey, 47 (84%) reported having at least one dedicated personality disorder service and 43 (77%) reported having both generic and dedicated services. The remaining 4 organisations (7%) stated that they did not have any generic services and that all services were specialist; all offered dedicated personality disorder services. Nine organisations (16%) did not have any dedicated personality disorder services, and all of these stated that their generic services catered to personality disorder. Patients were reported to have equal access to dedicated personality disorder services in 31 (55%) of the organisations surveyed.

The number of dedicated personality disorder services per organisation ranged from 1 to 5 (mean 1.7, s.d. = 1.1). Across the 52 English mental health NHS trusts, 71 dedicated personality disorder services and 48 generic services were described, a mean of 1.37 dedicated service per organisation (range 0–5). The four independent service providers described ten dedicated personality disorder services; a mean of 2.50 dedicated service per organisation (range 1–5). *Figure 1* compares the findings with the survey of 2002. To aid comparison, the independent sector organisations have been removed from the 2015 results so that only English NHS mental health trusts are referred to. Tables 2, 3, 4, 5 and 6 summarise the characteristics of the dedicated and generic services across all domains surveyed.

Secondary study aims: quality indicators of available services

1. Is there a multidisciplinary team available?

Across services, teams varied widely in their multi-disciplinary composition (*Table 2*). Within services, team make-up was significantly less diverse in dedicated than in generic services, with the latter utilising almost twice as many different types of professional on average (dedicated personality disorder services mean 5.7, s.d. = 3.0; generic services mean 10.5, s.d. = 5.1 ($= 4.85$, 95% CI 6.37 to 3.32, $P < 0.01$)). Dedicated services remained less professionally diverse than generic services after adjusting for the range of biopsychosocial interventions available, the provision of personality disorder-specific interventions, and the profession of the service lead ($= 3.14$, 95% CI 4.46 to 1.82, $P < 0.01$). This suggests that the less diverse workforce in dedicated services was not simply due to providing a more focused range of interventions.

2. Is care managed under the CPA process?

Almost all services used the CPA as their management framework. There was no difference between dedicated and generic services in CPA usage (odds ratio (OR) = 0.22, 95% CI 0.04 to 1.47, $P = 0.12$).

3. Are patients offered specific interventions for personality disorder within a biopsychosocial approach?

Across services, there was a fairly wide availability of a number of different biological, psychological and social interventions. *Table 3* includes the mean biopsychosocial ratings stratified by service type. Generic services had significantly higher biopsychosocial ratings than dedicated ones, indicating a greater availability and diversity of interventions ($= 3.02$, 95% CI 2.32 to 3.73, $P < 0.01$). However, services led by medics offered a greater range of interventions than those led by other professionals ($= 1.09$, 95% CI 0.97 to 2.84, $P < 0.01$), as did services with a more diverse professional make-up ($= 0.38$, 95% CI 0.32 to 0.45, $P < 0.01$). Biopsychosocial intervention provision did not differ between dedicated and generic services after adjusting for these factors ($= 0.69$, 95% CI 0.29 to 1.68, $P = 0.17$). Contrary to hypothesis, the availability of interventions developed specifically for personality disorder (such as dialectical behaviour therapy (DBT), mentalisation-based therapy (MBT), schema-focused therapy (SFT) and systems training for emotional predictability and problem solving (STEPPS)) did not differ significantly between dedicated and generic services (OR = 0.91, 95% CI 0.37 to 2.21, $P = 0.83$).

4. Are services involved in education, training and research?

Most services were involved in at least one of these activities (*Table 4*). The rates of participation in these activities for dedicated services were approximately twice those of generic services, and dedicated services were significantly more likely than generic services to be involved in all three of these activities (i.e. education, training and research) (OR = 6.18, 95% CI 2.29 to 16.69, $P < 0.01$). This difference remained significant after adjusting for the profession of the service lead and for the professional diversity of the team (OR = 31.67, 95% CI 4.26 to 235.5, $P < 0.01$).

5. What level of patient and carer involvement do services employ?

Table 5 contains the mean patient and carer ratings stratified by service type. Very few services had no patient or carer involvement, and the odds of having any involvement activity did not differ between dedicated and generic services (OR = 1.17, 95% CI 0.42 to 3.22, $P = 0.77$). However, dedicated services had significantly higher patient and carer involvement ratings than generic ones, indicating involvement in a greater number of service development, care planning, service delivery, training and leadership activities (= 6.29, 95% CI 3.03 to 9.55, $P < 0.01$). This difference remained significant after adjusting for the profession of the service lead and for the professional diversity of the team (= 9.76, 95% CI 3.90 to 15.62, $P < 0.01$).

6. What exclusion criteria, if any, are applied by services?

No services excluded individuals on the basis of a diagnosis of personality disorder. Across both dedicated and generic services, the most common exclusion criterion was uncontrolled substance misuse, followed by active risk to others (*Table 6*). Almost half of services (43%) had no exclusion criteria. Dedicated services were significantly more likely than generic ones to have exclusion criteria (OR = 10.95, 95% CI 3.31 to 36.19, $P < 0.01$). This difference remained significant after adjusting for the profession of the service lead and for the professional diversity of the team (OR = 5.02, 95% CI 1.24 to 20.35, $P = 0.02$).

Discussion

This national survey was the first of its kind and captured data provided by 56 relevant mental health organisations in England. With a response rate of 91% for English mental health NHS trusts, and a sample of independent service providers, we can be confident the survey is representative of personality disorder provision in England.

The majority of organisations described both dedicated personality disorder services (84%) and generic services (91%), and in organisations with no dedicated services all provision for personality disorder was through a generic service. This quantifies the progress made in this area since 2002 and points to a fivefold increase in organisations providing dedicated personality disorder services.⁹

This represents substantial progress in a decade in which the economic landscape has been challenging. Yet, while on this measure we can see substantial progress at an organisational level, the survey indicates a worrying level of variability at a local level, with only 55% ($n = 31$) of organisations indicating equal access to the dedicated services they provide.

The 2003 NIMHE publication formally introduced the concept of dedicated personality disorder service as distinguished from generic service, and this distinction has been further developed in the current paper.⁹ We had *a priori* assumptions about the nature of dedicated and generic services (*Table 1*), and this survey allows a more detailed conceptual analysis. The survey methodology steered respondents to consider the concept of dedicated *v.* generic services. Analysis of the descriptive and statistical differences between the 81 dedicated and 51 generic services allows us to draw some conclusions about these two types of service provision. For instance, we found that generic services draw from a wide range of professional disciplines, which is in line with their broader remit. Seemingly, dedicated services draw from a more restricted range of professional disciplines; this supports the notion that they are specialist, niche services.

Contrary to our *a priori* hypothesis, dedicated services were no more likely to provide personality disorder-specific interventions when compared with generic services. Furthermore, generic services provide a significantly wider range of biopsychosocial interventions than dedicated ones, although there was some suggestion that this was influenced by their employment of a significantly more diverse workforce and by their higher rates of medical professional leadership. The accessibility of these interventions and the quality of their delivery are unknown; however, NICE guidance stipulates that specialist interventions are best delivered by specialist services.¹¹

The delivery of developmental activities is a clear priority for dedicated services, with almost all involved in training, and significantly more dedicated than generic services involved, indicating that they deliver both training and education and research. This is in keeping with both the 2003 NIMHE publication and NICE guidance.^{9,11,12} Patient and carer involvement is also prioritised by dedicated services, with patients and carers involved in significantly more service development, management and delivery activities than those in generic services. Dedicated services appear to show greater selectivity in patient choice than generic ones, as significantly more operate with exclusion criteria. Given that impulsivity is a diagnostic criterion for borderline and dissocial personality disorder, it is noteworthy that active risk to others (23%) and substance misuse (53%) were so widely quoted as exclusion criteria for dedicated personality disorder services.

Limitations

The response rate for the independent providers should be treated with caution as it is subject to selection bias. Responses were self-reported and there may have been variation in the interpretation of what constituted a dedicated personality disorder service.

In the comparisons made with generic services, the respondents were asked to provide an overview of all of the generic services within their organisation. Although this was pragmatically necessary, given the large numbers of generic services within any organisation, this approach requires the reader to consider the comparisons with appropriate caution. In particular, the findings which relate to the personality disorder-specific interventions and range of staff within the multidisciplinary team will be skewed by this methodology.

While this survey is able to give a good organisational-level description of service availability, mapping the local provision is achieved to a limited degree. Perhaps the most important consideration is that the indicators used in this survey to consider the quality can only provide a broad brush-stroke indication, owing to necessary methodological trade-offs for pragmatic purposes.

Understanding the consistency with which individual patients and carers can expect adherence to best practice and the timeliness of the interventions offered is beyond the scope of this survey. We believe this body of work begins to elucidate the questions which need to be considered, but it is a long way from achieving that. Indeed, the largest limitation of this work is that at best it provides a broad overview of provision. To properly understand what is actually delivered to those in need will require a more systematic and sustained effort to describe quality standards and ensure, perhaps through accreditation, that best practice is being followed.

Further developments

This paper charts the most systematic attempt to date at mapping the provision of care across England for those affected by personality disorder. What is clear is that the past decade or so has seen considerable progress in providing a service for this range of disorders. Despite this progress, data presented here provide evidence that there remains continued exclusion, variability of practice and inconsistencies in the availability of services.

The current NICE guidance, in step with the evidence base, supports the provision of a range of cost-effective interventions and the establishment of specialist services from which to deliver them. The initial offering presented here lends weight to the call for the establishment of authoritative commissioning guidance and service standards to ensure that patients and carers have access to the care that they need.

The National Personality Disorder Service Review Group work stream was seeded by a small project funding initiative through the Royal College of Psychiatrists' Faculty of General Adult Psychiatry in 2014 and West London Mental

Health Trust Research and Development. A multidisciplinary group was formed with representations from psychiatry, psychology, psychotherapy and expertise through lived experience of personality disorder. At various stages through the project the affiliates included: the Faculty of General Adult Psychiatry, West London Mental Health Trust Research and Development, Informed Thinking, The Medway Engagement Group and Network (MEGAN) and the Imperial College Centre for Mental Health. The project was granted approval as a service evaluation through the audit department of West London Mental Health Trust.

1.7.72 Perceptions and knowledge of antipsychotics among mental health professionals and patients

Abstract

Aims and method To assess the patients' most influential concerns regarding long-acting injectable antipsychotics (LAIs) and mental health professionals' preconceptions about these concerns. For both groups, to assess the level of knowledge about LAIs. This cross-sectional study used semi-structured interviews of patients with schizophrenia or schizoaffective disorder ($n = 164$), nurses ($n = 43$) and physicians ($n = 20$).

Results The mental health professionals overestimated many of the patients' fears of LAIs, and the expressed fears exceeded the actual experiences of patients already on LAIs. Acceptance to switch to LAIs was associated with shorter time from diagnosis. Nurses and patients disclosed limited knowledge of antipsychotics.

Clinical implications Physicians and nurses should aim to identify the individual patient's concerns about LAIs in the discussion about choice of antipsychotic treatment early in the course of illness.

Adherence to antipsychotic treatment is a major challenge and an important predictor of the outcome in patients with schizophrenia and schizoaffective disorder.¹ The risks of relapse and admission to hospital increase immediately after discontinuation, even with small treatment gaps.^{2–5} With oral antipsychotics, such gaps often go undetected until relapse – an issue that can be overcome by use of long-acting injectable antipsychotics (LAIs).⁵ There is growing evidence that, compared with oral treatment, LAIs reduce the risk of discontinuation, relapse and hospital admission.⁶ Furthermore, owing to superior pharmacokinetics, the use of LAIs is considered to increase the likelihood of finding the lowest effective dose, which subsequently reduces the risk of side-effects.^{7,8}

Despite the identified advantages, LAIs are not used as widely as might be expected. The prescription frequency varies greatly between countries,⁹ indicating that factors other than the patient's attitude influence the utilisation rate. While patients' attitudes towards LAIs become more positive with increased knowledge and experience of the treatment,¹⁰ clinicians often overestimate patients' resistance against LAIs, anticipating that they will be concerned about the injection procedure.^{10–12} This impedes so-called shared decision-making, an approach with the potential to increase adherence.¹³ Patients are frequently excluded from the discussion about the choice of antipsychotic formulation,¹⁴ and one reason may be resistance arising from mental health professionals' preconceptions.

We aimed to investigate the specific concerns that affect patients' perceptions of LAIs, and to what extent mental health professionals' preconceptions agree with these perceptions. Furthermore, we aimed to identify knowledge gaps about antipsychotic formulations among both patients and mental health professionals.

Method

Design

We conducted a cross-sectional study of mental health professionals' and patients' perceptions and knowledge regarding antipsychotic treatment in a psychiatry catchment area in Stockholm, Sweden, operated by PRIMA Adult Psychiatry. Data were collected in semi-structured interviews performed by a research nurse (L.C.) at the participant's home clinic between January and October 2015. The participants were enrolled upon giving written informed consent. The study was approved by the regional ethical review board in Stockholm (ref. 2015/47-31).

Participants and setting

We studied three categories of participants: (a) patients on LAIs; (b) patients on oral treatment; (c) mental health professionals, including physicians and nurses.

We identified all patients with schizophrenia or schizoaffective disorder. Patients with no medical treatment or with previous but discontinued LAIs, as well as patients who had been on LAIs >5 years were excluded. Other exclusion criteria were language barriers (i.e. need of interpreter in consultations), cognitive impairment and severe autism spectrum disorders. We collected information on patients' age, gender, years with diagnosis, marital status, number of children, highest achieved academic degree and occupation. The patients on oral medication were block randomised on diagnosis (schizophrenia/schizoaffective disorder), gender and age to two separate arms. The first group was included in this study to represent those on oral medication, while the second group did not participate and will act as controls in a future intervention study.

All physicians and nurses working in the psychosis sector of PRIMA were asked to participate. We recorded age, gender and extent of experience within the psychiatric field.

Questionnaires

We conducted semi-structured interviews based on different questionnaires specific to each participant category and designed for the present study. Participants graded their potential concerns with a mark on a continuous 100 mm scale ranging from 0 ('Does not affect at all') to 100 ('Decisive to decline LAIs'). Potential concerns included in the questionnaire were pain at administration, possible observation time of 3h, embarrassment at administration, restricted autonomy, feeling of being controlled, being obliged to show up at the clinic regularly, lack of ability to decide when medication is administered, and stigmatisation. The questions were designed to address the participant appropriately, for example, mental health professionals: 'To what extent do you think fear of pain affects the patients' perception?'; patients on oral medication: 'To what extent does fear of pain affect your perception?'; and patients on LAIs: 'To what extent does pain affect your perception?'. The investigated concerns were predefined based on a literature review and clinical experience.^{10,15,16}

Questions about knowledge of the differences between LAIs and oral treatment regarding achieved plasma concentration, side-effects and risk of readmission to hospital were identical for all participants and included pre-specified nominal options. In questions regarding clinical approach among mental health professionals, participants were asked to state items freely. Physicians stated their most common reasons for prescribing LAIs, and their strategies to encourage patients to consider LAIs. Furthermore, they were asked to speculate what the patients' key reasons for accepting LAIs are. These answers were assessed using thematic analysis after the study was complete.

Nurses were asked whether they tried to influence patients' and physicians' choice of formulation (yes/no). Patients on oral medication were asked whether they had previously been offered LAIs and whether they knew of the features of being on LAIs. Finally, at the end of the interview, all patients were asked about their perspective on switching formulation (positive/negative).

Statistical analysis

Anonymised data were analysed using Prism 5.03 for Windows. Sample comparisons were made using Fisher's exact test for categorical variables (gender, positive/negative towards switching to LAI). The Mann-Whitney [*U*-test or Wilcoxon matched-pairs test was used for continuous variables (age, illness duration, mental health professionals' experience and questionnaire responses on a 100 mm scale), where appropriate.

Results

Inclusion and exclusion of study participants

We identified 875 patients in the catchment area with a diagnosis of either schizophrenia or schizoaffective disorder; 341 patients were currently being treated with LAIs (39%). Of the 875 patients, 302 met our inclusion criteria. Finally, 101 patients on oral treatment and 63 on LAIs participated in the study. The reasons for not participating are presented in *Fig. 1*. All 21 physicians and 46 nurses working in the psychosis sector of PRIMA were asked to participate; 1 physician and 3 nurses declined owing to lack of time.

Participant characteristics

There were no statistical differences regarding characteristics between patients on LAIs and patients on oral medication, except that patients on oral medication were more likely to have achieved a higher academic degree (*Table 1*). The median age of the 20 physicians was 47 years (range 34–69) and 45% were women. The median number of completed years in the psychiatric field was 6.5 years (range 0–20). The 43 nurses had a median age of 51 years (range 27–67) and 81% were women. The median length of experience in the psychiatric field was 12 years (range 0–36), and 51% were specialists in psychiatric care.

Characteristics of interviewed patients

Characteristics	Patients on oral treatment (<i>n</i> = 101)	Patients on LAIs (<i>n</i> = 63)	<i>P</i>
Females, <i>n</i> (%)	46 (46)	26 (41)	n.s.
Age, years: median (range)	50 (21–84)	51 (24–74)	n.s.
Diagnosis, <i>n</i> (%)			
Schizophrenia	71 (70)	41 (65)	n.s.
Schizoaffective disorder	30 (30)	22 (35)	n.s.
Duration of illness, years: median (range)	21 (1–55)	18 (1–45)	n.s.
Highest education, <i>n</i> (%)			
Elementary school	21 (21)	24 (38)	0.020
High school	49 (49)	31 (49)	n.s.
University	31 (31)	8 (13)	0.0086
Employed, <i>n</i> (%)	19 (19)	7 (11)	n.s.
Marital status, <i>n</i> (%)			
Single	71 (70)	53 (84)	n.s.
Living independently	8 (8)	2 (3)	n.s.

Underage children living at home, <i>n</i> (%)	8 (8)	3 (5)	n.s.

LAIs, long-acting injectable antipsychotics; n.s., not significant.

Perceptions of LAI antipsychotics

Comparing patients on oral antipsychotics *v.* patients on LAIs, fears exceeded the actual experiences for all factors examined (Table 2, online Fig. DS1), but fear was only statistically significant for the concerns of being tied to the clinic (62 *v.* 28, $P = 0.018$) and loss of decision-making regarding when to take the medicine (45 *v.* 8, $P = 0.001$). Overall, patients' results tended to be polarised to either end of the 100 mm scale whereas the mental health professionals' results were more centred in their distribution.

Estimated and actual fears as well as experienced factors affecting the decision to decline long-acting injectable antipsychotics (LAIs)

Factors	Mental health professionals ($n = 63$)	Patients on oral treatment ($n = 101$)	P	Patients on LAIs ($n = 63$)	* P * a
Pain at the injection site	50.5 (11–95)	28 (0–100)	0.001	12 (0–100)	0.21
Being regularly tied to a clinic	49 (5–98)	62 (0–100)	0.24	28 (0–99)	0.018
Observation time at the clinic after one certain type of LAI	64 (4–98)	89 (0–100)	<0.0001	67 (3–98)	0.23
Embarrassment of having an injection	41 (1–93)	12 (0–98)	<0.0001	17 (0–100)	0.11
Reduction in autonomy	62 (5–93)	30 (0–98)	0.0025	10 (0–100)	0.18
Loss of ability to decide when to take the medication	56 (4–95)	45 (0–100)	0.13	8 (0–98)	0.001
Feeling of being controlled	56 (3–94)	25 (0–100)	0.013	13 (0–100)	0.58
Perceptions of stigma of being on LAI	51 (4–88)	17 (0–100)	0.0004	11 (0–100)	0.63

The questions were presented orally and adapted based on the participant category, *i.e.* mental health professionals, patients on oral treatment and patients on LAIs.

Patients on oral treatment *v.* patients on LAIs.

Only the 7 patients on long-acting injectable olanzapine who had experienced a 3 h observation time were included.

Patients on LAIs were asked to recall their fears before switching from oral treatment. They graded their recalled fears higher than the actual experiences regarding all factors except for observation time (online Table DS1). The differences were small, but reached statistical significance for pain (24 *v.* 12, $P < 0.0001$), embarrassment (9 *v.* 7, $P = 0.0006$), reduction in autonomy (13 *v.* 10, $P = 0.0027$) and loss of ability to decide when to take the medicine (14 *v.* 8, $P = 0.019$). Finally, there were no statistically significant differences between the graded fears of patients on oral treatment *v.* recalled fears in patients on LAIs (data not shown).

Mental health professionals overestimated the concerns of orally treated patients regarding feared pain (51 *v.* 28, $P = 0.001$), embarrassment (41 *v.* 12, $P < 0.0001$), reduction in autonomy (62 *v.* 30, $P = 0.0025$), feeling of being controlled (56 *v.* 25, $P = 0.013$), and stigma (51 *v.* 17, $P = 0.0004$; Table 2, online Fig. DS1). Conversely, they underestimated the patients' concerns regarding the 3h observation time required after injection of LAI olanzapine (64 *v.* 89, $P < 0.0001$).

Knowledge of oral and LAI antipsychotics

All physicians (100%) claimed that LAIs are associated with a more stable plasma concentration than oral treatment (Table 3). For nurses, patients on oral treatment and patients on LAIs, the corresponding proportions were 56%, 16% and 22%, respectively.

Mental health professionals' and patients' knowledge about oral v. long-acting injectable antipsychotics (LAIs) regarding plasma concentration, side-effects and frequency of readmission to hospital

Topic	Physicians (n = 20)	Nurses (n = 43)	Patients on oral treatment (n = 101)	Patients on LAIs (n = 63)
Plasma concentration, n (%)				
Lower/more stable with LAIs	20 (100)	24 (56)	16 (16)	14 (22)
Equal	0 (0)	11 (26)	23 (23)	20 (32)
Lower/more stable with oral	0 (0)	4 (9)	41 (41)	20 (32)
Don't know	0 (0)	4 (9)	21 (21)	9 (14)
Side-effects, n (%)				
Less with LAIs	15 (75)	12 (28)	18 (18)	27 (43)
Equal	3 (15)	17 (40)	25 (25)	19 (30)
Less with oral	1 (5)	11 (26)	45 (45)	11 (17)
Don't know	1 (5)	3 (7)	13 (13)	6 (10)
Risk of rehospitalisation, n (%)				
Less with LAIs	19 (95)	37 (86)	21 (21)	23 (36)
Equal	0 (0)	3 (7)	40 (40)	20 (32)
Less with oral	1 (5)	2 (5)	15 (15)	5 (8)
Don't know	0 (0)	1 (2)	25 (25)	15 (24)

Eligible answers were presented as pre-specified nominal options.

Of physicians, 90% stated that LAIs are superior or equal to oral treatment concerning side-effects. For nurses, patients on oral treatment and patients on LAIs, the corresponding proportions were 68%, 43% and 73%, respectively.

All physicians but one (95%) and 86% of nurses claimed that LAIs reduce the risk of readmission to hospital, while 21% of patients with oral treatment and 36% of patients on LAIs claimed LAIs to be superior in this matter.

Clinical approach to LAIs among mental health professionals

Poor adherence, limited insight and multiple relapses were the most common reasons for prescribing LAIs, mentioned by 80% of physicians. However, one-fourth considered LAIs an option even early in the disease course. Their strategies to encourage patients to consider LAIs were to inform them about the advantages of the formulation (65%) and about the risks and consequences of treatment discontinuation (40%). Exploring patients' fears was a strategy mentioned by 20% of physicians.

Half of physicians believed that not having to remember to take pills was the key reason for patients to accept LAIs. Other factors mentioned were good insight (40%) and that LAIs are associated with lower frequency of relapse (20%).

Of nurses, 31 (72%) replied that they actively tried to influence the patients' attitude towards one or the other formulation, and 29 (67%) actively tried to influence the physician's decision.

Patients' perspective on switching

Almost half of the patients on oral treatment (41%) declared that they had little or no knowledge of LAIs. At the end of the interview, they were asked whether they would switch to LAIs if offered by their treating physician. While 78 (77%) said no and three (3%) could not decide, 20 (20%) declared that they would agree to switch if offered such an option. The patients willing to switch had fewer years since diagnosis than those who were reluctant (12 v. 24, $P = 0.0013$; online Fig. DS2). Furthermore, the proportion of women was higher in the positive group (75% v. 44%, odds ratio (OR) = 3.9, $P = 0.023$). They considered pain (7 v. 40, $P = 0.020$), being tied to the clinic (26 v. 70, $P = 0.017$), reduction in autonomy (9 v. 30, $P = 0.034$) and stigma (6 v. 27, $P = 0.035$) to be less important issues than did the patients who were reluctant to switch to LAIs.

A total of 21 (33%) patients on LAIs would switch to oral treatment if they were offered it, 1 (1.6%) could not decide and 41 (65%) preferred to continue with LAIs. There were no statistically significant differences between patients who were positive v. patients who were negative about switching formulation with regard to age, number of years with diagnosis or gender. Those who opted to stay on LAIs were less concerned with the lack of autonomy (7 v. 40, $P = 0.015$) and the feeling of being controlled (9 v. 50, $P = 0.0011$). They also gave more correct answers regarding differences in side-effects between oral formulations and LAIs (85% v. 52%, OR = 5.3, $P = 0.012$).

Discussion

In this study, we found that patients' concerns with LAIs were minor except when considering observation time and being tied to the clinic, and that there was a mismatch in the assessment of specific concerns between the patients and the mental health professionals. We identified important knowledge gaps among patients and nurses. As many as one-fifth of the patients on oral medications were willing to switch to LAIs; these potential switchers were more recently diagnosed than those who were reluctant.

The patients on oral treatment were most concerned about observation time post-injection and about being tied to the clinic when asked about LAIs. This indicates that they valued their time and that practical issues surpassed in significance emotional ones such as stigma, a feeling of being controlled and embarrassment. All fears expressed by patients on oral treatment exceeded the actual experiences of patients on LAIs. This could be a result of selection bias, in that patients on LAIs were less concerned even before accepting LAI treatment. However, since patients on LAIs were speaking from experience, this difference may also reflect that these issues had a lower impact than expected once the patients had been started on LAIs. That the recalled concerns pre-LAIs were similar to the levels of concern among those still on oral treatment also supports this hypothesis.

Mental health professionals tended to answer questions by placing the indicator centrally on the 100 mm scale, which may reflect uncertainty as they were just estimating the patients' experiences. The patients' answers, on the other hand, were polarised, indicating that their opinions were more set. Patients also graded some factors distinctly low and others distinctly high. In light of this, physicians should be encouraged to learn more about the individual patient's concerns. Only 20% of physicians reported that they used this strategy when discussing treatment regimens.

According to previous studies, physicians' knowledge regarding antipsychotic formulations varies.^{16,17} Physicians in the current study showed very good knowledge. However, a significant proportion of the interviewed nurses had knowledge gaps concerning some of the advantages of LAIs. This could have a negative impact on the patient's attitude towards LAIs, especially as the majority of nurses claimed that they actively tried to influence both doctors and patients in the discussion on treatment choices. Patients already on LAIs had significantly better knowledge about the reduced side-effects with LAIs than patients on oral treatment. This most likely reflects their own experiences. It could also be an effect of information provided by mental health professionals – information many patients on oral treatment reported as lacking. This is of concern, as we know that patients' attitudes towards LAIs are likely to become more positive with increased knowledge and experience of the treatment.¹⁰ The physicians' observed reluctance to bring up the topic may be due to their anticipation that the patients are unlikely to accept the offered LAI. However, keeping the patients uninformed makes shared decision-making impossible.¹⁵

The majority of the patients on LAIs chose to keep this formulation and as many as 20% of the patients on oral treatment were willing to use LAIs. This is in line with a previous study in which 16% were positive towards a formulation

switch.¹⁴ This also supports the hypothesis that the use of LAIs could be limited by factors other than rejection by the patients.¹² Some physicians claimed that they offered LAIs early in the disease course, but their most common reasons for prescribing LAIs were poor adherence to oral medication and recurring relapses. Previous studies also report non-adherence^{16,17} and multiple relapses¹⁷ as key criteria for prescribing LAIs. This may be unfortunate as longer illness duration was associated with being reluctant to switch. Instead, this motivates a discussion of LAIs early on in the course of illness, especially as there is cumulative evidence that the use of LAIs as early as after the first admission to hospital decreases the risk of treatment discontinuation, relapse and readmission.^{4,5,18}

Limitations

Our study has several limitations. Not all patients in the targeted study population were included, and some patients could not be reached or were not present to complete the questionnaire. Some were only scheduled for visits once per calendar year, while the study was limited to 10 months. It is possible that patients were either too ill to present themselves or were stable enough to postpone yearly visits. The patients on LAIs were asked to declare their perceptions prior to starting on LAIs, which introduced recall bias. However, we excluded all patients on LAIs 5 years, reducing the effect of this bias. Finally, patients on LAIs are indisputably a selection of patients who have once accepted that formulation. However, the lack of significant differences between the graded fears of patients on oral treatment compared with recalled fears in patients with LAIs may indicate that this selection bias is of minor concern. A strength of this study was that all interviews were performed by the same person (L.C.), securing consistency across interviews.

Clinical implications

In conclusion, physicians should aim to set aside their own preconceptions and instead make time to identify the individual's specific fears regarding LAIs, preferably early in the course of the illness. In addition, there is room for improvement regarding patients' knowledge of antipsychotic formulations. Adequate education would be of value to strengthen nurses' knowledge about LAIs. Finally, there is room for improvement regarding patients' knowledge of antipsychotic formulations.

1.7.73 Mental capacity legislation in the UK: systematic review of the experiences of adults lacking capacity and their carers

Sam Wilson

Correspondence

Sam Wilson (samuel.wilson1@nhs.net)¹

date

2017-10

Abstract

Aims and method Capacity legislation in the UK allows substitute decision-making for adults lacking capacity. Research has explored the experiences of such adults and their carers in relation to the Adults with Incapacity (Scotland) Act 2000, and the Mental Capacity Act 2005 in England and Wales. A systematic review of the relevant research was performed using a framework method.

Results The legislation provided mechanisms for substitute decision-making which were seen as useful, but there were negative experiences. Decision-making did not always seem to follow the legislative principles. Awareness of the legislation was limited. Most research was qualitative and some was of low methodological quality. Data were too heterogeneous to allow comparisons between English and Scottish law.

Clinical implications Capacity legislation was generally viewed positively. However, some experiences were perceived negatively, and the potential benefits of the legislation were not always utilised.

In law, mental capacity is the ability to make decisions, and it relies on a number of attributes such as comprehension and reasoning.¹ Capacity legislation exists to allow legally valid decisions to be made about finances, welfare or medical treatment where the individual lacks mental capacity. In Scotland this legislation exists as the Adults with Incapacity (Scotland) Act 2000 (AWIA) and in England and Wales as the Mental Capacity Act 2005 (MCA). Northern Ireland has recently adopted the Mental Capacity Act (Northern Ireland) 2016.

Prior to the introduction of legislation, English capacity law was criticised by the Law Commission as being unsystematic and out of step with disability rights.² The Scottish Law Commission described Scottish capacity law as fragmented and archaic.³ The AWIA and the MCA were introduced to reform capacity law, and are similar in many respects. They set out principles which aim to promote the rights of adults who lack capacity, and create mechanisms to allow substitute decision-making, a process whereby another individual has the legal power to make decisions on the disabled adult's behalf. The MCA has a specific 'best interests' process, which allows some decisions to be made without court proceedings, whereas there is no equivalent process in the AWIA. The Northern Irish legislation mirrors the MCA in many regards. The terminology varies between jurisdictions, for example, guardianship in the AWIA is similar to deputyship in the MCA.

A number of studies have explored the experiences of adults lacking capacity and their carers in relation to the legislation, and this systematic review draws together findings from this area of research.

Method

This review systematically appraised the research evidence exploring how adults lacking capacity and their carers experienced capacity legislation. It followed the Centre for Reviews and Dissemination guideline.⁴ The process is summarised in *Fig. 1*. All experiences related to the AWIA and the MCA were considered of interest, from everyday decision-making to perceptions of court proceedings and their outcomes. There was no research relating to the Northern Irish legislation, because the review was undertaken prior to its adoption. In this review, ‘carers’ included family and professional carers who made substitute decisions in a day-to-day caring role.

Fig. 11: Flow chart of study selection process.

The primary research question was ‘What are the experiences and perceptions of adults lacking capacity, their carers and the general public in relation to capacity legislation in the UK?’ The secondary research question was whether such experiences varied between jurisdictions.

The published literature consisted of both quantitative and qualitative research. Studies were included if they were published after the year 2000 (the year of introduction of the AWIA) and consisted of quantitative or qualitative research about the experiences or perceptions of adults lacking capacity, their carers or members of the general public in relation to the MCA or AWIA. There was no restriction placed on diagnosis. Exclusion criteria included studies where the individuals were minors, studies of capacity to participate in research, and studies carried out prior to the implementation of whichever Act was relevant. Papers such as accounts of service development activities, assessments of educational interventions and legal commentaries were also excluded. Research publications from sources other than peer-reviewed journals were included, because it seemed likely that there would be a paucity of evidence in the peer-reviewed literature. Although this strategy increased the likelihood of low-quality evidence entering the review, this was addressed by consideration of quality in the synthesis of the results.

A literature search was performed during June 2015. The databases were Medline, PsycINFO, EMBASE, Web of Science, ESRC, Social Care Online, BAILII, HeinOnline and LexisLibrary. The search terms were the keywords ‘Mental Capacity Act’, ‘Adults with Incapacity Act’, and ‘Adults with Incapacity Scotland Act’. Each abstract was screened. Duplicate papers and papers originating outside the UK were not included. Additional papers were sought from reference lists, conference proceedings and contact with authors. The abstracts of the papers were compared with the exclusion criteria. The complete paper was read if it was unclear from the abstract whether the paper should be included. The remaining papers were read once to exclude irrelevant papers from the final sample.

Quality assessment was carried out using the Multi-Methods Appraisal Tool (MMAT),⁵ which was selected because it offered the ability to assess the quality of all the various types of studies in the sample. It consisted of screening questions followed by questions for quantitative, qualitative and mixed-methods studies. No studies were excluded from the final sample because of low quality.

This review followed guidance that items should be regarded as data for secondary research only if they were described as results or findings in the primary research.⁶ A data extraction form was developed during a reading of the final sample papers. The data extraction form consisted of headings taken from the results sections of the final sample papers. Results from each study were then extracted if they were relevant to any heading on the data extraction form. Analysis used a framework method⁷ with a matrix consisting of each study along the x-axis and each heading from the data extraction form along the y-axis.

Results

There were 11 papers in the final sample, containing 12 distinct studies. The type and quality of studies are summarised in *Table 1*. Most of the studies used qualitative or mixed methods. There was variation in the quality of studies; only 4 of the 12 studies were rated as having the highest methodological quality and had been published in peer-reviewed journals. The other eight studies presented their results clearly but failed to report important information.

Type and quality of studies in the final sample

Study	Act	Type	Peer-reviewed journal?	MMAT score
Badger (2009) ⁸	MCA	Multiple qualitative methods	No	3/4
Badger & Parnell (2009) ⁹	MCA	Multiple qualitative methods	No	2/4
Jevon (2014) ¹⁰	AWIA	Quantitative survey	No	2/4
Jingree (2015) ¹¹	MCA	Qualitative interviews	Yes	4/4
Killeen & Myers (2004) Ch. 4 ¹²	AWIA	Mixed-methods – quantitative survey and qualitative interviews	No	2/4
Killeen & Myers (2004) Ch. 5 ¹³	AWIA	Qualitative interviews	No	2/4
Manthorpe <i>et al</i> (2012) ¹⁴	MCA	Qualitative interviews	Yes	4/4
Mental Welfare Commission (2011) ¹⁵	AWIA	Qualitative interviews	No	2/4
Myron <i>et al</i> (2008) ¹⁶	MCA	Mixed-methods – questionnaires and qualitative interviews	No	1/4
Samsi & Manthorpe (2011) ¹⁷	MCA	Qualitative interviews	Yes	4/4

AWIA, Adults with Incapacity (Scotland) Act 2000; MCA, Mental Capacity Act 2005; MMAT, Multi-Methods Appraisal Tool.

Research aims and participants are summarised in *Table 2*. Although there were data related to experiences in courts in Scotland, there were no data related to the Court of Protection in England and Wales. The data about the AWIA related mainly to guardianship, and the data about the MCA related mainly to decision-making practices. Therefore, no direct comparison between specific elements of the AWIA and MCA could be made.

Aims and participants in studies in the final sample

Study	Act	Research aim	Population context	Participants
Badger (2009) ⁸	MCA	Explore decision-making	Intellectual disability	27 participants: 2 staff and 1 family member for each of 9 disabled adults in 3 settings (none of the 9 disabled adults directly involved)
Badger & Parnell (2009) ⁹	MCA	Explore decision-making	Not described	24 participants: 6 disabled adults with 2 staff and 1 family member for each
Jevon (2014) ¹⁰	AWIA	Assess experiences of guardians	Not described	193 welfare guardians (27% response rate)
Jingree (2015) ¹¹	MCA	Explore decision-making	Intellectual disability	15 support workers from a single service
Killeen & Myers (2004) Ch. 4 ¹²	AWIA	Explore power of attorney and intromission with funds	General public	3 individuals who had made a power of attorney and 5 individuals who had applied for intromission with funds (8% response rate)
Killeen & Myers (2004) Ch. 5 ¹³	AWIA	Understand the operation of guardianship	Mixed	58 professionals, carers, and adults with incapacity involved in 13 guardianship cases – exact composition not reported
Manthorpe <i>et al</i> (2012) ¹⁴	MCA	Assess links between personal and professional experiences of dementia	Dementia	123 professionals (70 of whom had experience as carers)
Mental Welfare Commission (2011) ¹⁵	AWIA	Assess experiences of guardians and supervisors	Not described	58 welfare guardians (family or carer)
Myron <i>et al</i> (2008) ¹⁶	MCA	Assess staff, family and patient knowledge of capacity	Mixed	73 staff, 20 disabled adults, and 6 carers
Samsi & Manthorpe (2011) ¹⁷	MCA	Understand how older people planned for their future	General public	37 self-identified ‘well’ people aged over 50 years
Samsi & Manthorpe (2013) ¹⁸	MCA	Explore decision-making	Dementia	12 dementia dyads (person with dementia plus their carer)
Williams <i>et al</i> (2012) ¹⁹	MCA	Explore decision-making	Mixed	385 participants, mostly professionals – 5 interviews from the perspective of carers

AWIA, Adults with Incapacity (Scotland) Act 2000; MCA, Mental Capacity Act 2005.

None of the four studies from Scotland had been published in peer-reviewed journals and none received the highest rating of methodological quality. Two of these studies were separate pieces of research in a single publication.^{12,13}

The findings are summarised in *Table 3*. For reasons of parsimony, the 15 items from the data extraction form were collapsed into four headings in the results, but all data were retained.

Summary of findings

Theme	Finding
Positive experiences	Having a legal basis for decision-making was recognised as useful Benefits such as increased safety and quality of life were sometimes described The ability to use the mechanisms of the Acts to plan for the future was seen as beneficial, although only a minority did this The legislation was sometimes perceived as empowering
Negative experiences	Court and other legal processes were seen as challenging and cumbersome, and costs may be off-putting Some participants had extremely negative experiences The legislation was sometimes perceived as disempowering
Decision making	Decisions were sometimes but not always made with the disabled adult's participation Carers sometimes struggled to make decisions in the best interests of the adult lacking capacity There could be conflicts of interest between the adult lacking capacity and the decision maker
Other issues	There were variable findings related to support and supervision There was a lack of understanding of the legislation on the part of the general public and carers A need for carers to be assertive was described The most common reason for applying for powers was because of a wish for a formal role in decision-making There were no findings about carers' abilities to assess capacity There were no findings about deprivation of liberty Data were mainly derived from carers

Positive experiences

One study from Scotland reported that family carers saw guardianship as positive because it offered them the ability to manage their relative's welfare and finances. Improved safety and quality of life were described in several cases. Half of the six adults with incapacity interviewed in this study described improvements in their quality of life.¹³ In a telephone survey, most guardians stated that guardianship was useful, but a minority reported that it made little difference, or found it a negative experience.¹⁵ In a postal survey of guardians, most of the participants described welfare guardianship as being useful, but the response rate (26.7%) in this study was low and the result may not represent the experience of carers.¹⁰ Those who had made a power of attorney or who had made a successful application for intromission with funds saw the process as a positive experience. However, there were only a total of eight participants in this mixed-methods study.¹²

Some older members of the general public in England saw potential benefits from making a power of attorney, but most described a disinclination to plan for the future. Any plans that were made were usually of a financial nature. Individuals living alone with no family described difficulty in appointing someone to look after their affairs.¹⁷ The finding of participants failing to make powers of attorney or advance decisions, despite believing in their utility, was repeated in a group of professionals who had personal experience as carers.¹⁴ Only a minority of elderly people made a power of attorney in another study by the same researchers.¹⁸

Negative experiences

One study involved 58 professionals, carers and adults with incapacity who had been involved in court proceedings for 13 guardianship cases in Scotland. The process was described as perplexing and inhibiting for carers, and confusing and stressful for adults who lacked capacity. The process made some carers feel 'isolated and under pressure' and was described in negative terms such as 'a nightmare' and 'an enormous waste of time'.¹³ By contrast, the instruments of the AWIA which did not require court proceedings were viewed generally positively.¹²

However, negative experiences were not just restricted to experiences in court. A minority of participants in the telephone survey of guardians found being a guardian to be a negative experience in general.¹⁵ One study of the MCA included five cases of best interests decision-making from the point of view of family carers, and the experience in each case was described as disempowering and distressing for the carers. No further details were given because the carers were not directly interviewed, but this finding contrasted markedly with the largely positive views of the MCA expressed by professional respondents in the same study.¹⁹

As well as the cases of carers appearing disempowered, some adults who lacked capacity were observed to resent the powers that others held over them.¹³ However, some carers in Scotland who had gone through processes to be formally appointed with decision-making powers saw themselves as empowered.^{12,13} In this review, the legislation was perceived as empowering' for some and disempowering for others.

Decision-making

A qualitative study of support workers found decision-making to be inconsistent with the MCA; there was no assumption of capacity, and decisions were rarely oriented towards best interests.¹¹ Other support workers described struggling to balance their duties under the MCA with duty of care and safeguarding obligations, and stated that limited resources restricted their ability to support decision-making in practice.⁹ Another group felt that organisational policies, the influences of others such as family and professionals, and their duty of care restricted their ability to engage the adults in best interests decision-making.⁸

Some decision-making was clearly compliant with the general principles of the legislation. All 12 carers for individuals with dementia described the importance of best interests decision-making. They stated that they attempted to maintain the autonomy of the adult who lacked capacity and took a decision-specific approach to each question. They described the use of strategies to enhance the disabled adult's participation in decision-making, and used their knowledge of the person's previous wishes. However, even these carers described conflicts of interest between their needs and those of the adult with incapacity, and admitted struggling to decide what constituted best interests.¹⁸ The situation was similar in Scotland, with carers reporting difficulties assessing the most beneficial course of action and understanding the views of the adult with incapacity.¹³

Overall, it appeared to be the case that immediate carers (whether family carers or support workers) sometimes found difficulty in making decisions which adhered to the principles of the legislation, and that there could be conflicts between the wishes of the adult lacking capacity and the priorities of the decision maker. Although the degree of engagement with the principles varied between studies, this finding was consistent in all the studies which examined this theme, including in two of the four highest-quality studies.^{11,18}

Other findings

Practical support

Older members of the public in England were generally unaware of potential resources to support making powers of attorney or advance decisions, and some suggested that this might be helpful.¹⁷ Carers described a lack of practical support for decision-making for the adult lacking capacity, and some would have liked more.¹⁸ In one study, carers could identify potential sources of support, but these were generic supports such as friends, relatives, general practitioners and social services.¹⁶ In Scotland, around 75% of guardians were satisfied with the level of supervision and support they had from their local authorities.¹⁵ Guardians in another study perceived that they received insufficient support but were subject to excessive scrutiny.¹³ The perception of excessive scrutiny was shared by holders of intromission with funds.¹²

Lack of knowledge of the legislation

There was a lack of awareness on the part of the general public about the legislation. None of the respondents in a study of older members of the public in England were aware of the MCA, or that it could potentially support their choices for the future, but a few understood the nature of a power of attorney.¹⁷ Only 3 of 12 ‘dementia dyads’ (consisting of a person with dementia and their carer) had heard of a power of attorney, and only a single pair had utilised one.¹⁸ This lack of understanding of the legislation was apparent even where carers had been trained or where they held specific powers. Support workers thought that they needed more training in using the MCA^{8,16} and were observed to be unclear about some of their duties under the MCA.⁹ Guardians in Scotland were ignorant of their responsibilities to document the use of powers, and were unaware that they could delegate them.¹⁵ Some respondents felt that improved sources of information were necessary.¹³ Organisations caring for disabled adults had policies about risk which needed to be revised to comply with the principles of the legislation, and education about the MCA was suggested not just for professionals, but for adults lacking capacity and family carers as well.⁸

Assertiveness of carers

Those professionals with personal experience of being family carers described a necessity for carers to be ‘assertive’ in using the MCA to compel health and social services to act in the best interests of the adult who lacked capacity.¹⁴ The need for guardians to be ‘assertive and articulate’ was also described in Scotland.¹³

Application for financial/welfare powers

Data about the reasons for making applications for formal financial or welfare powers were only found in studies from Scotland. In a survey of guardians, the most common reason described for applying for guardianship was a wish for a formal role in the care of the adult with incapacity.¹⁵ Carers applied for intromission with funds because they believed that they had no other means of managing the person's finances.¹²

Absent or limited data

There were no findings in relation to carers' abilities to assess capacity. No data in the sample related to experiences of formal legal proceedings under English law in the Court of Protection. There was no information about experiences of Deprivation of Liberty Safeguards. Although many adults lacking capacity participated in the studies in this review (*Table 1*), the experiences of carers dominated the findings (*Table 2*).

Discussion

Methods and limitations

This review offers a systematic appraisal of the empirical research literature exploring how adults lacking capacity and their carers experience capacity legislation in the UK. Both quantitative and qualitative data were sought in the process of this review, but most of the studies in the final sample used qualitative or mixed methods. The lack of quantitative studies presented difficulty in data synthesis, because methods for the systematic review of qualitative research are not well established.^{4,6} However, there were benefits from utilising qualitative data to answer this review's research questions. Qualitative methods were appropriate to answer the primary researchers' questions because they are concerned with experiences and perceptions,⁴ are not reliant on random sampling²⁰ and can draw conclusions from small sample sizes.²¹ However, this systematic review cannot make claims of generalisability because it is based mainly on qualitative data, and the prevalence of the experiences described in this review cannot be determined.

There are other limitations which mean that the findings of this review must be treated with caution. This review relied on a single researcher and therefore sampling of papers and quality assessment were carried out without independent checks to ensure consistency. Two-thirds of the studies had not been published in peer-reviewed journals and some were of low quality. Most of the data from England and Wales related to decision-making, and none related to aspects of English capacity law such as experiences in court. Some of the data from Scotland were more than 10 years old, and may not reflect current practices. Data were heterogeneous and the secondary research question could not be answered because direct comparisons between specific components of English and Scottish law were not possible. However, the data were not so heterogeneous as to prevent the use of framework analysis.

Findings

What does this systematic review say about the AWIA and the MCA from the perspectives of the people who are subject to these laws? This review found that the legislation provided family carers with the ability to manage decisions for adults lacking capacity on a legally valid basis, and the mechanisms to allow this were generally seen as satisfactory. There were reports of improved safety and quality of life in some cases, including from some adults who lacked capacity. The ability to make plans for future incapacity was seen as useful. These positive consequences of the AWIA and MCA suggest that the legislation has achieved its goals, at least judging by the standards set by the law reformers of the 1990s.^{2,3} However, although a detailed discussion of human rights is beyond the scope of this paper, it must be acknowledged that the paradigm of disability rights has changed since the drafting of these laws; for example, there is pressure from the United Nations' Committee on the Rights of Persons with Disabilities to replace existing capacity laws with alternative approaches which do not utilise substitute decision-making and which would allow legal capacity regardless of the level of mental impairment.²² These proposals are based on an interpretation of Article 12 of the UN Convention on the Rights of Person with Disabilities²³ which has excited controversy²⁴ and been criticised

as undermining rather than promoting the rights of people with mental illnesses.²⁵ However, if that interpretation of Article 12 is accepted as authoritative, then key areas of UK capacity legislation are incompatible with international law.²⁶

In this review, some positive consequences of the AWIA and the MCA were mitigated by other findings. Perhaps not unexpectedly, adults lacking capacity sometimes resented the powers held over them. There were experiences of both empowerment and disempowerment. Potential benefits such as advance planning were not always realised; for example, planning for the future was seen as potentially beneficial, but despite this few people made powers of attorney or advance decisions. This is an area of concern given the relative simplicity of such instruments compared with the cost and complexity of the legal proceedings which can become necessary when someone loses capacity. Awareness of the legislation seems to be lacking, and public education might increase the utilisation of advance planning. However, not everyone will have the desire or ability to nominate a suitable power of attorney.

Education about the legislation may also be beneficial. As well as a lack of knowledge about the legislation on the part of the general public, support workers and family carers who held specific powers were sometimes unaware of their responsibilities. Decision-making was not always fully compliant with the legislative principles. Although some of the studies with these findings were conducted shortly after the introduction of the legislation when knowledge might be expected to be limited,^{8,9,16} other studies continued to demonstrate this finding several years later.^{11,15}

Legislation could be experienced as either empowering or disempowering by carers. Although some adults lacking capacity described positive outcomes, others described concepts similar to disempowerment. The AWIA and the MCA have been lauded as progressive and empowering instruments.^{27,28} It is true that both are grounded in principles such as enablement, least restriction, and the participation of the adult who lacks capacity in decision-making. Nevertheless, these principles are only empowering in the sense that they return disabled people to the legal status of any other citizen, and do not give them any additional rights to allow them to overcome their impairments. Series²⁹ has observed that most of the mechanisms of the MCA have the effect of transferring power away from disabled adults, and for this reason disputes the claim that the MCA is empowering. The AWIA may be viewed as disempowering for the same reason.

In this review, negative experiences of the legislation related mainly to court proceedings, although data were lacking about the Court of Protection in England and Wales. The transfer of significant decision-making powers between individuals is always likely to require formal proceedings, which will often be perceived as challenging and costly by the applicants. What other options are there? Moving to a tribunal system could potentially decrease costs and reduce distress because the proceedings take place outside the courts. However, tribunals might prove more expensive because of the addition of an extra judicial tier,²⁷ and may not necessarily be experienced more positively than court proceedings.

The initial legislation did not deal with the provision of due legal process for adults without capacity who require restrictive care regimes but lack the ability to challenge their *de facto* detention (so-called 'Bournewood patients').³⁰ This gap in the law still exists in Scotland.³¹ In England and Wales, provisions to deal with this issue were made in the form of the Deprivation of Liberty Safeguards, but these were criticised by the House of Lords, which recommended the process be replaced.²⁷ Both the AWIA and the MCA are undergoing reform to deal with this issue. This review found no data about deprivation of liberty, and it is unfortunate that there are no perspectives from patients or their carers to inform the changes to this area of law.

Finally, the participation of disabled adults in research about capacity legislation needs to be improved. Most of the findings in this review were drawn from carers, despite many adults who lacked capacity having been recruited into the studies. It is disappointing if researchers have made efforts to include such participants, only for those voices to be lost, and future research should take care to avoid this.

This study formed part of an MSc in Mental Health and Law from Queen Mary University of London. Dr Erminia Colucci, Dr Ruth Fletcher and Dr Yasmin Khatib commented on the design of this study and drafts of the manuscript. Dr Lucy Series suggested additional papers for this review.

1.7.74 Does the cognitive therapy of depression rest on a mistake?

Abstract

Cognitive therapy for depression is common practice in today's National Health Service, yet it does not work well. Aaron Beck developed it after becoming disillusioned with the psychoanalytic theory and therapy he espoused and practised. But Beck's understanding of psychoanalysis appears to have been seriously flawed. Understood rightly, the psychoanalytic approach offers a cogent theory and therapy for depression which, unlike the cognitive approach, takes us to its emotional-motivational roots. A clinically successful therapy can afford to eschew theory and rest on its pragmatic laurels. This is not the case for cognitive therapy. The time is right to re-examine the psychoanalytic theory and treatment of depression.

Contents

- *Does the cognitive therapy of depression rest on a mistake?*
 - *Psychopathological theory*
 - *Therapeutic practice*
 - *Implications*

Cognitive-behavioural therapy (CBT) is, alongside antidepressant medication and counselling, today's mainstay treatment for depression in the UK. Such treatments tend to work better than nothing at all,¹ yet in general fare little better than placebo,^{2,3} suffer relatively high relapse rates, and often struggle to provide a complete remission.^{4,5}

CBT treatments for anxiety disorders, by comparison, appear more successful.⁶ They work by helping the patient articulate, then transcend, their underlying inchoate fears, the transformative learning happening directly within action and experience. This bottom-up experiential focus contrasts with the cognitive treatment of depression, where the patient is more typically trained in an arduous top-down task of managing unhealthy habits of mind through attentional and behavioural training and rational self-management.⁷

One reason for the rather low remission and high relapse rates for CBT-treated depression may be that the treatment does not reach to the emotional roots of the problem. That CBT principally theorises and treats the maintaining, rather than identifies underlying, causes of depression was acknowledged by Aaron Beck, the American psychiatrist who developed the cognitive aspect of this pragmatic depression treatment in the 1950s.⁷

The psychoanalytic psychology Beck displaced had a theory of the root cause of depression: avoidance of intolerable emotion blocks healthy emotional functioning, depletes uncontrived self-possession, and lowers self-esteem.⁸ But his clinical experience (as a psychoanalytic psychotherapist) and scientific research (on depression, anger and dreaming) led Beck to discount the significance of such unconscious emotion. Ever the pragmatist, he focused instead on treating the conscious assumptions and ruminations of the patient which, he proposed, were maintaining their depressive state.

This article argues that the versions of psychoanalytic theory and therapy Beck espoused, practised and then rejected were recondite and implausible. The claim is that Beck mistakenly threw out the psychoanalytic baby of a significant psychological understanding and treatment of depression with the bathwater of a rather idiosyncratic understanding of psychoanalytic theory and practice. The thesis offered is theoretical rather than scientific: it considers the fundamental conceptual matter of how that theory is itself to be understood, rather than the secondary empirical matter of evidence for or against hypotheses derived from particular interpretations of it. But given the availability of far more plausible versions of psychoanalytic theory and practice that outline and treat depression at its emotional roots, and given the relatively poor success of CBT for depression, the time is now right to put the psychoanalytic theory back on the table and test hypotheses and therapies derived from it.

Psychopathological theory

An important theme in psychoanalytic psychopathology has depression resulting from the avoidance of feelings of loss. When the acute sadness of letting go of a beloved or an aspiration is too painful, the patient may avoid it by shutting down and instead become flat and morose. This, however, prevents adaptation to loss, since sadness is simply the most fundamental form that our recognition of loss takes. Another especially significant theme has depression resulting from the unconscious avoidance of anger towards those to whom we are attached. Rather than risk the feared relational fallout from expressing anger, the patient unconsciously depletes herself, trading that sense of self-worth that would be provided by an angrily assertive sense of injustice for the stability of her relationship. A third theme has depression resulting from the unconscious avoidance of fear. Rather than face the vicissitudes of uncontrollable fate in one's love and work, the patient instead constructs and lives in a dismal and diminished version of himself, his situation and his future. Even if life thereby becomes grim, at least now it will not take him by surprise.

Such ideas form but three strands of a more complex psychoanalytic conceptualisation of depression,⁸⁻¹⁰ but are fairly widespread in both popular and clinical culture for good reason. For clinically what we discover, again and again in straightforward cases, is a depressed person who avoids sadness, fear and in particular anger by going flat, downgrading her sense of her own value, shutting down self-assertion, not allowing herself to get even reasonable hopes up, falsely characterising herself as perpetrator rather than victim of relational injustices, characterising herself as deserving of treatment which reasonable others would consider unjust, denying the significance of her unmet emotional needs, and envisaging a world in which the exercise of agency appears foolhardy. In more complex cases, however, we find masochistic self-abasement added to an anger-avoiding dynamic: unconscious hatred towards another breaks through the attempts at self-suppression and gives rise to intolerable guilt, and this in turn inspires self-punishment where the anger towards the other is 'retroflexed' (taken out on oneself), leading to further and darker melancholic misery.⁹

It was by way of a reaction against such psychoanalytic theory that a young, psychoanalytically minded American psychiatrist and dream researcher developed the theory and practice of cognitive therapy. Following a helpful personal experience of psychoanalysis, Aaron Beck treated several depressed patients using psychoanalytical methods, applied (albeit unsuccessfully) for membership of the American Institute of Psychoanalysis, and published a few papers on psychoanalytic psychotherapy and on the themes of his depressed patients' dreams.^{11,12} Reading these today we learn in particular of his scientific interest in the increased prevalence of thwarted, deprived, excluded, rejected, injured and ashamed themes in his patients' dreams, and of his clinical interpretation of these along psychoanalytic lines.

Already in these early papers, however, we find a curious feature which presages his later rejection of psychoanalysis: although most of the themes Beck describes (e.g. 'I was in a restaurant but the waiters would not serve me'; 'Everyone was invited to the party but me'; 'My fiancée married someone else') appear interpretable in terms of the simple hypothesis of motivated self-depletion, surprisingly he interprets them all in terms of the more complex dynamic of self-hatred: the depressed patient's misery is always seen as deliberately rather than incidentally self-inflicted, reflecting his 'need to suffer'.¹³ Dreams such as not getting food that is requested, or being rejected – which in themselves appear at most to indicate a need to safely anticipate setbacks or protect cherished others from one's resentment by portraying

life as hopeless and oneself as worthless – are instead counterintuitively read as ‘the representation of self-punitive tendencies ... the depressed person feels guilt about his ego-alien drives and punishes himself for them.’¹¹

The question naturally arises as to why Beck was so drawn to the masochism hypothesis. And this is particularly significant because it was when his later experimental and clinical investigations – including his patients’ appropriately negative reactions to interpretations overly organised by this hypothesis – rightly led him to doubt whether he really was meeting everywhere with self-hatred, that he threw out the entirety of the baby of the general psychoanalytic theory of depression along with the specific counterintuitive bathwater of an over-reaching application of the masochism hypothesis. Which is to say that the entire project of explaining why a patient may be unconsciously motivated to think and feel and act in depressive ways was abandoned; in Beck’s hands their condition now collapsed into a habitual rut of self-maintaining negative thought, feeling and behaviour.

One answer to why Beck was so compelled by the masochism hypothesis that it overrode his recognition of the frequent sufficiency of the simpler theory of motivated self-depletion is apparent in the early papers themselves. Beck somehow entirely forgets about the psychoanalytic ideas of depression as due either to thwarted mourning or to avoided fear, becoming solely preoccupied by the idea of it as due to suppressed anger. Such depression as did not appear to evince anger (since, one imagines, it was really due to suppressed sadness or fear) could then only be brought into line with the suppressed anger hypothesis by positing that such a patient was masochistically contriving to make herself depressed.

Another answer only becomes apparent in Beck’s later writings; it concerns the nature of dreaming. (Grasping this takes a little patience, but it is worth the effort.) In these later writings he tells us that what he was actually trying to do in his early research was to set the clinical psychoanalytic theory of depression as a function of suppressed anger on a firmer scientific basis by providing quantitative psychological evidence of unconscious anger in the dreams of his depressed patients.^{14,15} Although he did not report it at the time, what he later tells us he found is what has also been established since:¹⁶ that as a group people with depression have fewer themes of anger in their dreams than people who do not have depression. This puzzled him, as somehow he had understood the Freudian idea of dreams being the ‘royal road to the unconscious’¹⁷ to mean that feelings unacceptable to the waking patient ought to show up straightforwardly in their dreams.¹⁴ The finding of fewer angry themes in the dreams of patients with depression therefore appeared to contradict the psychoanalytic hypothesis of depression as resulting from suppressed anger. This troubled Beck, but – at least until he found independent evidence of the implausibility of this interpretation – he realised he could save the psychoanalytic theory by interpreting the very dreaming of such miserable dreams as masochistically motivated (‘he makes himself dream such miserable dreams because he hates himself’).

What is deeply unclear in all of this is why Beck thought that Freud’s theory posited that unconscious emotions ought to be directly manifest and countable in dreams. After all, Freud’s theory was that dreams serve to protect sleep by helping prevent the dreamer’s anxious recognition of emotions they find unacceptable, such as anger towards loved ones. In that theory dream construction involves the disguise – through displacement, condensation, reversal, negation and projection – of such impulses and emotions as threaten a comfortable sense of self–other relations. (Freud’s ‘royal road’ refers not to a direct, undisguised revelation of the unconscious, but rather to dreams offering particularly rich sites for interpreting the products of defences against intolerable feelings and motivations – by contrast with the myriad, emotionally irrelevant concerns of waking life.) In retrospect it seems at least possible that Beck’s enthusiasm to formulate and test a psychoanalytic hypothesis using the quantitative methods of empirical psychology ended up getting the better of his grasp of the psychoanalytic theory itself.

To sum up so far: a central plank of cognitive therapy’s origin myth has it that it developed out of an apparent scientific disconfirmation of the clinical psychoanalytic theory of depression as a motivationally explicable state.¹⁴ But in retrospect what seems more likely to have happened is that an inappropriate quantitative methodology deployed to provide support for an unlikely theory of depressive dreaming actually found against it; that an implausibly general theory of depressive masochism was developed to save the floundering analytic theory; and that when this overly general masochism theory was dropped for good reason, the whole idea of symptoms as motivated by the avoidance of intolerable feelings – i.e. the whole idea of a depth psychology – was jettisoned for no good reason at all.

Therapeutic practice

As described above, the development of cognitive therapy's psychopathological theory rests on its unwarranted rejection of the psychoanalytic notion of depression as unconsciously motivated. The development of cognitive therapy's psychotherapeutic technique, however, depends on its rejection of the centrality for psychotherapeutic practice of what psychoanalysis terms the 'transference relationship'.⁷ A curious aspect, then, of Beck's development of cognitive therapy is that it was actually inspired by his encounter with, and dawning realisation of the clinical significance of, what are clearly recognisable as his patients' transferences to him.

First, a note on 'transference'. A defining preoccupation of psychoanalysis is with how immersion in relationships which inspire concern and attachment – such as those with psychotherapists, partners, parents, employers, etc. – so readily elicits unrealistic fearful and idealising expectations concerning others' views of us. These relentlessly maintained, emotionally charged expectations are seen by psychoanalysis as being at the root of much psychopathology, and their manifestations inside and outside of therapy are known as negative and positive transferences. They can be easy to attend from, as it were, but powerfully difficult to attend to – i.e. they are often unconscious – and their patterns are typically transferred from one significant other to another over time.^{18,19} The task of psychoanalytic therapy is the patient's emancipation from distorting transference patterns, a task prosecuted by first facilitating the flourishing and then the subsequent experiential emancipation from the transferences between patient and psychotherapist, an experience that can then generalise to the transferences in the rest of the patient's life. Much of a psychoanalytical psychotherapist's training has to do with developing his ability to make room for and be emotionally touched, yet not inexorably swept along, by the patient's transference so he can think about, experience, describe, and help liberate the patient from her unconscious depressogenic emotional habits.

To return to cognitive therapy. As Beck¹⁵ tells the story, he had a patient who would lie on the couch each session and regale him with lurid tales of her sexual exploits, while he sat back and offered somewhat by-the-book psychoanalytic interpretations regarding the content of whatever it had occurred to her to say. At the end of one session, however, Beck asked his patient how she was feeling; she replied 'anxious'. Beck first suggested to her, in an interpretation focusing only on intra-psychic issues, that conflicts about sex were making her anxious. She cautiously responded, however, to the effect that her real worry was interpersonal: her worry was that he was bored by her. Beck then began to see 'that there's a whole stream of pre-conscious thinking that goes on that the patient doesn't normally communicate to the analyst'¹⁵ – especially pessimistic, biased, black-and-white, over-general irrational expectations concerning what the therapist thinks and feels about the patient. Beck came to call these transference expectations the patient's 'negative automatic thoughts' (NATs) and, drawing on the 'rational therapy' of Albert Ellis,²⁰ went on to develop a significant range of procedures to help the patient attend to and challenge their NATs.

There are several curious things about this and related narratives Beck offers.²¹ The first is that Beck the novice psychoanalyst started out (as one does) by naively listening to and interpreting the explicit content of what the patient freely said, rather than listening in with an analytic ear to what she was not saying, to the unconscious dimension of the transference (i.e. listening to how he featured latently in her mind), or listening in to his own countertransference (i.e. to the feelings provoked in him by, in particular, the performative rather than declarative aspect of her discourse). Thus, despite the patient's manifest lack of inhibition in talking about sex, Beck still interprets her anxiety as due to sexual conflict.

The second is that when Beck shows a real interest in his patient, asking her how she feels, she is able to acknowledge her transference to him, and they can understand it together to beneficial effect. We go on to hear that these worries (which, despite, or perhaps because of, being so very omnipresent in her mind she never discussed before) are actually common for her in other settings too. As the therapeutic relationship is strengthened (by Beck's concerned question about her actual feelings), the emotionally alive experience of the transference (her worries about Beck being bored by her) also begins to be acknowledged and worked through, and interpretative speculation about intra-psychic conflict is foregone.

The most striking thing about Beck's narrative, however, is that this therapy-potentiating emotional experience of the transference is set aside almost as soon as it is encountered. Anyone who has been in psychotherapy will know how replete it is with holding back acknowledgement, both to oneself and to the therapist, of one's thoughts and impulses for fear of encountering one's own or the therapist's disapproval, despite such fears speaking right to the heart of such emotional difficulties as brought one to therapy in the first place. Notwithstanding the simplicity of the 'fundamental

rule' of psychoanalysis – to 'free associate', i.e. say whatever is actually on your mind (which is not the same as saying whatever you feel like saying!) – the fact is that no one can truly follow it,^{21,22} since we naturally associate away from rather than towards conflictual emotional preoccupations.²³ This is why the therapist's job is often to listen not so much to the content of what is said as to performative matters of style, timing and omission. Beck, however, construes NATs as merely incidentally hard for the patient to articulate and challenge – due to a lack of training in attending to and reporting on them²¹ – rather than because of their emotional valence. This, I submit, is intuitively implausible. More consonant with everyday clinical and personal experience is the notion that his patient did not elaborate her actual worries because she feared they might not be disconfirmed – and chose instead to distract herself and please him with endless talk about sex, presumably since, as we all know, Freudians do have rather a reputation for being interested in such matters!

Cognitive therapists are often accused of ignoring the importance of the therapeutic relationship, but as Beck's daughter Judith Beck explains, this is false – cognitive therapy 'requires a good therapeutic relationship. Therapists do many things to build a strong alliance. For example, they work collaboratively with clients ... ask for feedback... and conduct themselves as genuine, warm, empathic, interested, caring human beings.'²⁴ However, as psychoanalytical psychotherapist Jonathan Shedler responds, 'This is the kind of relationship I would expect from my hair stylist or real estate broker. From a psychotherapist, I expect something else. [Beck appears] to have no concept that the therapy relationship provides a special window into the patient's inner world, or a relationship laboratory and sanctuary in which lifelong patterns can be recognized and understood, and new ones created.'²⁵ Shedler's optimism regarding his hair stylist and estate agent perhaps warrants some cognitive restructuring, but his point about the therapeutic relationship stands.

A relationship which is not merely instrumentally useful (as intended by cognitive therapy), but itself intended as the unique locus of change (as in psychoanalytic therapy), is one which both activates the patient's latent transference fears (that the therapist is untrustworthy, angry etc.) and simultaneously provides enough of a working alliance to enable such prototypical fears to be experienced, understood and worked through in real time. With a merely collaborative and empathic focus the opportunity is lost for the real-time eliciting and challenging of the patient's underlying emotional preoccupations. The result is somewhat like trying to conduct exposure therapy for a phobia without physically encountering the fearful stimulus, or like a chat between two adults about the difficulties of a child left waiting in the next room.

A popular canard has it that psychoanalytic psychotherapy is unhelpfully preoccupied with the past, whereas CBT is practically focused on the present. This ignores the way both therapies tend to formulate current disturbance in terms of childhood-acquired pathogenic beliefs. More importantly, it ignores the fact that, at the level of technique, CBT tends to focus on matters arising in the patient's past week, whereas a transference-focused psychotherapist hones in on uncomfortable transference feelings alive right now between patient and therapist. Rather than providing merely intellectual insight to further an ongoing project of dreary self-management, itself supplementing an already exhausting project of defensively managing intolerable feelings, psychoanalytic psychotherapy instead offers an intrinsically mutative emotional exchange which already constitutes a growth in self-possession and a change of heart, obviating the need for such self-management.

Implications

Work in the transference is designed to facilitate a patient's living exposure to their real underlying fears about how they would be seen if they were to allow themselves their own true feelings. The opportunity is thereby provided for a true change of heart – i.e. for emancipation from depressive cognition through an experiential recovery, acceptance and integration of hitherto unconscious emotional experience. Ideally, this would reduce the need to manage the dismal distal products of this emotional evasion with therapeutic techniques of behavioural activation, cognitive challenge or mindfulness. The result of such an effective therapy for depression would be akin to that sometimes achieved by CBT for anxiety conditions: a transformative learning, from the experiential ground up, that reinstates true self-possession.

The time is past for studies comparing outcomes of self-professed cognitive therapy/CBT and psychoanalytic practitioners. The apparent success of particular therapies in such trials is better predicted and explained not by therapeutic model²⁶ but by the theoretical orientation of the lead experimenter,²⁷ the personal qualities of the therapists,²⁸ or by theory drawn from quite different models.²⁹ Beck himself expressed the wish that cognitive therapy as a school die out,³⁰

the apt thought here being that what matters is not the treatment model but rather the particular treatment qualities which are individually worthy of study.

CBT treatments for depression often suffer high drop-out rates.³¹ One possible explanation for this is a lack of attention to transference. Sometimes this may be because negative transference undermines the therapeutic collaboration, although ideally CBT therapists are trained in recognising and managing this.⁷ At other times it may be because psychotherapeutic relationships that are merely collaborative, rather than offering experiential work in the transference, do not hit the therapeutic spot. Recently, however, there has been a resurgence in the general theory of,⁸ clinical practice and treatment manual for,³² and outcome studies supporting a transference-involving psychoanalytic approach to depression. With regard to outcome, outstanding results in helping patients with treatment-resistant depression which is not readily resolved by CBT have been obtained by particular practitioners of psychoanalytic psychotherapy³³ and somewhat optimistic results have been obtained with similar patients in the multi-practitioner Tavistock Adult Depression Study.³⁴

The present article has not been concerned to argue for a psychoanalytic approach to depression on the basis of empirical evidence. Instead, it noted that Beck's development of a cognitive approach to depression was predicated on his rejection of a psychoanalytic understanding of depression in particular, of the dynamic unconscious in general, and of psychoanalytic psychotherapeutic methods – and that his rationale for all this was flawed. What he developed in its stead does not stand or fall on this basis, and there are several benefits (especially clinical pragmatism and a strong research tradition) to the therapy he developed. But, given both the flawed rationale for rejecting a psychoanalytic approach which, rightly understood, possesses considerable clinical plausibility, and given the relatively poor results obtained by CBT for depression in much clinical practice, the time is surely right to revisit the psychoanalytic model.

1.7.75 The cognitive therapy of depression rests on substantial theoretical, empirical and clinical foundations: a reply to Dr Gipps

Abstract

Dr Gipps claims that the cognitive therapy for depression rests on a mistake. But his anachronistic analysis of Beck's early research from the perspective of current psychoanalytic theory misses the point. The value of the research was not that it disproved psychoanalytic theory, but that it generated a model of depression that has revolutionised psychotherapy research. Psychoanalysts are belatedly adopting research methods that Beck pioneered half a century ago. The cognitive model of depression has explanatory power for both maintenance and vulnerability and has substantial research underpinning it. Cognitive therapy for depression has a larger body of evidence for its efficacy and relapse prevention effect than any other psychotherapy. Transference-focused approaches to depression have yet to establish themselves in the same way.

- *The cognitive therapy of depression rests on substantial theoretical, empirical and clinical foundations: a reply to Dr Gipps*
 - *Psychopathological theory*
 - *Therapeutic practice*
 - *Conclusions*

Dr Gipps's polemic against Beck's cognitive therapy for depression rests on two assumptions. First, that cognitive therapy 'doesn't work very well' for the condition, and second, that the cognitive model is invalid because it is based on a flawed understanding of psychoanalysis. The first statement is misleading – cognitive-behavioural therapy (CBT) has the most comprehensive evidence base of all the psychological therapies. The second statement is largely irrelevant – the cognitive model of depression rests on a substantial body of research that is independent of the experiences that led to its original formulation. This reply will review the evidence for the effectiveness of psychological treatments for depression, highlighting the selectiveness of Dr Gipps's interpretation of the literature. It will then examine the cognitive model, demonstrating that it is far richer than he suggests, and has developed and changed in the light of extensive research. Finally, Gipps's caricature of CBT practice will be challenged: contemporary CBT does have something to say about experiential avoidance and interpersonal processes. It has the flexibility to address these as and when necessary without making them the sole vehicle for change. Gipps seems to believe that by denigrating Beck's psychoanalytic credentials and claiming his theory is based on a misunderstanding he can somehow erase nearly 60 years of research supporting the cognitive model. This is merely opinion, not reasoned scientific discourse.

Dr Gipps argues that current treatments for depression 'fare little better than placebo' so we should turn to psychoanalysis. He claims poor results for medication, counselling and CBT, but neglects to mention that trials of psychodynamic psychotherapy have not demonstrated it does better than CBT (the reverse may actually be the case).¹ If we take a non-partisan approach, the conclusion is that a number of treatments work for depression. For instance, a recent meta-analysis of randomised controlled trials (RCTs) reported effect sizes for CBT, counselling and short-term psychodynamic psychotherapy at 0.67, 0.57 and 0.69, respectively.² Dr Gipps, however, disingenuously selects a small uncontrolled trial of intensive short-term dynamic psychotherapy ($n = 10$) as his argument for the potential superiority of the psychodynamic approach.³ All these psychological treatments are as effective as antidepressants, but the superiority of all treatments over placebo may, as he suggests, be less than was once assumed.⁴ There is indeed a powerful placebo effect in mild depression, but this seems to lessen as severity of depression increases.⁵⁻⁹ It is also important to note that although placebo may do well in the short term, patients are more likely to relapse.¹⁰ Cognitive therapy still has the largest evidence base of all the psychotherapies for depression; not only is it effective in the acute phase, but it also reduces relapse.^{11,12} Its effects are not restricted to RCTs: in naturalistic settings 40% of patients recover and 64% show reliable improvement.¹³ The empirical data give us no reason to abandon CBT for depression.

Psychopathological theory

The implication of Dr Gipps's rather condescending analysis is that cognitive therapy would not have been created if Aaron Beck had been a better psychoanalyst (we are pointedly told that Beck failed entry to the American Institute of Psychoanalysis). According to Gipps, Beck got the wrong end of the stick, and his misunderstanding of theory led him to devise a set of experiments that set psychopathology off on the wrong track for the next half century. The problem here is that Beck's early work is scrutinised from the perspective of current psychoanalytic theory rather than seen in its historical context. It appears the 'mistake' Beck made was to be unaware of British psychoanalysis when he carried out his ground-breaking research in the late 1950s. Gipps's main reference is Trevor Lubbe's 2011 book written from the perspective of the British object relations school, which Beck is unlikely to have encountered in his analytic training in the USA – a training inclined towards instinctual and ego theories. Should we then abandon all Freud's work because his theories, originally framed in biological terms, were based on a misunderstanding of modern neurology?¹⁴ Gipps describes clearly what he sees as the current consensus of psychoanalytic thinking on depression which has unconscious avoidance of emotion at its centre: avoidance of feelings of loss, avoidance of anger towards those to whom we are

attached, and avoidance of fear. Rather than face these feelings the patient retreats into depression, preferring to live 'in a dismal and diminished version of himself, his situation and his future.' Beck's investigations tested one aspect of the anger-avoidance theory of depression: the masochism hypothesis. Anger towards another is repressed because it is unacceptable, but it breaks through and is then turned on the self. This internalised hostility leads to self-punishment, manifested in the self-criticism and self-abasement found in depression. Gipps wonders why Beck was drawn to the masochism hypothesis to the exclusion of others. The simple answer is that the introjected anger hypothesis was the prevailing theory of depression in American psychoanalysis at the time. Even in 1988 David Milrod could still write that 'the essential elements in a depression are the self-directed aggression and the mood state to which it leads'.¹⁵ In this context Beck's investigation of internalised hostility is very reasonable, and his research design perfectly acceptable for its time. But the significance of this research is not that it disproved psychoanalytic theory, but that it stimulated a powerful new theory. Whether one accepts the cognitive model or not, it has made an enormous contribution to the development of empirically based research in depression. Beck showed that it was possible to construct a theory that was refutable, and his steadfast focus on testing his theories has led to changes and modifications on the basis of research evidence. This is in contrast to psychoanalysis, which tends to change on the basis of new theoretical or clinical trends, but rarely in response to new research evidence. The first outcome study of cognitive therapy for depression, for instance, demonstrated that psychological therapy could be as effective as pharmacotherapy and showed that therapy could be operationalised and manualised.¹⁶ Even psychoanalysts now admit the value of treatment manuals!¹⁷ Any studies demonstrating the efficacy of psychoanalytic psychotherapy therefore owe a considerable methodological debt to Beck's pioneering work in outcome research.

So what is this mistaken cognitive model of depression? According to Beck, pervasive negative thinking is at the centre of depression: negative views of the self, the world and the future. These thoughts result from an information processing bias that selectively attends to negative events, negatively interprets situations, and encodes them as negative memories. These processes result from the activation of underlying cognitive structures or schemas, in the form of dysfunctional beliefs.^{18–20}

There is considerable evidence for this cross-sectional model: for a shift in information processing, for the reciprocal interaction between low mood and negative thinking, and for the presence of dysfunctional beliefs in depression.^{21,22} Beck also formulated a developmental model to explain vulnerability to depression. Negative events in childhood, for example loss of a parent, lead to negative beliefs which become activated when specific events impinge on these schemas. Beck revised this theory in the light of findings that severe life events are not always necessary to precipitate depression. An accumulation of milder stressful events can contribute, and with each successive episode the severity of event needed to trigger depression becomes lower (the kindling effect).²³ A further refinement of the model came with the discovery that when a depressed mood was evoked people prone to depression exhibited negative cognitive biases (cognitive reactivity).²⁴ These new findings were integrated into the theory using the concept of the depressive mode – a network of cognitive affective, motivational, behavioural and physiological schemas activated in depression. The mode is 'a complex neural network, including multiple relevant brain regions that are activated or deactivated during depression' (p. 971).¹⁹ With repeated depressive episodes the network of beliefs becomes stronger and relatively autonomous, so that minor stressors trigger the depressive mode. The cognitive model provides a comprehensive account of both vulnerability to and maintenance of depressive episodes. It does focus on unconscious processes, i.e. schemas and information processing biases, but these are unconscious because they are automatic, not because they are repressed. Regardless of its origins, the cognitive model stands on its own merits as an account of significant phenomena in depression.

Therapeutic practice

Dr Gipps's main criticism of CBT practice seems to be that it is not psychoanalysis. The collaborative, problem-solving relationship which is at the heart of good CBT is ridiculed as superficial because it apparently misses the opportunity to work with the transference. CBT, unlike psychoanalysis, is a problem-focused therapy, and one of its strengths lies in the way the problem is placed on the table and the therapist and patient work together to solve it. In depression this allows for a partnership in solving realistic problems and the identification of blocks to problem-solving arising from the patient's negative thought processes. For instance, negative predictions about being rejected may lead a patient to be socially avoidant, further reinforcing their depression. The therapist helps the patient test their beliefs by attending a social event and noting the outcome. This 'collaborative empiricism', together with the structure and focus

of therapy, engages the healthy adult functioning mode and minimises regressive transference so that the patient can learn strategies to help them out of their depression.²⁵ When negative interpretations of the therapist's behaviour arise these can be worked on together, for instance by noting how the patient's fear that the therapist may be cross with them is an example of a pattern of depressive misinterpretation that occurs outside the session with others. As the developmental conceptualisation is deepened over the course of therapy, the underlying assumptions that drive this reaction might be identified (e.g. 'If I make a mistake I'll be rejected'), their origins in parental criticism discussed, and the schemas modified. This is work with the transference but in the service of learning how to manage negative reactions activated when the person is depressed. With patients with personality disturbance the focus on the interpersonal relationship becomes more important and changing interpersonal schemas becomes one of the key goals of therapy. This is what Gipps calls the 'real-time eliciting and challenging of the patient's underlying emotional preoccupations.' However, CBT has the flexibility to work with the therapeutic process when necessary, but is not shackled to it as the only vehicle for change.

A second, more interesting, point made by Gipps concerns the role of experiential avoidance in depression. This is central to CBT for anxiety, where much of therapy focuses on identifying negative predictions and setting up behavioural experiments to test the fear. This is indeed often done in real time, through experiments in the session such as panic induction. This is of course very effective without any reference to transference. Recent developments in 'third-wave' CBT explicitly address emotional avoidance, and there is room for more attention to this within the standard cognitive model of depression. In mindfulness-based cognitive therapy, for instance, mindfulness meditation is taught as a skill to help patients practise moving from the ruminative depressive mode into a mode where they are present for whatever they are experiencing, approaching difficult feelings rather than moving away from them.²⁶ Although this concept of avoidance of emotions is similar to that in the psychoanalytic model, the significant differences are that it is not conceptualised as a motivated avoidance arising from a dynamic unconscious, and that it is perfectly possible to work with it outside the transference.

Dr Gipps's final criticism of CBT practice regards its project of 'dreary self-management'. Psychoanalytic psychotherapy, by contrast, 'offers an intrinsically mutative emotional exchange which . . . constitutes a growth in self-possession and a change of heart, obviating the need for such self-management.' This is wonderful news. Many of us would love to engage in a therapy that magically transforms us so that we do not have to pay attention to our habitual patterns that so frustratingly trip us up, but this is not what good psychodynamic psychotherapy is actually about. It involves noticing reactions outside the session as well as within, and considerable repetitive work on the self. Depression is a relapsing condition and it is patronising and misleading to imply that learning ways to manage it is unnecessary. Patients who successfully negotiate the vicissitudes of recurrent depression learn to identify risk factors that make them vulnerable, recognise how structuring their week helps to maintain positive mood, and how they can easily fall into negative thought patterns. Cognitive therapy gives them tools for doing this, but also changes underlying beliefs, to reduce vulnerability to depression.

Conclusions

Cognitive therapy is a tried and tested therapy for depression. It has a proven relapse prevention effect, but is not a panacea and is not the only effective treatment for depression. Most of these therapies do not work with the transference, and there is nothing to suggest that a transference-focused therapy will be hugely more effective or reduce dropout rates. The results from the two reported trials of psychoanalytic therapy are promising, but much more research is needed before they can be compared with the accumulated evidence for the effectiveness of CBT. Dr Gipps's article is based on a mistaken reading of the research into CBT as a therapy, and an anachronistic approach which judges Beck's evaluation of psychoanalytic theory in 1959 by the standards of 2016. What Beck developed stands not on this, but on almost 60 years of research. This has not only generated a robust theoretical model of depression, but has given psychoanalysts methodologies they now use to evaluate their own theories and therapies. The cognitive model of depression is likely to be around for another 60 years, but it will evolve and change on the basis of empirical research rather than theoretical whimsy.

1.7.76 Suicide patterns on the London Underground railway system, 2000–2010

2017-10

Abstract

Aims and Method Suicidal acts on underground railway networks are an area of public health concern. Our aim was to review recent epidemiological patterns of suicidal acts on the London Underground to inform future preventive interventions. Data from 2000 to 2010 were obtained from the British Transport Police via a Freedom of Information request.

Results The mean annual rate of suicidal acts from 2000 to 2010 was 5.8 per 100 million passenger journey stages. Of those who died by suicide, 77.3% were of White Northern European ethnicity. A fifth had a history of mental illness.

Clinical implications The widening gap between the number of recorded suicide attempts and completed suicides is encouraging. Further research is required regarding the role of drug and alcohol use, psychiatric history and area of residence. Installation of platform screen doors should be considered in future railway network expansion.

The London Underground was built in 1863 and was the world's first underground railway system.¹ Today it comprises 11 train lines serving a total of 270 stations across 402 km.¹ In 2015/16 it saw the completion of 1.34 billion journeys across its network.¹ Suicide on underground railway systems is a major cause for public health concern. Railway suicide can have a traumatic impact on both train drivers² and witnesses, and can lead to significant train delays, with substantial economic consequences.³

Between 1940–49 and 1980–89 the mean number of suicidal acts per year on the London Underground rose from 36.1 to 94.1.⁴ Previous studies have suggested an association between the rising number of suicidal acts across the national railway and increasing volumes of passengers across railway networks;^{5,6} however, this finding has been inconsistent across studies.⁷ Use of preventive measures to stop suicidal acts on railways has been the focus of several studies, for example, concentrating on changes to the immediate environment, media reporting and interagency collaborations.⁸

Our aim was to review recent epidemiological patterns of suicidal acts on the London Underground to better inform future preventive interventions.

Method

Data covering deaths by suicide between 2004 and 2010 and 'person under train' incidents between 2000 and 2010 were obtained by one of the authors (M.R.) on 7 October 2011 through a Freedom of Information request to the British Transport Police. Data covering completed suicides between 2000 and 2003 could not be provided owing to changes in coding. No further information in relation to this was provided by the British Transport Police.

The data provided by the British Transport Police included demographic information (age, gender, ethnicity) of suicide victims between 2004 and 2010. Age was categorised as: <15 years, 15–44 years, 45–74 years and > 75 years. The authors also received figures pertaining to all suicide attempts (which included incidents where individuals were prevented from jumping in front of a train or accessing the tracks) and all 'person under train' incidents (intentional and accidental) between 2000 and 2010.

Information regarding the total number of journeys completed on the London Underground was obtained from the publicly accessible Transport for London (TfL) 2011 *Travel in London* report.⁹ Passenger journeys were recorded as 'journey stages', where a journey stage represents a segment of a trip made on a particular mode of transport. For example, a journey made up of two stages could include a walking stage to the Underground station followed by a second stage on the Underground network.¹⁰

Results

Between 2000 and 2010 there were 644 recorded suicide attempts on the London Underground. The mean annual rate of suicide attempts during this period was 5.8 per 100 million journey stages (95% CI 5.0–6.5). Between 2004 and 2010 there were 132 deaths by suicide. The mean annual rate of individuals who died by suicide during this period was 1.8 per 100 million journey stages (95% CI 1.4–2.2). In addition, there were 38 deaths in which the coroner recorded an open verdict and 9 deaths in which the inquest had not yet taken place or in which the British Transport Police did not have access to the outcome of the verdict. The total number of 'person under train' incidents between 2000 and 2010, which included both intentional and accidental acts, was 433. The mean annual rate of 'person under train' incidents during this period was 3.9 per 100 million journey stages (95% CI 3.6–4.2).

Figure 1 shows an increase in the number of suicide attempts from 2004 to 2009, which is more marked than the increase in the number of incidents of death by suicide. The number of 'person under train' incidents, however, remained relatively constant. Our data revealed a small increase in the number of suicide attempts and 'person under train' incidents during May–August, with a peak in June, as illustrated in *Fig. 2*.

Fig. 12: Suicide attempts v. deaths by suicide, 2000–2010.

Tables 1 and 2 display the age and ethnicity distribution for males and females in incidents of deaths by suicide 2004–2010. Age at death was not available for two male individuals, and ethnicity data were not available for one

male individual. Of the deaths by suicide, two-thirds ($n = 88$) were male and a third ($n = 44$) were female. The average age at death was 40.7 years in males and 45.5 years in females.

Of the 132 individuals who completed suicide on the London Underground, 110 (83.3%) were resident in London at the time of the event. Information was unavailable for one individual. A history of mental illness was confirmed in 20.5% of individuals ($n = 27$).

The Northern Line had the greatest number of recorded suicide attempts ($n = 145$) between 2000 and 2010, followed by the Central Line ($n = 99$) and Piccadilly Line ($n = 92$). The lowest numbers of suicide attempts during that period were recorded on the Jubilee Line ($n = 27$) and Bakerloo Line ($n = 33$).

King's Cross St Pancras station saw the highest number of suicide attempts between 2000 and 2010 ($n = 18$), followed by Mile End ($n = 17$), Victoria ($n = 16$), Camden Town ($n = 15$), Archway ($n = 13$), Liverpool Street ($n = 13$), Oxford Circus ($n = 12$), Green Park ($n = 12$) and Earl's Court ($n = 11$). Suicide attempts led to delays in underground railway services; between 2000 and 2010 the Northern Line and Piccadilly Line experienced the greatest total delays (8484 min and 5521 min, respectively). The Jubilee Line recorded total delays of 2396 min and the Bakerloo Line 1911 min over the same period (*Fig. 3*).

Discussion

Suicide patterns over time

There was a marked increase in the number of suicide attempts across the London Underground from 2004 onwards, although this trend was beginning to reverse in 2009. Although there was also a rise in deaths by suicide during that period, this was of a lesser degree. In their 2016 paper looking at suicide trends across the entire England and Wales railway system, Taylor *et al* found that male suicide rates had increased from 6 to 8.4 per million from 2000 to 2013, with the greatest increase observed between 2010 and 2013, from 6.4 to 8.4 per million.¹¹ By contrast, female suicide rates remained relatively constant. Although previous studies looking at suicide attempts on underground railway systems have suggested a case fatality rate of 43 to 55%^{4,12,13} (compared with 90% on overground railways¹⁴), this does not fully

explain the extent of the difference observed. Increased reporting of suicide attempts by London Underground staff may be a factor, as well as the introduction of preventive interventions allowing for the early identification of persons at risk.

TfL has worked towards suicide prevention since the 1990s.¹⁵ This has included strategically placed Samaritans campaign posters and telephones within stations. More recently there has been further collaborative work with the Samaritans to train staff in identifying persons at risk, and giving them the confidence to intervene.¹⁶ Additional interventions have included platform-edge barriers on the Jubilee Line and gates to prevent passengers from entering tunnels at existing stations, as well as use of video surveillance and markings/warning signs to prevent individuals from approaching the platform edge.¹⁵ Presence of staff on platforms during rush-hour periods may also be helpful. The increase in the number of suicide attempts and deaths by suicide in 2008 and 2009 may in part be explained by the financial crisis of 2008.¹⁷

The number of journey stages made on the London Underground increased from 0.976 million in 2004 to 1.065 million in 2009.⁹ There have been several studies exploring a potential link between higher numbers of passenger journeys and the incidence of suicide, with variable findings. Sonneck *et al* found no such association on the Viennese subway,⁷ whereas in Stockholm, Sweden, and The Netherlands, authors noted a positive association.^{5,6} Although Waterloo station is the busiest in terms of passenger flow,¹⁸ it does not feature in the top 20 stations for suicide attempts on the London Underground in 2000–2010.

Our data did not reveal any marked variation in suicide attempts across the year, although there was a small increase in events during May to August, with a peak in June. Findings in other studies have been variable. Although Dinkel *et al* found no association between seasons of the year and suicide events,¹⁹ others have noted a small increase in suicide events during the summer months⁴ or during the months of April and September.²⁰ Even though summer months are associated with higher numbers of tourists in London, it is unclear whether this has had an effect on the number of suicide attempts during those months. Although a majority of those who died by suicide on the London Underground were mostly resident in the city, the time of year of their death was not available, nor was the proportion of London residents represented among those individuals who attempted suicide.

Demographics

The stark overrepresentation of men in the 15- to 44-year age group (61.4%, $n = 57$) among those who died by suicide was in keeping with national figures (England), where the proportion of males is approximately two-thirds.²¹ The overall gender distribution of suicide victims on the London Underground was very similar to that recorded nationally during the same period (2004–2010), with 66.9% of cases being male and 33.1% female. By contrast, the proportion of females aged over 75 years was almost double that of males (6.8% and 3.5% respectively), although the numbers were very small and therefore need to be interpreted with caution.

This is the first study looking at the ethnic distribution of suicide victims on the London Underground. The predominance of individuals of White Northern European background (>75%) is significant in a place like London where people of White ethnic background make up less than 60% of the total population,²² in particular since 83.3% of individuals who died by suicide on the London Underground were resident in the city. Moreover, use of the London Underground is evenly distributed across different ethnicities.²³ There are currently no data available on the ethnicity of individuals who die by suicide nationally, hence we do not know whether individuals of White Northern European ethnicity are also overrepresented relative to other ethnic groups. Similarly, we do not know whether individuals of White Northern European ethnicity are overrepresented in suicide incidents occurring across the rest of the national railway network or involving violent suicide methods.

In our sample a fifth of individuals had a history of mental illness. Unfortunately, no further data were available regarding their diagnosis, level of psychiatric care at the time of suicide or whether they were current or recent in-patients of a psychiatric unit. Proximity of stations or railway suicide ‘hot spots’ to psychiatric hospitals has been highlighted as a risk factor for suicide in several studies,^{4,5,12,24,25} although the result was not found to be significant across the Stockholm railway system.⁵ In their 1987 study of 100 individuals who had attempted suicide on the London Underground, Cocks found that 13 were current psychiatric in-patients, and 2 had been discharged within 48 h of the event.²⁶ Fifteen individuals had expressed suicidal ideation in the 24 h preceding the event. Although proximity to a

psychiatric hospital was not taken into account in this paper, the presence of a history of mental illness in a fifth of those who died by suicide highlights the need for staff working in psychiatric hospitals to be aware of the proximity of any nearby Underground stations in their assessment of risk in patients.

Additional risk factors

In Stockholm, authors found that the stations with the highest suicide rates were associated with higher levels of surrounding drug-related crime.²⁷ Previous studies have shown that consumption of alcohol or drugs was a characteristic of about 10 to 20% of individuals who had attempted or died by suicide on an underground railway system.^{12,28,29} In the UK National Confidential Inquiry into Suicide and Homicide by People with Mental Illness, the authors noted that 54% of those who died by suicide and had been in contact with mental health services over the past year had a history of alcohol and/or drug misuse.³⁰ Intoxication with drugs or alcohol can increase the risk of impulsive and risk-taking behaviour and may have been a contributing factor in the incidents observed on the London Underground, including ‘person under train’ incidents of accidental cause. Unfortunately, the British Transport Police do not currently collect this information. Consumption of alcohol on the London Underground is forbidden; however, consideration must be given as to how to manage the risk of suicidal behaviour or accidental injury in intoxicated individuals.

Use of preventive measures

Several recent studies looking at suicide attempts on underground and overground railway systems have focused on the use of preventive measures. Diminishing ease of access to the track through barrier methods is suggested as an effective intervention, although Cox *et al* noted a lack of studies demonstrating this.³¹ In Seoul, the presence of platform screen doors (PSDs) reduced suicides on the underground network by 89%.³² PSDs are continuous panels that separate the platform from the train, only opening when the train is in the station. Half-length PSDs (1.6 m) were less effective than full-length PSDs; however, full-length PSDs were 120–150% more expensive to install.³² The effectiveness of PSDs was also noted in Hong Kong.³³ Portions of the Jubilee Line include the presence of PSDs, which may be a contributory factor to the lower number of suicide attempts observed on this line relative to the rest of the network. The presence of PSDs would also reduce the risk of accidental falls on to the railway tracks, thus reducing the number of ‘person under train’ incidents. Although the cost of installing these doors makes their presence across the railway network unlikely in the near future, their potential for significantly reducing the number of injuries or deaths on the tracks should be considered when planning future network renovation or expansion.

Other proposed interventions include increasing the presence of drainage pits, as mortality at London Underground stations that have a drainage pit was 44% v. 76% at those stations without, in incidents of individuals falling or jumping in front of trains.³⁴ These drainage pits were originally constructed to drain water between the tracks in deep-tunnel stations. Installation of blue lights at platforms was put forward as an effective measure by Matsubayashi *et al* in 2013³⁵ but this benefit was minimised by Ichikawa *et al* the following year.³⁶ Another suggested measure is reducing the average speed of trains entering the station at peak times.²⁹ In Vienna, changing the way in which media reported suicides on the underground by making it less dramatic was followed by a reduction in suicide.⁷

Strengths and limitations

This is the most recent study looking at patterns of suicide on the London Underground since 1994. It is also the first study looking at ethnicity within incidents of death by suicide on the Underground, and the findings raise new and important dimensions when seeking to introduce preventive measures.

There were several limitations to the study: no data were available for deaths by suicide between 2000 and 2003 owing to changes in coding, and death by suicide could not be confirmed in 47 cases owing to the recording of an open verdict or the outcome of the inquest not being available. Because of the relatively rare occurrence of deaths by suicide on the London Underground the numbers used in the study were small, leading to possible sample size bias. The limited breadth of information collected by the British Transport Police meant that certain risk factors (e.g. use of drugs/alcohol

or whether individuals were psychiatric in-patients at the time of the event) could not be adequately explored in our sample. The study is further limited by the absence of data beyond 2010.

Conclusions

Suicide on the London Underground railway system continues to be an important public health issue. The widening gap between the number of recorded suicide attempts and deaths by suicide is encouraging and may reflect the introduction of preventive measures. Use of PSDs has been proven to be effective for both suicidal acts and accidental ‘person under train’ incidents and needs to be considered when planning railway renovation or construction projects. The overrepresentation of people of White Northern European ethnicity among those who attempted suicide requires further exploration, as does the proportion of non-residents involved in suicide attempts on the London Underground across the year to better target preventive interventions. Finally, the collection of data on alcohol and drug use, as well as a more detailed psychiatric history, would help to inform further research and implementation of preventive measures for suicidal acts on the London Underground.

We thank Dr Neel Halder for his invaluable guidance and support as a mentor under the *BJPsych Bulletin* author mentoring scheme.

1.7.77 Psychiatric neurosurgery in the 21st century: overview and the growth of deep brain stimulation

Abstract

Ambulatory deep brain stimulation (DBS) became possible in the late 1980s and was initially used to treat people with movement disorders. Trials of DBS in people with treatment-resistant psychiatric disorder began in the late 1990s, initially focusing on obsessive–compulsive disorder, major depressive disorder and Tourette syndrome. Despite methodological issues, including small participant numbers and lack of consensus over brain targets, DBS is now being trialled in a wide range of psychiatric conditions. There has also been more modest increase in ablative procedures. This paper reviews these developments in the light of contemporary brain science, considers future directions and discusses why the approach has not been adopted more widely within psychiatry.

In 2014 the Mayo Clinic posted an online video in which a musician plays the violin while a neurosurgeon operates on his brain. Electrodes are being directed to an area of his thalamus with the aim of suppressing an essential tremor by electrical stimulation. Playing the violin during surgery was the best way to test whether the electrodes were in the right place. They were, and the operation was a success.¹

Deep brain stimulation (DBS) was first used to treat severe tremor in people with Parkinson's disease in 1987 and was subsequently found effective in severe dystonia.² Since then, tens of thousands of people have undergone the procedure for movement disorders and the technique has largely replaced earlier lesion-based methods. The most recent application, to 'benign' essential tremor, perhaps highlights its relatively low side-effect profile and patient acceptance. In 1999 a Belgian team used DBS in three people with treatment-resistant obsessive-compulsive disorder (OCD), with favourable results. There have since been DBS trials in a wide range of psychiatric conditions, and a more modest increase in ablative procedures.³ 2014 saw the publication of *Psychosurgery: New Techniques for Brain Disorders* by French neurosurgeon Marc Lévêque, the first 'state of the art' textbook to use that term in 40 years.⁴ It was a translation from the French; Anglophone practitioners in the field prefer a word with less toxic associations: neuromodulation.⁵

Whatever you call it, the use of DBS – and to a lesser extent lesion-based psychiatric neurosurgery – is on the rise, and this paper will review these developments. The aim is to inform rather than tilt opinion in a particular direction, but given the polarising nature of the subject it seems relevant to state the perspective from which it is written. The author is a retired neuropsychiatrist who formerly worked in a comprehensive service for working-age adults, within which the most frequent neurological diagnosis was acquired brain injury. While in training, he obtained a doctorate in electroencephalogram-based psychophysiology. A history project on psychiatric neurosurgery in the mid-20th century led to several outcomes, including an essay that prompted the Editor to commission this review.⁶

Background

Renewed interest in psychiatric neurosurgery has occurred against a background of major revisions in the way we think about the brain. At the beginning of the 20th century, anatomist Santiago y Cajal wrote: "Once brain development has ended the fount of growth and regeneration of axons and dendrites dries up irrevocably. In adult centres the nerve paths are something fixed, ended and immutable".⁷ That 'immutable' view of neurons held sway within brain science for much of the past century, although there were dissenting voices, particularly between the World Wars.⁸ The brain's capacity to structurally adapt and even regenerate was eventually demonstrated at the end of the century, by magnetic resonance imaging (MRI), functional MRI (fMRI) and other techniques. In addition, simplistic notions of functional localisation are being replaced by task-related and 'default' systems and networks.⁹ The past 25 years have also witnessed a transformation in our understanding of glial cells. Once viewed simply as the brain's scaffolding and housekeepers, they are now known to guide brain development, shape response to injury, modulate synaptic transmission, and operate an independent chemically based communication system.¹⁰ How all this produces mind remains a topic rich in speculation, with recent theories encompassing 'embodied' cognition and quantum biology.^{11,12} The implication of all this for psychiatry remains to be determined.

In the 1930s neurologist Egas Moniz speculated that in the brains of some people with chronic mental illness, 'the cellular bodies remain altogether normal ... but their multiple liaisons, very variable in normal people ... have arrangements that are more or less fixed'.¹³ He believed the most likely location for such an aberration was the pathway

between the prefrontal cortex and the thalamus. In 1935/6 he tested his theory by directing a surgeon to produce small lesions in that area, in 20 patients with mental illness – the first ‘prefrontal leucotomy’ series. Moniz’s targeted and theory-based approach was soon eclipsed by Freeman & Watts’ more destructive and indiscriminate procedure.¹⁴ The extensive damage that it produced often rendered behaviourally disturbed hospital patients with psychosis docile and, in some cases, dischargeable. The potential economic benefits of that were not lost on the architects of the UK’s National Health Service (NHS): in its first 5 years, there were more than 7000 leucotomies.¹⁵

Chlorpromazine rendered such destructive procedures in people with psychosis unnecessary and over the following 20 years psychosurgery teams – focusing on a narrower range of disorders – sought maximum benefit from minimum damage. Nonetheless, public distrust and dissenting voices increased, particularly in the USA, a trend fuelled by experiments on behaviourally disturbed children and aggressive prisoners.¹⁶ Beginning in 1974 a US Congressional Committee held hearings on psychosurgery, with a view to a possible ban. In the end, they recommended better regulation and, in any event, the number of operations fell dramatically over the next 30 years.¹⁴

Ambulatory DBS became possible in the 1980s because of technical developments (MRI, microprocessors, batteries, etc.) but also because the brain structures and pathways that produce movement had been mapped. Although the structures underlying emotion and behaviour, and the paths between them, have also been mapped, exactly how they produce the complexities of emotional life is much less clear. For that reason, a wide variety of brain areas have been targeted in this new wave of psychiatric neurosurgery. Despite the many theories as to how and why DBS and ablative procedures improve some psychiatric conditions, we do not actually know.

Technicalities: electrodes and procedures

All but two of the procedures in current use involve insertion of electrodes into the brain. The exceptions are vagus nerve stimulation (VNS) and gamma knife capsulotomy. Such surgery usually involves attaching a stereotactic cage to the head as a means of directing electrodes to brain locations mapped by MRI. VNS involves isolating the left vagus nerve in the carotid sheath in the neck and looping two electrodes around it. Electrodes in both cases are wired to a programmable stimulator placed subcutaneously in the upper chest wall (*Fig. 1*).¹⁷

Fig. 13: Illustration of an implanted deep brain stimulation system.

Each electrode includes an anode and a cathode. When an electrical current is applied the brain tissue between them joins the circuit. Three to five volts are usually applied in DBS at pulse frequencies above 100/s. At such frequencies brain tissue immediately surrounding the electrodes is deactivated/depolarised. However, just outside that area, volume conduction leads to electrical stimulation of axons, propagated upstream to cell bodies and downstream to synapses, interrupting local brain function while also producing effects more remotely. At frequencies below 100 – 15 pulses/s, for example, in VNS – stimulation is also produced in the tissue immediately surrounding the electrodes. Electrodes have been used experimentally to stimulate brain tissue in humans since the late 1940s.¹⁸ They have also been used to produce lesions, through thermocoagulation. In anterior cingulotomy, for example, a 10 mm exposed portion of the electrode is heated to 85°C for 60 s.

In gamma knife surgery, multiple narrow beams of gamma radiation intersect at a pre-mapped point in the brain, hence the skull is not opened.¹⁷

Brain targets and treatment rationales

Box 1 summarises the brain targets used in most psychiatric neurosurgery over the past 20 years, and the conditions treated in each case. The targets for current lesion surgery are those that have been found to produce the most benefit with the fewest adverse effects. The targets used for psychiatric DBS were chosen in four ways.

1. The first trial, in 1999, targeted the anterior limb of the internal capsule because lesion surgery to that area has been found in some cases to reduce the symptoms of severe OCD.³ The anterior cingulate and subcaudate areas, and the combination of the two, were chosen for similar reasons, in relation to major depressive disorder (MDD).
2. The subthalamic nucleus (STN) is the favoured target in Parkinson's disease. Following DBS, some patients with comorbid OCD experienced a reduction in the severity of those symptoms, hence its selection for trials in OCD.
3. fMRI has revealed increased metabolic activity in the subgenual cortex and habenula in some patients with MDD. Hence, those areas were targeted based on the hypothesis that such hyperactivity may be causal, rather than simply a manifestation of depression.
4. Tourette syndrome sits on the boundary between movement and compulsive disorder, which has contributed to the wide range of brain targets available, including the thalamus, STN, globus pallidum, nucleus accumbens and internal capsule.

Box 1 Brain targets used in psychiatric neurosurgery

Stimulation procedures

Deep brain

- Anterior limb internal capsule (obsessive-compulsive disorder (OCD), depression, anorexia nervosa)
- Nucleus accumbens (OCD, depression, anorexia nervosa, addictions)
- Subgenual cortex (depression)
- Globus pallidus (Tourette syndrome)
- Habenula (depression)
- Posterior hypothalamus (aggressive behaviour)
- Thalamus centromedian nucleus (Tourette syndrome)
- Subthalamic nucleus (OCD)
- Inferior thalamic peduncle (depression)
- Nucleus basalis (Alzheimer's disease)
- Fornix (Alzheimer's disease)
- Basolateral amygdala (post-traumatic stress disorder)

Cortical surface (epidural)

- Dorsolateral frontal (depression)
- Orbitofrontal (depression)

Vagus nerve (depression)

Ablative procedures

Thermocoagulation

- Anterior capsulotomy (OCD, depression)
- Cingulotomy (OCD, depression, addiction)
- Limbic leucotomy (OCD)
- Subcaudate tractotomy (depression, OCD)
- Nucleus accumbens (addiction)

radiosurgery ('gamma knife')

- Capsulotomy (OCD)

VNS was first used in the 1990s to treat some forms of refractory epilepsy. Improvement in the mood of some individuals was noticed, an effect that was independent of seizure response. Trials in treatment-resistant depression yielded positive outcomes, but a later study including a 'sham' surgery group suggested a significant placebo effect.¹⁹

Several authors have sought to explain the beneficial effects of stimulation-based procedures and lesion surgery on depressed mood and anxiety by reference to two cortico-striato-thalamocortical (CSTQ 'loops'.²⁰ Similar loops were previously identified in relation to movement, prior to the introduction of DBS, including inhibitory (GABA-based) and excitatory (glutamate-based) pathways.²¹ The CSTC loops, by contrast, involve a wider range of neurotransmitters, with complex interactions that are yet to be defined. Such 'circuits' may, however, explain the variety of targets that seem to produce at least some benefit in psychiatric DBS studies. It seems reasonable to speculate that tapping into and stimulating the loop at many points could influence and modify the whole network.

Protocols, conditions and outcomes

Lesion-based, ablative surgery continues to be available, including at two centres in the UK, but in most countries it is confined to a very small number of cases each year.^{22,23} The exceptions are Russia and China where it is now frequently used in the treatment of addiction.^{24,25} Radiosurgery has made lesion surgery possible without opening the skull and one report confirmed efficacy in OCD comparable to older techniques.²⁶ At the Editor's direction, the remainder of this review will focus on DBS.

The investigators who first applied DBS to the treatment of psychiatric disorders were aware of the legacy of past psychosurgical excesses and the ethical issues it raised. With that in mind a collaborative group drew up a list of research guidelines, published in 2002.²⁷ They include independent evaluation of potential participants according to strict diagnostic, severity and duration criteria; the need to ensure that individuals are able to give informed consent at the outset and for as long as the treatment continues; and ensuring DBS is never used for 'political, law enforcement or social purposes'.²⁷ Most investigators also use established severity ratings and response criteria based on them (such as a 35% or more reduction on the Yale-Brown Obsessive Compulsive Scale²⁸).

In the early years the focus of DBS studies was on people with treatment-resistant OCD, Tourette syndrome and MDD. The textbook cited at the beginning of this paper tabulates all such studies up to 2013 for each of these diagnoses, including patient numbers, brain targets, follow-up times and reported outcomes.²⁹ In summary: OCD: 11 studies involving 9 targets in a total of 86 patients followed up from 3 to 31 months; positive outcomes in 33–100% Tourette syndrome: 10 studies involving 7 targets in 40 patients followed up from 3 to 36 months; positive outcomes in 23–82% MDD: 6 studies involving 5 targets in 55 patients followed up from 12 to 36 months; positive outcomes in 30–75%.

The longer the duration of the follow-up overall, the better outcomes tended to be, but no one target appeared markedly superior. Whereas in movement disorder, and to an extent in Tourette syndrome, improvement occurred soon after stimulation commenced, in OCD and MDD improvement took many weeks to begin, symptoms diminishing further as time progressed. This perhaps indicates that rather than simply turning off ‘malfunctioning’ neurons, stimulation causes gradual beneficial change in the networks and systems it taps into. One exception to this delayed response was a study in which seven people with MDD received DBS to the medial forebrain bundle. The pulse frequency was lower than usual (see ‘Technicalities’ section) and at 1 year positive responses were reported in six people; all began to improve within a week of stimulation commencing.³⁰

Despite these apparently favourable outcomes, the small patient numbers, bewildering array of brain targets, variable follow-up times, and the impossibility of the double-blind placebo control methods, may lead many to conclude that the efficacy of this approach is far from proven. Although Lévêque considers the efficacy of DBS in OCD to be established, in relation to MDD he concedes that ‘although the benign nature of these techniques is in the process of being established, their efficacy remains difficult to demonstrate’.²⁹ Nonetheless, he and others offer several reasons why these outcomes should be taken seriously.

1. The patients treated have severe conditions that have failed to respond to all other treatments over a prolonged period.
2. Some studies target structures that had proved effective in lesion-based surgery (stimulation being used to simulate a lesion).
3. DBS allows for a form of ‘double blind’ methodology as the stimulating device may be turned on and off, the status at any point being kept from patient and assessor.
4. In some clinically improved cases temporary deterioration followed battery failure or inadvertent disconnection.^{30,31}

Although the reversible nature of DBS makes it more acceptable than lesion surgery, is it as effective in psychiatric applications, and does it result in fewer side-effects? The technique may only simulate a lesion, but if the patient requires that simulation to be in place for the rest of their life, what is the difference, apart from indefinite maintenance costs? A recent paper addressed that question by reviewing outcomes in 20 studies of treatment-resistant OCD.³² 108 patients who underwent capsulotomy were compared with 62 patients who received stimulation to the internal capsule or the nucleus accumbens. Of those undergoing capsulotomy 62% responded favourably, compared with 52% of those undergoing stimulation, but the difference was not statistically significant. Weight gain, which was common after lesion surgery, did not occur with stimulation. Apathy and disinhibition were also experienced by a small number of patients after lesion surgery but not during DBS.

Adverse effects reported after DBS include postoperative problems such as wound infection, haemorrhage (asymptomatic or resulting in transient motor signs), single seizures and syncopal episodes.³³ Additional undesirable effects develop when the stimulator is turned on but seem generally to disappear once the stimulation parameters are altered (voltage, frequency, etc.). These include physical symptoms such as paraesthesia, muscle contractions, dysarthria, diplopia and strabismus, and psychiatric features, particularly excitement, irritability and occasionally hypomania. Cognitive function is usually assessed before and during treatment and a recent review concluded that no adverse cognitive effects had occurred. In fact, as time progressed improvements in scores tended to occur, mirroring improvements in mental state.³⁴ The most common longer-term problems in psychiatric and movement disorder applications seem to be device-based. For example, one study of 84 patients with Parkinson’s disease recorded hardware-related complications in 8.4% of patients each year, including lead fractures, migrations and disconnections.³⁵ Technical improvements have doubtless occurred since that report, but the consequences of such mishaps in patients with severe psychiatric disorders may be grave, and are among the reasons that regular ongoing follow-up is deemed important.

A further stimulation technique that does not involve penetrating the brain has recently been tried in people with MDD.³⁶ Electrodes were placed in the epidural space over the dorsolateral frontal cortex in a single-blind study of 12 patients who were followed up for 2 years, with results comparable to the best DBS studies. A later paper discussed the combination of this technique with psychotherapy, a fascinating subject, sadly beyond the scope of this review.³⁷

The major advantage of DBS over lesion-based surgery is that if it does not work the hardware can be turned off and removed. In the longer term, stimulation could be stopped temporarily to assess whether it is still necessary. But as we now know, the brain is not 'immutable' and unresponsive to such challenge. It adjusts and adapts, chemically and structurally to changing circumstances and, in fact, the delayed onset of improvement in some of these applications seems to depend on such adaptation. The long-term implications of such changes are not clear.

In light of the relatively low side-effect profile of DBS in these early trials and apparently favourable outcomes, the technique has been extended to a number of other conditions including addiction,³⁸ eating disorder,³⁹ posttraumatic stress disorder (PTSD),⁴⁰ early Alzheimer's disease⁴¹ and, most controversially, aggressive behaviour disorder.⁴² Each of these has a defining clinical feature that suggests a particular brain target (in turn, nucleus accumbens, hypothalamus, amygdala, mammillary-fornix-hippocampal complex/nucleus basalis, hypothalamus). Although it is probably too early to comment on the outcome of this work, the target selections in two of these conditions are illustrative of the current approach and will be described briefly. The amygdala is being targeted in PTSD as a result of post brain-injury MRI and fMRI evidence (amygdala damage protecting against developing the condition and evidence of increased metabolic activity), and a positive response to amygdala stimulation in an animal model. The fornix is being targeted in early Alzheimer's disease as a way into the mammillary-fornix-hippocampal complex. This follows the serendipitous finding of improved memory and increased hippocampal volume following stimulation of the anterior hypothalamus undertaken for an unrelated condition, and animal studies showing stimulation-related neural growth.⁴³

The future

In 2013 President Obama launched a US\$100 million research programme with the acronym B.R.A.I.N (Brain Research through Advancing Innovative Neurotechnologies).⁴⁴ 'Emerging technologies' would be applied to the investigation of brain function and the treatment of disorders. This would include nanotechnology and, in relation to treatments, 'wireless fully implantable neural interface medical devices for human use ... closed loop systems able to deliver targeted neural stimulation'.⁴⁵ A patient group singled out for such innovative treatments was injured war-fighters, particularly those with treatment-resistant PTSD and memory problems due to acquired brain injury. This was a remarkable proposal, not least because at that point no 'wired' device-based treatments had been found useful or even trialled in either condition, and closed loop technology had only been used in cardiac dysrhythmia and epilepsy.⁴⁶

Closed loop technology has been more widely identified as important for the future of this work. In the context of epilepsy, implanted closed loop devices monitor an area where seizure originates, detect electrical activity that indicate a seizure is due, and respond with electrical stimulation or cooling to interrupt it.⁴⁶ In the psychiatric context, the possibilities of such devices include using nanotechnology to measure neurotransmitter levels and trigger therapeutic outputs.⁴⁷

Another development of possible importance is optogenetics. Light-sensitive ion channels that respond to different colours are delivered to and incorporated into individual neurons via a virus. Light channelled into the brain via fiberoptics can then be used to turn on and off such channels. Although this sounds the stuff of science fiction, a similar procedure has apparently succeeded in animal studies and trials in humans are expected in due course.^{48,49}

Conclusions

Given the torment of severe treatment-resistant depression, OCD and other psychiatric conditions, and the enthusiasm for DBS in relation to movement disorder, it is reasonable to ask why the technique has not been more widely adopted in psychiatry? A neurosurgeon recently addressed this question and identified a number of reasons: the legacy of ‘old-fashioned’ psychiatric surgery, the complexity and heterogeneity of psychiatric symptoms, and the multitude of brain circuits likely to be involved in them, ‘tricky ethical questions related to potential manipulation of the mind’, difficulty in conducting large trials in these conditions, and inconsistent results.⁵⁰ He might have added lack of consensus over targets in the conditions most often treated and the limited number of ‘placebo’ (sham treatment) controlled trials. Nonetheless, the US Food and Drug Administration gave approval for DBS in treatment-resistant OCD in 2009, albeit through a ‘humanitarian device exemption’.³³

In the UK, new medical procedures tend to be adopted and funded following pressure from patients and their interest groups, clinicians, medical Royal Colleges and the media. It is difficult to envisage such pressure for psychiatric DBS at the moment. The legacy of mid-20th century psychosurgery includes not only public and professional distrust (the charity OCD-UK ‘do not recommend DBS as a treatment for OCD *and remain concerned that the dangers associated with the procedure continue to be overlooked by the medical community*’⁵¹ – my italics) but also ethical and methodological rules that require complex, expensive, multiprofessional teams. In 2013 the NHS Commissioning Board published DBS guidelines for the treatment of movement disorders. They included an estimated cost of £26 070 for each procedure, but acknowledge that savings resulting from clinical and quality-of-life improvements offset ongoing maintenance costs.⁵²

In an afterword to the psychosurgery text mentioned at the beginning of this paper, and a related article, Marwan Hariz, a particularly cautious and thoughtful ‘functional’ neurosurgeon, warns that ‘hying’ DBS in psychiatry at this stage could lead to its demise.⁵⁰ He also expresses concern at recent suggestions that the technique could be used to enhance ‘normal’ functioning or even control antisocial behaviour. ‘Neuromodulation’ he concludes, ‘should not be allowed to become neuromanipulation’.⁵³ It remains to be seen whether a new generation of ‘millennial’ psychiatrists and neurosurgeons armed with these emerging technologies will follow his advice.

1.7.78 Teaching provision for old age psychiatry in medical schools in the UK and Ireland: a survey

Abstract

Aims and method This work builds on a survey first done in 1999 to understand how old age psychiatry teaching is embedded in undergraduate medical schools in the UK and Ireland and the influence of academic old age psychiatrists on teaching processes. We invited deans of 31 medical schools in the UK and Ireland in 2015 to complete an online survey to reassess the situation 16 years later.

Results Response rate was 74%. As found in the original survey, there was variation across medical schools in how old age psychiatry is taught. Half of schools stated there was not enough space in the curriculum dedicated to old age psychiatry, and not all medical school curricula offered a clinical attachment. Medical schools that involved academic old age psychiatrists in teaching (59%) showed a greater diversity of teaching methods.

Clinical implications There is a need to recognise the importance of old age psychiatry teaching, with the consensus of opinion continuing to be that more curriculum space needs to be given to old age psychiatry. To achieve this we advocate increasing the number of old age psychiatrists with teaching roles, as relying on academics to teach and lead on curriculum development is challenging given their greater research pressures.

With the ageing population and high prevalence of mental health burden in the UK, it is becoming increasingly important that medical school undergraduate curricula for old age psychiatry advance in line with future demographic needs. This has been recognised by the General Medical Council (GMC) in *Tomorrow's Doctors*,¹ which stresses the importance of students learning about the special problems associated with older people's health. The Royal College of Psychiatrists has subsequently mapped the core undergraduate psychiatry curriculum outcomes² on to the competencies listed in *Tomorrow's Doctors*. Other UK national drivers, including the National Health Service (NHS) Outcomes Framework³ and the prime minister's dementia strategy,⁴ have highlighted the need for the future workforce to be competent in caring for the needs of the older person.

More broadly, there is also an increasing recognition that there is a shortage of old age psychiatrists, and recruitment of trainees is less than for other specialties (fill rate is 67% for training posts compared with 80% in psychiatry as a whole). The Centre for Workforce Intelligence (CfWI) in their in-depth review of the psychiatry workforce⁵ highlighted old age psychiatry as a particular concern, with the strongest risk of a larger demand–supply shortfall due to weak workforce growth. Currently, there are 1.1 full-time old age psychiatry certificate of completion of training (CCT) post holders per 100 000 population, but the workforce growth is not proportional to the growth in the older population, and baseline demand and supply projections anticipate a shortage of around 315 CCT holders in old age psychiatry by 2033.

In 2012, the Royal College of Psychiatrists published its recruitment strategy,⁶ with the primary aim of increasing recruitment into core psychiatry training, but the recommendations can be extended to old age psychiatry specialty training. Arguably, the concept of increased exposure to old age psychiatry and looking at the undergraduate experience

could be key to understanding why medical school graduates may or may not consider this specialty as an appealing career choice.

This study builds on a previous survey, carried out in 1999, which found that schools with established old age psychiatry academic departments devoted more time to undergraduate teaching of old age psychiatry, covered more topics and used a wider range of teaching methods.⁷ The aim of the current study was to determine how old age psychiatry teaching is embedded in undergraduate medical schools in the UK and Ireland. More than 15 years on from the original survey, we sought to demonstrate how undergraduate provision of old age psychiatry teaching has changed nationally and identify any ongoing gaps. Similar surveys have been carried out by other non-psychiatric specialties facing similar recruitment concerns, in particular geriatric medicine.^{8,9}

Method

The study took place between January and November 2015. A questionnaire (available in the *appendix*) was developed and published in electronic format using the Survey Monkey software (www.surveymonkey.com). It enquired about the teaching provision of undergraduate old age psychiatry, covering whether or not the curriculum included teaching of old age psychiatry; where in the curriculum this teaching took place; whether academic old age psychiatrists (i.e. person(s) working in old age psychiatry but with a significant aspect of their job plan including research and/or medical education) were involved in the organisation of teaching; the duration of attachment to the specialty; the form and content of the teaching; and the nature of the student assessment. There were free-text spaces for respondents to qualify their answers if necessary. The questionnaire was reviewed and the study endorsed by the Faculty of Old Age Psychiatry of the Royal College of Psychiatrists.

The deans of all 31 UK medical schools were contacted by email and letter, asking them to identify a respondent with sufficient awareness of the undergraduate curriculum to allow completion of the survey, and requesting that the letter or email be forwarded to them. Where initial approaches and reminders were unsuccessful, members of the undergraduate leads forum were contacted through the Faculty of Old Age Psychiatry and invited to identify a respondent. As this was a survey requesting information already in the public domain, no formal consent procedure was undertaken and implied consent was assumed through participation.

The project met the Newcastle University preliminary ethical assessment guidelines, indicating that a full university ethics committee review was not required.

Results

Responses were received from 23 (74%) medical schools. No schools responded that they did not wish to participate but 8 did not respond to any form of communication (written, electronic and/or telephone). One (4%) response was from a dean, 9 (40%) from a senior lecturer, 5 (22%) from a consultant psychiatrist or programme director, 3 (13%) from a reader in old age psychiatry, 4 (17%) from a professor and 1 (4%) from a consultant physician.

Overall, 50% of respondents felt that there was not sufficient curriculum space designated to old age psychiatry; however, many appreciated the overlap with other specialties, including adult psychiatry, neurology and care of the elderly.

Staffing establishment of academic old age psychiatry

Figure 1 shows the current staffing establishment of academic old age psychiatry. More than half of schools (59%) reported that academic old age psychiatrists were involved in the organisation and delivery of undergraduate teaching, compared with 40% in the original survey. We found that 41% of schools have an academic old age psychiatrist represented on the board of studies or equivalent.

Fig. 14: Staffing establishment of academic old age psychiatrists.

Organisation and delivery of teaching

A designated clinical attachment in old age psychiatry was present in 86% of schools. Of those, in 13% the duration of the clinical attachment was dependent on individual student choice and in 41% there was the opportunity to spend more time in old age psychiatry. All respondents indicated that the majority of the teaching on cognitive assessment and dementia was delivered by an old age psychiatrist. There was no consistency between schools on when these topics were first covered, with 14% covering them in the first year, 23% in the second year, 36% in the third year, 23% in the fourth year and 5% in the fifth year.

With regard to time spent teaching old age psychiatry in the undergraduate curriculum, again there was no consistent standard, and reports ranged from a 1 h formal lecture to 25 days if the teaching on dementia/delirium covered by other specialties was included. This amount of time overlaps with that found in the original survey, in which time ranged from 1 to 40 days. Both the present and previous survey⁷ found that other, more informal/unstructured teaching was also given, but there was difficulty in quantifying the amount as this tends to depend on the clinical attachment. Some schools also offered self-directed teaching through podcasts or e-lectures (lectures delivered online), which depended on student interest and motivation.

A variety of teaching methods were used (*Table 1*), but with a large proportion primarily using lectures and tutorials as the main format of teaching (82% and 86%, respectively, v. 73% and 55% in the original survey). As with the original survey, schools where academic old age psychiatrists were involved in the organisation and delivery of teaching showed greater teaching method diversity and more use of innovative methods of teaching, such as interprofessional learning, e-learning and simulation, than those schools where there was no academic involvement. However, the overall figures were low (*Table 1*) and significance was only reached for simulation ($P = 0.03$) and home visits ($P = 0.02$). Of all schools, 50% responded that they involved carers or patients when delivering organised teaching sessions.

Method of teaching delivery

	<i>n</i> (%)		
Lectures	12 (92)	6 (60)	0.13
Tutorials	11 (85)	8 (80)	0.57
Bedside teaching	10 (77)	7 (70)	1.00
Problem-based learning	5 (38)	4 (40)	1.00
Interprofessional education	7 (54)	3 (30)	0.40
e-learning	8 (62)	2 (20)	0.09
Simulation	5 (38)	0 (0)	0.03*
Home visits	13 (100)	6 (60)	0.02*
Joint teaching	6 (46)	2 (20)	0.38
Other	0 (0)	1 (10)	0.43

Binomial probability $P = 0.03$ for all the teaching methods where there is academic involvement.

$P < 0.05$.

Content and assessment of old age psychiatry teaching

In 95% of schools the undergraduate curriculum contained specific old age psychiatry outcomes, compared with 100% of schools in the original survey, where the undergraduate curriculum contained some theoretical or clinical teaching of old age psychiatry. All schools were teaching cognitive assessment and dementia (95% in the original survey) but, as found in the original survey, fewer indicated that they covered affective disorders (82% v. 91%) or psychotic disorders (77% v. 82%). Even fewer covered service organisation (36% v. 59%) (*Table 2*). A variety of assessment methods are used (*Table 3*), with the most common (82%) being the observed structured clinical examination (OSCE). In the original survey, student assessment was most commonly by 'formal examination' (68%) and assessment of performance during the clinical attachment (64%).

Teaching content

Topic	Schools with academic old age psychiatrist involvement (<i>N</i> = 13)	Schools without academic old age psychiatrist involvement (<i>N</i> = 10)	χ^2 (<i>P</i>)
Cognitive assessment	13 (100)	10 (100)	1.00
Dementia	13 (100)	10 (100)	1.00
Delirium	10 (77)	10 (100)	0.23
Affective disorders	10 (77)	8 (80)	1.00
Psychotic disorders	9 (69)	8 (80)	0.66
Service organisation	4 (31)	4 (40)	0.69
Mental Health Act	11 (85)	7 (78)	0.62
Cultural issues	7 (54)	4 (44)	0.68
Other	2 (15)	0 (0)	0.49

Teaching and assessment methods in old age psychiatry

Assessment	Schools (<i>N</i> = 23) <i>n</i> (%)
Formal examination	11 (49)
OSCE	18 (82)
Long case	4 (18)
MCQ	14 (63)
Coursework	6 (27)
e-portfolio	3 (13)
Logbook	10 (45)
Essay	4 (18)

MCQ, multiple-choice questions; OSCE, observed structured clinical examination.

Table 2 also shows the content of teaching according to whether there is academic involvement which did not reach significance for any topic.

Discussion

Arguably, the most powerful message from this survey is that 50% of respondents did not feel that sufficient curriculum space is designated to old age psychiatry. This had been a concern in the original survey, in which 57% of schools had reported that there were significant obstacles to introducing and maintaining old age psychiatry teaching in the undergraduate curriculum. This raises the question of how much progress has been made over the past 15 years. Similar surveys done in elderly care medicine, a specialty facing a similar recruitment problem, have also found that inadequate time (<2 weeks) is spent teaching about subjects related to ageing, including dementia, which does not reflect the predominance of older patients in most doctors' workload.^{8,9,10}

The main finding in the original survey undertaken in 1999 had been that those medical schools with established academic old age psychiatry departments provided more teaching of old age psychiatry and are more likely to embrace new teaching methods.⁷ Our survey showed that 59% of schools have academic old age psychiatrists involved in the organisation and delivery of undergraduate teaching and 41% have an academic old age psychiatrist represented on the board of studies or equivalent. Similar to the original survey the main finding from the current survey is that schools where academic old age psychiatrists are involved in the organisation and delivery of teaching are more likely to use a greater diversity of teaching methods; however, only the use of simulation and home visits were found to be significant.

These results should be interpreted in the context that academics now may be less engaged in organising teaching (unless they are specifically medical educators) as they have predominantly research roles and greater research pressures. This highlights a need to drive up the number of other old age psychiatrists with teaching roles.

In the original survey all of the schools reported that the undergraduate curriculum contained some theoretical and/or clinical teaching of old age psychiatry and in our survey 95% of schools reported that their undergraduate curriculum contains specific old age psychiatry outcomes. Worryingly not all schools offer a clinical attachment in old age psychiatry (86%, slightly higher than in the original survey (82%)), and in those that did, the organisation of this is variable. As with the original survey, the amount of time offered varies considerably, and in some schools student exposure to old age psychiatry depends on individual clinical attachments. A wide range of teaching formats are reported, with the commonest methods being lectures and tutorials. Other methods, such as interprofessional teaching, e-learning and simulation, are less common (*Table 1*). Similarly, there was relatively low patient and carer involvement in teaching (50%).

Low use of interprofessional teaching and involvement of patients and carers in particular are missed opportunities, as evidence has shown that interprofessional education (IPE) can be used to significantly improve confidence and change attitudes in staff managing older patients with dementia or delirium.¹¹ This style of teaching delivery could therefore also be applied to undergraduates, especially at a time when the expectation from the GMC is for greater IPE within curricula to improve team-working skills.^{1,11} As such, teaching on topics relevant to old age psychiatry could be the hook through which it is possible to drive up the amount of IPE, and hence development of team-working skills within the broader medical curricula, as well as fostering more positive attitudes towards the older patient and improving recruitment into this specialty.

As regards the content of teaching, all schools are delivering teaching on dementia and cognitive assessment and the majority (91%) are teaching on delirium. It is concerning that not all schools cover affective and psychotic disorders (82% and 77%, respectively) in this age group as, unlike dementia and delirium, these topics are less likely to be covered by other specialties, and their presentation and management differ considerably compared with general adult psychiatry. As with the original survey,⁷ cultural issues were covered less (50%). Academic involvement in teaching did not lead to any significant difference in the content of teaching, which should be expected if medical schools are using a standard curriculum and is perhaps reassuring given that not all medical schools will have academic old age psychiatrists involved in the organisation of teaching.

In contrast to the original survey, where student assessment was most commonly by a 'formal examination', this survey showed that an OSCE was the most commonly used method of assessment, with other techniques, such as assessed

coursework and portfolios or logbooks, less frequently reported (*Table 3*). The need to ensure that teaching and assessment in medical schools is done to a high standard is crucial as assessment drives learning. However, we do not advocate a standardised assessment process as there are contextual variations in teaching nationally. What is important for educators is to understand what is being assessed and thereby select the correct assessment format as per the Millers Pyramid,¹² i.e. multiple choice questions to test knowledge, OSCEs to assess performance. This would enable assessment processes to be undertaken in an appropriate manner and for schools to demonstrate that learning outcomes have been achieved by students.

Implications for recruitment

Given the concerns about recruitment into old age psychiatry, it is important to consider the influence of the undergraduate curriculum experience of old age psychiatry on postgraduate career choice. A survey of graduates from Liverpool University 5 years post-qualification¹³ found that the majority felt their career choice was primarily dictated by their postgraduate experience rather than their undergraduate clinical attachments. However, in another survey of graduates, Goldacre *et al*^{14,15} found that factors during undergraduate experience significantly outweighed any inclinations before entry to medical school concerning the influence on career choice. They also found that career choices were greatly influenced by a particular teacher or department. The importance of a good role model has also been identified by surveys in other specialties,^{16–18} highlighting the importance of individuals in fostering enthusiasm and interest in a specialty.

Specialties with similar recruitment problems to old age psychiatry have found that the most significant factors influencing final-year medical students in their career choice were clinical mentors and specialty-themed, problem-based learning cases.¹⁸ However, for psychiatry as a whole, other studies have found that attitude changes towards considering a career in this specialty were similar whether students were taught with problem-based learning or with a more traditional curriculum.^{19,20}

In elderly care medicine, a study done at the University of Aberdeen²¹ found that an intensive 8-day programme increased the likelihood of fourth-year medical students considering this specialty as a career. Several US studies have shown that a positive attitude towards older people increases the likelihood of pursuing a career in care of the elderly and that increased exposure to this specialty during medical school has a positive influence on attitudes.^{22–24} This supports the view that the most effective interventions to increase recruitment of elderly care physicians should focus on positively influencing medical students' attitudes during medical school through meaningful experiences during clinical attachments, findings which could be extrapolated to include old age psychiatry. Indeed, US and Canadian surveys looking at factors that influence medical students choosing old age psychiatry as a career have found that one of the key factors is completing an old age psychiatry rotation alongside specific teacher attributes and training experiences.^{25,26} These findings support our key recommendations (*Box 1*).

Strengths and limitations

The response rate to this survey was good (74%), although it must be acknowledged that there may still have been a response bias, with a poorer return from the schools without a strong academic old age psychiatry department or representative for undergraduate teaching provision in old age psychiatry. Consequently, we may have underestimated the poorest end of the spectrum.

Box 1 Key recommendations

1. Old age psychiatry should be offered as a clinical attachment in all medical schools.
2. All schools should deliver specific old age psychiatry outcomes in the undergraduate curriculum including affective and psychotic disorders, legal and cultural issues.
3. A minimum time delivering formal teaching and time spent on clinical attachment should be agreed by the College with medical schools to ensure adequate exposure in old age psychiatry.
4. Schools should strive to drive up the number of old age psychiatrists with teaching roles and ensure they are supported in delivering a greater diversity of teaching methods and acting as positive role models.

5. There should be greater use of patients and carers in teaching to help foster positive attitudes.
6. The use of interprofessional learning should be recognised in driving up the status of old age psychiatry and ability to practise effectively in collaboration with other professions.
7. There is a need to ensure that schools teach and assess to a similar high standard in order to demonstrate that old age psychiatry outcomes have been addressed.
8. Future surveys should look at surveying medical students on their opinion and experience of old age psychiatry as well as career intentions.

Of the responding schools, data were collected from only one representative, with the hope that the respondent identified from each school would be whoever had suitable knowledge of the undergraduate curriculum. There is a possibility, however, that some of these representatives may have had an inadequate or biased overview of the undergraduate curriculum and that not all information was reported or accurate.

It was apparent through some of the free-text responses that some schools found it difficult to quantify the length of time spent teaching curriculum outcomes specific to old age psychiatry. For medical schools with an integrated curriculum, it may have been difficult to extract this information, as there is an overlap with other specialties who may have delivered this teaching.

It must be acknowledged that a limitation in the comparisons of academic old age psychiatrist involvement is that results reported were uncorrected and it is likely that there may have been no significant difference due to the overall numbers being low, and the number of comparisons being made. A further limitation was that the survey explores the taught curriculum and does not cover student-selected topics or the fact that some medical students may choose to do a research period in old age psychiatry. There are also no data regarding the opinion of medical students, and subsequently the influence of individual schools' undergraduate experience on career intention. Consequently, the assumption could not be made that medical schools with a mandatory clinical attachment in old age psychiatry and embracing more innovative methods of teaching delivery had a positive effect on intention to pursue old age psychiatry as a career. Further research is needed to explore the experience of the curriculum on paper and the 'hidden curriculum' experienced by the students by means of surveys and focus groups of undergraduate students as well as following up cohorts of students into their chosen career.

Recommendations

With the ageing population and increasing complexity of their needs, it is imperative that the future generations of doctors are suitably equipped with the knowledge, skills and attitudes for dealing with future challenges. It is especially important that the undergraduate experience fosters positive attitudes about old age psychiatry as a specialty and potential future career to try to address the workforce crisis we currently face. This survey of teacher practice has highlighted that there is still variation across medical schools in how old age psychiatry is taught, and made recommendations in how undergraduate experience of old age psychiatry can be enhanced. The value of interprofessional learning, as well as more involvement of patients and carers, should be recognised in improving the attractiveness and status of old age psychiatry. Although there may have been progress over the past 15 years in embedding old age-specific outcomes in the undergraduate curriculum, the consensus of opinion does continue to be that more curriculum space needs to be given to old age psychiatry.

1. Which medical school are you responding on behalf of? _____
2. What is your job title? _____
3. What is the current staffing establishment in academic old age psychiatry?
(number of posts 0 1 2 3 4 5 >5) (professor/reader/senior lecturer/lecturer/research fellow/research assistant)
4. Which of the following best describes the style of teaching at your medical school? (traditional (i.e. lectures and tutorials during years 2–3 followed by the clinical years), integrated (i.e. clinical attachments from year 1), problem-based (i.e. student-centred teaching), other.)
5. Does the undergraduate curriculum contain specific old age psychiatry outcomes? (yes/no/don't know)

6. Which topics are covered? Tick all that apply (cognitive assessment/dementia/delirium/affective disorders/psychotic disorders/depression/service organisation/Mental Health Act/cultural issues/other/none of the above)
7. How much time is spent teaching old age psychiatry in the undergraduate curriculum? (e.g. approximate number of days) _____
8. When is dementia and cognitive assessment first covered? (first year/second year/third year/fourth year/fifth year)
9. Are there plans to incorporate the recent Health Education England dementia curriculum into the teaching program? (yes/no/don't know)
10. Who delivers the majority of the teaching on cognitive assessment and dementia? (old age psychiatrist/other (please specify))
11. Is there a clinical attachment in old age psychiatry? (yes/no)
12. Is the duration of a clinical attachment in old age psychiatry dependent on individual student choice? (yes/no/compulsory attachment with opportunity to spend more time on old age psychiatry/compulsory attachment with no further opportunity to spend more time on old age psychiatry)
13. Which teaching methods are used for old age psychiatry teaching? Tick all that apply (lectures/tutorials/bedside teaching/problem-based learning/inter-professional/e-learning/simulation/home visits/joint teaching/other)
14. Are carers or patients involved in the delivery of teaching? (yes/no)
15. Which methods are used to examine students on old age psychiatry? (formal examination/OSCE/long case/MCQ/coursework/e-portfolio/logbook/essay/other)
16. Are academic old age psychiatrists involved in the organisation and delivery of undergraduate teaching of old age psychiatry? (yes/no/don't know)
17. Are academic old age psychiatrists represented on your board of studies or equivalent? (yes/no/don't know)
18. Do you think that there is sufficient curriculum space given to old age psychiatry? (yes/no)
19. Any other comments re: teaching of old age psychiatry? _____
20. Would you like a copy of the results? (yes/no)

- *Profile: Derek Summerfield – politics and psychiatry*
 - *The personal and the political*
 - *Problem with the concept of global mental health*

Preparing for this interview, I was aware of Dr Summerfield's political commitment. After all, he was the principal psychiatrist for Freedom from Torture (Medical Foundation for the Care of Victims of Torture) from 1991 until 2000. He is an outspoken critic of what he describes as the complicity of the Israeli Medical Association (IMA) and Israeli doctors posted to interrogation units in relation to the torture of Palestinian refugees, which has led to him receiving many accusations of anti-Semitism and becoming the subject of a libel suit by the President of the IMA. He is a member of the Critical Psychiatry Network. Before training in psychiatry, he worked as a government medical officer in Zimbabwe to 'repay his debt' to Africa. This was clearly going to be an encounter with a man of the left, passionate about social justice.

The personal and the political

I was curious about how Dr Summerfield sees the personal and the political. Can they ever be separated? What exactly is the role of the psychiatrist in relation to social justice? Should what I will call 'ethico-political awareness' be part of psychiatric training, given the huge relevance to mental health of the context in which our patients live?

If senior psychiatrists should be leading the profession, can this ethico-political thinking be encouraged by example only, or more explicitly within the syllabus? And how does Derek Summerfield see his role within the profession? Is he an individual firebrand, grit in the oyster, provocateur, thinking iconoclast, leading by example and seeking influence via publication, or does he have a more intergenerational mission? (It emerges that he has recently canvassed the juniors at the Maudsley Hospital and recommended they should not comply with trust training in relation to the controversial government Prevent strategy of 2015, intended to detect early radicalisation in pupils, students or patients, which he regards as outrageous state intrusion into clinical confidentiality and a form of McCarthyism.)

More widely, in the recent climate of junior doctor strikes, dire warnings from the British Medical Association, hot controversy over the National Health Service as a public service, what, if any, are the political obligations of (a) doctors in general and (b) psychiatrists in particular? I got my answer loud and clear in a note he sent me a few days after the interview: "There is the doctor as doctor, but also (ethically imperative) the doctor as sentient citizen . . . To do with a fundamental duty to attend not just to the particulars of the patient sitting in front of us, but also to the political and socioeconomic factors that produce distress and disease. Doctors have largely not done this. End of sermon . . ." Dr Summerfield is actually not preachy: he is amusing, not pompous, but self-deprecating – yet utterly (and perhaps unfashionably) serious. Of course he knows that not all doctors or psychiatrists share his views. Indeed, he is realistic: "With exceptions, doctors are not politically engaged. The average doctor doesn't have a social activist bone in his body. . . as a profession we are closer to those in power than those without it. . . medicine is basically an entrenched profession, and we behave like one . . . after the revolutions in places like Cuba, Mozambique, the vast majority of doctors left the country . . ." I wonder how he was viewed by the international and non-homogeneous group of South London and Maudsley NHS Foundation Trust (SLAM) junior psychiatrists when they received his open letter about the Prevent strategy training. Is he admired as a model of the thinking critical psychiatrist, or dismissed as eccentric or even dangerously insurrectionist?

Derek Summerfield was born 68 years ago in Cape Town, South Africa, into a non-medical family, but grew up in Bulawayo, the second city, after Harare, of Zimbabwe (then Rhodesia). He studied physics initially ('the headmaster persuaded bright White boys to do science'), then worked in a shipping company in Cape Town, and did some teaching. He always wanted to be a journalist (and now thinks he'd do law and anthropology if he was starting out again), but nevertheless began medicine, aged 24, at St Mary's Medical School in Paddington, London.

'I failed everything, and nearly left in the first year. I had no interest or feel for science in the preclinical years, but when I got onto the wards I felt an intellectual thrill at last.'

He did house jobs (i.e. FY1) in Oxford and Cambridge, and went on to become a medical registrar with MRCP Part 1. During this period he did several stints in Zimbabwe during and after the civil war, no walk in the park. In Chiredzi, in the war-ravaged rural south-east, there were 200 beds and 2 doctors. He was the paediatrician, 'with 50 desperately sick kids at any one time ... 5 of whom died each day'. He saw up close and personal the effect of poverty on health: 'even measles was 80–100 times more fatal in these malnourished kids'.

He finally decided on psychiatry in 1982, now aged 34, and went to St George's Hospital. While working there he met a beautiful and much younger woman, now a consultant clinical psychologist and psychoanalyst at the Tavistock, Francesca Huhne. They have a 20-year-old daughter, who is reading History at university. He and Francesca subsequently studied war-wounded men from both sides of the civil war in Nicaragua together. He has been a consultant to Oxfam, and for many years was a research associate at the Refugee Studies Centre, University of Oxford.

He joined Freedom from Torture (Medical Foundation for the Care of Victims of Torture) full-time in 1991, where he treated around 800 patients, often seeking asylum in the UK: Bosnians, Sri Lankans, Iraqis, Turkish Kurds, Africans and Palestinians, with 95% of consultations requiring interpreters. But with his lifetime history of independent thinking and acting on principle, this appointment did not end amicably: he was 'asked to leave' Freedom from Torture in 2000 because the organisation was concerned that his widely published questioning of the category of posttraumatic stress disorder (PTSD) might deter funders.¹ He sees the diagnosis of PTSD in the context of refugees as the 'pseudo-scientific pathologising of people affected by war ... the medicalisation of their situation diminishes the importance of work and the rebuilding of social networks ... the broken social world is the lot of the asylum seeker'.²

After leaving Freedom from Torture, he contacted Dr Maurice Lipsedge, who suggested that he should consider applying for his job in SLAM, from which he was retiring. This was in the HIV mental health team, initially part time, then full time.

The HIV team at its zenith had four psychologists and acted as a community mental health team with an HIV focus. He enjoyed the interest of the 'two different groups of patients ... African women and British gay men'. The service was greatly reduced in 2016, owing to both financial constraints and the mainstreaming of HIV. He accepts this process as reasonable, given the changes in HIV treatment and prognosis, with life expectancy being almost normal now, if the medicines are taken reliably. (And many African women don't always do this, and he would like to understand why.)

He has no immediate plans to retire and is busy with a variety of work outside the 'day job'. He's involved with the new medical school in Bulawayo, his home town, helping with the undergraduate curriculum, and will teach there: 'I still feel a debt to Africa'. He advises Oxfam: In the 80s they suddenly got very interested in the mental health of victims of war'. Derek Summerfield helped evaluate their projects in Bosnia, and steered Oxfam away from a PTSD-centred approach to victims of that war: 'I persuaded them not to go down the counselling route ... if you ask Muslim adolescents in Tuzla what they want, they want a bit of normality. They actually requested some fabric so they could put on a fashion show'.

Problem with the concept of global mental health

He has published widely from the standpoint of a fundamental opposition to the medicalisation of human distress and the assumption that Western psychiatry is universally valid, which he sees as a kind of cultural imperialism.^{3,4}

He offers a critique and deconstruction of international attitudes to the mental health of victims of war.² He stresses how the global effects of wars are largely experienced by people living in poverty, and he sees the danger of the PTSD diagnosis as pathologising of the individual rather than attending to the effects of poverty and the need for reconstruction of the social fabric.²

He makes a more general critique of the concept of 'global mental health', highly critical of 'taking depression into a country which has no such concept, followed by the marketing of antidepressants ... Western cultural values parading as medical facts'.^{3,4} His critique extends to the cultural relativism of psychiatric diagnoses in general: as if disease had an objective existence, independent of the gaze of the diagnostician.

The origin of PTSD as a diagnosis was for disturbed Vietnam war veterans in the USA with the benign intention of lobbying to get decent care for them by emphasising the traumatogenic nature of war, thus legitimising a position of victimhood, moral exculpation and receipt of disability pensions. In Summerfield's view, the development of this concept of PTSD needs to be understood in the wider social context of the 'rise of expressive psychologically minded individualism, personal rights, entitlement and grievance,' as opposed to the previously socially sanctioned stiff upper lip self-management of trauma. Now PTSD has become a 'certificate of impairment'. It is the only diagnosis which contains its aetiology within itself, while in fact, he claims, premorbid factors such as psychiatric history or a negative thinking style are more important than the actual event itself in the aetiology of symptoms.¹

Conflating normality and pathology 'devalues the currency of true illness'.

He is an old fighter, brave and almost proud of his battle scars: 'No-one has been called an anti-Semite in the medical press more than me'. He feels the campaign he convened against medical complicity with torture in Israel is the 'best thing I've done in my career'. So the life and views of Derek Summerfield are a challenge to all doctors, even those with different political views: is it acceptable for doctors to absent themselves from political engagement as being outside their remit, or are we ethically obliged to be properly aware of the sociopolitical context of our work? People with unflinching integrity have always made others uncomfortable: consider the unpopularity of Jesus overturning stalls in the temple market.

If we take our ethical obligations as doctors seriously, we need intellectually rigorous and dogged colleagues like Derek Summerfield to point up our innate conservatism and political passivity.

1.7.80 Paul Haydon Rogers FRCP FRCPsych

: Formerly Consultant Psychiatrist and Medical Director, St Crispin Hospital, Northampton

- *Paul Haydon Rogers FRCP FRCPsych*
– : *Formerly Consultant Psychiatrist and Medical Director, St Crispin Hospital, Northampton*

Paul Rogers died on 11 February 2016, aged 96, after a short illness. For the last 10 years of his life he lived independently and happily in a support and care complex in the grounds of St Crispin hospital (now converted into apartments) where he had worked from 1955 to 1979. During his time at St Crispin, where he established community-based services, he was responsible for the introduction of new treatments, particularly the newly developed psychotropic drugs. He developed child guidance clinics in the area and was also involved in the planning of Princess Marina Hospital for people with learning difficulties. After retirement from the National Health Service (NHS) he worked with the Health Advisory Service and as a member of the Mental Health Review Tribunal dealing with difficult issues at Broadmoor and Rampton high-security hospitals. In Northampton, he pioneered the recognition of stress at work and helped to create a local charity to advise employers and provide counselling for employees.

A son of the manse, he was born in Cardiff in 1919 and from an early age wanted to be a doctor. After attending Caterham School and Christ's College Cambridge, he qualified in 1943 at the London Hospital, now The Royal London Hospital. Shortly afterwards, he served as captain in the Royal Army Medical Corps in Normandy, Egypt and Palestine. On demobilisation in 1947 he returned to the London Hospital to pursue his ambition to become a consultant physician. Unfortunately, at this time, there was ferocious competition for promotion because of the high number of doctors returning from the forces after the Second World War. So, instead, he retrained at the Maudsley Hospital to become a psychiatrist. Nevertheless, he remained a physician at heart, adopting a medical approach and placing great emphasis

on diagnosis and the use of physical methods of treatment. Although he was insistent that he did not do psychotherapy, he had all the personal qualities of an excellent psychotherapist: empathy, non-possessive warmth, genuineness and a supportive non-judgemental approach.

Paul was a consummate professional dedicated to his work and the NHS, and as a role model he influenced several younger colleagues to take up psychiatry. He had no time for private practice or medical politics. His focus was the care and management of his patients. They loved him and on the rare occasions I took his clinic their disappointment was palpable. Modest, unassuming, understated and unassertive, he combined the qualities of an English gentleman with attributes of Welsh nonconformity and liberalism, reflecting his deep roots in west Wales. Basic Christian values guided his life and he had no regard for social class – a good example of this was his lifelong friendship with his batman, the only link he maintained with his time in the army. The Guardian was his newspaper and he espoused its core values.

He was devoted to his family and only looked for the good in everyone. He supported many charities and was pre-occupied with people, who, as he put it, were ‘less fortunate than I am through no fault of their own’. In retirement, activities linked to psychiatry gradually declined and were replaced by his only hobby – gardening. He enjoyed growing food for the house and his garden was always a pleasure to see. Over the years and into advanced old age he enjoyed excellent health; so much so that his close relatives were lulled into thinking that he would always be around and that his support, consideration and wise advice would always be available. He grew old gracefully in every way, retaining his core liberal values to the end.

Marjorie, his wife, and his younger daughter, Helen, predeceased him. He is survived by his sister, daughter and son.

2017-10

Contents

- *Costas Stefanis MD*
 - : *Formerly Professor of Psychiatry and Head, Department of Psychiatry, University of Athens Medical School; Director, Eginition University Psychiatric Hospital, Athens*

Costas Stefanis, who died recently at the age of 88, was the leading figure in psychiatry in Greece for 30 years, from the time of his appointment as professor of psychiatry in 1970. In collaboration with British-trained colleagues he transformed Greek psychiatry and mental health services, steering away from a previously narrow traditional psychoanalytic approach towards a much broader biopsychosocial direction. He expanded the provision of generic and

specialist mental health services and was quick to adopt the new emerging trends of community care by developing the first community mental health centre in Greece. He developed a strong research programme, having himself – early in his career, while in the USA and Canada – carried out pioneering work on the functional role of pyramidal neurons in the sensorimotor cortex. He had an international reputation as an expert on the mode of action of neurotransmitters functioning on central nervous system synapses.

Several generations of Greek psychiatrists and allied professionals were trained by him, including me. Many became his associates and were inspired to go on to acquire international recognition and reputation. In 1989, in Athens, he founded the University Mental Health Research Institute – which undertook much neurobiological and psychosocial research into mental disorders – and remained president and director until his death.

He also played a major part in international psychiatry. As president of the World Psychiatric Association (WPA) from 1983 to 1990, he was responsible for an organisation in crisis. The political use of psychiatry in the Soviet Union to incarcerate political dissidents on the grounds of mental illness led to an explosive climate within the WPA. In 1983, after major criticism from societies in other countries – which made it likely that it was facing expulsion – the All-Union Society of Psychiatrists and Neuropathologists of the USSR withdrew from the WPA. Years later, at the WPA congress held in Athens in 1989, the general secretary of that Society publicly acknowledged that political abuse of psychiatry had indeed taken place and the organisation was reinstated as a member. This by no means ended the unhappy situation in the Soviet Union, which to some extent continues to this day, but a greater degree of openness was achieved. Costas Stefanis was among those responsible for reaching a conciliatory approach on issues with significant ethical and political dimensions.

Costas Stefanis became active in the political life of his country. Between 1996 and 2000 he served as honorary member of the Greek Parliament in the reformist social-democratic government and was Minister of Health and Welfare from 2002 to 2004. During his ministerial tenure, he was president of the Council of Ministers of Health of the European Union and succeeded in achieving approval for anti-stigma legislation regarding mental illness. On behalf of the EU member states, he signed the World Health Organization's International Treaty on Tobacco Advertising. In Greece, he was responsible for four major bills passed by Parliament – on public health; reform and decentralisation of health services; the organisation of primary health care and provisions for prevention and social reintegration. Unfortunately, most of them are still awaiting implementation.

He received numerous distinctions and awards. In 1994 he was elected life member of the Athens Academy of Sciences and Arts – the highest level of scientific recognition in Greece – and served as its president in 2006. He was awarded the Medal of the Cross of the President of the Hellenic Republic in recognition of his distinguished service to the country. In acknowledgement of his contribution to psychiatry, the World Federation of Societies of Biological Psychiatry and International Neuropsychiatric Association established an international prize: the Costas Stefanis Award for Excellence in Psychiatry and the Neurosciences. He was elected honorary member and fellow of several scientific associations and he authored numerous peer-reviewed articles as well as books and articles in the lay press.

Costas Stefanis was born in Greece in 1928 and graduated from the Medical School of Athens University in 1953. He trained in neurology and psychiatry in Athens and subsequently served as a fellow in basic neurophysiology at McGill University, Montreal, and as a research scientist at the National Institute of Mental Health and Saint Elizabeth Mental Hospital (Bethesda, Maryland and Washington, DC).

He was a highly intelligent, conscientious professional who, during difficult times, strove to improve psychiatric and mental health service provision not only in Greece but worldwide, thus improving the lives of thousands of people. He died on 29 October 2016 after a long illness stoically borne, remaining active in offering advice and ideas to the end. He was devoted to his family and is survived by his wife Adela, two sons – Nicos, professor of psychiatry, and Leonidas, professor of neurology – his daughter Evanthia, a film maker, and four grandchildren.

The death of Costas Stefanis will be felt as a great loss to psychiatry by many clinical, academic and international colleagues who had the privilege of knowing and working with him.

1.7.82 Kurt Schapira MD FRCP FRCPsych DPM

: Formerly Consultant Psychiatrist, Newcastle Health Authority, Honorary Lecturer in Psychiatry, University of Newcastle

Kenneth Davison Hamish McClelland Alan Kerr Martin Schapira

date

2017-10

Contents

- *Kurt Schapira MD FRCP FRCPsych DPM*
 - : *Formerly Consultant Psychiatrist, Newcastle Health Authority, Honorary Lecturer in Psychiatry, University of Newcastle*

Shortly after completing his house officer posts and national service in the Royal Army Medical Corps, Kurt Schapira, who died recently aged 87, was appointed a research fellow to the eminent neurologist Henry Miller. More than 1150 patients with multiple sclerosis resident in Northumberland and Durham on 1 January 1958 were reviewed by Dr Schapira. Using this material, he jointly wrote 16 scientific articles on various aspects of multiple sclerosis – including its epidemiology and clinical features – many of which are still cited today. The study made a major contribution to knowledge of this condition.¹ Subsequently, fascinated by the emotional effects of multiple sclerosis on the patients, Dr Schapira decided to switch to psychiatry. He participated in Martin Roth's landmark studies on anxiety and depression and undertook his own research into suicide and attempted suicide, as well as on the treatment of anorexia nervosa. His longitudinal studies relating suicide rates to social factors and the availability of lethal methods were influential in demonstrating the importance of a public health preventive approach to suicide.² He published several articles on these and other topics, including, with others, a much-quoted paper on the influence of tablet colour in the treatment of anxiety and depressive states.³

Born in Vienna to orthodox Jewish parents, Kurt's childhood was disrupted by the death of his mother when he was aged 7 years. This was followed by the incarceration of his father by the Nazis in Dachau and then Buchenwald concentration camps. Fortunately, his father was released from Buchenwald and allowed to travel to England before the Second World War. Kurt lived in Berlin with a maternal aunt until the age of 10, when he obtained a place on a Kindertransport train to England. Having successfully negotiated a path through the British educational system, Kurt was admitted to medical school in Newcastle – then part of the University of Durham – and qualified as a doctor in 1952.

He trained in psychiatry in the university department of psychiatry in Newcastle, headed at that time by Martin Roth and James Gibbons. Within the department he was promoted to first assistant and then senior lecturer. In 1974 he became consultant psychiatrist to the Newcastle Health Authority while retaining his university connection as an honorary lecturer. He continued in this position until his retirement from the NHS in 1989.

He lectured widely both in the UK and abroad, as far afield as Brisbane, Minnesota, Montreal and Jerusalem. During his retirement he remained active in research, especially into factors influencing the incidence of suicide in Newcastle over three decades. His last published article on the subject⁴ – in collaboration with others, including his son Martin – appeared as recently as June 2016.

He undertook many responsibilities in both National Health Service and university administration and was a member of several university committees. Within the Royal College of Psychiatrists, he was a member of Council (1979–82), the Education Committee (1979–82) and the Board of Assessors of the *British Journal of Psychiatry* (1970–75), as well as examiner for the membership and various other psychiatry-related degrees at home and abroad. He was also elected President of the Section of Psychiatry, Royal Society of Medicine (1980) and President of the North of England Medico-Legal Society (1982).

Kurt enjoyed teaching and regularly topped the students' ratings for the quality of his lectures, which were notable for their combination of wit and erudition. These attributes rendered him a popular speaker to non-medical audiences, especially on the art of Chagall, Salvador Dali and Van Gogh, and the artistic portrayal of doctors and lawyers. He was a connoisseur of opera and classical music, particularly Verdi and Mozart.

He was generous with his time in acceding to invitations to speak about his childhood experiences to a variety of audiences, from schoolchildren to prisoners, and was proud to meet Prince Charles recently at a reception for Kindertransport survivors. A genial extrovert and renowned raconteur, whose personality raised the spirits of his friends and colleagues, he had a fund of humorous anecdotes, enhanced in the telling by a trace of a Viennese accent. He often expressed his indebtedness to England for accepting him as a refugee. Considering his many contributions to the sum of human health and happiness, any debt has been more than repaid.

He leaves Eva, his wife of 51 years, 3 children, 5 grandchildren, 4 great grandchildren and an older sister.

The book is in two parts. The first consists of 16 interviews with eminent female psychiatrists and psychologists, which were almost certainly conducted by email. The questions are standardised, the responses polished and there is no in-depth probing of replies – which as a qualitative researcher I would have found more revealing. The second part of the book is a series of rather brief chapters which provide a helpful template for recognising the barriers and considering how to overcome them. These include putting yourself first, projecting confidence even if you don't feel it, being memorable, persistent and something I've found to be particularly important – networking.

The problems described are all too familiar – I've been subjected to mansplaining, '*a man compelled to explain, especially to a woman, something that she already knows better than him.*' I've held back in conversation, fearful of asking questions. I've been the only woman in a committee room except for the person taking the minutes. Yet, all of these very talented women demonstrate how a combination of real passion for what you are interested in and the ambition to push yourself forwards, even when times are challenging, has resulted in outstanding academic success.

Almost all the interviewees are now at the pinnacle of their careers. Many came from similar professional families and more than a few acknowledge the role played by a supportive partner with the kind of job that made it easier to be both an academic clinician and a mother. There is no one still 'finding their way' that a younger me might have identified with and the majority work in biological psychiatry – the editors' own field – in the USA. I might have found it helpful to read their stories when I was younger, but on the other hand, I might have been more than a little intimidated too.

1.7.84 Mental health law across the UK†

Tony Zigmond

Correspondence

Tony Zigmond (aszigmond@me.com)¹

date

2017-12

Abstract

The criteria governing medical treatment without consent in the three legal jurisdictions of the UK – England and Wales, Scotland and Northern Ireland – is discussed.

Contents

- *Mental health law across the UK†*

'A doctor is not that sinister figure which in former times he was represented to be, anxious simply to confine a man in a dungeon for life. He is treating mental disorder in exactly the same way as he treats any other disease.'

Lord Russell 1928¹

Nearly 20 years ago I wrote an editorial in this journal that there should be a medical incapacity act to 'provide for the medical treatment, both mental and physical, of those who lack capacity from whatever cause. It would establish a statutory framework offering the same protections to all patients who are unable to consent to medical intervention, from both physical and psychiatric conditions, and permit investigation and treatment of both the physical and mental

illnesses of such patients'.² Szmuckler & Holloway have not just argued for a single piece of legislation for all nonconsensual care and treatment saying that a mental health act is harmful,³ they have written a draft act under the heading of 'Fusion Law'.⁴ We may soon know whether we were right.

There are three distinct legal jurisdictions within the UK: England and Wales, Northern Ireland and Scotland. Until recently all had a mental health act to regulate the care and treatment of people with a mental illness while relying on common law to do the same for the physically ill. The powers given to doctors and other healthcare professionals by the two regimes was very different.

Within a year or two either side of the turn of this century, all the jurisdictions started to review their relevant legislation, not only their mental health law but also the necessity for replacing common law with statutory provision for the non-consensual treatment of physical illness, not least to ensure compliance with the European Convention on Human Rights as required by the Human Rights Act 1998. Scotland passed its Adults with Incapacity (Scotland) Act 2000, England and Wales its Mental Capacity Act 2005, Northern Ireland its Mental Capacity Act (Northern Ireland) 2016. For their mental health acts, each started with a review: Richardson for England and Wales published in 1999,⁵ Millan for Scotland in 2001⁶ and Bamford for Northern Ireland in 2007.⁷ Each considered whether or not their mental health act should include a 'capacity' criterion for medical treatment without consent.

The courts have been consistent about the role of capacity when adults make a decision about medical treatment. Lord Reid in 1972 said: "There is no doubt that a person of full age and capacity cannot be ordered to undergo a blood test against his will. ... the real reason is that English law goes to great lengths to protect a person of full age and capacity from interference with his personal liberty. We have too often seen freedom disappear in other countries not only by coups d'état but by gradual erosion: and often it is the first step that counts. So it would be unwise to make even minor concessions".⁸ Lord Donaldson, then Master of the Rolls, in 1992 said: "Prima facie every adult has the right and capacity to decide whether or not he will accept medical treatment, even if a refusal may risk permanent injury to his health or even lead to premature death".⁹ Ten years later Dame Butler-Sloss said the same: "A competent patient has an absolute right to refuse to consent to medical treatment for any reason, rational or irrational, or for no reason at all, even when that decision may lead to his or her death".¹⁰ They all emphasised the importance of autonomy. Although common law has now been replaced by statute law, the provisions of capacity legislation fully reflect these sentiments. I note that all the Judges were, of course, incorrect. A competent person with a mental illness may have no right to refuse treatment.

To return to the reviews. The first principle of Recommendation 3.3 in the Millan report is 'Non discrimination – People with mental disorder should whenever possible retain the same rights and entitlements as those with other health needs' (p. 23).⁶ So, should capacity be a criterion as it is for those with other health needs? The report sets out the arguments against the capacity criterion including that there were difficulties assessing capacity, particularly in patients with mood disorders, obsessive-compulsive disorders and eating disorders; 'Such patients might retain legal capacity but be at such risk as to justify intervention' (p.55).⁶ The committee was also told by some psychiatrists that "incapacity was a concept which they would find difficult to measure and apply. The British Medical Association (BMA) suggested that a capacity test would make it harder for GPs and doctors in, for example, Accident and Emergency Departments to come to a decision, and might lead to a reluctance to use the Act. The United Kingdom Central Council for Nursing, Midwifery and Health Visiting (UKCC), while in favour of making the justification for non-consensual interventions more explicit, suggested that professionals were not equipped to apply sophisticated tests of capacity fairly' (p.55).⁶ These comments about difficulties assessing capacity are noteworthy because no individual or organisation said they could not operate or abide by the provisions of that country's incapacity act which, of course, requires assessment of capacity.

The Millan committee advised "that it should not be possible for a compulsory intervention to be made under mental health law unless there is evidence that the person's judgement is significantly impaired, as a result of mental disorder, so as to justify the intervention. This expresses a broadly similar concept to incapacity, but is felt to be a less legalistic formulation, and one which may be easier to apply in practice' (p. 57).⁶ Significantly impaired decision-making as a result of the mental disorder (SIDMA) is a criterion for compulsion in the Mental Health (Care and Treatment) (Scotland) Act 2005. Millan had asked the question as to whether a mental health act was necessary and decided it was. Richardson also considered the question of capacity. Similar to Millan, 'The principles governing mental health care should be the same as those which govern physical health' (p. 21)⁵ wherever possible. Although deciding that incapacity should not be a criterion because 'Mental disorder unlike most physical health problems may occasionally

have wider consequences for the individual's family and carer, and very occasionally for unconnected members of the public' (p. 19),⁵ the report suggested a form of words which would require the assessment of, and taking into account, the patient's capacity. Patients with capacity could only be detained if they presented a higher degree of risk compared with patients who lacked capacity. The government rejected this proposal. That a distinct mental health act was required was not questioned. There is no 'capacity' or 'SIDMA' criterion, nor a distinction between patients who retain capacity and those who do not, in the Mental Health Act 1983 (amended in 2007). To have such a criterion would have meant, according to Lord Hunt during the debate on the 2007 Bill, 'abandoning one of the most fundamental objectives of the Act, namely that compulsory intervention should be based on need and risk'.¹¹ To spell it out, in England and Wales a person can be forced to accept treatment for their mental illness if there is a health risk to themselves or others despite retaining full decision-making capacity. The equivalent law for physical illness, the Mental Capacity Act 2005, only applies if the person cannot consent because they lack capacity to do so. Patients with capacity who refuse consent cannot be forced to accept treatment no matter what the risks.

Northern Ireland has taken rather longer to determine their way forward. The outcome of the Bamford review and the provisions of their new act are detailed by Lynch *et al.*¹² There is to be no mental health act. The Mental Capacity Act (Northern Ireland) 2016 gives exactly the same legal framework for the non-consensual medical treatment of all citizens no matter what their illness.

Parity of esteem, a flagship policy of the Royal College of Psychiatrists, is best described, according to the College, as: 'Valuing mental health equally with physical health' (p. 3).¹³ The College has described a range of equalities which need to be achieved although, perhaps surprisingly, there is no mention of equality under the law. Northern Ireland now has equality under the law. The day after the judgment in the case of Ms B,¹⁰ *The Independent* newspaper wrote 'Never again may a clinician administer treatment against the will of a mentally competent patient'.¹⁴ In Northern Ireland that will soon be true.

Earl Howe, in his closing statement during the passage of the Mental Health Bill 2007 (England and Wales), quoted the Millan committee, 'It should not be the function of mental health law to impose treatment on those who are clearly able to make decisions for themselves' and then continued, 'As it is we are, in a real sense, back in the world of Enoch Powell and 1959. Patient empowerment and respect for the wishes of the patient are acknowledged features of good clinical practice in all other areas of healthcare – but not, it seems, in mental health'.¹⁵ The Mental Health (Northern Ireland) Act 2016 gives psychiatrists the same legal powers as all other doctors, and psychiatric patients the same autonomy and respect as all other patients. Where Northern Ireland has led surely other UK jurisdictions, and countries across the world, will follow.

1.7.85 Newspaper depictions of mental and physical health

to evaluate the impact on mental health reporting over time. We repeated a survey we did 15 years ago using the same methods. Nine UK daily newspapers were surveyed over a 4-week period and coded with a schema to analyse the reporting of mental health compared with physical health.

Results In total, 963 articles – 200 on mental health and 763 on physical health – were identified. Over half of the articles on mental health were negative in tone: 18.5% indicated an association with violence compared with 0.3% of articles on physical health. However, there were more quotes from patients with mental disorders than physical disorders (22.5% v. 19.7%) and an equal mention of treatment and rehabilitation.

Clinical implications Mental health in print media remains tainted by themes of violence, however some improvement in reporting in recent years is evident, in particular by providing a voice for people with mental illness.

Newspapers and other forms of mass media are influential in transmitting key information and ideas, including social commentary.^{1,2} Consequently, their role in reporting on mental illness is seen as one of the main conduits through which the public, especially those without personal exposure to mental illness, learn and come into contact with issues surrounding mental health.^{3,4}

For many years it has been recognised that media reporting of mental illness is heavily biased in representing a misleading link between mental illness and violence, with preferential reporting for sensationalist stories depicting individuals with mental disorders as being aggressive, dangerous and unpredictable.^{1,4-7} Such widespread negative portrayals have reinforced the continued stigmatisation and lack of acceptance among those with psychiatric diagnoses, possibly increasing social distance and contributing to morbidity and distress. Of particular concern is the potential ‘internalisation’ of prejudices portrayed by the media, such that people with mental illnesses also begin to take on the view that they are dangerous and unstable.⁸ Furthermore, there is a corresponding lack of voice for people of mental illness,^{6,8} with few personal accounts of their burden of disease and similarly little representation from qualified healthcare professionals.^{6,9} All of this contributes to creating a stereotyped, isolated group without social status and acceptance.¹⁰

In a similar vein, there is a disappointing lack of coverage of stories on recovery and rehabilitation following mental illness.^{5,6} This potentially leads both the public and policy makers to erroneously believe that recovery is rare. We highlighted this in a newspaper survey 15 years ago in which we found that the reporting of mental illness and people with mental illness tended to be negative, whereas that of physical illness was much more likely to be positive in tone.¹¹ This may even influence health resource allocations to conditions that have a higher perceived chance of cure.⁴

As far back as the 1960s, Nunally noted that mental health representations in media were few and distorted, limited to ‘neurotic behaviour’ in evening dramas where ‘the afflicted person often enters the scene staring glassy-eyed, with his mouth widely agape, mumbling incoherent phrases or laughing uncontrollably’.¹² Steadman & Coccozza¹³ also showed

that media depictions are often skewed towards extremes. Their findings on public perception of the ‘criminally insane’ (mentally disordered offenders) are salient, with 61% of the public surveyed responding that they feared former mentally disordered offenders ‘a lot’.¹³ However, as the authors noted, the mentally disordered offenders named by the public following intensive coverage tend not to have any legal claim to be ‘criminally insane’, and are merely assumed to be as such by the media.

Although those with mental illness are reportedly 2–6 times more likely to commit violence than matched controls,^{5,14} the National Confidential Inquiry into Suicide and Homicide by People with Mental Illness¹⁵ found that only 5% of the homicides carried out in the general population between 2001 and 2011 were by those with an abnormal mental state ($n = 52$). However, an additional 14% had been in contact with mental health services in the preceding 12 months. Therefore, the vast majority of perpetrators of homicide do not have a mental illness at the time of the offence ($n = 951$). Contrast this with the statistics for suicide in the same report: 30% of all completed suicides in the 10-year period analysed were by patients already known to mental health services ($n = 2678$). The figures identified are 14 times higher than for homicide. From this, it is reasonable to infer that an individual with a mental health disorder is far more likely to self-harm than harm others. This important point is also often missing from media reports seeking to capitalise on the sensationalist angle and, by doing so, dehumanise the patient to the extent that they are defined by their illness. Similarly, it is clear that people with mental illness are much more likely to be ‘victims’ of crime than perpetrators.^{16,17} This discrepancy in public perception between perpetrator and victim among those with mental illness has also been highlighted in other studies,^{18,19} acknowledging the need to shift attention away from the perceived threat to the public, to providing support and protection for the truly vulnerable. In this regard, the media has been counterproductive in reinforcing misleading stereotypes about public safety while simultaneously underreporting key statistics on mental health.

Although viral campaigns such as Rethink Mental Illness’ ‘Find Mike’²⁰ have been highly successful in bringing mental illness to some public attention, it is difficult to assess their impact. Based on our previous survey,¹¹ we hypothesised that: mental health reporting would still be consistently more negative in tone compared with reporting of physical health issues, and patients would be consistently underrepresented in media depictions compared with physical health reports. Additionally, regarding the link with violence and criminality, we further hypothesised that the association between mental illness and violence would continue to pervade mental health reporting.

Method

The method followed that of Lawrie.¹¹ Nine weekday UK daily newspapers (Scottish editions) were surveyed over a period of 4 weeks between 4 March and 4 April 2014. The papers chosen represent a selection of popular broadsheet (*The Times*, *The Telegraph*, *The Independent*, *The Guardian*, *The Scotsman*, *The Herald*) and tabloid (*Daily Mail*, *The Sun*, *Daily Record*) publications in the UK, with a reported range in circulation of between 64 279 (*The Independent*) and 2 048 977 (*The Sun*) in February 2014.²¹ Only national newspapers were included in this analysis, as they have the widest distribution.

Print copies of the newspapers were obtained from the Reference Library of Edinburgh on the day of publication and manually screened for headlines relating to mental health or psychiatry and general health issues. Two tabloids, *The Sun* and *Daily Record*, were purchased each day, as they were not subscribed to by library services, yet have the highest circulation figures in the UK.

Articles relating to mental health and physical health were identified initially through headline screening. The main body of text was then read and coded as positive, negative or neutral, if the article was mainly stating facts or had mixed elements. As such, it is possible to have a disparity between tone of headline and article. Each article was then analysed and coded to a schema with eight variables, which noted key themes (*Table 1*).

Coding schema for newspaper articles

Variable	Description
Quote from patient, relative or charity	Direct or paraphrased quote from a patient with the illness in question, relative or advocacy organisation
Quote from professional	Quote from a healthcare professional in charge of the patient's care or spokesperson for government organisations, etc.
Association with violence	Any article where a person portrayed as having a mental illness or under the influence of drugs/alcohol engages in criminal or dangerous activity where others are put at risk or harmed. Suicide or self-harm is not included in this category
Mention of treatment/rehabilitation	Either specific (e.g. Prozac), general (anti-depressants, cognitive-behavioural therapy), alternative (mindfulness, yoga) or relating to the Mental Health Act 1983 where treatment is noted under a compulsory treatment order
Substance misuse	Articles relating to addiction, overdose or psychiatric effects of substance misuse were classified as relating to mental health. Physical effects of drug usage, including side-effects, were classified under physical health
System failure/negligence	Any article where substandard care is delivered by a single person or on an organisational level, resulting in adverse outcomes. Shortcomings range from IT failures and changes in social policy to deliberate mistreatment
Innovations in research	Articles where a new diagnostic method, treatment or better understanding of a named disease is reached
Medical advocacy/raising awareness	Where the primary purpose of the article is to transmit information about a particular disease profile or set of symptoms or charity efforts. For example Autism Awareness Week, United Nations World Down Syndrome Day, 'Check 'Em Tuesday' – a campaign run by <i>The Sun</i> to increase uptake of self-screening for breast cancer

Inclusion and exclusion criteria

The sports and business sections were surveyed, however property and automobile inserts were excluded due to likely lack of relevance. Primary newspaper articles, editorials and opinion pieces were included in the data collection. Advertisements, letters to the editor, film and entertainment reviews and obituaries were omitted. Articles with only a passing or chance reference to mental or physical health were also omitted.

All articles concerning mental disorders recognised by the DSM-5,²² psychiatry or psychiatrists were included, as well as generic, undefined mental conditions with the exception of paedophilia and the paraphilias, as their classification as a mental illness in DSM-5 is controversial. For physical health, all articles relating to other general medical issues were collected. Articles concerning the National Health Service (NHS) or other organisational bodies were included only if there was a demonstrable mention of impact on patient health and safety.

Results

In total, 963 health-related articles were collected during the 4-week period. Of these, 763 (79.2%) concerned physical health, whereas 200 (20.8%) were about mental health. Although there was a slight preponderance towards neutral pieces (38.0%) in the physical health category, compared with positive (28.6%) and negative (32.9%) reporting, the majority of articles concerning mental health were negative in tone (50.5%), with only a small number of positive (22.0%) or neutral articles (27.5%) (*Box 1*). This striking disparity between mental and physical health reporting underscores a key finding that mental health reporting remains consistently more negative than physical health, which is in line with the results from Lawrie's¹¹ study over a decade previously (ratio of positive to negative articles for physical health: 218/251; and for mental health: 44/101; odds ratio (OR) 1.99, 95% confidence interval (CI) 1.34–2.97). In addition, we found a prominent and stigmatising association between mental illness and violence as 18.5% of mental health articles featured violence as a major theme, compared with 0.3% of physical health articles (OR = 86.37, 95% CI 20.60–362.1) (*Table 2*).

Comparison of variables between physical and mental health reporting

Variable	Physical health, <i>n</i> (%)	Mental health, <i>n</i> (%)
Total number of articles	763	200
Positive	218 (28.6)	44 (22.0)
Negative	251 (32.9)	101 (50.5)
Neutral	290 (38.0)	55 (27.5)
Quote from patient/charity	150 (19.7)	45 (22.5)
Quote from professional	285 (37.4)	58 (29.0)
Association with violence	2 (0.3)	37 (18.5)
Mention of treatment/rehabilitation	217 (28.4)	48 (24.0)
Substance misuse	31 (4.1)	22 (11.0)
Medical advocacy/raising awareness	131 (17.2)	26 (13.0)
System failure/negligence	118 (15.5)	25 (12.5)
Innovations in research	184 (24.1)	22 (11.0)

Although previous studies have shown that patients with mental illness are underrepresented in newspaper articles,^{6,8} we found this not to be the case, with a higher proportion of quotes from patients with mental illness, their relatives or mental health charities (22.5%) compared with physical health (19.7%) (ratio of quotes in physical health: 150/613; mental health: 45/155; OR=0.84, 95% CI 0.58–1.23). There appears to be comparatively fewer quotes from professionals in relation to mental health however, highlighting the need of the psychiatric profession to make a conscious effort to engage with the media, and vice versa.²³ Interestingly, whereas previous studies have highlighted a lack of reporting on treatment and rehabilitation for mental health,^{4–6} here we found the rates to be comparable to that of physical health articles (24.0% v. 28.4% respectively) and previous reports.⁶

Box 1 Examples of positive, negative and neutral headlines for mental and physical health

Physical health

Positive

‘US Aids baby may be cured’

‘Cholesterol drugs may slow MS, study shows’

Negative

‘Three-year old died after hospital delay’

‘“Sickness culture” claim as 1 in 3 has long-term illness’

Neutral

‘Statins have no side-effects, study finds’

‘Smoking link to breast cancer in older women’

Mental health

Positive

‘Depression and self-harming are taboo ... that’s why I’m determined to speak out’

‘Ketamine trial provides fresh hope for long-term depressed’

Negative

‘Mentally ill man in bus knife attack’

‘School accused of excluding girl with anorexia to avoid copycats’

Neutral

‘Give dementia patients trial drugs en masse’

‘Depression must be seen as a societal disorder’

The disorders most commonly associated with violence were personality disorders as well as undefined ‘mental illnesses’ and post-traumatic stress disorder, which make up 13.5% of all articles pertaining to mental health. Surprisingly, sensationalist stories about schizophrenia were minimal and comparable to reporting on other mental disorders, whereas dementia and eating disorders were least likely to be reported as associated with violence (*Table 3*).

A breakdown of newspaper articles according to diagnosis and association with violence

Diagnosis	Articles <i>n</i> (%)	Association with violence, <i>n</i> (%)
Suicide	31 (15.5)	0
Mood disorder	26 (13)	2 (1.0)
Dementia	32 (16)	0
Eating disorder	12 (6)	0
Developmental disorder	17 (8.5)	3 (1.5)
Substance misuse	13 (6.5)	2 (1.0)
Personality disorder	11 (5.5)	14 (7.0)
Schizophrenia/psychosis	10 (5)	3 (1.5)
Other ^a	49 (24.5)	13 (6.5)

Includes multiple disorders, undefined and post-traumatic stress disorder.

Based on the previous data that show people with mental illnesses are more likely to be victims of crime rather than perpetrators, we were interested to see whether this correlated with media reports. We found that people with mental illness are twice as likely to be portrayed as a perpetrator (34/200) compared with a victim (17/200), in direct contrast to the available data.^{16,18,19,24}

Given that 18.5% of articles on mental health concern violent acts and are seen as a threat to the public, we asked what made up the rest of the negative reporting. On further analysis, it appears that a significant proportion of the negative articles pertain to the stigmatisation and abuse of people with mental health within society, as well as lack of funding and adequate care provision. Examples include headlines such as: ‘The great mental health betrayal’ (*The Independent*, 13 March 2014), an article about the unlawful detaining of people with mental health illnesses in care homes and hospitals, and ‘Mental health and race – the blight of dual discrimination’ (*The Guardian*, 26 March 2014), which highlights the additional burden of being an ethnic minority with mental illness. The remainder of the negative articles are reports on suicide (15.5%).

Overall, there was no significant difference between mental health reporting in broadsheets compared with tabloids.

Discussion

We found that mental health reporting makes up a fifth of all articles concerning health in a selection of UK print media over the course of a month. This is lower than found in a similar study by Pieters *et al*²⁵ in Belgium but comparable to the figures obtained by Lawrie in the UK¹¹ over a decade ago, reflecting little change in the frequency of reporting on mental health. Half of all articles on mental health are negative in tone, which is a much greater proportion than for physical health, but nonetheless represents a small reduction compared with Lawrie's study. On the other hand, the association with violence remains prominent, with 18.5% of articles carrying a theme of danger or criminality.

In the intervening 15 years, several campaigns by mental health charities both in the UK and abroad have sought to lessen the stigma attached to mental illness and encourage open dialogue about mental health. Media coverage is important to the success of such campaigns in influencing public opinion and increasing exposure. In light of this, we asked whether there is any evidence that media reporting on mental illness is improving (see below). Although previous studies have commented on the lack of voice for people with mental illness, we have found this not to be the case with a higher proportion of quotes from patients with mental illnesses compared with physical health. Although there are fewer representations of healthcare professionals in psychiatry, this may reflect reluctance among the profession as a whole to engage with the media, as psychiatrists too are affected by stigma.^{26,27}

Mental illness and violence

The link between mental illness and violence is unfortunately still pervasively reported – being part of about a fifth of all articles on mental health. The figure obtained in this study (18.5%) is lower than previous reports of association with violence.⁶ However, other studies have utilised more restricted search criteria, only using specific keywords such as 'schizo', 'mental', 'deranged' and 'psycho', which does not encompass the whole spectrum of mental illnesses.^{5,6,28,29} As most studies also used a computerised database programme (such as the LexisNexis) to generate articles, limiting the search criteria to only the above keywords will bias the results to find articles on schizophrenia or those that include derogatory terms such as 'psycho' or 'deranged', which are inherently stigmatic and more likely to be associated with violence.²⁹ In contrast, mental illnesses not usually considered violent, such as eating and mood disorders, would be excluded from the analysis.

In our study we found that schizophrenia and psychotic disorders make up a minority (5%) of reporting on mental illness and only 1.5% of these articles featured violence. Although there is little contention that mental disorders are disproportionately associated with violence in the media, one possible explanation for the strength of the association between the two is that it is an artefact created by selective searching among newspaper databases. We suggest the effect would be diluted if all articles on psychiatry, including conditions such as mood and anxiety disorders, were incorporated in the analysis.^{30,31}

In this study, we also found that people with mental disorders are twice as likely to be portrayed as a perpetrator of crime compared with a victim. This is another illustration of how the media can be misleading on key facts. Education for journalists and guidance on the reporting of mental health issues is central to bringing about a change in reporting trends. However, this may be easier said than done. One study attempted to correct journalists' erroneous views about mental illness with a short presentation on schizophrenia prior to a press conference regarding a high-profile assault carried out by a man with a serious mental illness. Although they found that journalists had a good recall for the details several weeks later, the presentation did not ultimately affect the writing of the article.³² This suggests that collaborations with the media will have a greater chance of success and change in reporting if they are mutually beneficial and desired. One example of this is UK mental health charity, Mind, which has set up a series of media awards for responsible and ethical reporting of mental health issues (www.mind.org.uk/news-campaigns/mind-media-awards), as well as reporting guidelines for different conditions.^{33,34}

Strengths and limitations

The main strength of the study is that all papers were hand-searched according to the criteria set out in the Method. This abolishes the need to search based on keywords, potentially increasing the yield of articles. Similarly, the scope and definition of 'mental illness' is wider than in previous studies, allowing for a greater overview of the subject in media. In the current study, the use of one investigator to locate and rate the articles, is both a potential advantage – in reducing interrater variability – but also a disadvantage in that no interrater reliability could be established (although we did discuss and resolve any uncertainties between the authors). The main limitation is that the coding schema used is a relatively blunt tool and cannot convey the complexity or depth of a newspaper story. Second, the categorisation of articles into mental and physical health does not allow for overlap in coverage, although that only occurred in a small minority of articles. Furthermore, the short time frame of the study means it can only provide a snapshot of mental health reporting in the UK. Last, there were two mental health stories that garnered a considerable amount of media attention in this time period and subsequently have the ability to bias the data. One was the suicide of a famous fashion designer and another, the death of a woman who had murdered her three children and was subsequently labelled as having a personality disorder. Both stories were extensively reported on over multiple days. However, they were included in the analysis as this study was designed to encompass all the news on mental health over 4 consecutive weeks, rather than the sampling of random time points, and different reports had different foci as new information about the cases came to light.

Conclusions

Despite several prominent government-led and charity campaigns, mental illness and individuals with mental illness continue to experience stigmatisation and stereotyping. Although it is encouraging that people with mental disorders are being increasingly represented in print media, and there appears to be an overall increase in non-stigmatising articles,³⁵ much remains to be done to address the inaccurate and stigmatising association with violence, and raise the profile of mental illness as a whole.

The particular reasons for the ongoing negative headlines about mental illness, and what could or should be done about them, are beyond the scope of this study. Our results do however indicate that there is a clear need for more reporting about mental health in general, and for more accurate reporting about violence and for more accounts of innovative research developments in particular. We therefore suggest that there is much to be gained from further ongoing engagement between patients and psychiatrists and the media, with an emphasis on realistic depictions of the lives patients lead and of recent research advances.

Many thanks to the staff at the Reference Library of Edinburgh for meticulously collating the newspapers used each day.

1.7.86 Implementation of a novel primary care pathway for patients with severe and enduring mental illness

Abstract

Aims and method New collaborative care models with an emphasis on primary care are required for long-term management of patients with severe and enduring mental illness (SMI). We conducted a descriptive evaluation of clinical outcomes of the first 3 years of a novel enhanced primary care (EPC) service. Data from 2818 patients and staff survey results were analysed.

Results 2310 patients were discharged to EPC (508 not assessed as clinically suitable or patients/general practitioners declined the transfer); mean length of stay with secondary care service of the cohort was 9.8 years (range 0–24). 717 patients (31%) have been discharged to primary care only out of the EPC services and 233 patients (10%) have been transferred back to secondary care. Patient and staff satisfaction with the new EPC model was high. No severe untoward incidents were recorded.

Clinical implications The data suggest that EPC can be safely provided for a significant proportion of patients with SMI, who traditionally received long-term secondary care support. The novel EPC model can be utilised as a template for the provision of cost-effective, recovery-oriented and non-stigmatising care in the community.

* *Limitations and outlook*

Mental healthcare for the majority of patients with severe and enduring mental illness (SMI) was historically provided predominantly by specialist secondary care services in the UK. Hereby, most patients with long-term chronic conditions received open-ended health and social care support and relatively few were discharged back to primary care for ongoing case management. More recently, patients with SMI are increasingly considered for clinical management by less specialised, generic primary healthcare services and in collaborative care models.¹⁻³ Most of these schemes have not been robustly evaluated through clinical and controlled trials. There is however good evidence to suggest that collaborative chronic care models foster patient self-management and can improve mental and physical outcomes for patients with mental health problems.³

In England, the introduction of clinical commissioning groups (CCGs) in 2013⁴ and the significant public spending savings plan with annual targets for all National Health Service (NHS) provider organisations⁵ resulted in a nationwide review of mental healthcare provisions and piloting of novel care pathways. Secondary mental healthcare providers have started to reduce the number of cases held by specialist community mental health teams, including assertive outreach and community rehabilitation teams. The NHS policy paper *No Health Without Mental Health*⁶ emphasised the need for integration of care for physical and mental health needs; provider and commissioner organisations therefore started to engage in various local service redesign projects. In East London, enhanced primary care (EPC) services for patients with SMI were developed and implemented in 2012, following a whole system review which attempted to address the issue of plateauing resources. The overall aim of the EPC service is to foster recovery of patients with SMI, to safely discharge them to primary care settings that attend to their mental healthcare needs. Three years after its launch, clinical outcomes of the novel care pathway for patients with SMI, patient/staff satisfaction were evaluated and are reported in this paper.

Method

Data collection and analysis

This evaluation is based on a retrospective data analysis of routinely collected data on all the patients referred to and/or fully discharged from secondary care to the EPC service since its inception (reporting period from 1 August 2012 to 31 July 2015). Electronic clinical data-sets included: total number of identified/discharged patients; number of patients who refused to be transferred to the new service and where either general practitioners (GPs) or consultant psychiatrists assessed patients as not suitable; diagnoses and ICD-10⁷ codes, gender, ethnicity, duration of service provided by secondary care, number of admissions to hospital; number of patients re-referred to secondary care or readmitted/relapsed analysis of main characteristics of this subgroup of patients.

In addition we conducted an analysis of available information collected regarding staff satisfaction (semi-structured interviews and questionnaires) and summarised data from a patient satisfaction survey (Client's Assessment of Treatment Scale⁸) for the new service from one of the three localities (Newham).

Description of the new EPC service

The model was developed in partnership between East London NHS Foundation Trust and the three East London CCGs (Newham, City & Hackney, Tower Hamlets) across primary/secondary care teams by interdisciplinary working groups; those involved were people participation leads, GPs, consultant psychiatrists, senior community psychiatry nurses, psychologists and social work leads. The initial target was defined as 300 patients per year per locality. The EPC care pathway allows providing mental healthcare flexibly according to patients' needs and to step up (secondary mental health services) or step down (generic primary care) in a seamless way without administrative hurdles.

EPC care pathway elements

Elements of the EPC care pathway were as follows: Regular GP reviews (in addition to quality and outcome requirements), the development of a recovery care plan, practice nurse administration of depot medication, and specific assessment of risk factors for physical illness, signposting into healthy lifestyle services. Enhanced support to primary care from consultant psychiatrists with regular practice-based mental health multidisciplinary review meetings. Training and education to GPs on managing SMI in primary care, and for practice nurses on psychopharmacology and therapeutic depot administration. EPC mental health teams consisting of registered mental nurses, employed by East London NHS Foundation Trust but working within general practice, to support discharge into the EPC and provide recovery-oriented support to patients on an ongoing basis.

The philosophy of the service operationally distinguishes clearly between: specialist acute and rehabilitation treatment for patients with severe or complex needs and/or those identified as presenting with significant risks to self or others associated with their illness (continued to be provided by secondary care services); and long-term condition management aiming to provide monitoring and maintenance support for patients with stable chronic SMI (provided by the new EPC teams). Inclusion criteria for the EPC transfer were defined as follows: Aged 18 years or older, resident in one of the three East London boroughs and currently under the care of secondary care services. Established diagnosis of an SMI that would warrant their inclusion on the practice severe and enduring mental illness (SEMI) register. Identified care needs above those that would ordinarily be provided for under normal primary care, either medical or social needs, that require additional support. Patient agrees to the support offered via the EPC clinic. Sustained clinical progress with less frequent support from secondary care and no identified need for specialist interventions and treatments. Last acute psychiatric hospital admission more than 12 months ago, no current risks to self or others identified; patient is well-established on a medication regime and requires minimal assistance with concordance, but does require regular monitoring and review. Patient has settled accommodation, is able to meet their own basic living needs. Patients requiring lithium prescribing or depot injections in primary care are included.

Teaching, training and supervision

Primary care liaison nurses (PCLNs) of the EPC teams were recruited from secondary care services and all had experience in providing mental healthcare to patients with SMI. A list of essential competencies, skills and experiences were identified as significant requirements for the recruitment of the EPC workforce and included the following areas: history taking/mental state examination, engagement skills and basic knowledge of principles pertaining to a positive therapeutic relationship, risk assessment and management, recovery care and social psychiatry, and psychiatric emergencies. Additional training was offered to PCLNs.

The provision of the EPC service is supported through weekly team meetings, monthly supervision sessions, and six monthly appraisal/reviews, aiming to maintain and update knowledge and skills.

The three localities agreed on mandatory training requirements for primary care staff as part of the EPC contract with their primary care practices and the EPC team provided training for staff in GP practices including mental health awareness training for practice reception staff and depot training for nurses.

Subsequently, in 2015 a website with a wide range of teaching and self-learning materials for all primary care staff was developed with funding from Health Education England North Central and East London, launched into public domain in 2016 (<http://primary-mentalhealth-care.elft.nhs.uk>).

Service aims and expected outcomes

- To support patients to achieve their recovery goals through a process of joint planning that places patients at the centre.
- To empower people to self-manage their own recovery journey and reach a position where they can reduce their contact with mental health services.
- To mark the recovery journey by recognising achievements while being transferred to receive care in EPC and at the point of discharge from EPC.
- To improve the patient experience and outcomes through enhanced multidisciplinary team working that addresses mental health, physical health and social need as part of an integrated approach.
- To improve patient experience and outcomes through the provision of care in a normalised setting, close to home and to assist the navigation of patients towards resources that supports their recovery.
- To enable the development of capacity, confidence and competence in relation to mental health treatment and care in the primary care workforce.

The service elements were developed accordingly, centred on a 'My Recovery Plan' and associated 'My Safety Plan' documents for time-limited EPC interventions according to recovery goals set by the patient (with a recommended duration of up to a year after which the patient is supposed to be discharged into generic primary care services). The time-limited nature of the service was to be made clear to the patients at the outset and the service provides a fast-track option back to secondary care services if needs change.

Team composition

The service is predominantly delivered by psychiatric PCLNs. The three localities agreed on different staffing compositions according to local variations of service needs and/or perceived requirements in respect of multidisciplinary inputs from health professionals.

In Newham, psychiatrist input is provided by one consultant with protected time in the job plan and by catchment area consultants as required based on a sectorised/practice-aligned service model; in Tower Hamlets consultants with a primary base in general practice deliver psychiatric expertise; and in City & Hackney a model with a dedicated EPC service consultant was established.

Following a 12-month review the team of healthcare professionals was complemented by a group of peer support workers, who provide patients with emotional and practical support as they approach discharge from secondary care services. All the peer supporters have personal experience of in-patient and community mental healthcare and support patients flexibly based on their own experiences of recovery. A summary of the current team structures and allocated posts is provided in *Table 1*.

Staffing composition in enhanced primary care (EPC) teams in each locality *a*

Directorate	Total WTE per team	Admin Band 4	Occupational therapist	Clinical psychologist	Nurse Band 6	Nurse Band 7	Consultant	Peer/supervisor Band 3/4	Service manager Band 8a	Team case-load capacity

CH, City & Hackney; NH, Newham; TH, Tower Hamlets; WTE, whole time equivalent.

Original and current from 2016. Phased increase in size of service with new investment following a service review in 2014–2015.

Consisting of each of the four current primary care consultants devoting 2.5 sessions a week to the EPC service and primary care liaison.

Consisting of time dedicated to EPC and primary care liaison by the four assessment and brief treatment consultants providing support to practices and one consultant with 0.1 WTE leading on EPC.

Consisting of a dedicated consultant providing two sessions a week to provide clinical support to the EPC team and the Compass Primary Care Psychology service, and each of the community mental health team consultants providing one session a fortnight to supporting the primary care practices to which they are aligned.

EPC provides an open general advice service to GPs to assist in the treatment of patients that have been discharged from EPC and secondary care. The arrangements vary between the three East London boroughs but all include case-based discussions between GPs and consultant psychiatrists during regular multidisciplinary clinical meetings at primary care level.

Results

Service activity summary

As per 31 July 2015, the three East London EPC teams provided care for 1370 patients. Since August 2012 the services considered in total 2810 patients, of which 480 were not proceeded with because the patients declined transfer ($n = 149$), the GP declined the transfer ($n = 90$) or the secondary care eventually decided the transfer was not clinically appropriate ($n = 241$). Therefore, 2330 patients have received an active service from EPC services since their inception. In total, 717 patients were transferred to primary care only from EPC with variations across teams. The total number of patients discharged from EPC to primary care alone has significantly increased beyond the reporting period of this service evaluation due to changes in operational policy and as a result of the teaching and training efforts to upskill GPs, resulting in increased throughput.

All referral and case-load data with developments to 30 October 2016 are summarised in *Table 2*.

Patient characteristics

The majority of patients referred to EPC had a significant history of SMI with an average (mean) duration of care provided under care programme approach (CPA) standards by secondary care services (community mental health teams) of 9.7 years (range 0–24). The mean age of patients was 45.7 years (range 18–65; 12.1% 18–30 years and 77.3% 30–60 years); 54% of patients were female and 46% were male. Overall, 47.4% were single/living alone, 26.3% were married/civil partner and 11.6% were separated/divorced/widowed/surviving civil partner. Given the high percentage of Black and ethnic minorities living in East London, the distribution of ethnicity across the sample reflects the diversity: Asian or Asian British 24%, Black or Black British/African–Caribbean 19.8%, White British or other White 38.5%, other ethnic groups 17.8%.

The main diagnoses of patients were: schizophreniform or other psychotic disorders (ICD-10 codes F20–29) 37.2%, mood (affective) disorders (F30–39) 32.1%, anxiety/stress-related/somatoform and other non-psychotic mental disorders (F40–48) 11% and disorders of adult personality and behaviour (F60–69) 4.1%.

According to Department of Health guidance⁹ the main cluster codes on transfer to EPC were: cluster 10–13: 48.9% (11: 19.4%; 12: 21.5%; 13: 7.1%); cluster 4–7: 26.1%. The number of patients referred back to secondary care due to clinical issues (relapse concerns) was 237 (City & Hackney $n = 65$, Newham $n = 124$, Tower Hamlets $n = 48$).

Feedback from patients

Both EPC staff reports and results from questionnaire surveys suggest that the vast majority of patients regarded the new service arrangements as both helpful and adequate according to their needs. We conducted a more detailed survey in one of the three localities (Newham), using the structured Client's Assessment of Treatment Scale. Results from 126 patients who completed the survey (mean age 49.2 years, range 26–71; 66 female, 60 male) are indicative of comparatively high levels of patient satisfaction (most scores across the group rated with a mean of 8–9 out of 10) (*Table 3*).

Results from 126 patients who completed the Client's Assessment of Treatment Scale

	Mean	Range	s.d.
Do you believe you are receiving the right treatment/care for you here?	8.8	4–10	1.6
Does your general practitioner understand you and is she/he engaged in your treatment/care?	8.4	1–10	1.9
Does your named nurse understand you and is she/he engaged in your treatment/care?	9.0	2–10	1.5
Are relations with other staff members here pleasant or unpleasant for you?	8.5	0–10	2.0
Do you believe you are receiving the right medication for you?	8.9	0–10	1.7
Do you believe the other elements of treatment/care here are right for you?	9.4	4–10	1.3
Do you feel respected and regarded well here?	9.0	4–10	1.5
Has treatment/care here been helpful for you?	9.0	4–10	1.4

Feedback from GPs

GPs across all three localities engaged very well with the three EPC teams and expressed high levels of satisfaction; they acknowledged that the EPC service improved care for their patients. A brief survey questionnaire distributed to 61 GP surgeries in Newham was returned by 52 GPs. All but two GPs stated that the EPC helped to change their perception of/and relationship with mental health services.

Another GP survey was conducted in Tower Hamlets and revealed the following feedback (first figure 6 months after service implementation based on 61 responses (from 36 surgeries), second figure 1 year later based on 23 responses); this survey indicates that the EPC model contributed to developing GP's skills and knowledge of psychotropic prescribing (Very confident 3.3/13%, Confident 44.3/47.8%, Neutral 33.4/34.8%, Not confident 18.0/4.4%). In addition, satisfaction rates with practice-based multi-disciplinary meetings as well as the network-linked PCLNs was largely positive and increased over time.

We conducted a subgroup analysis of patients from Newham EPC who were re-referred to secondary care from EPC due to a relapse (significant increase in symptoms) of their mental disorder or other reasons; $n = 124$ out of 787, 15.8%.

Relapse due to a range of stressors (iatrogenic, non-adherence, etc.) was $n = 69$; relapse with acute admission to hospital, $n = 8$; and non-engagement and requests to be discharged from GP, $n = 9$. Requests for medication review by secondary services/GP referred back: $n = 26$; social circumstances: $n = 4$; and patient demanding to be referred back to consultant: $n = 3$.

Only for 3 out of 124 re-referred patients with a change in prescribed dose of medication were identified, all others had been on stable medication as per discharge plan from secondary care. The number of EPC face-to-face contacts for this group varied from 0 to 8, most patients had been seen on 1–3 occasions by their PCLN. The diagnostic codes, PCLN clinics and GP surgeries were equally distributed across this group.

Discussion

The data-set considered for this service evaluation comprised of a large sample of over 2000 patients with predominantly chronic severe mental illness (schizophreniform, psychotic or severe affective disorder, care clusters 10–13 and 4–7) and the observation period of 3 years seems adequate to allow for a critical appraisal of performance data. The overall results from this service evaluation suggest that a significant proportion of patients with SMI, who were traditionally seen long term with open-ended care plans in secondary care, can be successfully discharged to enhanced primary mental healthcare services. This is even more so significant given the fact that prior to transfer of care, patients had been receiving specialist mental health services for on average of nearly 10 years. The number of relapses and referrals to secondary care services has been low, even though the overall referral rate to EPC has risen. A significant number of patients who received EPC services are now supported by primary care alone.

The success of this novel care pathway is based on very close collaboration between primary and secondary care health professionals and service characteristics that provide seamless care across boundaries: all PCLNs were employed through secondary mental health services and mostly recruited from existing mental health teams, which enabled them to provide clinical expertise into the new service – quick access to secondary care for crisis management was built into the service structure.

Only about 14% of patients were not taken into EPC clinic care following the initial referral and this is indicative of a carefully conducted and initially conservative selection process, also taking patient preferences into account. Patient feedback was very positive and no severe untoward incidents occurred during the observational period.

Although mental healthcare services for patients with SMI have traditionally been regarded as too specialised for primary care, most patients regard primary care provisions as a significant milestone in their recovery journey.¹⁰ The care pathway development was conducted based on a much clearer distinction between elements focusing on supporting people to maintain stability and monitor symptoms versus elements providing active recovery-oriented treatment. This allowed refocusing of specialist services and deconstructing the 'shifted out-patient clinic' model,¹¹ essentially a replacement model, which does not provide opportunities for enhanced linkage and face-to-face consultations between

the primary care physician and the psychiatrist.¹² By contrast, the consultation-liaison collaboration model provides regular face-to-face contact between the psychiatrist or mental health worker and the GP.¹³

The survey results suggest that the support primary care doctors receive from consultant psychiatrists is a vital part of the scheme. The precise arrangements vary across the three boroughs but each primary care practice has an aligned consultant who visits the surgery regularly, is available for advice especially on potential referrals to secondary care and who assists the surgeries to become more mental health sensitive and informed.

The main difficulties with the new care pathway identified in the context of this service evaluation are related to the wider context of recovery-focused care with an emphasis on integration with mainstream community services, such as employment, training and leisure activities. Depending on pre-existing skill and knowledge base within each of the participating GP surgeries, the quality of mental state monitoring and therapeutic engagement is likely to vary significantly. More emphasis must therefore be given towards developing robust and ongoing teaching and training curricula for primary care practitioners. Another significant challenge is the variation in access to psychological therapy services and social care from locality to locality depending on the level and specification of integrated care pathways. This is a crucially important issue for the success of EPC services, safeguarding against compromising the quality of care.

A further significant increase of the number of people who experience a mental health problem in England has been predicted (i.e. 14.2%, from 8.65 million in 2007 to 9.88 million in 2026) as a result of population growth.¹⁴ More research of innovative and collaborative schemes for high-quality cost-effective mental healthcare is required, assessing the impact of working across primary and secondary care.¹⁵

The promotion of psychological resources and capabilities at a family and community level to support people experiencing mental ill health appears to be a promising complementary strategy for both primary and secondary prevention. Last but not least there seems to be a real case to extend the role of district nurses, to strengthen the role of GP champions in mental healthcare¹⁶ and to involve patients as teachers in interprofessional learning as already pointed out by Lester *et al*¹⁷ in their discussion paper on integrated primary mental healthcare more than 10 years ago.

Limitations and outlook

This is a retrospective analysis of routinely collected data for service evaluation, not a formal research study. Patients were identified by their secondary care clinicians as potentially suitable for transfer to the EPC clinic and there was no control condition. The Client's Assessment of Treatment Scale satisfaction scores and relapse indicator analysis was only available for one of the three localities and only a subgroup of about 25% of patients open to the EPC service completed the survey.

Empirical research is needed to establish detailed patient characteristics as predictors for successful transfer of care. Longer-term and controlled follow-up studies are required to establish care quality and effectiveness issues across various components of the health and social care pathway (e.g. social inclusion, subjective quality of life, psychopathological symptom levels) following discharge from secondary care services, compared with continuing specialist treatment. It will be important to assess differences between inner-city and more rural areas to establish as to whether the claim, that the delivery of mental healthcare in primary settings is 'more accessible, affordable and acceptable for the population'¹⁸ can be substantiated.

1.7.87 National survey of training of psychiatrists on advance directives to refuse treatment in bipolar disorder

Abstract

Aims and method To determine features associated with better perceived quality of training for psychiatrists on advance decision-making in the Mental Capacity Act 2005 (MCA), and whether the quality or amount of training were associated with positive attitudes or use of advance decisions to refuse treatment (ADRTs) by psychiatrists in people with bipolar disorder. An anonymised national survey of 650 trainee and consultant psychiatrists in England and Wales was performed.

Results Good or better quality of training was associated with use of case summaries, role-play, ADRTs, assessment of mental capacity and its fluctuation. Good or better quality and two or more sessions of MCA training were associated with more positive attitudes and reported use of ADRTs, although many psychiatrists would never discuss them clinically with people with bipolar disorder.

Clinical implications Consistent delivery of better-quality training is required for all psychiatrists to increase use of ADRTs in people with bipolar disorder.

The Mental Capacity Act 2005 (MCA) in England and Wales provides a legal framework for personal welfare and financial decisions to be made in advance by individuals, who later due to an impairment or disturbance of functioning in the mind or brain, may be unable to make these decisions for themselves. If capacity is not present, a decision can be made on behalf of the person based on what is in their best interests taking consideration of their wishes using three specific provisions of the MCA for advance decision-making: advance decision to refuse treatment (ADRT), a legally binding provision preventing specific treatment; advance statement of wishes and feelings, a non-legally binding statement of preferences for treatment, and/or personal and financial affairs; lasting power of attorney, a legally binding direction identifying who will look after the person's personal and financial affairs. Clinicians and their employers, especially psychiatrists, are legally required to 'have regard to' MCA guidance and, if later asked, prove that they did.

¹ Therefore there is an expectation that psychiatrists receive training in the MCA. However, the methods and amount of training that psychiatrists should receive are not specified, nor has the quality or amount of training been related to attitudes or use of ADRTs in practice. We chose to examine the attitudes to and use of ADRTs by psychiatrists as these may be seen as restrictive in terms of treatment offered by psychiatrists to people with bipolar disorder. In a national survey of general adult and old age psychiatrists in England and Wales, we wished to explore how the quality and amount of training they have received may be associated with their implementation of ADRTs in people where capacity is lost (e.g. mania, severe depression) and regained (e.g. bipolar disorder) to complement a survey of patient experience in bipolar disorder. ²

Method

Objectives and design

Our objectives were: to determine what aspects of training in the MCA were associated with higher or lower perceived quality of training in the view of psychiatrists; and to examine whether the quality and amount of training were associated with reported attitudes or use of ADRT in people with bipolar disorder. We anticipated that high-quality training may be required to overcome professional resistance to the use of ADRTs should any be present.

Participants

Inclusion/exclusion criteria were: participants practice within England and Wales, i.e. the jurisdiction of the MCA specialise in either general adult or old age psychiatry they were consultant psychiatrists or in training grades (CT1-CT3, ST4-ST6).

Procedure

We aimed to recruit a national sample of 500 psychiatrists in a 12-month period for the survey. No data were available for a formal power calculation. The study was advertised with the help of the National Institute of Health Research-funded Mental Health Research Network (MHRN) and the Royal College of Psychiatrists. The College agreed to publicise the study by tweeting the link to the survey and the study team also attended a national conference organised by the College to publicise the study. Consultants, senior and junior trainees in general adult and old age psychiatry were selected from different regions to ensure maximum variance of practical clinical experience. To maximise the participation rate of psychiatrists and the frankness of their responses, we anonymised the survey, not asking for personal information such as age, gender or workplace, and placed it online or if they preferred we administered it face to face, by telephone or posted it.

Measures

The survey was divided into nine sections that addressed the following topics: Section A: Preliminary information – position, years since qualification, place of work (e.g. in-patient, crisis team), geographic location. Section B: MCA training – how many sessions attended, whether mandatory, how recent, whether training considered advance decision-making that included ADRTs, nature of training, quality of training (e.g. in your opinion how much of the training focused on advance decision-making (including ADRTs) – a significant amount, a reasonable amount, a minimal amount, none?). Section C: ADRTs and bipolar disorder – whether psychiatrists had experience of patients making ADRTs, whether they had advised on making ADRTs, content of ADRTs, factors influencing their decision to advise regarding ADRTs. Section D: ADRTs and other conditions – content of ADRTs. Section E: ADRTs and the Mental Health Act 1983 – whether psychiatrists had encountered ADRTs in context of patients admitted to psychiatric units or sectioned under the Mental Health Act. Section F: ADRTs in clinical practice – how often should they be discussed (e.g. in your opinion how often do you feel that discussion of ADRTs should take place – at every consultation, every 6 months, at care programme approach meetings, only when I think I might be relevant, only when another health or

social care professional raises the topic, only if the patient or carer raises the topic or never?). Section G: Advance statement of wishes and feelings – whether psychiatrists had experience of patients using these; what was contained, whether the frequency was changing among people with bipolar disorder. Section H: ADRTs and implementation of the MCA – whether psychiatrists had experience of patients using ADRTs and their contents. Section I: Lasting power of attorney – whether psychiatrists had experience of patients making lasting powers of attorney, who advised on these.

Analysis

Descriptive statistics were employed in the survey to explore the professional characteristics of psychiatrists and their experience of training. Univariate analysis indicated that several demographic or service provision factors may be associated with the use of the MCA. Binary logistic regression was applied to three separate analyses: the quality of training (dependent variable) perceived by psychiatrists was explored in relation to the methods, site and content of training the quality of training (dependent variable) was then related to attitudes and experiences of psychiatrists to implementing ADRTs in their clinical practice the amount of training (dependent variable) was related to their attitudes and experiences of implementing ADRTs. Checks for collinearity were applied by exploring the Spearman correlations between the independent variables that might enter the logistic regression. None of the independent variables were excluded because of collinearity. Odds ratios (ORs) and 95% confidence intervals (CIs) are presented for any significant variables.

Results

A total of 650 psychiatrists were recruited for the survey. *Table 1* shows the grade, work setting, country of medical training and duration of time since medical qualification of this sample. Within the sample, there were 374 (57.5%) consultants in general adult or old age psychiatry, and the remainder were trainees, with a slight majority qualified in medicine outside the UK. Psychiatrists were recruited for the study between May 2011 and June 2012. Of 607 respondents who identified the geographic location of their work, 133 (21.9%) were from the West Midlands, 116 (19.1%) from the East Midlands, 80 (13.2%) from the South West, 116 (19.1%) from the South East, 74 (12.2%) from the East of England, 46 (7.6%) from London and 10 (1.6%) from the North West of England.

ACT, assertive community treatment; EIP, early intervention in psychosis; NHS, National Health Service.

Categories are not mutually exclusive.

Table 1 shows the number of training sessions, methods used for training, source of the training, quality of training and reasons for attending the training: 595 (91.5%) had attended at least one training session on the MCA; 465 (71.5%) had attended two or more sessions; and 326 (50.1%) had been to a training session in the previous year. Of the 595

psychiatrists trained in the MCA 489 (75.2%) had been trained by their local National Health Service (NHS) trust. The quality of the training was perceived to be high, with 446 (75.0% receiving training) rating it as good, very good or excellent (Table 1). However, 209 (35.1% receiving training) psychiatrists stated that either minimal or no attention was paid to ADRTs in the training sessions.

Table 2 examines the binary multiple logistic regression associations between the quality of training and the methods of training, the site of training, the number of training sessions and topics covered in the training. Compared with average or poor training, good or better (very good or excellent) training was associated positively with the use of case summaries, role play, coverage of advance decision-making (including ADRTs) and assessment of capacity. Video feedback was only carried out in good or better quality of training (44 or 9.9%, Fisher's exact 2-tailed test $P < 0.001$). Average or poor training was associated with training in their own NHS trust compared with good or better training (Table 2). In relation to the specific use of advance decision-making including ADRTs and the need to be able to assess fluctuating capacity in conditions such as bipolar disorder with highly variable severity and therefore capacity, it is notable that even good or better-quality training covered these issues in only just over 45% and 37% of cases respectively.

55 psychiatrists received no Mental Capacity Act training, 7 missing responses.

Including advance decision to refuse treatment.

Only 94 (14.5%) of surveyed psychiatrists had encountered a patient with bipolar disorder who had made an ADRT; 136 (20.9%) had encountered a patient with bipolar disorder who had made an oral or written statement of wishes and feelings; and 91 (14.0%) had encountered a patient with bipolar disorder who had made a lasting power of attorney relating to health or personal welfare. Of the 259 psychiatrists expressing an opinion, 208 (80.3%) considered that the number of people with bipolar disorder making ADRTs had remained the same since the implementation of the MCA in 2007, and 41 (15.8%) considered that it had increased by less than 10%. Of the 252 psychiatrists expressing a view regarding statements of wishes and feelings by people with bipolar disorder, 187 (74.2%) thought that the frequency remained the same since the MCA came into force, and 46 (18.3%) that it had increased by less than 10%.

Table 3 displays the binary multiple logistic regression associations between the quality of training and the discussion of ADRT with patients with bipolar disorder or other patients who may lose mental capacity but then regain it. Compared with average or poor training, good or better training was associated with fewer psychiatrists who never discuss ADRTs with patients, and fewer psychiatrists who believed that they had insufficient time to discuss ADRTs with patients. Table 4 shows that compared with only receiving one training session on the MCA receiving two or more training sessions was associated with more psychiatrists discussing ADRTs at care programme approach meetings and fewer psychiatrists who believed that they had insufficient training to discuss ADRTs with patients. There were no other associations between the quality of MCA training or number of MCA training sessions and reported practice or beliefs about implementing ADRTs.

Relationship between quality of training in the Mental Capacity Act 2005 and barriers to implementing ADRTs *a*

	Q uality of tr aining						
Never d iscuss ADRTs	96	21.5	48	32.9	0.53	0.3 5–0.79	0.010

ADRTs, advance decisions to refuse treatment.

55 psychiatrists received no Mental Capacity Act training, 7 missing responses on quality of training and 3 missing responses on amount of training.

Relationship between amount of training in the Mental Capacity Act 2005 and barriers to implementing ADRTs *a*

	A mount of tra ining	Mu ltiva riate stati stics					
Di scuss ADRTs rout inely at care prog ramme app roach mee tings	77	16.6	11	8.7	2.372	1.17 –4.83	0.017
In suff icient tra ining to do ADRTs	178	38.3	80	63.8	0.41	0.27 –0.63	< 0.001

ADRTs, advance decisions to refuse treatment.

55 psychiatrists received no Mental Capacity Act training, 7 missing responses on quality of training and 3 missing responses on amount of training.

However, 206 (46.3%) psychiatrists would not discuss ADRTs even if the person with bipolar disorder or carer raised it, and even after good or better training 96 (21.5%) would never discuss ADRTs. Furthermore, 177 (39.7%) and 178 (38.3%) of psychiatrists still believed they had insufficient training and time to discuss ADRTs in clinical practice despite good or better training and two or more training sessions respectively.

Discussion

Although the need for training of psychiatrists and other clinical health staff in the MCA is often recommended or even required,^{1,3,4} and clinical guidelines also support the importance of considering the MCA in people with bipolar disorder,⁵ there is an assumption that all training is likely to help clinicians become more familiar with the MCA and that such training will improve attitudes and use in practice of the MCA by psychiatrists. We found that there was plenty of training in the MCA being offered to and taken up by psychiatrists at trainee and consultant level; 92% of trainee and consultant psychiatrists had received at least one training session on the MCA, with 50% receiving the training in the past year. Although 75% of psychiatrists rated their training in the MCA as good or better, ADRTs were only covered in 65% of the MCA training.

Psychiatrists preferred MCA training that was not didactic and merely information giving, rating training as good or better that utilised discussion of the MCA in relation to case summaries, used role-play, and covered topics such as ADRT, the assessment of capacity and the assessment of fluctuating capacity. Although the assessment of mental capacity was usually covered in MCA training, the topic of fluctuating capacity was rarely discussed, whereas the potentially challenging issue of ADRTs was discussed in only 39% of MCA training attended by psychiatrists. Therefore in the view of the authors, training of psychiatrists was rarely of sufficient quality to meet the needs of people with bipolar disorder under the MCA Training arranged by NHS trust was not perceived to be as good as training provided by the Royal College of Psychiatrists, law firms or other external agencies. The reasons for this view are unclear.

There was some evidence that good- or better-quality MCA training received by psychiatrists was associated with fewer psychiatrists reporting that they would never discuss ADRTs under any circumstances. Receipt of two or more sessions of MCA training was associated with an increased likelihood that ADRTs would be discussed routinely in

multidisciplinary care programme approach meetings. Both better quality and more training sessions were associated with a reduced likelihood that psychiatrists had insufficient time to address ADRTs. Although these data are associations and not a comparison of interventions delivered in a randomised controlled trial, there was some evidence that higher-quality training and more than one training session may be helpful in both improving the attitudes to and use in clinical practice of ADRTs by psychiatrists in patients with bipolar disorder or other patients who lose and then regain mental capacity. Another alternative explanation is that psychiatrists who are interested in helping people with bipolar disorder through the MCA attend more than one session of training and find better-quality training.

Nevertheless offering training in the MCA that psychiatrists perceive as good or better quality seems insufficient to improving their attitudes to ADRTs and their use in practice in people with bipolar disorder. Even after good or better training, 22% of psychiatrists would never discuss ADRTs under any circumstances, 46% would not discuss ADRTs even if the person with bipolar disorder or carer raised it, and 39% believed they had insufficient training and time to discuss ADRTs in clinical practice. These findings chime with the experience of people with bipolar disorder in a national survey we carried out² where neither knowledge nor use of ADRTs were associated with seeing a psychiatrist, although knowledge and use of ADRTs were associated with seeing other mental health professionals and attendance at peer support groups.

A strength of the survey was that to our knowledge it is the first of its sort inquiring into quality of training of psychiatrists and relating it to their attitudes and use of ADRTs with people with bipolar disorder. The survey was large, national and deliberately anonymised so that psychiatrists would feel able to comment frankly without any possible constraint. We judged that this advantage of the methodology outweighed the disadvantage that we do not know how many psychiatrists had the opportunity to take part in the survey but decided not to. We also do not know much about the characteristics of psychiatrists in terms of the demographic characteristics of who did or did not take part in the survey. A further limitation was that this survey was completed 4 years ago so the quality of training and use of ADRTs in clinical practice may have improved. Furthermore, by concentrating on MCA training in relation to ADRTs in bipolar disorder, we cannot comment on other aspects of MCA training on other forms of advance decision-making, application of ADRTs in people who are less likely to regain mental capacity and deprivation of liberty.

The findings confirm those of a 4-year re-audit study where increases in MCA training and improved documentation had a minimal impact on the recording of the MCA by psychiatrists in patient records.⁶ There seems to be some consistency in studies of advance planning that the therapeutic relationship between mental health professionals, including psychiatrists, and their patients is improved with advance planning.^{7,8} The House of Lords heard much evidence that the implementation of the MCA had failed to make much of an impact on clinical practice in the way that was intended, and made 39 recommendations to improve the implementation of the MCA.³ We have not had the opportunity to study the effects of these recommendations but note that none of these relate to the quality or amount of training that psychiatrists or other health professionals receive in relation to the MCA. The Academy of Royal Medical Colleges were asked to report on measures to improve the uptake of the MCA.^{3,4} So far it has organised educational events on the MCA but has not made recommendations on the content, form or amount or frequency of training that psychiatrists or other health professionals should receive in relation to the MCA.⁹

Therefore we conclude that there is a need to improve the quality of training that psychiatrists receive on the MCA so that fluctuating capacity and ADRTs are covered, and that techniques such as case summaries and role-play are employed to improve confidence and competencies of psychiatrists in its use. There may be a case for adding training in the MCA to mandatory training under the Mental Health Act section 22 training regulations. There is a need for further implementation research on ways to improve the knowledge and use of the MCA including ADRTs, by people with bipolar disorder or other conditions where capacity is lost and then regained, and also on how to improve the attitudes of psychiatrists and assist them further to discuss ADRTs with people who have bipolar disorder or similar conditions.

1.7.88 Assessing the second-hand effects of a new no-smoking policy in an acute mental health trust

Abstract

Aims and method To examine whether a new no-smoking policy in an in-patient mental health setting had any effects outside of smoking cessation. Our hypothesis stated that a forced smoking ban for in-patients may result in an increased susceptibility for clinical incidents, aggression and lower admission rates. All patients admitted to adult in-patient mental health services in Coventry and Warwickshire Partnership NHS Trust were included in the analysis. Data 6 months post-implementation of the smoking policy (1 July 2015 to 1 January 2016) were compared with the same period 1 year prior (1 July 2014 to 1 January 2015). Patient demographics, admission rates, ward occupancy, average lengths of stay, numbers of reported incidents and use of the Mental Health Act 1983 (MHA) were compared.

Results We analysed 4223 admissions. We found a significantly increased number of admissions under the MHA ($P = 0.007$), a significantly greater number of reported smoking-related incidents ($P < 0.001$) and aggression-related incidents in the psychiatric intensive care unit ($P < 0.001$). However, we found no significant difference in capacity of in-patient wards ($P = 0.39$), admission length ($P = 0.34$) or total aggression-related incidents ($P = 0.86$).

Clinical implications Although further comparisons over longer time periods are necessary, our results suggest that enforced smoking cessation on acutely unwell psychiatric patients admitted to the most restricted environments may have some negative effects. Nicotine replacement therapy should be offered to all patients to minimise the risk of clinical incident.

Smoking rates among those with a mental illness are 70% higher than in the general population.¹ In fact, although the prevalence of smoking in the general population has decreased, this has not occurred for those with a mental illness.² In particular, the highest smoking rates are found in those acutely unwell with a psychiatric illness, in in-patient units.³⁻⁶

Multiple explanations for such high smoking rates within the mental health sector have been put forward, including symptom control and amelioration,⁷ boredom or loneliness,^{8,9} an increased propensity to experience more severe nicotine withdrawal symptoms than the general population,^{10,11} for relaxation in a stressful environment,^{9,12} a common genetic vulnerability⁵ or that people with a mental illness are less susceptible to anti-smoking messages.¹³

As a result of relatively higher smoking rates, people with a mental illness also have higher mortality rates than the general population. Tobacco use contributes significantly to causes of ill health and mortality in those with mental health disorders.¹¹ Individuals at particular risk are patients with schizophrenia, who have a life expectancy 20% shorter than the general population.^{14,15} Tobacco use can also affect the effectiveness of some psychiatric medication, necessitating increased dosages and therefore purporting a higher chance of side-effects.¹⁶

The UK government implemented its smoke-free policy in July 2007, which extended to all ‘substantially enclosed’ public and work places. This included hospitals, with the aim of reducing the impact of second-hand smoke on patients and staff.¹⁷ This was extended to all types of in-patient units from 2008.

Guidance from the National Institute for Health and Care Excellence (NICE), published in 2013, aims to support smoking cessation, temporary abstinence from smoking and smoke-free policies in all secondary care settings.¹⁸ In this guidance, ‘secondary care’ refers to all publicly funded secondary and tertiary care facilities, including buildings, grounds and vehicles. It covers in-patient, residential and long-term care for severe mental illness in hospitals, psychiatric settings, specialist and secure units.

Prior to the introduction of the legislation, a relatively large survey of National Health Service (NHS) staff found that a third of psychiatric staff disagreed with smoke-free legislation compared with only one in ten of general staff.¹⁹ A survey of mental health units in England in January 2007 found that the vast majority (91%) believed mental health premises faced particular challenges due to the high smoking prevalence among patients, associated safety risks, and potential interactions with antipsychotic medication.²⁰ However, despite the challenges, the smoke-free policy has been rated positive overall. Cited advantages include a reduced exposure of patients and staff to second-hand smoke, an enhancement and support in patients’ motivation to stop smoking, improved sleeping patterns among patients, and the conversion of former smoking rooms into new recreational spaces.²⁰

Since the development of non-smoking policies within the NHS, debate has evolved around any potential infringement this might have on a patient's human rights. A patient at one of Scotland's high-security forensic hospitals recently won a court ruling that a blanket ban on smoking breached his human rights.²¹ According to Article 8 of the Human Rights Act 1998, everyone has the right to respect for his private life and his home. With regard to mental health units, lengthy hospital admissions may qualify as breach of one's private and home life.

The introduction of a non-smoking policy to mental health services remains a relatively novel practice. We are yet to fully appreciate its impact on in-patient services. Coventry and Warwickshire Partnership NHS Trust in the UK introduced a no-smoking policy within its mental health units on 1 July 2015. The Trust is one of the first to implement this policy following the growing evidence of high smoking rates and adverse health implications within the mental health population. Although the benefits of smoking cessation are widely acknowledged, there exists an assumption that enforcing smoking cessation on unwilling patients results in increased stress levels and therefore higher rates of aggression-related incidents.

Voluntary admission to an in-patient mental health ward requires the patient to agree to certain ward policies and procedures explained by the clinician. Within the Trust it is standard procedure to explain the non-smoking policy for both voluntary and involuntary admissions. The impacts outside of smoking cessation caused by a forced no-smoking policy has previously been analysed in a medium secure unit, finding no significant difficulties and that the widely anticipated problems did not materialise.²² We have been unable to find another study analysing similar changes in a typical psychiatric unit (mixed voluntary and involuntary patients).

Aims and objectives

The aim of the study was to examine whether a newly implemented no-smoking policy for patients in a typical in-patient mental health setting had any effects outside of smoking cessation. The objectives were first to compare admission rates and bed occupancy/capacity levels at comparable time periods pre- and post-implementation of the new no-smoking policy in a specified mental health trust. We also sought to compare the numbers of reported incidents occurring on the wards at comparable time periods pre- and post-implementation, focusing particularly on aggression-related and smoking-related incidents. In addition, we wanted to ascertain whether there was any significant difference in the use of the Mental Health Act 1983 at comparable time periods pre- and post-implementation of the new policy, and whether this was related to the change in smoking policy.

Method

Study location and Trust smoking policy

Data were collected from all patients admitted to mental health beds in Coventry and Warwickshire Partnership NHS Trust during the 12 months before and 6 months after implementation of the smoking ban. The change in policy was implemented on 1 July 2015, therefore data were collected between 1 July 2014 and 1 January 2016. The Trust smoking ban states that 'all staff, patients and visitors are not able to smoke tobacco products in Trust buildings or on Trust land.'²³ The Trust maintains a policy of offering nicotine replacement therapy to admitted patients, comprising of either an e-cigarette or nicotine transdermal patch.

Adult in-patient mental health services in the Trust comprise of three acute psychiatric units: the Caludon Centre in Coventry (112 beds), St Michael's Hospital in Warwick (41 beds) and the Pembleton Unit in Nuneaton (12 beds), with adult rehabilitation services provided at multiple sites (40 beds), for a catchment area of around 850 000 people.

Inclusion and exclusion criteria

All patients admitted to adult in-patient mental health services, both acute and rehabilitation, in Coventry and Warwickshire Partnership NHS Trust were included in analysis. To account for seasonal variation, data 6 months post-implementation of the smoking policy (1 July 2015 to 1 January 2016) were compared with the same 6 months the year prior to implementation of the smoking policy (1 July 2014 to 1 January 2015). There were no specific inclusion criteria for diagnosis or length of admission to help prevent selection bias. All sites within the Trust were included in the analysis.

Ethics

The study was approved by Coventry and Warwickshire Partnership NHS Trust as a service evaluation and as such did not need formal ethical approval from an NHS research ethics committee. Data were collated in an anonymised format from routine clinical records, by the authors.

Data collection

First, basic demographic data such as mean age and gender were obtained. Second, monthly admission rates and ward occupancy levels between the dates were collected. Third, monthly total numbers of reported incidents were obtained. All data were collected by data analysts within the Trust.

Statistical analysis

For the count data (number of admissions under the MELA, total incidents, aggression-related incidents, psychiatric intensive care unit (PICU) incidents and smoking incidents), Poisson regression was used to generate a significance value. Where data were provided as percentages (i.e. capacity), we converted to mean n based on the total Trust capacity ($n = 205$). The Shapiro-Wilk test for normality allowed a decision as to whether to use parametric or non-parametric statistical comparisons. All statistical comparisons were made using IBM SPSS Statistics 24.

Since we were measuring six outcomes in our analysis, a Bonferroni correction was applied. The α -value (0.05) was therefore adjusted to a significance value of $P = 0.008$.

PICU, psychiatric intensive care unit.

Number of patients admitted under the Mental Health Act 1983

Poisson regression found that the number of admissions under the MHA increased (1.13, 95% CI 1.03–1.23) at the boundary of our corrected α -value, $P = 0.007$, in the same 6 months the year following the introduction of the new smoking policy.

In-patient ward capacity

Our findings show that the bed capacity was at maximum or over-maximum at each month studied. Using the data adjusted into mean capacity, the Shapiro-Wilk test for normality ($P = 0.306$) allowed us to proceed with an unpaired t -test, which showed no significant difference ($P = 0.99$).

Average duration of in-patient admission in days

The Shapiro-Wilk test for normality ($P = 0.068$) allowed us to proceed with an unpaired t -test, which showed no significant difference ($P = 0.34$).

Total number of in-patient aggression-related incidents

Poisson regression revealed no significant difference in total aggression-related incidents following the introduction of the new smoking policy (1.02, 95% CI 0.90–1.12; $P = 0.70$).

Aggression-related incidents (PICU only)

Poisson regression revealed a significant increase in aggression-related incidents in PICU following the introduction of the new smoking policy (1.59, 95% CI 1.26–2.01; $P < 0.001$).

Smoking-related incidents

Poisson regression revealed a significant increase in smoking-related incidents following the introduction of the new smoking policy (3.10, 95% CI 2.55–4.46; $P < 0.001$).

Discussion

Main findings

We aimed to ascertain whether a new no-smoking policy for in-patients at a specified mental health trust might result in any less favourable effects outside of smoking cessation. We found a statistically significant increase in the number of admissions under the MHA, total number of reported aggression-related incidents on PICU, and a statistically significant increase in the number of reported smoking-related incidents. The majority of these findings may be expected. In consideration with our finding that in-patient bed capacity was at or over 100% for each of the months studied (potentially due to patients being ‘on leave’ from hospital but still named in beds), one might argue that the acutely stressed state necessary to be granted an admission into bedspace at a premium would have been of considerable severity. Such patients may also have been admitted against their will, further heightening stress levels. One may therefore consider that immediately and forcefully removing the right to smoking, a past-time that can bring comfort, reduce stress, ameliorate psychiatric symptoms and help to fight boredom, may be poorly timed.

Perhaps a more surprising finding is the statistically significant increase in patients admitted under the MHA. This was included as an outcome measure as it was hypothesised that patients may refuse informal admission based on the no-smoking policy. Although patient refusal for informal admission may have contributed to the effect, it is likely not the whole story, as that hypothesis relies on the provision of adequate information to patients, i.e. the new smoking policy is explained prior to admission. Other work²⁴ has shown that this is not always the case. It is also well known that detentions under the MHA have been on the rise across the UK over the past 10 years,²⁵ due to a multitude of factors (not smoking related) which we were unable to analyse in this study. In-depth case-note analysis may have allowed us to qualitatively ascertain whether the smoking policy played a part in this significant finding, and future research analysing this perhaps legitimate question could take this into account.

We found no significant difference in the total number of reported aggression-related incidents. At face value, this finding suggests that in an open-ward environment, the new smoking policy did not cause an increase in agitation or aggression, which contradicts the finding we obtained from PICU only. There are several possible explanations for this. First, the patients that are admitted to PICU are likely to be more acutely stressed than those admitted to an open ward and therefore the potential to cause an ‘incident’ might be increased. Second, the more strictly controlled environment in PICU may lend itself to better adherence of the smoking policy than for informal patients on an open ward (who may

be allowed out for ‘grounds leave’ each hour, or more), thus the new smoking policy may be felt more among patients on PICU. Third, there is the very likely possibility that not all incidents are reported. Incident reporting can sometimes be viewed as an arduous process, especially for staff with busy in-patient ward roles. Although this could affect the results both in the open-ward environment and on PICU, one could suggest that staff on PICU might be more familiar with and better trained to deal with incidents, thus incident reporting might be better adhered to.

We also found no significant difference in patients’ length of admission, suggesting that the new no-smoking policy did not positively or negatively affect the patient journey through mental health services. This might be an expected finding as the benefits of smoking cessation are known for long-term rather than short-term health. However, it is useful to address this result in light of our findings of increased smoking-related and aggression-related incidents, as it suggests that the new policy’s potential to predispose to aggression or agitation does not necessarily result in prolonged in-patient stay. We also found no significant difference in in-patient ward capacity, which could be expected considering capacity was at maximum or above maximum for each month studied.

Strategies and limitations

We believe this study is one of the first to assess the effects of a new no-smoking policy of psychiatric in-patients in the UK, in an age where the importance of physical health in psychiatric patients is becoming increasingly recognised, such that many more healthcare trusts may in future choose to adopt a similar policy. In using the entire sampling frame over a 6-month period, we have ensured a large sample size which may help to reduce the potential for type I or II statistical errors. We have reduced the impact of seasonal variation by comparing the same 6 months both in the year of introduction of the new no-smoking policy and the year preceding it. In comparing data across time, we can demonstrate a temporal association with the positive findings. Furthermore, regarding the new no-smoking policy being more strictly enforced on PICU, a dose-response relationship may be observed when comparing the non-significant open ward aggression-related findings with those obtained from PICU. In addition, we have included a range of measures that were chosen prior to commencing data collection.

There are however a number of limiting factors that should be taken into consideration. First and most importantly, we cannot show that the new no-smoking policy is causal to the positive findings. There could be many other causes for increased aggression-related incidents on PICU and it is therefore not clear how much (if at all) the change in smoking policy contributed. It is however less probable to consider reverse causality as a factor in this study, as it is unlikely that the no-smoking policy was enacted because of significant aggression-related incidents.

In addition, we are unable to determine the effect of any poor reporting practice on our findings. We have mentioned that reporting might be better in certain areas of in-patient psychiatric care than others which may skew our results and invalidate comparisons. Despite our efforts, we were unable to obtain a comparison of total number of reported incidents between the two time periods. This would have better highlighted the reporting practices in the Trust across the two time periods and may be useful for future work.

It may also be possible that the timing of our data collection may have affected the validity of our results. We chose to measure the 6 months immediately following the introduction of the new no-smoking policy. It is likely that group practice takes time to adapt and this may be an explanation for some of the negative findings in our results. It may have been more appropriate to choose a length of inclusion greater than 6 months to better visualise this, however we were limited by time and resources. Both adherence to the Trust smoking policy and the reporting of incidents (if common) may improve over time, and it therefore may be useful to repeat this study in the future to compare the results.

Finally, since our study only measured outcomes during in-patient stay, we were unable to ascertain any longer-term effects of the new smoking policy, such as the increased achievement of smoking cessation among patients admitted under the new no-smoking policy. Further work might seek to establish the longer-term effects of such a policy.

Other research has been carried out on this topic internationally, which correlates partially with our results. A 2002 systematic review²⁶ including studies from several countries found no significant behavioural effects when smoking bans were enacted in psychiatric units, although the review also notes that in the included studies, smoking bans were not associated with long-term smoking cessation among patients. More recently, a 2005 study²⁷ from the USA found no significant increase in aggression with the introduction of a new smoking ban. Furthermore, a survey²⁸ of mental health staff working at an Australian healthcare trust in 2013 found that although most staff preferred to work in a

smoke-free environment, around half of survey respondents found the smoking ban to be detrimental to acute patient care, which may give the impression of increased agitation or behavioural problems among patients involved.

Our results are therefore broadly in line with the findings of others. However, it is notable that we have shown a potential difference in the effects of a smoking ban on different patient groups across different settings. Further work might seek to clarify and further examine the reasons behind this finding.

Overall, the reasoning behind a smoke-free hospital environment is clear. The long-term health benefits of smoking cessation are numerous and well documented, and other work has shown staff to prefer a smoke-free working environment. However, there is the legitimate debate as to whether the acutely stressed state is the right time to impose this lifestyle change, and whether it is even ethical to do so. Our results show that, in general, a new smoke-free policy did not result in significant changes of reported aggressive behaviour or incidents, and did not affect the patient journey through mental health services. However, we found significantly increased smoking- and aggression-related incidents in more restricted environments. It is possible that the most highly agitated psychiatric patients are most susceptible to cause incidents with this enforced lifestyle change. Our finding of significantly increased use of the MHA may be explained by other factors, but also may warrant further research. Therefore, to reduce the impact this may have on both patients and staff tasked with dealing with any resultant incident, nicotine replacement therapy should be considered for all relevant patients.

The authors would like to extend their thanks to the data analysts of Coventry and Warwickshire Partnership NHS Trust for their support in obtaining the data used in this study, and to Pascal Perry-Cheung for his kind assistance.

1.7.89 A service evaluation of outcomes in two in-patient recovery units

Abstract

Aims and method To evaluate outcomes for patients during their admission or in the first year of treatment in two in-patient recovery units. Changes in health and social functioning, service use and need (rated by patients and staff) were evaluated.

Results In 43 patients treated, there was a large (30%) increase in patients discharged to their own tenancies, rather than supported accommodation. There was minimal change in Health of the Nation Outcome Scales (HoNOS) scores in the course of the admission but staff- and patient-rated unmet needs reduced and met needs increased. Needs changed mainly in domains relating to social functioning. Reductions in risk to self and others were rated by staff but not patients. There were no cases of patients being readmitted to acute hospital during the study period.

Clinical implications Although these results offer some support to the treatment approach described in these in-patient recovery units, further research in larger samples is needed to identify how these

From the start of 2011 it was decided to develop greater understanding of the outcomes of the work of our two 2gether Foundation National Health Service (NHS) Trust recovery in-patient units, by evaluating outcomes assessed by staff and patients at admission, mid-point and discharge from the units. These services have in the past decade adopted a strong recovery-based model of practice, in line with the UK government policy *No Health Without Mental Health*.¹ A major strategic aim in this policy is for more people with mental health problems to recover, defined as: ‘a greater ability to manage their own lives, stronger social relationships, a greater sense of purpose, the skills they need for living and working, improved chances in education, better employment rates and a suitable and stable place to live’.¹ The literature on personal recovery emphasises the individual journey in recovery, in which regaining hope, taking back control and finding new opportunities are key processes.² It has been argued that a transformation of mental health services is required for this to occur;³ mental health professionals recognising patients’ strengths and expertise as experts in their own health and acknowledging the importance of personal narratives, alongside other forms of evidence. The increasing focus in UK and international healthcare policy on recovery has occurred at a time of generally increasing personal autonomy in wider society while health services have shifted their focus towards helping every individual to make the most of their health, rather than relating mainly to those with illness.⁴

The recovery units studied provide active rehabilitation for 10 and 13 residents respectively. The units are remote from the main psychiatric hospital services but provide full in-patient support and are registered to take detained patients. The focus of the work in the units is with patients who have complex, severe mental illness, predominantly psychosis, characterised by treatment resistance and other complications. Treatment is provided through a full multi-disciplinary team and includes approaches to optimise health through use of medication, talking therapies including family work, guidance on healthy living, and treatment and support for substance use problems. A wide range of social approaches include help with daily living skills including budgeting, self-care, shopping and cooking, help with finances, benefits and accommodation, and support to develop interests and activity such as sport, leisure activities and work. The work in these units differs from acute in-patient work in focusing more on treating long-term, disabling mental health problems and impaired social functioning over longer time periods, rather than dealing with brief, episodic illness. Typical admissions last approximately 9 months, rather than just over 1 month in acute units (based on November 2016 2gether Foundation NHS Trust data).

The original model of the recovery units described was developed to help patients in their rehabilitation from long-stay hospitals,⁵ aiming to support patients with complex illness to reintegrate into the community. They have subsequently evolved to work mainly with patients who need longer-term rehabilitation after acute psychiatric admission or any

patients who have developed disability due to severe mental illness. Over the past 20 years in the UK, in association with NHS and local authority funding changes, there has been a disinvestment in these services,⁶ despite recognition in recent commissioning guidance⁷ that this form of treatment is needed as part of a spectrum of care provision in each district.

The evidence from research in this field has previously been reviewed,⁸ showing that in-patient recovery units can effectively support most patients accepted by them, the majority of whom can be resettled to less dependent community placements over a period of months or years. The research indicates that treatment in recovery units is associated with improvement in social functioning and social networks and reduced levels of negative symptoms in schizophrenia. Placements are associated with relatively few long-term readmissions. These findings have been replicated in other countries such as Australia, the USA Northern Ireland, Norway and Italy.⁹ The quality of the research evidence is however variable and there has been very little formal research carried out in this area.⁵ A recent study of outcomes 5 years after in-patient rehabilitation¹⁰ found that around 40% of patients had remained in stable accommodation or moved to independent placement and sustained this.

Although UK commissioning frameworks have consistently argued the need for services of this type to help patients with complex needs in their pathway from acute or secure hospital to the community, there still seems to be a shortage of appropriate residential places in some areas, particularly for those with the most severe and enduring mental health problems. A study of hospital services in Birmingham, UK,¹¹ showed that long-stay (more than 6 months) patients were consistently found to occupy 20% of acute beds. The authors noted that where staff made recommendations for community placements, 'by far the majority' required 24-hour residential care, suggesting a need to improve access to this sort of provision. A recent paper¹² noted that problems may arise from the fragmentation due to use of private sector psychiatry and made a strong case for local, well-organised, NHS rehabilitation services. A survey¹³ of English rehabilitation services showed that despite closures of nearly all NHS long-stay hospital beds, most areas still had active rehabilitation units available to help people with complex, treatment-resistant illness. In 93 local authority regions, most (77%) had short-term (up to 12 months) rehabilitation units, with an average of 13 beds. It appears that although services are available in most areas, the level of provision is variable and patchy. Hospital services in the UK continue to be under pressure and there are often suggestions of a need for more beds. However, it has been argued¹⁴ that alternatives to acute in-patient admission could reduce this pressure and that around one in four cases in acute units could be managed in a unit run by nurses or care workers.

Aims of the evaluation

This service evaluation aimed to describe, prospectively, aggregated outcomes for new residents over the duration of their admission or in the first year of treatment. The evaluation considered changes in health and social circumstances from admission to the units, to discharge or 1 year after admission. Utilisation of acute hospital treatment was monitored before and during treatment in the recovery units.

Method

This project was carried out as a service evaluation with a formal protocol and a project steering group which met regularly during the project's work. The County Research and Development Support Unit assessed and gave written agreement for the project, prior to commencement. The use of aggregated data was preferred to other methods, such as the use of within-participant findings. This was a pragmatic decision, as the introduction of routine outcome monitoring was hoped to improve and make more systematic individual care planning, as well as to enable individual and service-level evaluation of outcome. The measures used in the project were selected to support the new way of working.

Participants

At the point of admission to the unit, demographic and health-related data were collected for all patients, on a specially designed form. The patient's key worker rated the Camberwell Assessment of Need Short Appraisal Schedule (CANSAS) ¹⁵ and Health of the Nation Outcome Scales (HoNOS) ¹⁶ scores at the time of admission. CANSAS forms were given by key workers to patients for self-completion, with an explanation about how to complete them. Key workers were instructed to ensure that patient rating of need was independent of their own rating and access to support from local advocacy services was offered if this was considered helpful. Where a carer had a significant role with the patient, this individual was also approached to assess the needs of the patient (with consent, following the usual clinical permissions pathway).

To be included in the evaluation, patients were required to have continuous treatment for a minimum of 3 months in one of the units. This was to ensure that patients who were occasionally admitted briefly from the acute ward, due largely to problems such as homelessness leading to delays in discharge, but were not assessed to require the therapeutic approach of the recovery unit, did not bias the sample. It was also felt that patients discharged before 3 months would not have had time to engage meaningfully with the therapeutic work of these services.

The same ratings were repeated 6 months after admission and at discharge, or at the end of the first year of treatment. Demographic and health-related data were collected at the point of discharge from the unit or at the end of the first year of admission.

Measures

The CANSAS ¹⁵ rates need as 'absent' (no problem), 'met' (problem addressed by services) or 'unmet' (significant, ongoing problem) across 22 social and healthcare domains. The HoNOS ¹⁶ is a 12-item scale that rates various aspects of health and social functioning on a 5-point Likert scale to measure levels of problem severity.

Data management

At admission, patients were allocated a number for identification purposes and from this time all data were held anonymously, with the identification number only used on forms, held securely by the unit administration lead, who managed the data collection processes. Data sheets were held in a locked office in secure filing cabinets or on a password-protected Trust PC.

Statistical analysis

C.F. advised on the use of descriptive, demographic and illness-related information and the analysis of change scores from admission to discharge using aggregated HoNOS scores and CANSAS total, met and unmet need total scores. Data were entered into SPSS for analysis (SPSS version 18 for Windows). Non-parametric Wilcoxon matched pairs signed ranks tests were used to assess changes in mean HoNOS and CANSAS ratings.

Ethical consideration

This work was an attempt to evaluate whether the recovery units were effective in their intended work. It was a service evaluation and did not have a randomised controlled design. Information was collected as part of the work of the units and it was used at an individual level to more systematically understand patient need and plan treatment. There was no intention to use experimental tools or to compare units or employ a control group. As a result of the design it was noted that results would not be generalisable, although it was hoped that they may be of value at a time of greater attention to treatment outcomes and considering issues of service quality and innovation. Patient consent was not formally taken but was considered to be given by participation, where patients gave individual ratings of need and this was always explained to be optional and unrelated to the rest of the patient's treatment. Prior to starting the project, the need for

formal ethics committee submission was considered by our County Research Support Unit, which advised that this was not required and gave written approval for the project.

Results

Data collection was carried out in the two units from April 2011 to June 2014. During that time a total of 43 patients were admitted for a period of at least 3 months. Data were collected on the patients over this period, the gaps in data being largely due to the challenges of managing data collection within a standard clinical setting, rather than (with the infrastructure permitted by research funding) as a research project. Gaps in the data-set are reported within the results presented below. These related often to patient choice and willingness to participate in routine data collection. Although access to advocacy was freely available and advocates were working regularly in both units through the project, we do not know how often they provided specific support to patients in completing outcome measures. We believe this was rare and in the great majority of cases patients completed forms independently or with minor support from staff.

The study group of 43 patients included 28 (65%) male patients, aged 18–62 years (mean 36.5, s.d. = 10.3); 39 (91%) were single, 2 (5%) married and 2 (5%) divorced. Most patients ($n = 23$, 53%) were admitted from an acute psychiatric ward, the remainder ($n = 20$, 47%) direct from the community. In the year prior to the recovery unit admission, patients had spent a mean of 20.7 weeks (range 0–52, s.d. = 24.5) in a psychiatric hospital. Patients had experienced a mean of 1.0 admissions in the year before entering the recovery unit (range 0–4, s.d. = 0.55).

At the time of admission all patients were unemployed, and 23 (53%) lived in supported accommodation, 19 (44%) in their own tenancy and 1 (2%) with family. Overall, 27 (63%) were under an assertive outreach team, 11 (26%) under a community recovery team (community mental health team) and 5 (12%) under early intervention services.

Patients spent a mean of 380 days (s.d. = 177) in the recovery units; there were no recorded episodes of acute psychiatric readmission during this time. In total, 38 of discharges (74%) were planned and 5 patients (12%) were discharged for other reasons.

At the time of discharge, 42 (98%) were unemployed, 1 patient being a part-time student. Overall, 32 (74%) had their own tenancy, 4 (9%) were living in supported accommodation and 2 (5%) were living with family. In total, 29 (67%) were under an assertive outreach team, 11 (26%) under a community recovery team and 3 (7%) were under early intervention services.

The main changes over the course of this evaluation were: there was a small increase in employment following treatment in the units; there was a 30% increase in patients living in their own tenancy; and some patients were taken over by assertive outreach teams during their admission, mostly moving from early intervention teams.

No individuals were readmitted to acute in-patient care during their recovery in-patient admission.

Baseline and final mean HoNOS and CANSAS met/unmet need scores are presented in *Table 1*.

Mean HoNOS and CANSAS ratings at baseline and discharge/12-month follow-up

	Baseline rating Mean (s.d.)	Discharge/12-month rating Mean (s.d.)	Wilcoxon signed ranks 2-tailed test
HoNOS	19.9 (8.2)	18.5 (9.0)	Z= 1.46, P>0.05
Staff-rated CANSAS met need	7.2 (4.3)	7.3 (3.9)	Z= 0.41, P>0.05
Staff-rated CANSAS unmet need	3.7 (3.6)	3.4 (3.0)	Z= 0.76, P>0.05

CANSAS, Camberwell Assessment of Need Short Appraisal Schedule.

There were improvements in patient-rated met needs in domains relating to accommodation, social life, care of the home and daytime activity, most other domains showing no change or minor increases and decreases. There were reductions in patient-rated unmet needs in accommodation, daytime activity budgeting and intimate relationships, with about half the domains showing minimal change. It can be seen that the main changes in patient-rated need were in domains relating to social functioning.

There were increases in staff-rated met needs in domains relating to accommodation, social life and information about treatment. Apparent reductions in staff-rated met need in the domains safety to others, safety to self and use of non-prescribed drugs appeared to be explained by comparable increases in levels of 'no need' in these domains. Staff-rated unmet needs showed smaller levels of change, the domains which reduced most being accommodation, daytime activities and psychotic symptoms.

Discussion

We have shown that it is possible as part of routine clinical outcome measurement to assess longitudinal outcomes in a standard recovery in-patient setting, using staff- and patient-rated measures. The results included some gaps in data which were due largely to patients declining to complete CANSAS ratings of need or incomplete participation by staff members. However, the results seem likely to be reasonably representative of the patients admitted to the units over this time, other than those patients who were admitted and then discharged or readmitted to the acute ward within a short time (these patients were excluded from the study population).

Results and limitations of research

We found minimal change in HoNOS scores in the course of the recovery unit admission but overall staff and patient assessed unmet needs tended to reduce and met needs tended to increase, although not at a statistically significant level. This may have related to the relatively small sample size. The main changes in need found over the study period rated by staff and patients related to improved social functioning, a finding which accords with the primary clinical aims of these services; to help individuals to regain life skills lost through periods of severe illness and ideally to try to achieve the most independent living situation possible. Our evaluation included patient and staff evaluations of need, both being included as the research indicates that they differ, and that the patient's perspective may be particularly important.¹⁷ The reduction in staff-assessed risk to self and others was encouraging and may have linked to reduced substance misuse, as these units have a strict drug-free policy and during admission patients are supported to remain drug free. A recent survey¹⁸ of in-patient rehabilitation units in Birmingham, UK, found chronically high levels of

problematic and socially inappropriate behaviours and suggested that new approaches, focusing on engagement and the management of challenging behaviour, may be helpful.

A number of limitations result from the method of this service evaluation. There was no control group and, as a result, the findings cannot be generalised. We are only aware of the existence of one, small, randomised controlled trial in this area,¹⁹ and arguably this type of research is not really feasible in this setting,⁵ although it remains vital to learn more about outcomes in these important and relatively expensive services. The numbers in our study group were small and it would be helpful to compare our results with studies using similar outcome measures in other settings, ideally with larger patient groups. Further limitations arise from the lack of data relating to progress at different time points during the treatment in the recovery units: it is possible that greater benefits occur early or later in the treatment process, which we were unable to evaluate. The scales used allow limited understanding of the patient experience, which could be more fully accessed through the use of qualitative studies and a number of tools assessing aspects of patient-rated recovery are now available.²⁰ Qualitative studies in this area have emphasised the importance of choice and autonomy for many patients²¹ and have shown the potential for personal recovery to be facilitated through appropriate supported living accommodation.²²

Of interest, poorer outcomes were associated with non-adherence to medication and our finding that most patients were discharged to assertive outreach teams suggests that many patients will continue to need a high level of support following treatment in recovery units. A recent study using retrospective care records⁹ found significantly reduced hospital admission 2 years after in-patient rehabilitation and that a substantial proportion of the sample went into more independent living. We found a large increase (30%) in the number of patients discharged to their own tenancies, rather than supported accommodation.

Consideration of findings against previous research

At a time of increasing pressure on in-patient services, our findings accord with previous research²³ suggesting that alternatives to acute in-patient care could reduce this pressure and that many cases could be managed in facilities such as recovery units. More than half the admissions to our in-patient recovery units were from acute wards and their ability to manage cases effectively without return to hospital and, most importantly, achieve clinical improvements, emphasises the importance of having these services available in each region/district where acute units operate. Our findings were in line with previous research¹⁴ showing improved outcomes in terms of accommodation and stable social functioning following treatment in recovery units. It is important to have a long-term perspective due to the ongoing, high levels of chronic morbidity in this population.¹⁰ There is a continuing need for different types of supported accommodation, although in our study a substantial number progressed to fully independent living.

Research in supported accommodation has been classified⁵ into three domains: quality of care; external evaluation and quality of life; and subjective satisfaction by the resident. In terms of quality of care, the most important factors appear to be the effectiveness of an individually centred, targeted programme of care and the quality of the physical environment. A systematic review of the quality of care in longer-term mental healthcare settings²³ found eight domains of institutional care that were key to recovery: living conditions, interventions for schizophrenia, physical health, restraint and seclusion, staff training and support, therapeutic relationship, autonomy and patient involvement. The two units investigated have both embraced the recovery approach, working alongside patients in pursuit of their goals and promoting autonomy and empowerment of the individual. Previous research²⁴ has shown that quality of care is heavily determined by the personality and orientation of project leaders and staff working in these units drew on extensive experience of local rehabilitation/recovery work, which has resulted in three major reviews and redevelopment of services and extensive staff training in recovery methods. The units were both accredited as 'excellent' in 2016 within the rehab-AIMS national benchmarking of rehabilitation units.²⁵ However, the results in our study show that the patient population is highly disabled with high levels of need and high usage of hospital care. Our results, showing clinical stability alongside progress in personal and social domains, was encouraging and hopeful. These units support many patients who due to their illness have difficulty creating their own structure, with consequent loss of internal security and often associated fears of losing control. The provision of support, treatment and therapeutic approaches available 24 hours provides an important support²⁶ which enables patients to feel stable, secure and then able to progress with rebuilding their lives. It is however important to consider differences between professional and patient preferences. When asked their view, patients have tended to prefer the option of their own, independent accommodation²⁷ over

rehabilitation or supported accommodation. Family members tend to align with the professional view and prefer their relatives being cared for in staffed environments.²⁸ An important criticism of staffed settings is the potential for institutional regimes and a poor rehabilitative culture, which could impede independence and autonomy.²⁹ Conversely, some patients and family members have reported that independent tenancies can be socially isolating²⁷ and it seems that many patients benefit from treatment in these units, particularly if they maintain a collaborative approach and provide a wide range of therapeutic options.

We would like to thank the recovery units' staff and patients for their support with this project and for completing the necessary rating scales required. We thank Natasha Wallace for her administration and support more widely for the project.

1.7.90 Weekend new patient reviews in psychiatry: evaluation of activity over 3 months

Michael Rutherford Mark Potter

Michael Rutherford

(michael.rutherford@swlstg-tr.nhs.uk)¹

date

2017-12

Abstract

Aims and method South West London and St George's Mental Health NHS Trust developed a system of weekend new patient reviews by higher trainees to provide senior medical input 7 days a week. To evaluate the effectiveness of these reviews, the notes for all patients admitted over 3 months were examined. The mean length of stay for patients before and after the introduction of the weekend new patient reviews were compared via unpaired *t*-test.

Results A total of 88 patients were seen: 84.4% of patients were seen within 24 h of admission. Higher trainees instituted some changes in 78.9% of patients. The most frequent action was to modify medication, in 47.8%. The average length of stay after the introduction of weekend reviews was not significantly different.

Clinical implications Weekend reviews of newly admitted patients by higher trainees is a feasible method for providing senior input to patients admitted out of hours.

– Discussion

* Conclusions

Medical specialties of various types are increasingly being requested to deliver senior-led care throughout weekends and bank holidays. This 7-day working is felt to be potentially beneficial for patient care and has been started by many acute specialties. The Academy of Medical Royal Colleges released a report in 2013 outlining how this could be achieved for different specialties, including psychiatry.¹ They recommended that 21–30% of psychiatric in-patients would benefit from a daily consultant-led review; mainly those who have been newly admitted or are clinically unstable. They stated that all new admissions, especially those under the Mental Health Act 1983, should receive a review the following day to initiate a treatment plan, including medication, observation levels, physical and psychosocial investigations and referrals.

The Academy of Medical Royal Colleges also advised that their recommendations were considered in light of the requirements of the local organisation as practice is likely to vary depending on geographic location, organisation size, on-call staffing and number of in-patient units. They also acknowledged that to achieve these outcomes, certain interventions and investigations would need to be available, such as pathology access.

Method

South West London and St George's Mental Health NHS Trust developed a system of weekend ward reviews led by higher trainees with consultant advice. The higher trainees in the Trust were on a full-shift on-call rota with 09:00 h to 21:00 h shifts on weekends and bank holidays. Patients admitted out of hours on Fridays, Saturdays or up to 09:00 h on Sunday morning are reviewed by the on-call higher trainee the next day. Patients admitted after 09:00 h on Sunday are reviewed on Monday by the ward team, unless it is a bank holiday, in which case they are reviewed by the higher trainee on call that day. After the higher trainee has completed their reviews for a given site, they contact the on-call consultant to discuss the cases and ensure the management plans instituted are appropriate. This occasionally led to changes in treatment plan. This provides an opportunity for supervision and training and ensures consultant input. The role of the reviews was to ensure that the patients received prompt assessment by a senior clinician and a comprehensive management plan could be instituted. They were not intended to facilitate immediate discharge, although it was hoped that earlier treatment would reduce the time patients had to spend on the ward.

To evaluate the activity involved in the weekend new patient reviews, the notes for all patients admitted between 17:00 h on Friday and 09:00 h on Sunday between 1 January 2016 and 31 March 2016 were identified via the RiO system used by the Trust. This provided information regarding the timing of their admission. The clinical notes of each of these patients were examined to determine the reason for their admission, when they were seen by the on-call higher trainee, the diagnosis made and any actions taken as a result of the weekend review. The mean length of stay for patients admitted between 17:00 h on Friday and 09:00 h on Sunday and 1 January 2015 to 31 March 2015 were also compared via unpaired *t*-test. The number of serious untoward incidents in each time period was also compared via Mann–Whitney *U*-test.

Results

A total of 88 patients were seen over the 3-month period. This equates to 6.8 patients appropriate for senior review each weekend.

Of those admitted, 46 (52.3%) were male. The average age was 41.9 years (range 18–84, s.d. = 17.8). For males the average age was 41.4 years (range 18–84, s.d. = 19.6) and for females it was 42.5 years (range 19–83, s.d. = 15.9). These differences were not significant on *t*-test.

The time from admission to senior review is indicated in *Table 1*. A total of 11 patients were not seen at all. Of these, 4 were admitted via the 136 Suite in the Trust.

Time from admission to senior review

Review within	Number of patients	Cumulative number	Cumulative percentage of patients seen
12 hours	17	17	22.1
24 hours	48	65	84.4
36 hours	8	73	94.8
48 hours	4	77	100

Diagnoses were made by the higher trainee in 73 patients. The other 15 patients were diagnosed during later assessments. These diagnoses are shown in *Table 2*. There were no significant differences between patients diagnosed by the higher trainee or at a later point on two-tailed *z*-tests.

Diagnoses made by higher trainees, the diagnoses of patients not seen or not diagnosed by the higher trainee

	Diagnosed by higher trainee	Diagnosed subsequently	Total diagnoses			
Psychosis	31	42.5	8	53.3	39	44.3
Depression	17	23.3	7	46.7	24	27.2
Mania/hypomania	7	9.6	1	6.7	8	9.1

The length of stay for patients admitted between Friday 17:00 h and Sunday 09:00 h between 1 January and 31 March in 2015 was 26 days (s.d. = 37) and for the same period of time in 2016 the length of stay was 28 days (s.d. = 43). This was not significant.

The number of serious untoward incidents between January and March 2015 was 13, and during the same period in 2016 it was 28; this was significant ($P = 0.0652$). However, when serious untoward incidents were limited to those occurring in acute services and out of hours, there was 1 incident between January and March 2015 and 3 incidents in the same time period in 2016; these numbers were too low to be analysed and so did not reach significance.

Discussion

A substantial number of patients, 88 in total, were eligible for weekend review over the 3 months covered by the service evaluation and 77 of these were actually seen. A substantial minority of those not seen were admitted through the Trust's dedicated 136 Suite. This mode of admission may be a weak point in the current system, possibly as a patient detained to the suite could be viewed as having been admitted at that point, despite still awaiting formal assessment and possible admission. Patients admitted via the 136 Suite should still have been reviewed the following day.

Of those patients seen by the higher trainees, the vast majority (84.4%) were seen within 24 h and most of the rest, up to 94.8%, were seen within 36 h. Many of those seen between 24 and 36 h had been admitted during the morning on a Saturday and the higher trainee was unable to see them until the afternoon on Sunday. A small number (5.2%) were seen after 36 h had elapsed. The reasons for this are unclear but could be as a result of temporary limited provision of higher trainee cover due to illness.

The characteristics of the patients admitted do not appear to be remarkable, although it would have been useful to have a comparison group of patients admitted during the week to determine whether there were significant differences between the two, in terms of demographics, admission reason and diagnosis. It is unclear why some higher trainees did not formulate diagnoses for the patients they reviewed, but there appears to be no significant differences between those diagnosed during the weekend or following later assessments.

Higher trainees performed or recommended a wide variety of interventions for patients, instituting some changes in 78.9% of cases. The most frequent action was to start some form of medication; this was done for 31.2% of patients. If increasing and stopping medication is also considered, then medication changes were performed in 47.8% of cases seen by the higher trainees. These were in addition to prescriptions made by admitting core trainees.

The next largest group of interventions were recommended physical investigations and interventions, again, which had not been instituted on admission. This occurred in 14.3% of patients reviewed. These varied from instituting monitoring of fluid and food intake to obtaining specific investigations, such as lithium levels.

A variety of other interventions were performed. It is reassuring that only 2 patients needed to have a recommendation for detention under the Mental Health Act completed. The others appear to be appropriately informally or already detained under the Mental Health Act. The limited number of discharges would be at least partially explained by this not being the proposed aim of the weekend reviews.

In 22.1% of patients seen over the weekends no action was taken by the higher trainee. This could be due to all reasonable interventions already having been performed by an experienced core trainee or patients requiring a period of observation before any definitive management plans are made.

Despite these interventions being initiated earlier than expected, there was no change in the average length of stay for patients who were eligible for new patient reviews. This could be explained by the interventions only being delivered

24–48 h earlier than they otherwise would have been. The reviews were also not intended to facilitate immediate discharge. A greater focus on expediting discharge over the weekend may have led to a reduced length of stay.

Although the overall number of serious untoward incidents was significantly higher in 2016 than 2015, there was no significant difference when they were restricted to those associated with acute out-of-hours services which would appear most clearly related to the introduction of weekend new patient reviews. The overall increase in incidents may be due to a continuing Trust drive to improve reporting with a view to improving services, rather than a true increase and so the figures are difficult to interpret accurately in this context.

This system did not require any changes in rota patterns for higher trainees. The system was such that the reviews were carried out during the scheduled 09:00 h to 21:00 h shift, with reviews ceasing at 21:00 h so that patients could rest adequately without their evening or night being disrupted. On rare occasions when all the planned reviews could not be completed, they were postponed until the next day. Furthermore, as mentioned above, the focus of the reviews was not discharge; this prevented difficulties in coordinating with social care and other agencies during the weekend. The system used by the Trust enabled it to provide senior medical input 7 days a week in acute services without disrupting weekday working or leading to any of the other concerns raised by some authors.²

Conclusions

There has been increasing emphasis on providing more senior weekend medical input across all specialties.¹ In psychiatry, the recommendations were mainly in terms of newly admitted patients.

Weekend reviews of newly admitted patients by higher trainees, with consultant support, is a feasible and appropriate method for providing senior input to these patients who could potentially remain on a ward for more than 48 h without being seen by any clinician more senior than a core trainee. This would not be considered appropriate in any other medical specialty. If we are to be committed to parity of esteem in healthcare, then it is reasonable for patients admitted to psychiatric wards to be reviewed by a senior clinician within 24 h, as they would in any other hospital.³ This is particularly pertinent as the higher trainees provided some intervention in most patients, modifying medications in just under half of those admitted. It may be valuable to determine how this compares with patients reviewed during medical or surgical post-take rounds.

1.7.91 New models of care: a liaison psychiatry service for medically unexplained symptoms and frequent attenders in primary care

Abstract

Aims and method This paper describes the process of setting up and the early results from a new liaison psychiatry service in primary care for people identified as frequent general practice attenders with long-term conditions or medically unexplained symptoms. Using a rapid evidence synthesis, we identified existing service models, mechanisms to identify and refer patients, and outcomes for the service. Considering this evidence, with local contingencies we defined options and resources. We agreed a model to set up a service in three diverse general practices. An evaluation explored the feasibility of the service and of collecting data for clinical, service and economic outcomes.

Results High levels of patient and staff satisfaction, and reductions in the utilisation of primary and secondary healthcare, with associated cost savings are reported.

Clinical implications A multidisciplinary liaison psychiatry service integrated in primary care is feasible and may be evaluated using routinely collected data.

Medically unexplained symptoms (MUS) and comorbid physical and mental health conditions place a significant burden on individuals and the economy.^{1,2} Annual costs of MUS have been estimated at £3.1 billion³ and of comorbid conditions at £18 billion.⁴ Policy makers suggest innovative approaches be deployed to improve care for patients and make savings across the system.⁵

The Authors own the copyrights to the individual articles.

These patients frequently return to general practitioners (GPs) with unresolved and new complaints. Despite being referred to specialist services their problems remain, which is demoralising for all. Current primary care configurations do not adequately provide for this population. Standard secondary care mental health services rarely have staff with relevant expertise and are insufficiently close to primary care services to influence presentations. Improving Access to Psychological Therapies (IAPT) services are unsuitable due to these patients' high level of medical complexity. Access problems are further compounded by patients not meeting the referral criteria for specialist mental health services.

The skill base in liaison psychiatry services renders them an ideal source of expertise. Until recently such services were hospital-based but they can be integrated within primary care services.⁶⁻⁸ We report a novel pilot primary care liaison psychiatry service – the Primary Care Wellbeing Service (PCWS) in Bradford and Airedale, West Yorkshire. The service was targeted to frequent attenders with MUS or psychological difficulties associated with their underlying long-term conditions. This report is a description of the planning, set up and evaluation and feasibility of the preliminary project.

Method

A partnership board of clinical experts, academics and commissioners met monthly to develop and have oversight of the service; the original impetus came from local Clinical Commissioning Groups (CCGs).

A rapid evidence review helped identify service models, staffing and skill mix, patient selection and outcome measures for the service. Review findings in the context of local practitioner preferences and resources were used to agree the service configuration. The Project Board secured 15 months' funding for the preliminary project. An evaluation by the Commissioning Support Unit (CSU) assessed the feasibility of service design, implementation, collecting the data and effectiveness.

Data collection

Electronic patient health records (primary and secondary care and mental health) and measures of patient-reported outcomes, experience, and staff experience, were collected as follows: Healthcare utilisation: defined as any patient event recorded in the electronic record system; a specific Read code for the service was applied to the patient record at each practice and anonymised data extracted for 12 months prior to and 9 months following referral for secondary care data, and 11 months following referral for primary care and mental health data, providing healthcare activity and costs. Clinical effectiveness: at referral and then every 2 months during follow-up using the 9-item Patient Health Questionnaire (PHQ-9),⁹ 15-item Patient Health Questionnaire (PHQ-15),¹⁰ 7-item Generalised Anxiety Disorder scale (GAD-7)¹¹ and the EuroQol 5-dimension, 5-level health status measure (EQ-5D-5L).¹² A clinician-reported outcome measure assessed perceived improvement in the patient's condition by referring clinician. Staff experience: a referrer satisfaction scale, 6 months after the referral or at patient's discharge from the PCWS; and a survey administered at the end of the pilot. Patient experience: a brief patient-reported measure at discharge comprising (a) patient satisfaction with the service; (b) two questions asking what was good about the service and what could be improved; and (c) would they recommend the service? Case studies were used to illustrate individual formulations and negotiations that took place.

Data analysis

Feasibility of data collection was judged by the completeness of measures, using summary descriptive statistics. For healthcare utilisation and costs, a before-and-after 'time series' approach provided an indication of service effectiveness. Data points were taken from the 12-month period prior to the start of the PCWS and were truncated at 9 months post intervention for secondary care data, giving data points for months 1–21 and 11 months post intervention for primary care and mental health service data at months 1–23. Qualitative data were collated and themes reported.

The service

The literature review confirmed there was no ‘off the peg’ solution, providing information about key issues to consider when designing the service.

Service model and setting

An integrated service with specialist mental health professionals based in and collaborating with three GP practices was established. Practices were selected on the basis of expressions of interest, willingness to commit time and resources. Practices were of average size and served areas of high socioeconomic deprivation. One practice also had a high minority ethnic population.

Staffing

The team comprised a team manager, mental health occupational therapist, physiotherapist, psychology assistant, consultant psychiatrist, consultant psychologist, psychologist and administrator. Specialist advice was provided by the consultants. GP practices contributed both GP and practice nurse time.

Patient selection and referral

Most studies in the published literature used some combination of case-finding measures for mental disorder alongside frequency or cost of healthcare to identify the target population. A preliminary study in a local practice used the PHQ-9 and a search of GP electronic databases to identify distressed patients and frequent attenders. Of the 100 patients assessed with the PHQ-9, only 6 were identified who were not already in contact with services and who also had significant mood symptoms. They all declined referral. Using standardised case-finding measures failed to identify relevant candidates for this service.

Instead, GPs identified patients using a combination of their own knowledge of patients alongside a risk stratification tool. They focused on those who had a presumed diagnosis of MUS or patients with long-term conditions experiencing significant psychological difficulties, and who were also frequent attenders in primary and secondary care. Attendance was considered to be frequent when a patient had more than the average number of primary care consultations or hospital admissions and when patients’ problems remained unresolved and were escalating in cost. A discussion of potential candidates helped achieve consensus about appropriate referrals and practices were then asked to refer ten patients each, providing information on goals for referral and a summary of the patient’s health record.

Outcomes

Organisational level outcomes (health service use, healthcare costs, medication use) and patient-level outcomes (mental and physical health, physical functioning, and quality of life).

Results

In total, 28 patients were referred, with 27 appropriate referrals. One was unsuitable due to alcohol dependency and substance misuse. There was a delay of 6 months in receiving referrals from one practice, as the GP lead for the pilot left the practice. Complete data for healthcare utilisation and cost were available for 19/21 patients in 2 practices.

Health issues

A range of difficulties were identified including neuro-developmental problems; undiagnosed autism; significant health anxieties or preoccupation with illness; chronic pain and overuse of opioids; non-epileptic attacks and medically unexplained loss of movement and pain; and other maladaptive behaviours (e.g. misuse of insulin). Most patients had significant psychosocial difficulties including relationship problems, recent and past life adversity. High levels of physical morbidity such as ischaemic heart disease, chronic obstructive pulmonary disease, arthritis and head injury were also found.

Patient engagement

Patients were offered an initial joint assessment by two team members; the choice of health professionals took account of referral information about the presentation and degree of readiness to engage. For example, patients reluctant to see a mental health specialist were contacted first by the physiotherapist or occupational therapist. A flexible approach to timing and location of appointments was taken. We were able to engage with 22 of 27 patients either fully or partly with the service.

Interventions

Initial formulation developed for each patient was reviewed iteratively as alternative interventions were trialed, focused on referral goals. There were four components to interventions as follows: Taking stock and formulating the problem: review of medical notes to reconsider evidence for established diagnoses and medication reviews. Developing a function-based approach, occupationally oriented and focused on improving activities of daily living by accessing community resources; adaptations to home and mobility; introducing non-medical ways of managing pain. Psychological approaches included negotiation of a shared formulation and approach to management, with basic stress and anxiety management. Where indicated, specific therapies such as mindfulness, eye movement desensitisation and reprocessing (EMDR), trauma-focused work and acceptance commitment therapy (ACT). Service-level approaches included non-contingent access to practice staff to manage escalating demands and avoid unscheduled hospital and Accident and Emergency attendance; liaison with GPs and other specialists to agree a consistent approach.

Feasibility of data collection

Of the 19 patients for whom data could be collected there were only 8 complete data-sets for EQ-5D-5L, GAD-7 and PHQ-9, and 7 complete data-sets for PHQ-15 and EQ-5D-5L.

Healthcare utilisation data from the clinical system were readily available, although it was not possible to collect out-of-hours data. However, gathering information on prescriptions and costs of medication was prohibitively resource intensive.

Feasibility and effectiveness of the service

Across the whole patient cohort, secondary care activity reduced by an average of nine events per month. In the 9 months after the implementation of the PCWS, 177 fewer events occurred in secondary care (*Fig. 1*).

Nine months after implementation the total cost of activity was £63 950 less than the previous year (*Fig. 1*). The cost of secondary care activity reduced by an average of £3702 per month after the implementation of the PCWS (*Fig. 2*). Primary care activity had also reduced across the whole patient cohort by an average of 11 events per month.

Primary care

Time spent delivering care reduced by an average of 7 min per month. A substitution effect was observed in primary care with GPs delivering an average of 12 appointments and 127 min less to the patient cohort since the implementation of the PCWS. In contrast, other clinical staff delivered one additional appointment and 120 min more to the patient cohort.

Primary care costs were reduced across the whole scheme by an average of £171 per month for the cohort of 19 patients. In some cases, interventions led to significant changes in symptoms and health-seeking behaviours (*Box 1*). In others, work is still ongoing and longer-term intervention will be needed.

Discussion

What works in a research study does not easily translate into routine clinical practice in the National Health Service (NHS). In this study, academics and GP commissioners worked with specialist mental health providers to consider the evidence and identify local resources to design the best service configuration for patients with MUS, long-term conditions and frequent attenders in primary care. There is no short-term solution for these complex patients but a liaison psychiatry service based within primary care and as part of a long-term care plan shows great promise.

Identifying the patient group for the service and managing complexity

The service presented here addresses a common problem for GPs, which traditional diagnostic categories do not describe well and standard mental health services do not currently manage well. This is not the first attempt at establishing primary care-based liaison services. The service described, however, is unique because it eschews traditional collaborative care approaches¹³ and screening for anxiety and depression widely described in the research literature.^{13,14} In clinical practice that type of screening does not identify the right candidates to work with. The GPs and practice staff identified patients for this study by focusing on those patients with MUS or long-term conditions who were struggling to cope and that were returning with unresolved physical and emotional problems with rising healthcare costs. This was facilitated by a discussion of the case and the development of the vignette prior to referral to the PCWS. There was a level of detail in identifying this type of patient that required consideration and scrutiny by practice staff which could not be picked up by electronic systems or case-finding measures alone.

Patients with such complex conditions cannot be managed in standard ways following a protocol. They require a creative approach to person-centred care that supports their identification and management. In almost all cases the GPs were correct in identifying the right patients for the service via their clinical presentation, the exception being someone who required support from specialist addiction services.

Box 1 Case study

Patient A was a frequent attender at Accident and Emergency, the GP practice and mental health services, with a range of physical and non-psychotic mental health symptoms. She had a suprapubic catheter due to incomplete bladder emptying and detrusor overactivity; she found it too distressing to self-catheterise using a urethral catheter because of a history of sexual abuse. As she was struggling with the suprapubic catheter, an operation was planned to create a conduit between the skin and bladder to make catheterisation easier. However, there was concern that this would not address the underlying reasons for her frequent presentations, and would in fact increase her physical health problems, for example,

increasing her risk of urinary infection. Following referral to the Primary Care Wellbeing Service (PCWS), a review of her case notes revealed that her urodynamic studies had been normal. The team liaised with the surgeon, who agreed to a trial of bladder retraining. The team worked to engage patient A and to develop a shared formulation with her about the reasons for her urological difficulties and accept that her physical health difficulties could be managed in a non-operative way. We recognised the importance that all staff conveyed the same message to the patient and that care did not suddenly decrease while other changes in care took place. With input from the practice nurse and the PCWS team, she was able to start passing urine again without the catheter.

Challenges to service delivery and data collection

Our findings suggest that such services are feasible to deliver but that practices can struggle without sufficient staff to deliver the service. This accords with the literature¹⁵ which suggests an assessment of practice readiness be performed but this might not account for unexpected changes in practice staffing and infrastructure. Patients and staff that completed satisfaction measures were satisfied with the service, although it is possible that those that did not complete measures did not have such a positive experience. Further, it was not possible to routinely collect self-reported outcome measures in routine practice for this service. Given that these practices were highly motivated to take part, it is unlikely that collecting self-report measures, as part of an evaluation package, would be feasible in less motivated practices. Feedback from staff suggested that they were not able to collect this additional data. Any additional work to use self-report measures in practice needs to consider the burden of additional work for practice staff against the need to collect this information. However, routinely collected data on service use and cost proved to be feasible to collect as this is already part of the existing monitoring systems. Again, out-of-hours information was not collected as part of this. Case studies enabled practitioners to consider how well the patient progressed helping to sustain the service in its early phases using cases as a feedback loop as proposed in the literature.¹⁵

Implementing new service models requires a long-term view

There are challenges in setting up and maintaining such services, however. We cannot be sure that they will be cost-effective in the longer term, as the full costs of the service were not examined here only salary costs. This type of analysis would need to be evaluated in a larger study of effectiveness taking account of the commissioning cycle and utilising an economic evaluation. This pilot was only conducted in one metropolitan district in England. Population demographics, health service configurations and commissioning arrangements vary across the UK, and our findings and experience may not be generalisable. Moreover, GP practices taking part were selected for their willingness to engage with the pilot, with one out of the three being unable to launch the proposed service within the project time frame.

Findings from the evaluation are not definitive, but rather provide important data to inform the next stages of service development and evaluation. This pilot demonstrates that service developments can be implemented using NHS resources and commissioning processes, and evaluated using routinely collected data. However, including patient self-report and staff measures, which are not part of usual care, requires additional resources. Administering and collecting paper-based measures for patients and staff proved onerous, with incomplete data collection from all practices despite concerted efforts to collect these by the team.

Questions of sustainability and scaling up need to be considered. In this feasibility study, there were significant reductions in secondary care activity and cost. If such a service could be extended then a further study including full economic costs would be of interest. Such transformation requires commissioners to take a long-term view and to accept that cost savings may be negative or neutral in the first year or more.

Future proposals

To maintain the momentum and build on this project and other innovative pilots in the UK,^{6,7} we propose setting up a network of interested colleagues to critically consider the future development of primary care liaison psychiatry services. The purpose would be to share experience and to inform further implementation projects and design approaches to the particular problems of scaling up and managing the needs of patients with complex problems who are prone to relapse and likely to require repeated specialist help or longer-term care plans.

The Clinical Commissioning Groups of NHS Airedale, Wharfedale & Craven and NHS Bradford Districts commissioned the Health Economics, Evidence and Evaluation Service (HEEES) of Yorkshire and Humber Commissioning Support to evaluate the Primary Care Wellbeing Service pilot.

1.7.92 Systematic review into factors associated with the recruitment crisis in psychiatry in the UK: students', trainees' and consultants' views

Abid Choudry Saeed Farooq

2017-12

Abstract

Aims and method To review the literature to examine the factors that may be affecting recruitment into psychiatry in the UK. We systematically searched four databases to identify studies from 1974 to 2016 and identified 27 papers that met the specified inclusion criteria.

Results Most papers ($n = 24$) were based on questionnaire surveys. The population in all studies comprised of 1879 psychiatrists, 6733 students and 220 746 trainees. About 4–7% of students opt for a career in psychiatry. Enrichment activities helped to attract students more towards psychiatry than just total time spent in the specialty. Job content in terms of the lack of scientific basis, poor prognosis and stigma towards psychiatry, work-related stress and problems with training jobs were common barriers highlighted among students and trainees, affecting recruitment. Job satisfaction and family-friendly status of psychiatry was rated highly by students, with lifestyle factors appearing to be important for trainees who tend to choose psychiatry.

Clinical implications Negative attitudes and stigma towards psychiatry continue to persist. Teaching and training in psychiatry needs rethinking to improve student experience and recruitment into the specialty.

 - * *Limitations*

Psychiatry as a career has been negatively regarded and unpopular among medical students. About 3.6% of British graduates decide on a career in psychiatry whereas about 6% are needed.¹ From 2000 to 2011, the absolute number of consultant psychiatrists in England rose from 2904 to 4394 (an increase of 51%), with similar increases in Scotland and Wales, in line with the expansion of the consultant workforce in most secondary care specialties.¹ A need for more psychiatric consultant posts has been predicted based on projections of increasing workloads due to the increased population needs.² A perceived fall in the proportion of UK medical school graduates choosing a postgraduate career in psychiatry, and low competition ratios for first-year core specialist training (CT1) posts in psychiatry,³⁻⁵ has led to many questions about the way in which psychiatry is taught at medical school and how psychiatry could be made as an attractive career option.⁶⁻⁸

Low recruitment in psychiatry is a global issue, highlighted in a number of publications.^{9,10} However, the problem also has country-specific dimensions, as each country has different factors such as the pay scale for the specialty, medical education system and training programmes, which may attract or dissuade medical students from a career in psychiatry. The subject has not been reviewed systematically especially in the context of recruitment in the UK. The review question was: what are the factors that influence recruitment to psychiatry as a career choice and how can this be improved? The aim of this paper is to systematically review the literature from the UK on psychiatry as a career choice. We are specifically interested in identifying the factors that influence the recruitment into psychiatry with emphasis on barriers and facilitators affecting recruitment. A greater understanding of the views ranging from medical students to trainees and consultants working in the UK may enable curriculum developers and recruitment leads to design programmes that attract students and trainees to psychiatry as a career and improve students' attitudes towards psychiatry in the long term.

Method

We followed the PRISMA statement¹¹ as a guide for conducting the systematic review. The following electronic databases were searched from 1974 onwards: Medline, EMBASE, CINAHL, PsycINFO. These databases were selected in view of the fact that almost all the literature published from the UK would be covered in these databases. Keywords used in the searches included: medical students, trainees, doctors, consultant, attitudes, psychiatry, career, undergraduate psychiatry. Boolean operations and truncations were added to allow for alternative endings in the keyword searches. The search was last updated in August 2016.

We included studies that described a UK sample, were published in English in a peer-reviewed journal and provided original data on careers in psychiatry or factors affecting recruitment in psychiatry. We excluded studies that had the primary objective of addressing other issues that were not directly relevant to recruitment in psychiatry but only mentioned their effects on career choice as a secondary effect. Studies which provided data on medical careers in general were included if these provided data relevant to psychiatric careers or recruitment.

The electronic search returned 601 relevant abstracts and titles. We screened the titles and abstracts and excluded the studies that were not directly relevant to the objectives of the review. Therefore we excluded the studies that did not describe a UK sample or did not provide the original data. We also excluded the studies that described the recruitment to certain subspecialties and therefore not relevant to the recruitment to psychiatry in general. After screening these titles and abstracts we decided to examine 56 full text papers. Finally, we included 27 papers in the review. Further details are provided in *Fig. 1*. The studies were conducted in a number of different populations, settings and periods, and also used diverse methodologies varying from surveys to statistics derived from databases. The 30-item Attitudes Towards Psychiatry (ATP-30),¹² a validated tool used to assess attitudes of students towards psychiatry, was used in four papers; other papers used different questionnaires to assess attitudes. Due to the diverse methodologies it was inappropriate to pool the data to produce a statistical summary. We therefore describe the main findings and produce a narrative summary of results.

Results

Characteristics of included studies

Table 1 shows the characteristics of the 27 studies included in the review. The majority of studies ($n = 24$) were surveys and questionnaire-based studies. The other studies included one database study of doctors entering training posts and two retrospective cohort studies, which looked at which medical school psychiatrists had attended. These reported on medical students ($n = 12$), trainees ($n = 10$), medical students and trainees ($n = 1$), trainees and consultants ($n = 1$) and consultants ($n = 3$). One of these studies looked at data from postgraduate departments in different medical schools, and one study reported on the database of applicants to MMC (Modernising Medical Careers) for training posts.

Data not used from this paper just broad findings in review.

In survey-based studies response rates varied from 16% to 100%. Mean response rate from the papers which had figures available ($n = 20$) was 63.3%. The population in all studies comprised of 1879 psychiatrists, 6733 students and 220 746 trainees. One database study¹³ looked at 31 434 trainee doctors, and studies by Goldacre *et al* were aimed at all doctors in training, accounting for large numbers of respondents in the trainee subcategory.^{14–18}

The influence of the medical school and teaching practices

Most of the research addressing the influence of the medical school and teaching practices on selecting psychiatry as a career was carried out in the 1970's and 1980's. Two studies by Brook *et al*^{19,20} looked at the medical school of origin for 531 psychiatrists between 1961 and 1970 and reported no significant relationship between schools that had a professional unit or specific teaching programme and students pursuing psychiatry in the long term. However, it was noted that those schools that produced fewer psychiatrists tended to have either a recently established professional unit or none.¹⁹

No clear pattern emerged in terms of the type of teaching offered at each university and the impact this had on choice of psychiatry as a career in the long term.¹⁹ All four Scottish schools, and Cambridge and Oxford were noted to be higher in terms of producing psychiatrists, attributed possibly to the well-established professional units such as the Maudsley and Bethlem Royal hospitals.¹⁹ The personality, charisma and enthusiasm of teachers were associated with an increase in the uptake of psychiatry in the long term.^{19,21}

Brook *et al*²¹ found that the effectiveness of teaching rather than the amount of teaching had an effect on student attitudes and recruitment into psychiatry. The attitude of non-psychiatric teachers appeared to be influential with doctors experiencing negative attitudes of other doctors towards psychiatry.²¹ The two hospitals which ranked top in terms of producing psychiatrists had changed their teaching model. One stressed the importance of psychiatry as being part of general medicine, emphasising the effectiveness of physical therapy, whereas the other placed emphasis on liaison psychiatry and psychotherapy.²¹

More recent work by Collier *et al*²² looked into the teaching time allocated for psychiatry in foundation programmes across the country. They found that only 2.3% of teaching was dedicated to psychiatry compared with 44.1% to medical and surgical topics.²² Exposure to psychiatry remained limited with 4 out of 17 hospitals in the survey not having any teaching on psychiatry for medical students.²² Doctors generally led a higher proportion of medicine and surgery teaching sessions (63%) compared with psychiatry (48%).²²

Medical students' views of psychiatry and factors affecting career choice

Twelve studies examined the factors affecting medical students' career choice and one study looked at both medical students and trainees. Petrides *et al*²³ studied the theoretical understanding of how different medical specialties are perceived and how choices are made. Psychiatrists were found to have a more artistic approach to medicine, seeing interpreting and responding imaginatively to a range of medical, social, ethical and other problems. This is in keeping with early work by Levine *et al*²⁴ who also found that there was a group of students who were 'psychologically minded' and they could be identified and encouraged to make psychiatry as career choice.

Budd *et al*²⁶ found that job satisfaction (98%, $n = 128$) and family-friendly status of psychiatry (79%, $n = 103$) were important for students who rated psychiatry as one of their top three choices.²⁶ The academic status was significantly less important (48%) for students who placed psychiatry as their top three specialty schools v. 63% for those who did not place psychiatry in their top three choice.²⁶

Choice of psychiatry as a career among medical and sixth form students

The number of students choosing psychiatry has remained fairly stable at around 4–7%.^{25–27} Three per cent of students from six medical schools placed psychiatry as their first choice, with 18% seriously considering it.²⁰ Halder *et al*²⁸ found similar results in 18 medical schools; 16% chose psychiatry as a future career on entering medical school but by the final year only 3% had decided to pursue a career in the subject. These results were replicated by Farooq *et al*²⁷ In a survey of sixth form students, Maidment *et al*²⁹ reported that 60.9% ($n = 363$) indicated that it would be very likely or they would definitely want to pursue psychiatry as a career. In terms of overall intentions to pursue a career in a specialty, the ratings for psychiatry was similar to general medicine at 12.4% ($n = 72$) v. 12.2% ($n = 69$) respectively.²⁹

Effect of undergraduate attachment and education on choosing psychiatry as a career

Positive attitudes towards psychiatry and the influence by a teacher during the attachment correlated with an intention to pursue psychiatry as a career in the long term.²⁹⁻³¹ Three studies highlighted the importance of psychiatric attachment. Student attitudes improved as the attachment progressed.^{26,30,31} Maidment *et al*²⁹ found 1.4% of fourth-year medical students expressed a definite intention to pursue which rose to 4.7% after their attachment.²⁹ McParland *et al*³⁰ reported that 19% ($n = 58/309$) of students were very attracted to psychiatry or had a definite intention to pursue psychiatry at the start of the placement, which increased to 27% ($n = 101/373$) of students at the end of the attachment. The importance of the undergraduate experience was highlighted by a recent study showing 50% of consultants and 37% of trainees surveyed decided on a career in psychiatry while still at medical school.³²

Calvert *et al*³³ looked into the attitudes of medical students towards psychiatry and psychiatric patients at year 1, 3 and 5 in medical school. First-year medical students were more likely to have stereotypical views compared with third- and fifth-year students, and were more likely to agree with statements such as 'Psychiatry deals with imaginary illness' (mean 1.4, s.d. = 0.9, $P < 0.5$).³³ Fifth-year students (mean 3.2, s.d. = 1.4) showed lower agreement than third-year medical students (mean 3.6, s.d. = 1.2, $P < 0.5$) with the statement 'Psychiatry is as a challenging career'.³³ As they progressed through medical school, students recognised that mental illness has serious morbidity and that people do recover from mental illness,³³ showing that attitudes towards psychiatric patients improved with greater clinical experience but possibly became more negative towards psychiatry as a career.

Other factors that appeared to affect students positively included enrichment activities, i.e. activities beyond standard teaching and clinical placements led to a significantly increased interest in psychiatry.²⁸ These included research experience in psychiatry (13% v. 4% in those not interested in psychiatry, $P = 0.001$), university psychiatry clubs (38% v. 11%, $P < 0.001$), psychiatry electives (14% v. 1%, $P < 0.001$) and psychiatry special study modules (38% v. 16%, $P < 0.001$).²⁸

McParland *et al*³⁰ identified factors which increased interest in psychiatry, including: influence or encouragement by someone during the attachment (74%, $n = 282$), particularly the influence by consultants (43%, $n = 163$), exposure to interesting and stimulating ideas (29%, $n = 110$), liking someone's approach (27%, $n = 103$), feeling someone believed in their ability (11%, $n = 41$) and having formed close working relationships (9%, $n = 33$).³⁰ Other factors that had a significant impact were: receiving encouragement from the consultants ($n = 374$, $P < 0.001$, $r = 0.26$), seeing patients respond to treatment ($n = 374$, $P < 0.001$, $r = 0.20$) and having a direct role in the involvement of patient care ($n = 374$, $P < 0.001$, $r = 0.26$).³⁰

Factors which did not affect career choice of medical students

Seeing patients in different settings or different phases of the illness had no effect on career choice of medical students when deciding their career intentions.²⁸ Interestingly, one study found that the earning potential and status of psychiatry had no effect on selecting psychiatry as a career choice.²⁶ Other factors related to teaching such as quality of rating of small group teaching and lectures,²⁸ the curriculum type used^{30,31} and performance at viva examinations and multiple choice questions also had no effect on the career choice.³¹

Factors discouraging medical students to choose psychiatry as a career

Curtis-Barton *et al*²⁵ in their survey ($n = 467$) found that the factors discouraging students to pursue a career in psychiatry included: prognosis of patients (62%), perception that there is a lack of evidence in diagnosis (51%), lack of scientific basis (53%) and the amount of bureaucracy and paperwork in the specialty (48%). Other discouraging factors included the stigma towards psychiatry (30%), the standing of the profession among medical colleagues (31%) and comments by other specialists (26%).^{25,34} Psychiatry scored the lowest among the specialties as a career choice. Students described psychiatry as boring, unscientific, depressing, stressful, frustrating and 'not enjoying the rotation'.³⁵

Many students experienced psychiatry as being different to other specialties. For some this was a reason not to pursue psychiatry as a career but for others it was a positive aspect of the specialty. Students felt ward rounds focused on 'social

issues' rather than medical conditions. Some found it an 'emotional burden' and others felt that psychiatry could not 'fix' people and no one is being cured.³⁴

A survey by Korszun *et al*³⁶ examined the views of trainee, academics and clinicians on students not taking up psychiatry. The following factors were identified as deterring the students from psychiatry: negative attitudes towards psychiatrists from other doctors and health professionals (57%), stigmatisation of psychiatry (40%), stigma associated with mental health disorders (39%), poor teaching and role modelling from psychiatrists (37%), psychiatry not seen as medical or scientific enough (26%) and poor morale among psychiatrists (26%).³⁶

Factors affecting trainees' and consultants' choice of psychiatry

Fazel *et al*¹³ found that psychiatry was the sixth most popular specialty out of ten specialty groups for trainees applying for training places. A higher proportion of female graduates were shown to choose psychiatry between 1974 (32%) and 1999 (59%).¹³ However, a more recent survey showed a slight decline in the number of women choosing psychiatry over the last decade, 4.9% (1999) v. 4.6% (2009).¹⁷

Goldacre *et al*¹⁴ examined career choices for medical students over the past 40 years. The number of doctors choosing psychiatry as a career has hardly changed and remains around 4–5%, which is similar to figures from 1975.¹⁴ It was noted that students who went on to work in psychiatry 10 years after graduation, 52% (224 out of 428) had chosen psychiatry in the first year after graduation and 71% (308 out of 434) had chosen it in year 3.¹⁴

In common with the factors attracting students towards psychiatry, numerous studies identified factors that appear to attract trainees towards psychiatry. The major attractions for choosing psychiatry are listed in *Box 1*. Denman *et al*³² found that the most common factor influencing core trainees' (60%) and consultants' (70%) decisions to specialise in psychiatry was emphasis on the patient as a whole.³² Trainees highlighted that mental health was an area of need (53%) and empathy and concerns for people with mental illness (53%) were important reasons for choosing psychiatry.³²

Box 1 Factors attracting medical students and trainees in pursuing psychiatry as a career

Medical students

- Encouragement by colleagues^{24,26,30,31}
- Influence by someone during the placement^{24,30}
- Females are more likely to favour a career in psychiatry^{24,27,30}
- Family history of mental illness was associated with choosing psychiatry²⁴
- Quality of experience^{26,27,30,33}
- Role models can have a positive impact on students pursuing a career in psychiatry^{28,30,33}
- Enrichment activities^{27,28}

Trainees

- Hours and conditions of work^{17,31,32}
- The doctor's personal assessment of their aptitudes and skills,^{17,31,32} for example recognising factors such as using one's intellect to help others³⁷
- Experience of the subject as a student^{17,31}
- Inclinations before medical school and a positive student experience^{17,37}
- Attitudes and inclination to psychiatry as a medical student^{24,31,37}

- Lifestyle factors ^{32,37}
- Encouragement from consultants and senior doctors ³¹
- Emphasis on the patient as a whole person and empathy/concern for mentally ill people ³²

Barriers associated with not choosing psychiatry as a long-term career choice for trainees

Barras & Harris ³⁸ explored trainee's experiences ($n = 359$) within psychiatry. Trainee attitudes were grouped into different categories. The attitudes towards psychiatry (12.6%), professional role (12%) and day-to-day working (11.3%) were identified as the main negative factors. Trainees raised concerns with the training programmes in psychiatry, such as problems with the rota and not having enough time with patients. ³⁸ Many trainees felt frustrated with the Annual Review of Competence Progression (ARCP) process and workplace-based assessments, as well as the duplication of paperwork being a constant frustration. ³⁸

The studies identified a number of barriers against choosing psychiatry as a career (*Box 2*).

Trainees felt improvements were needed in terms of training opportunities and felt this could be enhanced by providing a variety of jobs, increasing research opportunities and increasing medical aspects of training. ³⁸

Work looking into consultant psychiatrists' views into why they chose psychiatry was limited to two papers. ^{32,39} Dein *et al* ³⁹ found that the majority of consultants (46%) chose psychiatry as a career soon after leaving medical school, and a recent study surveying consultants in the West Midlands found that 50% had made their choice by graduation from medical school. ³² The main reasons cited by consultants for choosing psychiatry as a career included: empathy for those with a mental disorder (36.1%), interface with neuroscience (25%), expectation of better working conditions in psychiatry (20%) and influence of teaching at medical school (19.4%). ³⁹ Denman *et al* ³² highlighted several 'very important' reasons for consultants choosing psychiatry including: career in psychiatry would be intellectually challenging (60%), sense of fulfilment expected from seeing patients improve (47%) and enjoyment of problem-solving (47%). Lifestyle factors such as salary, better working conditions and quality of life were shown to be more important reasons for choosing psychiatry for trainees compared with consultants. ³²

Box 2 Barriers associated with not choosing psychiatry as a career

- Job content (71.7%) ($n = 71$) (including the lack of scientific basis, job not being clinical, poor prognosis) ^{15,17,25,35,36,38}
- Poor public image of psychiatry ^{15,25,36}
- Lack of respect towards psychiatry as a specialty by other specialties ^{15,25,36}
- Work-related stress cited by (49%) ¹⁵ trainees in psychiatry ³⁸
- 25–50% of trainees leaving psychiatry as a specialty cited lack of resources as one of the main reasons which was significantly more than those rejecting general practice and trauma and orthopaedics ^{15,38}
- 25–50% of trainees leaving psychiatry ^{15,16,38} highlighted:
 - a. lack of adequately supervised training
 - b. lack of evidence base to diagnosis and treatment
 - c. lack of improvement in patients
 - d. work-life balance
 - e. work not clinical enough
- Physical risks involved in the job ¹⁵
- Sense of eroded professionalism ^{36,38}
- Too much paperwork and duplication ^{25,36,38}

- Problems with rota and not enough time with patients ³⁸
- Trainees leaving the scheme felt frustrated with workplace-based assessments ³⁸
- Low morale among workforce ³³
- Future role of psychiatrists being eroded ³³

Discussion

This is the first systematic review of literature which examined factors that influence the choice of psychiatry as a career in the UK. The main findings are that enrichment activities help to attract students more towards psychiatry than just total time spent in the specialty. Job satisfaction and family-friendly status of psychiatry was rated highly by students who tend to choose psychiatry. Role models and encouragement from consultants may increase the number of students who want to pursue psychiatry as a career. The major factors that appeared to dissuade medical students/trainees from pursuing psychiatry as a career included: an apparent lack of scientific basis of psychiatry and work not being clinical enough, perception that psychiatry is more concerned about social issues, the bureaucracy, paperwork, apparent poor prognosis of patients, stigma towards psychiatry as a specialty, low morale, and onerous workloads as a consultant.

We are aware of one previous systematic review that examined medical students' attitudes towards psychiatry internationally. ⁴⁰ In common with our study this systematic review alongside another survey of psychiatrists ³⁶ highlighted the stigma towards mental illness as a major barrier influencing negative medical views towards psychiatry. ⁴⁰ Stigma towards psychiatry as a specialty arises from a variety of sources, notably from medical students themselves. In addition, this stigma could arise from ward staff attitudes towards patients and from other doctors in other specialties, which detract students. ^{13,25,34}

Other reviews have looked at one aspect such as the effect of clinical experience of psychiatry on medical students' attitudes towards the specialty. ⁴¹ Lyons ⁴⁰ highlighted the impact of poor-quality teaching leading to negative attitudes towards psychiatry and highlighted the need to address psychiatry curricula and introduce novel teaching strategies. ⁴⁰ El-Sayeh *et al* ⁴² have previously highlighted the importance of teaching and the various methods which could be utilised to try to improve the student experience and in turn help attract students towards psychiatry. The recent survey by Korszun *et al* ³⁶ highlighted that the number of clinicians compared with academics and trainees agreed that they did not have time to teach medical students ($P < 0.001$). Both clinicians (42%) and academics (47%) felt that teaching medical students did not contribute to their future career prospects compared with 21% of trainees ($P < 0.001$) ³⁶ Fewer clinicians considered teaching to be a significant component of their appraisal compared with trainees and academics. ³⁶ The combination of poor teaching practices due to lack of resources or commitment and the stigma reinforce the poor image of psychiatry.

We feel that the findings of our study support the recommendations made by Mukherjee *et al* ⁴³ which identify a number of steps to address the crisis in psychiatry recruitment at different nodal points in a medical career, i.e. prior to entry to medical school, during medical education and after graduation.

Improving recruitment

This study highlights the need to change the experience of psychiatry at undergraduate and postgraduate level in keeping with work by Shah *et al* ⁴⁴ who highlighted early medical experience, influence of seniors and the aspects related to working environment as areas that could be affected positively which in turn could have a positive effect on choosing psychiatry as a career. Kelley *et al* ⁴⁵ highlighted the impact of foundation programme experience in psychiatry, with a significantly higher proportion of trainees pursuing a career in psychiatry compared with those without any exposure to psychiatry (14.9% v. 1.8%). This correlates with earlier findings by Shah *et al* ⁴⁴ that found a significant correlation between those Scottish students considering psychiatry as a career and having held a psychiatry post. ⁴³ A recent survey by Denman *et al* ³² showed that 43% of psychiatry trainees made their decision to specialise in psychiatry during the foundation years, correlating with increased exposure to psychiatry during the foundation years with 80% of trainees in this survey completing a post in psychiatry during the foundation years. Specific enrichment activities beyond standard teaching and clinical placements such as research experience in psychiatry, university psychiatry clubs, summer schools,

⁴⁶ psychiatry electives and psychiatry special study modules appear to be a way in which medical students will gain invaluable experiences and improve their attitudes to psychiatry. These need to be adopted and evaluated in future programmes to enhance recruitment in psychiatry Collier *et al* ²² found that only 2.3% of teaching was dedicated to psychiatry compared with 44.1% to medical and surgical topics, which does not help the poor image of psychiatry. This and similar issues need to be addressed at institutional level.

A number of studies found that psychiatry has a perception that it is not a 'scientific' or 'medical' discipline. ^{15,36,38} Medical students and trainees expressed the views about the weakened medical identity of psychiatry. The erosion of the role of the psychiatrist was cited by some psychiatry trainees as a potential factor that would make them consider leaving psychiatry training. ³⁸ This unfortunately is not helped by negative comments or 'bad-mouthing' of psychiatry. ^{36,47}

Interventions such as anti-stigma films and Medfest ⁴⁸ have been shown to improve medical students' attitudes to psychiatrists, serious mental illness and psychiatry, at least in the short term. ^{48,49} However, it appears that there is need to reconsider the content of psychiatric training and the undergraduate curriculum. It has been suggested that moving undergraduate teaching from in-patient to general hospital settings such as liaison psychiatry will allow students to see patients with problems that are relevant to medical practice. ⁴⁷ Setting up and evaluating such programmes that have the potential to offer a different and enjoyable experience for medical students and foundation doctors should be a priority to improve the image of and recruitment into psychiatry.

Limitations

A limitation of the study is that almost all data are based on surveys and databases. This represents a cross-sectional view on the subject. The lack of any comparisons with other specialties, which may have similar recruitment rates, is particularly concerning. The focus on UK studies is also a limitation but was necessary to understand the factors affecting recruitment in this country. We noted with some concern that there are only a few studies that address the positive aspects of psychiatry, ^{26–28,30–33} which may attract students and trainees towards psychiatry, and how these can be used for improving the recruitment. Future studies need to address this gap in the literature. Finally, we feel that the problems underlying the recruitment in psychiatry perhaps also reflect the lack of parity of esteem. Unless mental health is valued equally with physical health, the misconceptions and distorted perceptions about psychiatry as a discipline in which a medical career can be fruitfully pursued will linger on and will hinder aspiring physicians from considering psychiatry as a career option.

1.7.93 Mental Capacity Act (Northern Ireland) 2016 †

Abstract

Mental health legislation in Northern Ireland has always been separate from legislation in the rest of the UK; the Mental Health (Northern Ireland) Order (MHO) had been in place since 1986. In common with other jurisdictions, this legislation utilises the presence of mental disorder and risk as criteria for detention and involuntary treatment. The MHO has been replaced by the Mental Capacity Act (Northern Ireland) 2016 (MCA), an example of ‘fusion’ legislation in which impairment of decision-making capacity and best interests are the only criteria to be used when making decisions across health and social care. In this paper, we outline the development of the MCA to date, and discuss its potential to improve mental healthcare by placing the treatment of mental illness within the same legislative framework as physical illnesses.

The Mental Capacity Act (Northern Ireland) 2016 (MCA) is an example of a ‘fusion’ legislation – a generic law applicable across all medical specialties and social care where an intervention is proposed and the person has impaired decision-making capacity.

The MCA was enacted in May 2016. Since then, the Department of Health has completed phase 1 of the implementation work; creating a first working draft of a code of practice, and working on forms and draft regulations associated with the Act. This work has been shared with a ‘virtual’ MCA Reference Group, composed of a wide range of stakeholders. The first full draft of the code of practice, forms and regulations have recently been circulated to the MCA Reference Group and the second phase, a pre-consultation phase on the full draft, has just begun.

Background

The Bamford review of mental health and learning disability, established in 2002, was a wide-ranging examination of the delivery of mental health and learning disability services in Northern Ireland.

In addition to the examination of service delivery, the review also undertook a review of the mental health legislation, the Mental Health (Northern Ireland) Order (MHO), which had been on the statute books since 1986. Criteria for involuntary treatment of mental illness under the MHO were based on diagnosis and risk; the presence of mental illness or severe mental impairment, and failure to detain leading to a substantial risk of serious physical harm to self or others. In addition, certain conditions were specifically excluded – no person could be detained solely on the grounds of personality disorder, dependence on alcohol or other drugs, or sexual deviancy.

There was no specific or separate mental capacity legislation in Northern Ireland. Decisions on the treatment of incapacitous patients are taken under common law, with decisions based on a presumption of capacity and the doctrine of necessity (best interests).

The Bamford review decided that the legislation was not compliant with essential principles (autonomy, justice, benefit and least harm). In 2007, it recommended that: ¹ There should be a single comprehensive legislative framework for the reform of mental health legislation and the introduction of capacity. The framework should be based on agreed principles. These principles should apply to all healthcare decisions, as well as welfare and financial needs. Impairment of decision-making capacity should be a mandatory prerequisite for any interference with a person's autonomy without their consent. Individuals who are subject to the criminal justice system should have access to assessment, treatment and care which is equivalent to that available to other people.

A public consultation was held in 2011. There was strong support for the proposal of a single legislative framework. It was therefore decided to fuse mental capacity and mental health law into a single bill. The resulting draft bill was the subject of another consultation in 2014, followed by its introduction to the Stormont Assembly. There, it underwent further consideration and amendment, and was passed as the Mental Capacity Act (Northern Ireland), receiving Royal Assent in May 2016.

Aims and principles

Fusion legislation provides equally for all circumstances in which a person's autonomy might be compromised on health grounds. It puts impaired decision-making capacity at the heart of all non-consensual interventions. By treating mental and physical illnesses equally under the law, it reduces stigma associated with separate mental health legislation, and is respectful of a person's autonomy and decision-making capacity whether they have a mental or a physical illness.

Compatibility with international statements on human rights, particularly the European Convention on Human Rights (ECHR) ² and the United Nation's Convention on the Rights of Persons with Disabilities (CRPD), ³ is an issue for any legislation dealing with involuntary treatment. Conventional mental health legislation, which uses a diagnostic test for involuntary treatment, could be regarded as being incompatible with Article 14 (1) (b) of the CRPD – 'the existence of a disability shall in no case justify a deprivation of liberty'. No UK mental health legislation is currently compliant with the CRPD.

Proponents of fusion legislation argue that capacity, as the test for involuntary treatment, is a functional test, i.e. a particular ability at a particular time, and therefore not directly linked to diagnosis or disability. However, the MCA retains a 'diagnostic' element; the person is unable to make a decision because of an impairment of, or a disturbance in, the functioning of the mind or brain. It therefore arguably still fails to satisfy Article 14 (1) (b) of the CRPD. Nevertheless, the MCA is fully compliant with the ECHR, and its strong rights- and principles-based ethos moves the legislation significantly towards CRPD compliance.

Content of the MCA

The MCA revokes the MHO for those aged 16 and over and puts common law into statute.

Capacity test

Statutory decision-making will come into play when a person lacks capacity. There is a presumption that the person has capacity, there must be no unjustified assumptions based on age, appearance or condition, there must be a respect for decisions even if unwise, the person must be given all practical help and support, and the act must always be in the person's best interests.

There are two tests to be satisfied in reaching a decision about a person's decision-making capacity: a diagnostic test – there must be an impairment of, or a disturbance in, the functioning of the mind or brain, and; a functional test – the person is unable to understand the information relevant to the decision, to retain the information long enough to make the decision, to appreciate the relevance of that information and use or weigh the information as part of the process of making that decision, and communicate the decision. There must be a causal link between the two tests – the person is unable to make a decision because of impairment or disturbance in the brain or mind.

Looking at the functional test, the specific difference between this and other definitions of lack of capacity is the use of the word 'appreciate'. The consultation document ⁴ emphasises the importance of the inclusion of the appreciation element: its inclusion moves a decision about capacity from a purely cognitive test (p. 13, para. 2.22). The consultation document gives as an example: 'A person whose insight is distorted by their illness or a person suffering from delusional thinking as a result of their illness may not, therefore, meet this element of the test' (p. 13, para. 2.22). ⁴

Protection from liability

The legislation puts into statute the common-law definition of necessity and protects the person (D) doing the act from liability if D takes reasonable steps to establish whether the person (P) lacks capacity in relation to the matter in question and D reasonably believes that it is in P's best interests for the act to be done. There is therefore a shift in emphasis from the MHO, which confers statutory powers, to a situation where non-consensual intervention is predicated on protection from liability for D.

Future decision-making

The Act includes a robust lasting powers of attorney system. A lasting powers of attorney must be registered with the Office of Public Guardian before being activated and extends to health and welfare decisions, when the attorney reasonable believes that the person lacks capacity and must always act in the person's best interests.

In addition, advance decisions to refuse treatment must be complied with, if valid and applicable under common law. This means that an effective advance decision to refuse treatment for a mental disorder (or indeed any disorder) cannot be overridden, if made when P had capacity. However, the Act allows that, if there is doubt, D will be protected from liability if he or she gives life-sustaining treatment or treatment required to prevent a serious deterioration in P's condition. Advance decisions were not put into statute in order for the courts to continue to develop the law in the light of the MCA.

Safeguards

The Act provides for a proportionate increase in the number of safeguards that must be met if D is to be protected from liability as the seriousness of the interventions or acts being done to P increases. These additional safeguards must be met in addition to the general safeguards.

- For acts of restraint, D must reasonably believe that there is a risk of harm to P, and that the act of restraint is proportionate to the likelihood and seriousness of that harm.
- For serious interventions or treatment with serious consequences, there must be a formal assessment of capacity and a written statement of incapacity by a suitably qualified person, and a nominated person must be in place, who should be consulted and whose views should be taken into account. Serious interventions include, but are not limited to, serious treatment for physical illness, any intervention that causes the person serious distress or serious side-effects, affects seriously the options that will be available to P in the future or has a serious effect on his/her day-to-day life. The decision whether or not an act is a serious intervention or treatment with serious consequences rests with D. However, some acts are always serious interventions. These are: (a) deprivation of liberty, (b) attendance for certain treatments requirement and (c) community residence requirement.
- Certain serious interventions must be authorised by a trust panel. These include acts (a), (b) and (c) above, or the act is the provision of treatment with serious consequences and the nominated person objects, P resists or it is being done while the person is being deprived of their liberty.
- For attendance for certain treatment requirements, D must reasonably believe that failure to impose the requirement would be more likely than not to result in P not receiving the treatment.
- For community residence requirements, the prevention of harm condition must be met.

The trust panel will be made up of three persons with relevant expertise. The application will be made by a 'prescribed person' and must include a medical report and a care plan. The statutory criteria will differ depending on the measure for which authorisation is being sought.

- For treatment with serious consequences when the act amounts to a deprivation of liberty, the 'prevention of serious harm' condition must be met. D must reasonably believe that failure to detain P in circumstances amounting to a deprivation of liberty would create a risk of serious harm to P or serious physical harm to others, and the detention of P is a proportionate response to the likelihood of harm and the seriousness of the harm concerned.
- For attendance for certain treatment requirements, D must reasonably believe that failure to impose the requirement would be more likely than not to result in the person not receiving the treatment.
- For community residence requirements, the 'prevention of harm' condition must be met.
- For compulsory treatment with serious consequences against the wishes of the nominated person, the 'prevention of serious harm' condition must be met.

A second opinion is required when the act is the provision of electroconvulsive therapy or is a treatment with serious consequences where the question of best interests is finely balanced, or is the continuation of medication beyond 3 months (if the medication is treatment with serious consequences) when the person is an in-patient or in a care home, or is subject to requirements to attend for treatment in the community.

The Act provides for the provision of an independent mental capacity advocate (IMCA). An IMCA must be in place when the Act requires an act to be authorised or, although not requiring authorisation, is a serious compulsory intervention. The role of the IMCA is to support and represent P; the IMCA must be consulted but is not a decision maker.

Where an authorisation has been granted, an application can be made to a review tribunal in respect of the authorisation. This provides a judicial review of the decision to ensure that it has been made in accordance with the law and that the criteria for the authorisation have been met. Applications to the tribunal can be made by P and the nominated person. Cases may also be referred to the tribunal by the Department of Health, the Attorney General or the High Court. The trust must refer to tribunals when authorisation has been extended for 1 year (for those aged 16–17) or 2 years (for those aged 18 or over).

The clauses describing the additional safeguards to be put in place do not apply when the situation is an emergency. D is protected from liability if there is a reasonable belief that delay would create an unacceptable risk of harm to P. However, D is expected to take reasonable steps to ensure that the safeguard is met by the relevant time.

Children and young people

The Act cannot be applied to children under the age of 16 because it puts into statute the common law presumption of capacity. For those aged 16–17, the MCA will operate alongside the Children (Northern Ireland) Order 1995, and additional safeguards will be put in place. The original MHO will continue to be in place for the small number of under-16s who require compulsory assessment/treatment in hospital for mental disorder. This has been the subject of some controversy; if the current legislation is discriminatory and stigmatising, it is difficult to argue for its continued use in one particular group. It has been argued that a legislative framework for those under 16 must be brought forward. This will be a difficult task, not least because a capacity-based framework will have to grapple with the complex question of emerging capacity in young people. The government has indicated that their intention is that there will eventually be legislation for those under 16, but at present, this is some way off.

Criminal justice provisions

There are new disposal options following a finding of unfitness to plead or insanity, including public protection orders (PPOs) and supervision and assessment orders. There are powers to remand an accused person to hospital, to transfer prisoners to hospital for treatment, for interim detention orders and for immediate hospital direction on conviction. Although the MCA contains powers for involuntary admission to hospital in various circumstances, treatment decisions are based on capacity to consent and subject to the core provisions of the Act. This means that there are circumstances under which a person can be admitted to hospital against their capacitous wishes; however, they cannot be treated against their capacitous wishes.

New criteria form the basis for entry into the criminal justice provisions. A ‘disorder’, a ‘disorder requiring treatment’ and ‘an impairment of, or disturbance in, the functioning of the offender’s mind or brain’ replace mental illness and severe mental impairment. A disorder is broadly defined to include any disorder or disability, whether mental or physical: a disorder requires treatment if any of its symptoms or manifestations could be alleviated or prevented from worsening by treatment.

A person can be remanded to hospital if the medical report condition or the treatment condition are met. The medical report condition is that the person has or may have a disorder, that a report should be made into that person’s condition, that an assessment would be impracticable in custody, and that it would be practicable to assess the person in hospital. The treatment condition is that the person has a disorder requiring treatment, that failure to provide in-patient treatment would ‘more likely than not’ result in serious physical or psychological harm to the accused person or serious physical harm to others, and that remanding the person to hospital would be likely to result in significantly better clinical outcomes.

PPOs replace hospital orders. A PPO can be made when detention conditions are met. These are that: ‘there is an impairment of, or a disturbance in, the offender’s mind or brain’, that ‘appropriate care and treatment is available’, that dealing with the person without detention ‘would create a risk, linked to the impairment or disturbance, of serious physical or psychological harm to others’ and that depriving the person of their liberty would be a proportionate response to the likelihood and seriousness of that harm. Restrictions may be added where the restriction conditions are met.

A prisoner can be transferred to hospital where they have a disorder requiring treatment, failure to provide treatment would be ‘more likely than not’ to result in serious harm to the person or serious physical harm to others, and appropriate treatment is available.

Patients admitted to hospital under the MCA criminal justice provisions will remain there following tribunal only if the ‘prevention of serious harm’ condition is met. The criteria for the ‘prevention of serious harm’ condition differ for those subject to PPO and for transferred prisoners or those subject to hospital direction. The criteria for those subject to PPO are: the person has ‘an impairment of, or a disturbance in, the functioning of the mind or brain’; releasing the

person would create a risk of serious harm to others; and depriving the person of their liberty is proportionate to the likelihood and seriousness of the risk.

The criteria for transferred prisoners or those subject to hospital direction are: the person has the disorder for which they were transferred; effective treatment can be given; and it is 'more likely than not' that discharging the person to prison would result in serious harm to the person or serious physical harm to others.

Discussion

The MCA is unique in that it repeals separate mental health legislation, replacing it with a single piece of legislation applicable across all medical specialisms and social care, whereby involuntary treatment is only permitted when the person (a) has impairment of decision-making capacity and (b) the intervention proposed is in the person's best interests.

The arguments for and against replacing conventional mental health legislation with a law based on capacity have been well rehearsed in a recent debate.⁵

The removal of mental health legislation that makes decisions about involuntary treatment based on diagnosis and risk will require a significant change in practice for professionals working in mental health in Northern Ireland. It is somewhat ironic that such a radical piece of legislation, based on non-discrimination, is being introduced in a jurisdiction that spends the lowest proportion of its health budget on mental health of any UK nation.⁶

The Act must work across a wide and diverse range of settings – care homes, mental health services (both in-patient and community) and general hospitals. It will affect staff who have little previous knowledge or experience of the principles behind capacity assessment. It is therefore imperative that a comprehensive training and supervision programme is put in place, which will have considerable resource implications.

The inclusion of the 'appreciation' element introduces a difference in the definition of capacity in the MCA compared with that used in other jurisdictions. The addition of the 'appreciation' element moves the definition of capacity away from purely cognitive terms towards the concept of capacity being affected by factors such as emotional colouring, delusions and lack of insight.⁷ Because of this difference, it cannot be assumed that studies that have demonstrated the reliability of capacity assessments⁸ will automatically apply in the case of the MCA. The reliability of the use of capacity assessments using this definition of capacity in routine clinical mental health practice requires to be evaluated.

The shift away from compulsory intervention based on in-patient treatment when a particular threshold of risk is reached may facilitate earlier intervention and allow for a proportionate response across a wide range of treatment and care settings. On the other hand, there is a more widely expressed concern that capacity legislation may delay appropriate treatment.

Trust panels can authorise a very wide range of interventions. As health and social care professionals work under the principle of beneficence, there is a risk of 'slippage', with staff making decisions about impaired capacity based on a person making foolish or unwise choices. This could lead to the unintended consequence of the Act leading to a greater rather than a lesser restriction of a person's autonomy and self-determination.

There is a plethora of issues that could potentially affect clinical practice; for example, exactly what constitutes serious interventions, how to manage fluctuating capacity, the question of decision-making capacity in patients with personality disorder, patients who retain capacity but present a risk to self or others, and the potential conflict between human rights (especially the right to life) and autonomy. Some of these issues may be addressed by the code of practice, others may be left to clinicians or courts.

Conclusions

Fusion legislation (of which the MCA is an example) is a radical change in the approach to involuntary psychiatric treatment. It is an exciting and innovative development and there are substantial potential benefits, including the reduction of stigma, the protection of patient autonomy, and the removal of confusing parallel mental health and mental capacity legislation. It is also more compliant with CRPD and ECHR. Much of the practical impact of the MCA depends on the development of a comprehensive code of practice and the provision of a comprehensive training and supervision programme. In addition, as Szmukler & Kelly have pointed out,⁵ the gathering of data on its implementation is vital and the MCA must be subject to a rigorous and comprehensive evaluation.

1.7.94 Measuring relational security in forensic mental health services

Verity Chester Regi T. Alexander Wendy Morgan

date

2017-12

Abstract

Aims and method Relational security is an important component of care and risk assessment in mental health services, but the utility of available measures remains under-researched. This study analysed the psychometric properties of two relational security tools, the See Think Act (STA) scale and the Relational Security Explorer (RSE).

Results The STA scale had good internal consistency and could highlight differences between occupational groups, whereas the RSE did not perform well as a psychometric measure.

Clinical implications The measures provide unique and complimentary perspectives on the quality of relational security within secure services, but have some limitations. Use of the RSE should be restricted to its intended purpose; to guide team discussions about relational security, and services should refrain from collecting and aggregating this data. Until further research validates their use, relational security measurement should be multidimensional and form part of a wider process of service quality assessment.

Serious incident investigations in forensic mental health services have been linked to relational security breakdowns. ¹ However, relational security has been described as the ‘poor relation’ ² when compared with physical or procedural security. This is most likely due to definition difficulties. Chester & Morgan ³ noted that numerous conceptualisations of relational security exist, all referencing different phenomena, such as ‘therapeutic relationships’ and ‘boundaries’, without describing how such concepts can affect security. ³ The authors noted that the most practically useful definitions emphasise exactly how relational issues affect security, in two stages: (1) staff knowledge of patients and therapeutic relationships; and (2) how patient knowledge and therapeutic relationships are used to foresee potential and manage actual security incidents, for example: ‘The professional relationships between staff and patients so that ... the staff to get to know ... their patients, their moods and problems, to facilitate interventions before these become major problems, or lead to incidents of a security nature’ (p. 171). ⁴ As such, relational security is intrinsically linked to short- and long-term assessment and management of risk in mental health and forensic services.

Relational security is therefore a service quality indicator of interest within forensic and general mental health services. Its measurement should allow practitioners to explore background causes and respond accordingly with appropriate interventions. Due to the definitional complexities, there are subsequent challenges to measurement. Previously available tools only measure partial aspects of relational security or individual patient needs. ³ However, two tools have been developed in recent years, the Relational Security Explorer ⁵ and the See Think Act scale. ² As limited research has examined the clinical utility of these measures, the present study examines their psychometric properties to support the aim of relational security measurement.

Method

Design

The study employed a within-participants (reliability testing) and between-participants (assessing the measures’ ability to identify differences between occupational groups according to the variables level of security, ward gender and length of experience working in secure services) cross-sectional questionnaire design.

Participants

Participants were recruited from a forensic service for people with intellectual disability. As guidance recommends that relational security implementation should involve all occupational groups working within secure services,⁶ the study invited all staff who have contact with patients as part of their role to take part in the study ($n = 216$), and of these 41% ($n = 89$) responded. The majority of the participants were female (63%), and the average length of service working in secure services was 6 years (range 0.12–20). The majority of participants were from the nursing department (57%), followed by occupational therapy (16%), psychology (9%), social work (6%), psychiatry (2%) and housekeeping (8%), and two participants identified their occupation as ‘other’. The level of security in which respondents worked in at the time of the study was medium (23.6%), low (27%) and locked rehabilitation (16.9%). There are no national data available which describe the demographics of the forensic mental health workforce, although the reported characteristics reflected the socio-demographic and occupational breakdown of the study service and the broader mental health workforce as a whole,⁷ being predominantly female and with nursing staff comprising the largest department followed by other members of the multidisciplinary team. As participants responded anonymously, it was not possible to undertake any analyses comparing participants with non-responders.

Measures

See Think Act (STA) scale²

The STA scale is the first attempt to create a direct measure of relational security. The 28 items were developed from the Department of Health conceptualisation of relational security,⁶ and reflect relational security scenarios (e.g. ‘We speak up if we think we can see that a colleague has been put in a difficult position that could weaken security’). Individual staff members complete the questionnaire in relation to the ward they work on, and select how closely their ward team resembles provided statements on a 4-point Likert scale, with scores of 3 ‘Just like our team’, 2 ‘Quite like our team’, 1 ‘A little like our team’ and 0 ‘Not like our team’. A principal components analysis confirmed a four-component structure of the measure: Therapeutic Risk Management, Pro-Social Team Culture, Boundaries and Patient Focus.² Initial examinations indicated good convergent validity with related measures (e.g. EssenCES⁸), and internally consistent subscales.² There is currently no normative data available for the STA scale.

The Relational Security Explorer (RSE)⁵

The RSE is a tool designed to help clinical teams working within secure settings to communicate and assess their competence in relational security. The tool requires users to provide a numerical score of their team’s confidence in eight areas of relational security: Therapy, Boundaries, Patient Mix, Patient Dynamic, Personal World, Physical Environment, Visitors and Outward Connections on a scale ranging from 1 (no confidence) to 10 (extremely confident). The RSE was not developed as a psychometric measure; however, the tool requests clinical teams to provide a numerical score of their confidence in each of the eight areas. In doing so, the tool lends itself for use as an outcomes measure and, anecdotally, the authors are aware of service’s collecting and analysing this data, despite it not being validated for this purpose. This is in line with the suggestion that when numerical indices and cut-off points are available, clinical decisions tend to be reduced to those numbers.⁹ Participants were asked to complete the RSE on an individual, rather than a team basis, to investigate the tool performance as an outcomes measure.

Procedure

The researcher arranged one-to-one meetings with staff eligible for the research, at which informed consent was sought. Once obtained, staff members were asked to complete and return the questionnaires. A debrief form was provided for participants, which detailed further information about the study.

Ethics

Ethical approval was obtained from the London Metropolitan University Research Ethics Review Panel. The National Research Ethics Service Committee for the East of England – Norfolk was also approached for ethical review of the project, who advised that as the relational security measures were being used in routine clinical practice within the study service, the study does not require National Health Service ethical approval.^{10,11}

Data analysis

Prior to analysis, assumption testing for parametric tests was completed. The assumption of homogeneity of variance was violated, and the data were negatively skewed, violating the assumption of normal distribution. Transformations of the data were attempted, but this did not reduce the skew. A number of cases appeared as outliers for all outcome variables, and notably, these cases were all from the housekeeping department. Data were therefore examined using non-parametric methods. This point was discussed with our statistician, who assured us that the loss of power associated with the non-parametric tests was small.

Therefore, internal consistency was examined using Spearman's Rho correlation to calculate the Corrected Item-Total Correlation (CITC) coefficient values for subscales of the STA and the RSE. Convergent validity was analysed by correlating subscales of the STA scale and the RSE using Spearman's Rho. The Sidak adjustment was used to adjust for multiple comparisons.

Non-parametric statistical tests were used to examine the association between scores on the STA and the RSE, and the variables requested in the demographic questionnaire (length of experience working in secure services, the ward and level of security worked on, the gender of the patients on their ward, and staff department/occupational discipline). Analysis between individual wards and staff occupational discipline could not be completed due to small and unequal numbers between the groups. To examine the association between level of security and the subscales of the two measures, the Kruskal-Wallis test was used. The Wilcoxon Mann-Whitney *U*-test was used to examine the association between gender of patients and the subscales. To examine the association between length of experience working in secure services and the subscales, Spearman's Rho correlation was used.

Results

Internal consistency

Internal consistency was assessed using CITC coefficients. A CITC value above 0.5 is considered high, but if less than 0.3, items within a subscale may be measuring more than one construct. All RSE subscales exceeded the CITC 0.30 cut-off, although there was some variation, with the Personal World subscale having the highest internal consistency at 0.80, and the Physical Environment subscale the lowest at 0.49. All the STA subscales had CITC scores over 0.9. *Table 1* displays the CITC coefficient values for each subscale of the two measures.

Corrected Item-Total Correlation (CITC)

Measure	CITC
Relational Security Explorer	
Therapy	0.66
Boundaries	0.61
Patient Mix	0.57
Patient Dynamic	0.65
Personal World	0.80
Physical Environment	0.49
Visitors	0.62
Outward Connections	0.68
See Think Act scale	
Therapeutic Risk Management	0.90
Pro-Social Team Culture	0.96
Boundaries	0.92
Patient Focus	0.92

Convergent validity between measures

There was little convergent validity between the subscales of the two measures. All four subscales of the STA scale correlated significantly with each other, whereas subscales of the RSE did not. The Spearman's Rho values are detailed in *Table 2*.

Correlation is significant at the 0.01 level.

Between-groups analysis

Level of security

Significant differences in scores on the two measures were found between staff working in different levels of security. Staff working on medium secure wards tended to have the lowest scores on both measures, followed by staff on low secure wards, with the highest scores on rehabilitation wards. On the STA scale, this reached statistical significance on the Therapeutic Risk Management ($P < 0.001$), Boundaries ($P = 0.012$) and Patient Focus ($P = 0.034$) subscales. There were also significant differences on the RSE, on the Patient Mix ($P < 0.001$), Patient Dynamic ($P = 0.008$) and Personal World ($P = 0.011$) subscales. Descriptive data for this variable are presented in *Table 3*.

Descriptive statistics for level of security on the See Think Act scale and Relational Security Explorer

	Level of security, mean (s.d.)		
See Think Act scale <i>a</i>			
Therapeutic Risk Management	2.34 (0.44)	2.54 (0.39)	2.8 (0.25)
Pro-Social Team Culture	2.34 (0.49)	2.52 (0.48)	2.68 (0.41)
Boundaries	2.5 (0.43)	2.64 (0.41)	2.83 (0.31)
Patient Focus	2.5 (0.45)	2.76 (0.49)	2.76 (0.34)
Relational Security Explorer <i>b</i>			
Therapy	7.46 (1.61)	7.47 (0.26)	8.07 (1.61)
Boundaries	7.85 (1.21)	8.3 (0.26)	8.3 (1.21)
Patient Mix	7.54 (0.97)	7.1 (1.56)	8.71 (0.61)
Patient Dynamic	7.15 (1.34)	7.1 (1.34)	8.3 (0.83)
Personal World	7.31 (1.7)	7.41 (1.18)	8.5 (1.09)
Physical Environment	7.23 (1.7)	7.88 (1.4)	8.07 (1.33)
Visitors	7.0 (1.09)	7.0 (1.12)	7.64 (1.98)
Outward Connections	7.23 (1.36)	7.17 (1.74)	8.07 (1.59)

The scale for the See Think Act scale is 0–3.

The scale for the Relational Security Explorer is 1–9.

Ward gender

There were no differences in STA scale scores between staff working on wards caring for male patients, as compared to female patients. However, on the RSE, staff working with male patients reported higher scores on the Patient Dynamic ($P = 0.024$) subscale, compared with staff working with female patients.

Length of experience working in secure services

There was no correlation between the number of years staff had been working in secure services, and their confidence in relational security, on the STA scale or the RSE.

Discussion

Serious incidents within forensic mental health services can be linked to breakdowns of relational security.¹ Available measures should therefore provide insight into the quality of relational security within services, direct exploration of strengths and weaknesses, and prompt timely, appropriate interventions before an incident occurs. Furthermore, tools should be accessible to all occupation groups.⁶ This study therefore evaluated the psychometric properties of the STA and the RSE, including internal consistency, convergent validity and their ability to highlight differences between groups.

Study limitations include a relatively small sample size, and participants being drawn from a single service, which limit generalisability. It is categorised as a preliminary study for these reasons. However, the study reports interesting findings in relation to the specific tools examined and the wider task of measuring relational security by investigating the perspectives of staff members across occupational professions and levels of security. The study setting, a secure intellectual disability service, may be viewed as a strength, as previous studies have been completed only within generic forensic psychiatric services, and as a weakness, due to the extent of the study findings generalising to non-intellectual disability services. Research comparing patient characteristics between mainstream forensic and specialist intellectual disability services is scarce, however there are a number of notable differences between the two populations which may have an effect on relational security. These include communication difficulties which could affect the development of therapeutic relationships, increased levels of behavioural incidents,¹² and higher assessed risk on structured clinical judgement tools.^{13–15} That said, the present research reports many findings which echo those of previous research.²

Test–re–test reliability was not examined in the present research, although it may be an interesting area for further study. At present, the stability of relational security levels are unclear, and it may not be realistic or relevant to expect stability over time, as relational security is a fundamentally a dynamic concept.

The internal consistency aspect of reliability was examined, with the STA scale demonstrating high levels in accordance with previous research.² Its subscales correlated significantly, suggesting they are statistically related concepts. Internal consistency for the RSE was adequate but its subscales did not all correlate significantly, possibly indicating that some of the concepts measured are statistically unrelated. Although the RSE and the STA both aim to measure relational security, convergent validity was low. Collectively, these findings suggest that the RSE does not perform as well as the STA as a psychometric outcome measure. This raises questions regarding the practice of collecting and analysing data from the RSE, despite not being validated for this purpose. Lodewijks *et al*⁹ explicitly advise against the use of numerical indices and cut-off points, due to clinicians' tendency to reduce clinical decisions to numbers if they are available.

Particular subscales of the two measures were able to detect differences between groups in relational security confidence, thus facilitating the comparison of wards and staff disciplines within a service, potentially between services comparisons, and directing intervention as necessary. Significant findings were reported between wards of different levels of security, with relational security confidence lowest on medium secure wards, increasing on low secure wards, and highest on rehabilitation wards. Tighe & Gudjonsson² also reported this effect, as well as authors investigating social climate in secure settings.^{16,17} A possible explanation for this is that medium secure wards represent the beginning of the care pathway accepting newly admitted patients and, as such, staff have had less opportunity to develop the knowledge of patients and therapeutic relationships necessary to achieve good relational security. As patients progress

through the low secure and rehabilitation stages of the care pathway, this provides an opportunity for the components necessary to relational security to develop.

The study also compared relational security confidence between staff working with male and female patients. This was examined as authors have documented difficulties in building therapeutic relationships with women, due to their clinical complexity.^{18,19} However, there were few differences between these two groups on the subscales of the two measures, although staff working with male patients reported higher scores on the Patient Dynamic ($P = 0.024$) subscale of the RSE.⁵

It was expected that staff with more experience working within secure services would be more confident in their judgements of relational security, but there were no significant associations. However, relational security relies on knowledge of patients and therapeutic relationships, within a dynamic environment. For example, if a new patient is admitted to a ward, all staff, regardless of experience will begin to develop their knowledge and their therapeutic relationships with this patient at the same time. Furthermore, if an experienced staff member is asked to move onto a different ward, they will know little about the patients on that ward and have to develop new knowledge and therapeutic relationships. In this sense, all staff members, regardless of experience, are repeatedly beginning and developing their knowledge of individual patients and new therapeutic relationships.

Housekeeping staff felt less confident in relational security, as compared to all other departments. This is probably due to the measures tapping into areas of clinical practice that housekeeping staff would not be involved in, and the comparable lack of training offered to this group. However, guidance recommends that relational security implementation should involve all occupational groups working within secure services.⁶ As housekeeping staff are a daily presence on forensic wards, they are equally as vulnerable to relational security issues and in a position to witness threats to security. Further research should investigate ways to support all occupational groups with relational security.

Measuring relational security: further considerations

Some points are of note when interpreting data obtained from relational security measures. Initial assumption testing indicated negatively skewed data, suggesting that most participants rated their confidence in relational security at the top end of each measures' respective scale. This could indicate that staff working in this particular service are highly confident in their relational security practice. However, it is unclear how confidence scores relate to the actual quality of relational security within a ward, for example is a highly confident team an experienced team or a complacent team? It could also indicate positive responding, as essentially, measures are asking individuals to rate themselves in an aspect of their role in which they are expected to be competent. Introducing some negatively worded items could improve this.

High scoring may also be due to the way the two tools conceptualise relational security. Both measures are based on the STA conceptualisation of relational security,⁶ which places much of the responsibility onto staff and teams, thus neglecting the 'quantitative' aspects of relational security, for example 'staff-to-patient ratio and amount of time spent in face-to-face contact' (p. 434)²⁰ and the supportive role and responsibility of service management. For example, to achieve quality therapeutic relationships with patients, ward staff and teams need to be stable, with minimum staff ward moves, turnover and absenteeism,³ factors outside of staff members' control. Incorporating items reflecting such aspects of relational security could provide a more comprehensive picture.

Normative data are not currently available for either of the two measures, which limits the interpretability of the results. Both measures are designed to be used by staff members in relation to one specific ward. However, many employees work across multiple wards in secure services, with 27% respondents in this sample working across wards. These participants were typically from occupational departments other than nursing, such as psychology, psychiatry, social work and occupational therapy.

Conclusions

The increased attention relational security is receiving within the forensic field is a welcome advance. There is growing awareness around the importance of this concept, and resources aiming to raise awareness and support the implementation of relational security are widely available.²¹ However, until recently there have been few mechanisms to assess the quality of relational security within services. The results of this study suggest that the STA scale and the RSE hold unique and complimentary roles attempting to support relational security. The RSE did not perform well as a psychometric measure, and therefore its use should be limited to its intended purpose – as a tool to guide team discussions about relational security – and services should refrain from using the RSE as an outcomes measure. However, deciding on a numerical score of relational security confidence may serve a function within the context of a team discussion, for example, if one team member feels the ward should score highly, whereas another member feels the ward should be given a lower score, this could suggest team splitting and form a basis for discussion. At present, the STA scale is best placed to provide insight into the quality of their relational security, while taking into account the aforementioned issues when interpreting the data.

Further research is needed in all areas of relational security: definition, implementation and measurement. This research should examine the relationship between relational security and negative outcomes, such as institutional aggression or serious incidents. Future studies should evaluate the clinical utility of the RSE, examine the psychometric properties and provide normative data for the STA. Until more is known about relational security, the approach to implementing and measuring it should be multidimensional,²² i.e. incorporating staff, patient and service management perspectives.

The authors are grateful to Paul Bassett for his help with statistical analysis.

1.7.95 Profile. The constant psychiatrist: an interview with Michael Kopelman

Norman Poole¹

- *Profile. The constant psychiatrist: an interview with Michael Kopelman*

From his journal-lined office in St Thomas' Hospital Professor Michael Kopelman could quietly yet assiduously observe the powerful in their Palace of Westminster just across the Thames. Following retirement in 2015 he has become ever more alarmed by the spectacle: “Our society, in my view, is becoming more and more authoritarian. It's very worrying the direction we are moving in. Even within our university system and the NHS things have become much less democratic than they used to be, and much more authoritarian. It's both sad and frightening.” A perpetually crumpled mac under his arm, the Professor appears much like an MI6 officer in a le Carré novel grown disillusioned with the culture of edicts, diktats and target-driven performance for the workers while those in positions of power sit removed and aloof.

¹

Norman Poole is a consultant neuropsychiatrist at St George's Hospital, South West London and St George's Mental Health NHS Trust.

‘Now it’s really the chief executive and his executive team who run things. With no disrespect to any particular individual, some of whom are very good, I can’t see that they have proper accountability. We doctors have accountability. We can be hauled before the GMC. But managers and commissioners, who are changing the healthcare environment, often for the worse, are not held to account in the same way.’

The Professor’s comportment is at one with his assertion, ‘These are matters I feel strongly about.’

Indeed. For just as the anti-heroes in le Carré’s novels battle with the bureaucracies in which they work, Professor Kopelman is exasperated by perceived wisdom, particularly with regard to a matter close to his professional heart, the modern memory clinic. ‘The memory clinics that are being set up under the Dementia Strategy are not what I would advocate.’ A Fellow of the Academy of Medical Sciences and founding member of the Memory Disorders Research Society, Professor Kopelman appreciates the diversity of problems that have an impact on cognition.

‘There is a wide range of memory disorders to be diagnosed, and the early diagnosis of dementia, even by the very experienced, is difficult. There are very sad implications if you get it wrong. The earlier we go for diagnosis the more likely we are to get it wrong, whatever the clinical/genetic/biomarker tools that we have.’

Criticising the consensus again, he says: “‘I think, and I’m not popular for saying this, that nurse-led diagnostic teams making early diagnosis is not the direction to go in. The direction to go is better care for those with established diagnoses of dementia. What we have at present is shameful, and in my view it’s actually now worse than in the 1980s.’” Professor Michael Kopelman. It is perhaps this disillusionment that partly drives his medico-legal work, in which he is fearless in tackling injustice head-on. On many occasions he has been involved in headline-grabbing courtroom dramas that could themselves be the stuff of fiction. Interestingly, he highlights a radical human rights lawyer as the anti-establishment role model for his own legal work.

‘Gareth Peirce is superb at using the legal rules to beat authoritarians and government. She plays within the system, but she does it better than the government lawyers and beats them. That fits my temperament. Not shouting or protesting on the streets, but playing the system to get justice for people.’

Clashes with the establishment have seen Professor Kopelman fight for the falsely convicted and for Guantánamo detainees. He said: “‘I got into false confession cases, which I see as a form of memory disorder, and was involved in overturning convictions; one from 50 years ago, another after 25 years, and a delusional memory case at 26 years.’” He added: “‘Then with two others – a therapist and a GP – I wrote a report in 2010 on people who had come back from Guantánamo, including some prominent names, and this resulted in them getting substantial amounts of compensation. Ken Clarke announcing this in Parliament made the somewhat ambiguous statement, “We must never let this happen again.” I feel in some ways I have done more good from this sort of work than anything else, and that’s what I’m going to do in my retirement.’” His colleagues obviously agree as Professor Kopelman has previously been elected to serve as president of the British Academy of Forensic Sciences.

This ability to perform scalpel-sharp analyses of intricate legal cases and their relation to esoteric psycho-pathology originates in his wide-ranging reading list at medical school and a first degree in psychology. ‘I had gone into psychology and enjoyed it, and before that – oh I hate to say the cliché – I was interested in people, and enjoyed literature from the psychological angle. So this is what I was curious about.’ Upon gaining a place studying medicine at Middlesex University, he was not your typical medical student: ‘I read Luria quite early on, when I should have been reading anatomy textbooks!’

Paradoxically, a contemporary model of memory claims that it evolved to enable planning for the future, or mental time travel.¹ Professor Kopelman’s forays into the science of memory were thus doubly prescient: “‘I’d been interested in the neuropsychology of memory, which was just developing at the end of the 60s and 70s. I was reading quite a lot of the amnesia stuff at an early stage and I was interested in the more biological aspects of psychology. I knew I would either do neurology with an interest in cognitive neurology or psychiatry with an interest in neuropsychiatry, and I’ve ended up in the middle discipline.’” That’s rather too modestly put given that Professor Kopelman actually ended up as president of both the British Neuropsychological Society and the International Neuropsychiatric Association, and is currently Presiding President of the International Neuropsychological Society.

The influence of psychology so early in his academic career may well contribute to his continued aversion to reductive thinking about mental disorder: ‘I get a bit anxious about what I call naive reductionism, the kind of approach that

thinks that all PTSD and depression are just disorders of the hippocampi or the frontal lobes or whatever. I think that is very simplistic.’ Adding, ‘We have to remember the brain is operating within a social context and not to underplay the importance of our social context.’ It is to his own social context that his mind now turns. Between confrontations with government barristers and completing research programmes at St Thomas’, where he can still be found a few days of the week, Professor Kopelman divides his time between a beautiful 18th-century home in Surrey and a cottage in Norfolk. It is apparent that similarities to le Carré’s heroes don’t just end with the raincoat.

1.7.96 Handbook of Secure Care

Lindsay Thomson¹

date

2017-12

Contents

- *Handbook of Secure Care*

The *Handbook of Secure Care* is a useful book for those new to the field of forensic mental health and is most relevant to those practising in England and Wales. It examines the relationship between mental disorder and offending, with individual chapters on personality disorder, intellectual disability, autism spectrum disorder and acquired brain injury. Strangely, there is little on psychosis which is the fundamental diagnosis within secure care.

The work considers the needs of specific populations such as women, young and older people, and outlines the provision of secure psychiatric services for these groups. It focuses on the basic components of secure care and includes information on risk assessment and management, and on recovery. The latter chapter is of particular use in defining the challenges we face in secure care and ways to redefine our conventional thinking. The fundamentals of psychological treatment in secure care are clearly set out and there is a helpful description of the role of nursing within that setting.

There is discussion in the first chapter on the evolution of secure and forensic mental healthcare, as well as information on the number of secure beds, but I would have welcomed an analysis of the overall estate, the needs for planning and the methods of provision. Similarly, details on pathways into or out of secure care, or on the legislation that allows us to detain people within these settings would have been valuable.

Notably, there is a good chapter by Penny & Exworthy on human rights in secure psychiatric care – the Human Rights Act 1998 underpins much of what we do in secure care, making this especially relevant. It is followed by a chapter on quality assurance and clinical audit. It is my view that the human rights considerations and the quality improvement agenda are so crucial to our work that it would have been beneficial to place these chapters near the beginning of the book to emphasise their importance.

2015-4

Abstract

This paper describes a model of training in leadership and project management skills for advanced trainees, using educational projects within the Severn School of Psychiatry. Fellowships lasting 1 year have been developed to enable trainees, working with a senior consultant trainer associated with the School of Psychiatry, to support important new educational initiatives. Linkage with the local university training and learning for health professionals research module has provided academic support for the trainees and the projects. Four examples for the first year of the programme are described and feedback from structured interviews with participants is presented. The development of the fellowships appears to have had wider benefits, in developing educational faculty in the School of Psychiatry and the trainees involved have had opportunities to extend their project management and leadership skills. The fellowship programme is continuing to develop, based on feedback from its first successful year.

Background

To increase the range of opportunities and quality of education within the Severn School of Psychiatry, we have in recent years developed a range of projects across the School. Although there is a strong group of trainers, training programme directors, tutors and directors of medical education (DME) who provide leadership, there is limited time within job planned allowances across the senior trainer group to permit extensive work within projects. Advanced trainees need to develop leadership skills and we felt an obvious vehicle to promote this was through co-leadership of educational projects. There are opportunities across the School for projects in areas of educational theory, quality assurance, review of educational processes, innovation and new methods of training/assessment. The Royal College of Psychiatrists' curricula for advanced training in each specialty contain specific leadership domains and recommendations for training in this area, but a survey of advanced trainees¹ showed that many questioned how prepared they felt for the role of consultant. The survey indicated they felt well prepared for the clinical role, but less prepared for leading, designing and changing services. There was felt to be a need for higher training to engage with the entirety of the new consultant role.

A business internship model, which now operates across all areas of the Severn School of Psychiatry, has provided opportunities for project-based management training. Similar to the paired learning initiative described elsewhere,² this has had wider benefits for the trainee population and also to the organisations where trainees have had opportunities to work on important trust management projects. We noted that as well as preparing trainees for the management aspects of their new consultant roles, it is important to prepare them fully for the educational role as the majority will become trainers. A smaller group will go on to develop higher-level training responsibilities, such as tutor, training programme directors, DME or head of school role. Project management has the potential to facilitate development across a wide range of areas because of its multifaceted nature and the requirement to work across a variety of interfaces.

Programme description

The project aimed to offer four educational fellowships over 1 year, allocated through competition. A number of senior faculty members took a lead role in overseeing the programme: the head of the School of Psychiatry (R.M.); the lead for the local MRCPsych core course (S.H.); the regional advisor (G.U.); the lead from the local university training and learning for healthcare professionals department (S.Atk.); and a local director of medical education (S.Arn.). The fellowships were made available by email invitation to all advanced trainees (approximately 50). Trainees were invited to submit an application to undertake a fellowship, through writing a 500-word statement, expressing their interest in this and their key relevant background skills. An assessment framework was developed to rank submissions to decide on appointment and fellows were appointed in the spring 2012, to start their fellowship from August of that year.

Fellowships lasted a minimum of 1 year, with the fellows meeting monthly for peer support, together with project leads and with educational supervision from the teaching and learning for healthcare professionals (TLHP) team. It was expected that trainees use non-clinical special interest time for the project. Each project was overseen and co-led by a consultant with a specific, related educational role. We suggested that the educational fellow worked with a core trainee in his or her trust, aiming to involve a wider number of trainees, to provide an interesting and attractive opportunity for the core trainee and also to give opportunities for the fellows to give academic/project supervision, viewing the core trainee as a research assistant in this context. Depending on commitments, core trainees were welcome to attend the fellowship supervision sessions.

The work required was expected to vary across the different projects, but some common requirements were set out: literature review and summary of relevant evidence; liaison with key stakeholders including service user and carer groups; liaison with the trainee group; development of option appraisals; preparation of reports; presentation of material to the wider educational community; and dissemination through deanery and regional/national training forums.

The fellows were automatically enrolled on the TLHP research methods module, with an expectation that each fellow attend two study days and complete assignments, based on their fellowship project. On successful completion of the course they would be awarded 20 credits at Masters level (approximately one-third of the Masters course) and were able to take this credit into any further work in this area. The costs of the module (approximately £1200) were supported by the Deanery, other than for one fellow who was funded directly by the DME. Meetings of the project group were held in the Deanery and any costs for specific activities related to projects were considered by the head of School, in collaboration with the school of psychiatry manager in the Deanery. The programme was managed through the School of Psychiatry and issues arising reported to the board and wider deanery colleagues as necessary. Further governance support was obtained as needed through the Severn Deanery Executive team, who supported the project.

Projects overview

Training across boundaries (TAB)

This project, led by R.M. and S.Aru., explored the development of training links between core psychiatry and medical/general practice posts. It aimed to provide opportunities for exposure to different medical specialties. Although this has been recommended in the psychiatry training literature, there were no examples in the literature that we could find to describe this. The project focused on core training years two and three across two mental health trusts. The project was carried out in a single 6-month period from February to July 2013. Trainees were encouraged to maintain a reflective log and ideally complete a workplace-based assessment in their project. Up to six TAB sessions were encouraged during the 6-month placement. The project was relatively successful, 12 trainees undertaking a TAB placement in the time specified. Placements included general practice, neurology, paediatrics, endocrinology, emergency medicine and neuroimaging. The programme was more trainee-led than expected. Feedback suggested trainees had a range of valued, positive training experiences and this project will be written up elsewhere.

Supervision project

This project, led by S.Aru. and L.M., focused on exploration of educational supervision. It was noted that despite supervision being a central aspect of psychiatric training, the literature was limited regarding the activity occurring within supervision sessions. Nine structured interviews of advanced trainees were carried out by L.M. These focused on experiences of supervision and were transcribed, then subjected to thematic analysis, with the expectation of disseminating the results.

Communication skills training project

This project was led by G.U. and H.T. The project noted a paucity of literature relating to the evidence around communication skills appropriate to basic psychiatric training. A programme of development of the communication skills training within the core psychiatric trainees' course was undertaken. This included use of videos and more systematic, structured feedback. This was developed into more refined skills assessment using simulation and is now being further developed with the use of a software package to formally rate aspects of communication skills and provide structured feedback to the interviewer.

Developing knowledge and skills among core trainees

This project was led by S.H. and K.S. The project started from an awareness of local and national difficulties in knowledge, skills and competence within the core psychiatric trainee group. It was noted that many trainees had problems passing the College clinical exam, despite successful completion of clinical competence requirements in placements. The project identified a range of different interventions potentially of use to help core trainees. These included a mock clinical assessment of skills and competencies (CASC) exam, additional communication skills training, cultural awareness training, cognitive assessment and targeted skills development. The project is being further developed in a second round of educational fellowships.

Results

In the first year of the fellowship there were 12 supervision sessions. Trainee attendance ranged from 5 to 11, in total 34 attendances across the year. Consultant attendance ranged from 9 to 11, total 40 attendances across the year.

Feedback from educational fellows

The educational fellows reported that the administration of the programme was effective and they felt well engaged in their projects and the supervision programme. There was some concern about the way trainees were linked to individual projects and the potential for trainee choice about projects undertaken. However, it was noted that within the projects there was substantial choice and multiple opportunities for individual development. Supervision was found to be helpful, particularly with regards to the attendance by the TLHP team. The network of supervision provided a useful prompt to ensure that projects did not stagnate and was found to be interesting, although in some cases the individual's supervision with project supervisors was felt to be more helpful in terms of project design and problem-solving.

Communication outside supervision ranged from two to four times per month, with trainees feeling they had appropriate levels of support. In terms of challenges encountered during the project, the fellows reported some difficulties in managing the project within time restraints and in two cases a risk of the project escalating into an unmanageable, larger scale research project. The trainees felt that more specific input from an educational specialist could have been valuable across the programme and that greater attention could have been paid to educational and management theory alongside the practical experiences gained. The two trainees who completed the TLHP research module found it helpful and highly relevant to their involvement in the fellowship. One trainee planned to attend the course at a later stage.

Trainees reported a range of different opportunities arising from their involvement. These included the development of teaching, mentoring and education research skills, as well as softer benefits such as increased confidence and networking with research experts. Trainees also gained understanding of the challenges of project management and dealing with resistance. Issues around data protection and consent were sometimes difficult and required negotiation with senior colleagues in the Deanery. Liaison across different disciplines was valued and one trainee reported that using formal project management systems such as a Gantt chart had been valuable. Two of the trainees reported that the fellowship had a significant impact in the development of leadership skills and enabling reflection on leadership style. A range of different skills including transactional, participative approaches were required and it was noted that developing a non-hierarchical, inclusive style of working with trainees and others had been important. It was felt that attention to the development of leadership skills could be helpful in future fellowship programmes. All four trainees recommended

the fellowship programme to other trainees and there were a range of other comments including the suggestion that this was the most helpful leadership/management training experience obtained so far.

Feedback from the consultant leads

This was obtained through a similar format. Advice from other consultant colleagues and the TLHP team within supervision sessions was found to be helpful, as was group support and input from trainees. It was noted that working with bright trainees who were highly motivated and interested in education enabled the development of a wider educational faculty. The consultant group noted that there had been some specific problems around transcription and information technology that had hindered the completion of some projects. It was noted that in some cases there was a process of continuing improvement/development, meaning that the completion of one aspect of a project would open up further developments. The consultants particularly valued the opportunity to work closely with senior trainees and to develop a major project. It was noted that issues around leadership and project management were centrally involved throughout the project and this provided many opportunities for training and learning. The fellowships also provided opportunities for creative development that was not constrained by bureaucracy and seemed to develop the skills of trainees who were likely to become the senior trainers of the future. There was significant learning around the area of leadership and project management in the consultant group also, particularly around the balance between guidance and instruction/direct facilitation. It was felt that ideally trainees should be allowed to develop their skills by testing their own ideas out. It was noted that coaching skills, rather than supervision or line management was most helpful in this context. The consultants all recommended the fellowship programme to other trainees and to other consultant colleagues, particularly those involved in a senior educational role.

Discussion

This paper presents a model for training advanced trainees in leadership, education and management through co-development of educational projects with senior educationalists in a school of psychiatry. It was apparent that, as reported in other educational literature,³ effective leadership of the projects was associated with being proactive and fully engaged with the group affected by the project. The educational fellow and paired consultant needed to integrate a clear project focus and vision, with effective implementation, for projects to progress effectively. Five factors have been associated with effective leadership⁴ (*Box 1*) and recognition of these featured frequently in feedback from consultants and educational fellows.

Box 1 Factors associated with effective leadership⁴

Modelling the way – leading by example in a manner that is consistent with leader’s stated values. Inspiring a shared vision – developing a compelling vision of the future and enlisting the commitment of others. Challenging the process – being on the look-out for opportunities to improve the organisation and being prepared to experiment. Enabling others to act – promoting collaborative working; empowering others; building trust. Encouraging the heart – recognising individuals’ contributions; celebrating accomplishments.

Other feedback noted that a key process in this project was the development of senior educational faculty (including the advanced trainees) and the development of a collegiate culture based on the principles of coaching and mentoring, which can have benefits for educational satisfaction, academic and personal development.⁵ There were obvious benefits for senior faculty in participation in this work and an aim of this project was to facilitate project management across the School, giving opportunities for the consultants to complete work that otherwise may not have been feasible. For the trainees, the project enabled holistic development, encompassing academic learning and the development of skills such as problem-solving and analysis. There is a need for training organisations to provide a portfolio of learning opportunities and resources, to facilitate the development of management and leadership skills among senior trainees.

The joint supervision sessions were valued by all participants. Others have noted⁶ that it is the process of bringing many constituencies into debates that facilitates transformation, rather than restricting the process to a small number of consensual voices. Such ideas fit naturally with theory around ‘sense making’, which emphasises the role, after the initial impetus has been set by leaders, of inclusive and widespread conversations and reflection, to explore new possibilities and the emerging pattern of changes.

Future plans

It is hoped that a number of this first phase of projects will produce publications and be presented at regional and College forums. The fellowship programme is now in its second year and has recruited four new trainees into new projects, with two new consultant leaders. The fellows from year one are invited to continue to attend supervision sessions as are the two consultants no longer actively working on projects. Feedback from year one was used to plan for greater choice of projects for trainees, increased academic and theory input to supervision sessions and the involvement in the TLHP module has been timed to fit better with the project timeline.

Work carried out in The Severn School of Psychiatry, Health Education England SW.

1.8.2 Advance care planning and palliative medicine in advanced dementia: a literature review

Ketan Dipak Jethwa Oluwademilade Onalaja

Correspondence

K. D. Jethwa

(kdjethwa@doctors.org.uk)¹

date

2015-4

Abstract

Aims and method To assess the factors that affect the clinical use of advanced care planning and palliative care interventions in patients with dementia. A literature search of Medline, Embase and PsycINFO was performed to identify themes in advanced care planning and palliative care in dementia.

Results In total, 64 articles were found, including 12 reviews, and three key areas emerged: barriers to advanced care planning, raising awareness and fostering communication between professionals and patients, and disease-specific interventions.

Clinical implications Most of the studies analysed were carried out in the USA or Continental Europe. This narrative review aims to help guide future primary research, systematic reviews and service development in the UK.

 - * *Limitations*

Advance care planning is a targeted intervention that promotes autonomy for end-of-life decisions. It is particularly important in dementia where the illness impairs individuals' decision-making abilities. Patients with advancing dementia experience significant comorbidities such as malnutrition and dehydration. They may have no advance care plan (ACP) in place and this can pose difficult management questions for their families and attending physicians concerning palliation and end-of-life care.

Method

A search of Medline, Embase and PsycINFO was performed to investigate the current literature on ACP and palliative care in dementia. The following search protocol was used: ([‘advance care plan*’] AND [‘palliat*’ OR ‘palliative care’ OR ‘end of life’] AND [‘dementia’ OR ‘Alzheimer’s’]).

Results

The search produced 64 journal articles, including 12 reviews. The titles and abstracts of these articles were reviewed. Those published in English and pertaining explicitly to palliative interventions or advance care planning in dementia were looked at more thoroughly.

The majority of the studies found were conducted in the USA or Continental Europe. This limits the generalisability of study findings to practice in the UK. For example, in the USA artificial nutrition is commonly used, whereas in the UK the National Institute for Health and Care Excellence (NICE) guidelines for dementia ¹ state that artificial nutrition should not commence if there is resistance to eating or difficulties in swallowing, related to progression of the disease. Differences in service configuration between countries also limit the generalisability of these studies, especially when considering the role of different agencies in delivering care. Assertive outreach in general psychiatry clearly demonstrates this. In the USA it is associated with improved outcomes and cost-effectiveness; however, these findings have not been replicated in Europe because of differences in the way services are organised. ²

The purpose of this literature review was to identify key themes for future research and development and how they may relate to practice in the UK.

Discussion

Our review of the relevant papers identified the following themes:

barriers to advanced care planning raising awareness and fostering communication between families and health professionals management issues specific to patients with dementia.

Barriers to advanced care planning

Patient-centred care involves the assessment of physical illness and its functional impact with consideration of the patient's preferences, needs and values, whereas ACP is a tool that aims to enhance individual autonomy in addressing end-of-life care. This approach becomes challenging when patients lack capacity to make their own decisions. At present, relatively few patients have such care plans in place. The reasons for this are multifactorial and are likely to represent both patient- and health professional-specific barriers.

In a Spanish study, a cohort of patients with mild Alzheimer's disease and 'proven decision-making capacity' were supported by a multidisciplinary team (MDT) to draw up an ACP.³ Of the 15 patients recruited only 1 drafted a plan. Psychiatric comorbidities (depression and anosognosia), complex family dynamics and a reluctance to engage with the process were cited as patient factors contributing to poor uptake. This initial study highlights the importance of identifying and managing psychiatric disorders in patients with cognitive impairment. This is especially important as improvement in affective symptoms may also result in some improvement in cognitive function, especially in the early stages of dementia.

Delivering advanced care planning and palliative care in acute general hospitals has also been investigated. An intervention, supporting carers, was delivered when a patient with severe dementia was admitted to hospital.⁴ A designated team discussed the various advanced care planning and palliative care options available and supported the formulation of an ACP. Thirty-three patients were recruited and even though discussions were well received only 7 eventually wrote an ACP. The poor uptake in this study may be related to the reluctance of carers to engage with the process because of the distress associated with the hospital admission of a relative. In addition, there is the possibility that once a patient has been admitted to hospital a carer may feel compelled to continue with management of the acute medical problem. In a cross-sectional survey of patients and their spouses it was found that there was moderate agreement between patients and their spouses when considering end-of-life care.⁵ However, if there was discord, spouses were more likely to ask for treatment. Despite this ambivalence, advanced care planning is important. Nursing models that emphasise advanced care planning, communication and comfort are associated with higher levels of satisfaction among family members when they are asked to reflect on their experience of the end-of-life care given to their relative.⁶

In this category, the following areas for service development and medical education were noted:

identification and management of psychiatric comorbidity
 identification of appropriate settings for the delivery of ACP interventions
 exploration of the patients' and families' ideas, concerns and expectations.

Raising awareness and fostering communication between families and health professionals

In a Dutch post-mortem chart review of 198 patients, advanced care planning and palliative care were discussed with 11% of patients.⁷ In this study, 62% of patients had palliative care records, 49% of cases were discussed at an MDT meeting and 76% of patients had a physician order limiting life-sustaining treatment. The current paucity of ACP and targeted palliative care interventions in dementia may relate to a poor understanding of the condition and its natural history. Dementia is a progressive and terminal disease. In a multi-site observational study, 94% of physicians thought of dementia as 'a disease you can die from' compared with 43% of families.⁸ However, in another study,⁹ 19% of the physicians questioned stated that they did not discuss ACP options with patients with mild to moderate Alzheimer's disease. Of the 81% who did discuss advanced care planning, 47% addressed end-of-life care specifically. In families where dementia was understood as a terminal condition, patient comfort was rated more highly than in those where dementia was not viewed as terminal. This may reflect acceptance of the diagnosis and an understanding of the natural course of the condition, thus giving families the opportunity to prepare both materially and psychologically.

The physician plays a key role in ensuring patients receive appropriate palliation and end-of-life care. In a multicentre cross-sectional survey of 594 nursing homes in Belgium, it was found that patients were more likely to receive palliative care if they had input from a general practitioner (a doctor who may initiate palliative care).¹⁰

However, more often than not, these decisions are taken when patients are very dependent and have lost capacity.¹¹ This may be following admission to an acute hospital. In a small survey of health professionals ($n = 16$), including physicians and specialist nurses, respondents reported feeling most confident in managing pain.¹² There was, however, significant variation in the knowledge of opioid dosing, management of constipation and artificial nutrition in patients

with advanced dementia. Given that these patients may not be able to articulate their discomfort, which may only manifest as increasing agitation, it is important that clinicians recognise and manage reversible causes of distress. The complexity of the illness and non-specific presentations mean the medical team may feel ill prepared to deal with specific end-of-life issues. This uneasiness is also present among nursing staff and can result in poor communication between staff and patients/carers.¹³ To tackle this, a role-play-based teaching package was delivered to palliative medicine fellows¹⁴ who afterwards felt more able to discuss ACP and identify caregiver burden. This type of teaching is effective but labour intensive. A 2-day residential course, the 'Dementia Difference Workshop', has been developed in Canada. At a focus group 1 year after the initial training session respondents reported feeling more confident in communicating with patients about ACP and that the course had led to a change in their practice.¹⁵ Internet-based e-learning is another alternative.¹⁶ However, although online courses are effective at delivering information, they may not directly help improve learners' communication skills. Both role-play and internet-based teaching methods are used in UK medical education and provide a key opportunity for raising awareness.

Advanced care planning discussions are associated with an increased rate of plan formulation.¹⁷ It is important that such discussions are undertaken in a supportive manner/setting to ensure understanding and involvement. Patients' educational level also seems to be an important factor, affecting understanding and uptake.¹⁸ The use of audiovisual media can help overcome this and make the material more readily accessible. Lack of communication and support are frequently cited as sources of stress for caregivers, especially when patients are admitted to nursing homes.¹⁹

It is important to clearly and accessibly document the capacity assessment, patients' preferences and their proxy (if appropriate). This is important for medico-legal reasons, as patients' wishes may also change. A retrospective chart review of 93 US patients²⁰ enrolled in a 'program of all-inclusive care for the elderly' found that patients had on average two (range 0–4) documented discussions per year considering end-of-life issues. It was found that, after adjusting for the number of medical comorbidities, including dementia, the longer the patient was enrolled the less aggressive they wanted their medical care to be. At enrolment 34.4% of patients requested full medical treatment while shortly before death this figure was much lower at 6.5%. The enrolment period ranged from 1.0 to 6.4 years with 46% enrolled for more than 3 years. It is, however, unclear whether this change was related to perceived or actual deterioration in health, reduced quality of life or awareness of the natural history of dementia. The recommendations of the Nuffield Dementia Report 2009, which propose a form of proxy decision-making in collaboration with the family, have been suggested as an alternative to legally binding advance decisions which may not be flexible enough to allow for changes in patients' preferences.²¹

Key areas for service development and medical education in this category were:

educational interventions for doctors and other health professionals to raise awareness of ACP and palliative care in dementia improving access to advance care planning and palliative care information for patients standardising documentation and ensuring services are dynamic to follow changes in patients' wishes.

Management issues specific to patients with dementia

The timing and triggers for palliative intervention remain unclear. It may be instigated in a number of settings including nursing homes, hospices or acute hospitals. In a sample of 198 patients, identified in a post-mortem study, 54% had dementia and 95% experienced one or more 'sentinel events' before the initiation of palliative care.⁷ These included febrile illness, pain or behavioural disturbance.

In the UK, the majority of patients with dementia are admitted to hospital. Lack of clinical improvement or worsening clinical biochemistry are common indications for palliation. This may include discussions with families about 'do not resuscitate' (DNR) orders, the cessation of active treatment and initiation of symptom control. End-of-life care is initiated by senior physicians. In addition, junior doctors need to be supported in managing acute behavioural disturbance and general deterioration. There is scope to develop a targeted management framework that takes into account the benefits and side-effects of treatment.²²

The acute hospital plays a key role in the palliative care delivered to patients. Hospital admissions are related to an excess of sentinel events in the community. The capacity of hospices and nursing homes to instigate supportive or palliative measures is currently limited. In the USA, a retrospective cohort study²³ of 240 patients investigating 'do not hospitalise orders' (DNHOs) discovered that 83.8% of patients had a DNHO in place and 24.6% of patients

had a hospital transfer in the 6 months preceding death. Factors found to be independently associated with DNHO were: aged older than 92 years, nursing home stay of more than 2 years, eating problems and the surrogate decision maker not being the patient's child. A qualitative study in the north-east of England, using semi-structured interviews and including representatives from community, hospital and ambulance services,²⁴ found uncertainty among staff about whether current services could meet patients' wishes. The main concerns highlighted included: responsibilities of different groups, aspects of ACP that are legally binding and inconsistencies between the forms used by different agencies. Clarification of roles, standardisation of documentation and shared care between primary and secondary care are organisational and legal issues that need to be addressed to facilitate continuity of care.

Intervention offered by special care units is a relatively under-researched area. A post-mortem review of the care of 422 nursing home residents (263 had dementia) by semi-structured interviews with care staff and 293 family caregivers found that patients with dementia had less shortness of breath, but required more physical restraint or sedative medication for behavioural disturbance.²⁵ Patients in residential care had more skin ulcers, poorer hygiene, less use of restraint and higher use of emergency medical services. This study was performed in the USA and no difference was found between patients with or without dementia in terms of pain, ACP, life-prolonging interventions or hospice use.

A further longitudinal study of 323 patients in 22 nursing homes in Boston, USA was performed.²⁶ It revealed that 43.7% of patients were cared for in a special care unit where they were more likely to receive treatment for dyspnoea, had fewer hospitalisations and were less likely to be fed via a nasogastric tube. Special care units are nursing homes where the structural design, training and activity programmes provide a supportive social environment for patients with dementia. Patients in standard nursing homes were more likely to receive analgesia, had fewer pressure ulcers, and antipsychotics were less frequently used. Staff in special care units reported higher levels of satisfaction.²⁷ Staff in special care units may have more experience in managing patients' personal care needs and behaviours, whereas those in nursing homes may have more experience in assessing and managing pain and pressure sores. A probable confounder in this study is the possibility that patients with more behavioural disturbance and higher care needs are more likely to be cared for in special units. The primary care physician may be in the best position to recognise when referral to a hospice or specialist unit is required.²⁸

Key areas for service development and medical education in this category are:

integration of dementia and pre-existing palliative care services
 integration of dementia and general medical services
 identification and management of causes of behavioural disturbance in dementia
 facilitating transfer of information and patient records between primary and secondary care
 legal issues surrounding the use of ACPs.

Advanced care planning and palliative care in UK dementia services

The 2008 *End of Life Care Strategy* published by the UK Department of Health was the first comprehensive strategy for dying people.²⁹ There have subsequently been a number of initiatives to improve advanced care planning and end-of-life care for patients with dementia, cancer and other chronic conditions.

The National Council for Palliative Care (www.ncpc.org.uk) has a section charged specifically with improving the provision of end-of-life care in dementia. In particular they are working on strengthening ties with pre-existing dementia services and palliative care services to ensure access and coordination between services. In some areas they are working closely with Admiral Nurses (www.dementiauk.org/what-we-do/admiral-nurses), specialist mental health nurses with additional training in dementia care. Given the unpredictability of the illness and questions over the timing and triggers for palliative intervention, integration of these two services will be invaluable in ensuring ACPs are drawn up and that appropriate end-of-life care is available when patients require it.

In 2012, the prime minister announced that dementia is now a national priority.³⁰ A Challenge on Dementia scheme was set up to raise awareness and improve services. One of its key aims is advanced care planning. The scheme highlights the following as examples of good practice that should be replicated across the country: a community-based approach using dementia-friendly environmental design and non-invasive assistive technology to help people remain in the community, and a psychiatry and general practice intervention to facilitate end-of-life care in the community. At a time of financial constraint and increasing demand for already stretched accident and emergency services, these interventions have been welcomed as means of reducing costs.

The experience of dementia special care units can offer insights that may be transferable to general hospital or nursing home settings. Patients in special care units experience greater comfort, treatment for dyspnoea and are less likely to be fed by a nasogastric tube. Having ‘dementia wards’ in general hospitals staffed by physicians, psychiatrists and specially trained nursing staff will help ensure patients receive appropriate medical care and pastoral support. In the community, ensuring nurses have generic medical skills, such as setting up subcutaneous fluids, will reduce the requirement for hospital admissions and will increase the nurses’ experience and confidence in delivering complex palliative interventions.

Limitations

The heterogeneity of study methodology, setting, reported outcome measures and small sample sizes reduce the generalisability of our findings. For example, end-of-life care discussions in out-patient and in-patient settings have different confounders, which will affect responses and outcomes. The majority of the studies are also retrospective or use post-mortem data that are open to recall bias and/or have incomplete/inconsistent data collection. More studies need to be undertaken in the UK, with larger sample sizes and standardised methods of reporting outcomes, to ensure applicability in the UK and comparison between studies.

This review has focused on the organisational factors associated with advanced care planning and palliative care in dementia. However, the disconnect between the willingness of carers and health professionals to discuss these issues,³¹ and the low levels of uptake and engagement reported in the studies reviewed, call for more exploration. This would require a wider review incorporating psychosocial literature exploring personal, cultural and other influences that shape people’s expectations towards death and end-of-life care. The role played by a lack of information, misperceptions about the course of the illness and the setting in which advanced care planning interventions are delivered have been cited in the studies reviewed as possible contributing factors.

1.8.3 Venous thromboembolism prophylaxis in mental healthcare: do the benefits outweigh the risks?

Rashmi Patel

Correspondence

Rashmi Patel (rcpsych@rpatel.co.uk)¹

date

2015-4

Abstract

Venous thromboembolism is an important cause of morbidity and mortality. In recent years, growing awareness has led to the development of strategies to prevent venous thromboembolism in individuals admitted to hospital who are deemed to be at high risk. However, there remains a considerable degree of uncertainty over whether these strategies are of overall benefit and there are few published studies on people who are admitted to psychiatric hospitals. In this editorial I review current clinical practice and areas of uncertainty with respect to venous thromboembolism prophylaxis and its implementation in mental healthcare settings.

 - *Benefits and risks of venous thromboembolism prophylaxis in mental healthcare settings*
 - *Discussion*

Previous estimates have suggested that venous thromboembolism is responsible for around 60 000 deaths in the UK each year.¹ It is thought that individuals admitted to hospital may be at increased risk of developing deep vein thrombosis and/or pulmonary embolism as a result of reduced mobility or intercurrent illness. Other important risk factors include older age (over 60 years), active malignancy, dehydration, inherited or acquired thrombophilia, obesity, previous venous thromboembolism or family history of venous thromboembolism, oral contraceptive pill use, hormone replacement therapy, pregnancy and varicose veins with phlebitis.^{2,3} These risk factors may be applicable to individuals admitted to hospital for medical, surgical or psychiatric care. For these reasons, current clinical guidelines recommend a risk assessment for all people who are admitted to hospital and prescription of a low-dose anticoagulant such as low molecular weight heparin (LMWH) and/or mechanical prophylaxis for those thought to be at high risk.² The decision as to whether to offer venous thromboembolism prophylaxis should be balanced against potential risks, particularly the risk of bleeding with LMWH.

Evidence base for venous thromboembolism prophylaxis in acute general hospitals

Numerous interventional studies have investigated the role of mechanical and pharmacological prophylaxis in reducing the risk of venous thromboembolism among those admitted to an acute general hospital. Studies have principally focused on patients undergoing orthopaedic surgery, non-orthopaedic surgery or no surgery. Interventional studies have demonstrated a reduction in symptomatic deep vein thrombosis among patients undergoing orthopaedic surgery who receive LMWH (relative risk (RR) = 0.50, 95% CI 0.43–0.59⁴). The use of LMWH in this group is not associated with a significant increase in major bleeding (RR = 0.81, 95% CI 0.38–1.72⁴). Prophylactic LMWH is also associated with a reduction in non-fatal symptomatic venous thromboembolism in patients who are undergoing non-orthopaedic surgery (RR = 0.31, 95% CI 0.12–0.81⁵) and possibly a reduction in symptomatic deep vein thrombosis (RR = 0.47, 95% CI 0.22–1.00⁶) and pulmonary embolism (odds ratio (OR) = 0.70, 95% CI 0.56–0.87⁷) in patients who are not undergoing surgery. However, this is balanced with a significantly increased risk of major bleeding (OR = 1.28, 1.05–1.56⁷). Furthermore, when considering fatal pulmonary embolism or overall mortality, prophylactic LMWH is not associated with significant benefit in any group.^{4–7}

Evidence base for venous thromboembolism prophylaxis in mental healthcare settings

In contrast to studies in acute general hospitals, there is relatively little published evidence investigating venous thromboembolism incidence and the role of pharmacological or mechanical prophylaxis in mental healthcare settings. A recent observational study that included systematic venous ultrasonography identified deep vein thrombosis in 10 out of 449 participants (2.2%) following 10 days of admission to a psychiatric hospital.⁸ A total of 16 out of 458 (3.5%) had experienced an episode of venous thromboembolism by 90 days following admission. Of these, three had a non-fatal pulmonary embolism. The study also showed that venous thromboembolism was more likely in older people (8.6% of those aged over 75 years), which may relate to greater exposure to risk factors such as immobility. Another study based on a review of hospital records revealed 17 confirmed cases of venous thromboembolism among 1495 people (1.1%) admitted to an in-patient mental health service for older people.⁹ This contrasts with an incidence of 2.4%

within 91 days among people undergoing total hip arthroplasty surgery¹⁰ and 1.45 per 1000 person years in the general population.¹¹

There is growing evidence from observational studies that suggests a possible association between antipsychotic medications and venous thromboembolism, particularly for clozapine and first-generation antipsychotics.¹² However, it has been difficult to establish whether this association could be a direct pharmacological consequence of antipsychotics (leading to a prothrombotic state) or if it is mediated through other risk factors that are consequences of antipsychotics, such as obesity or sedation leading to reduced mobility.¹³ Some studies have also pointed towards physical restraint as a potential risk factor for venous thromboembolism in mental healthcare settings.^{14–16}

Areas of uncertainty

A recent meta-analysis has led to increasing controversy over the potential benefits of pharmacological or mechanical measures to prevent venous thromboembolism among hospital patients who are not undergoing surgery.⁷ Although a reduction in non-fatal symptomatic venous thromboembolism was seen with LMWH prophylaxis, this is balanced with an increased risk of bleeding and no overall benefit in terms of reduced mortality. Furthermore, the relative benefit of prophylaxis only translates to a modest reduction in absolute risk; for every 1000 in-patients treated with LMWH, only three cases of pulmonary embolism are prevented balanced with four additional cases of major bleeding.⁷

There is also continued uncertainty about the true incidence of clinically significant venous thromboembolism.¹⁷ Although data from epidemiological modelling suggests that venous thromboembolism is responsible for around 60 000 deaths each year in the UK,¹ data from postmortem studies suggest a much lower rate of around 5680 per year.¹⁸ Whether pharmacological and mechanical prophylaxis could prevent all deaths from venous thromboembolism is also unclear.

Do people who develop venous thromboembolism always need treatment with anticoagulants?

Some observational studies have employed systematic ultrasound screening to identify asymptomatic as well as symptomatic deep vein thrombosis. Although deep vein thrombosis was identified in 10 out of 449 participants following admission to a psychiatric hospital, seven cases were of distal deep vein thrombosis of which only one case was symptomatic.⁸ The extent to which asymptomatic deep vein thrombosis predisposes an individual to increased risk of mortality remains uncertain, particularly with respect to asymptomatic distal deep vein thrombosis.¹⁹

The advent of computed tomography pulmonary angiography (CTPA) has led to a substantial increase in the radiological diagnosis of pulmonary embolism.²⁰ However, uncertainty is growing over the optimum treatment particularly with respect to whether all those with a radiological diagnosis of pulmonary embolism would benefit from anticoagulation.²¹ It is thought that small subsegmental emboli may not necessarily be associated with adverse clinical outcomes and that the risks of bleeding from treatment with anticoagulants may outweigh any benefits within this group.²²

Benefits and risks of venous thromboembolism prophylaxis in mental healthcare settings

There are no published interventional studies that have investigated the potential benefits of venous thromboembolism prophylaxis in mental healthcare in-patient settings. Despite this, there is ongoing interest in developing and utilising risk-screening tools to identify individuals at increased risk of venous thromboembolism for prophylaxis.²³ Furthermore, there is no published evidence that has investigated the potential harms of venous thromboembolism prophylaxis in this setting. Although risks of bleeding have been well characterised for people admitted to acute general hospitals, it is not clear whether the same risks apply elsewhere. In particular, prolonged use of LMWH can predispose to thrombocytopenia leading to an increased risk of bleeding.²⁴ The mean length of stay in an in-patient mental healthcare setting (adult: 52.1 days, older people: 93.2 days) is substantially greater than that of an acute medical unit (5.5 days).²⁵ With the exception of those taking clozapine, full blood count monitoring is not routinely performed in the mental healthcare in-patient setting. The extent to which staff in mental healthcare settings are trained to administer prophylaxis and recognise potential adverse complications is also unclear.³ For these reasons, it is possible that the risk of

thrombocytopenia from LMWH may be greater for those who receive it for venous thromboembolism prophylaxis in the mental healthcare setting.

Balancing the potential risks of bleeding and the potential benefits of preventing venous thromboembolism with pharmacological prophylaxis is problematic. Cost–utility analysis is a method by which the benefits and risks of an intervention may be balanced with respect to quality of life measures. A study investigating the application of cost–utility analysis to venous thromboembolism found that there was a wide degree of variation in individual estimates of cost–utility of both acute venous thromboembolism and bleeding complications from pharmacological prophylaxis.²⁶ However, in the mental healthcare in-patient setting, it is sometimes not possible for patients to weigh up benefits and risks of an intervention because of lack of mental capacity. Furthermore, there is little evidence to estimate the potential benefits and risks of venous thromboembolism prophylaxis among individuals who lack capacity as randomised controlled trials have excluded these individuals.¹⁷

Discussion

Venous thromboembolism remains an important cause of mortality in people who are admitted to hospital. However, in recent years, there has been ongoing uncertainty over the efficacy and risks of prophylaxis among in-patients who are not undergoing surgery^{6,7} and whether everyone with established venous thromboembolism would benefit from anticoagulant treatment.^{21,22} Although prophylaxis appears to reduce the incidence of non-fatal venous thromboembolism, there is no robust evidence that supports a reduction in mortality.^{4–7} This may be because of the balance with risk of bleeding for pharmacological prophylaxis.^{7,24} There is even less evidence to support its use in mental healthcare in-patient settings where no interventional studies have been published.

Despite this, substantial resources (over £30 million per year in England) have been invested into venous thromboembolism prevention programmes that claim to ‘save lives’.²⁷ Although it is claimed these investments have resulted in a modest overall saving (a yield of 2.7%²⁸), it is possible that there is a greater opportunity cost in mental healthcare settings where there is currently no evidence for the cost-effectiveness of venous thromboembolism prophylaxis.

It is clear that there is an ongoing need to improve the overall physical health of individuals with mental illness, particularly those with severe mental illness who have been shown to have a substantially lower life expectancy than the general population.²⁹ Although venous thromboembolism is an important cause of mortality, a greater degree of impact could be achieved by investing resources into improving detection and treatment of new cases³ as well as preventative strategies in mental healthcare for cardiovascular disease in general.³⁰ In summary, there is little evidence to support current strategies for venous thromboembolism prophylaxis in mental healthcare settings. Further study to develop and evaluate the effectiveness of novel venous thromboembolism prevention and early detection strategies is therefore warranted.

1.8.4 Psychiatry: Past, Present and Prospect

Elaine Murphy¹

Contents

- *Psychiatry: Past, Present and Prospect*

The editors of this prodigiously ambitious collection of personal essays hint that they strived with some difficulty to extract from their distinguished authors personal views of how psychiatry has developed during the course of the past 50 years. The editors did not want a series of academic reviews but more the experience and wisdom gleaned during successful careers. This is history but as reminiscence, memoir as well as critical scientific review. The editors have achieved magnificently what they set out to do and nearly all the individual essays are worth spending time absorbing. The book is quite simply the best account, a searingly honest one, of the progress we have made over the working lifetime of the internationally renowned authors of the essays, nearly all like your reviewer at the tail end of their careers.

Every practising psychiatrist and trainee should read this book. I did not just read it, I devoured it, but readers beware, I put down the finished book with a disturbing sense of disappointment. Have we really changed the prospects for our patients' lives so little in 50 years? Has so much neuroscientific research, psychopharmacology, sociology and changing political environments produced so little? I fear so. 'What's past is prologue', as pronounced by Shakespeare in *The Tempest*. The real story is yet to be revealed.

The perennial indecisiveness about the boundaries of psychiatry's responsibilities, the repeated creation of social movements that ultimately fail to shift patients' life chances, the deficiency in translating what we know from social psychiatric studies into practical treatment modalities, the ever-shifting ethical sands of risk and restraint and the almost total lack of significant improvement in medications after imipramine in 1940 and clozapine in the 1960s, all this makes disturbing reading. Yet many essays contain scholarly reviews of fruitful paths of research that have not quite yielded success yet, such as Peter McGuffin on genetics, Steven Hyman on neuroscience, Edwin Harari on personality disorders. We are always on the brink, looking upwards but not quite over the brow of the hill just yet. Inevitably, the reader is drawn to areas of one's own personal interest. This reviewer turned straight away to George Szumukler's entertaining review of the vicissitudes of legal controls versus professional judgement, Paul Mullen and Danny Sullivan's pithy and sceptical account of the development of forensic psychiatry and Julian Leff's *cri de coeur* bemoaning the loss of social psychiatry developments from its exciting origins. Why have we not implemented what we know from social skills training and education for patients with schizophrenia, for example? I fear the answer is that mental health services have plenty of doctors and nurses but insufficient numbers of educationalists, social work interventionists and behavioural trainers. The administrative context in which psychiatry is practised has remained almost unchanged in the past 50 years, asylums are gone but the care and treatment has barely changed. Scientific endeavour plods on, our understanding of aetiology makes modest progress, but clinical practitioners must do the best they can with inadequate tools, today just as our colleagues did 50 years ago.

I have one criticism and this is not of the authors or editors. Oxford University Press should surely have produced this book in a better-quality format. It is printed in a small font (although not as small as this journal!) and the cover is somewhere between dull and unfathomable; it looks cheap. A tome so rich in content deserves a more sumptuous coat.

1.8.5 Neglect of the complex: why psychotherapy for post-traumatic clinical presentations is often ineffective†

Frank M. Corrigan Alastair M. Hull

Abstract

Evidence of efficacy in studies of post-traumatic conditions is largely derived from studies in which variables are kept to a minimum. Extrapolation of treatments from uncomplicated disorders to complex conditions may therefore be called evidence-based without being evidenced. Complex conditions with polysymptomatic presentations and extensive comorbidity are being denied proper evaluation, and patients most severely traumatised from the early stages of their development are not provided with rigorously evaluated psychotherapies because they are more difficult to study in the manner approved by research protocols. Such evidence as there is suggests that the simple extension of treatments for uncomplicated disorders is seriously inadequate. This has significant implications for health services responsible for the provision of the most efficacious treatments to those whose disorders arise from severe trauma, often very early in their life.

Evidence-based and evidenced are not necessarily the same

Psychotherapy for post-traumatic clinical presentations is often restricted by the lack of evidence in support of approaches other than those validated for non-complex post-traumatic stress disorder (PTSD), such as cognitive-behavioural therapy (CBT)¹ and eye movement desensitisation and reprocessing (EMDR).^{2,3} Complex PTSD has different definitions but is essentially a multifaceted presentation arising from extreme stress, usually at an early developmental level. This leads to difficulty in regulating affective arousal; alterations in attention and consciousness such as amnesia and dissociation; somatisation; chronic characterological changes; and alterations in systems of meaning.⁴ The variability in the syndromes that result means that inexact use of terminology bedevils this clinical and research area. While PTSD is a theoretical umbrella term,⁵ we use ‘complex PTSD’ in this paper to refer to complex reactions to multiple traumatic stressor exposures and experiences, usually against a background of severe disturbances in primary caregiving relationships.

Complex presentations are often excluded from studies because they do not fit neatly into the simple nosological categorisations required for research power. This means that the most severe disorders are not studied adequately and

patients most affected by early trauma are often not recognised by services. Both historically and currently, at the individual as well as the societal level, dissociation from the acknowledgement of the severe impact of childhood abuse on the developing brain leads to inadequate provision of services. Assimilation into treatment models of the emerging affective neuroscience of adverse experience could help to redress the balance by shifting the focus from top-down regulation to bottom-up, body-based processing.

At present there is little regard for the subcortical generators of distress and an overemphasis on the cognitive strategies needed to manage the resulting emotions. At the institutional level this translates to a preoccupation with therapist supervision; attainment of symptom-reduction goals; invalidation of the importance of affective experience; and intolerance of clinical complexity. There are then imposed limitations on psychotherapy sessions and inadequate time and emphasis on therapeutic engagement. The concept of evidence needs to be expanded to include neuroscientific plausibility. The collection of outcome data needs to include biological data such as changes in functional imaging responses to trauma-related and apparently innocuous interpersonal stimuli. Neuroscientific plausibility can be a source of indirect evidence and affective neuroscience can be included in the rationale for novel treatments in complex PTSD. We explore this elsewhere (details available from the authors on request). However, acknowledgement of the magnitude of the problem would have severe financial implications for mental health services.

Limitations of the evidence base for the treatment of complex PTSD

Evidence-based therapy for mental disorders is often considered to be CBT as it has been shown to be of value in reducing symptoms in many disorders. CBT has been able to accumulate evidence in part through the readiness of funding bodies to provide for research when there is likely to be some observable and measurable benefit, however clinically relevant – in terms of symptoms or functioning. If research funding is not readily accessible for complex and prolonged interventions that are clinically applied in the phase-based treatment of complex PTSD, it is easy to arrive at the false conclusion that a lack of evidence for a particular therapy indicates that it is not effective. There is not, to our knowledge, any register of projects which have been refused financial support or discouraged from making a full application on the basis of cost. One example is sensorimotor psychotherapy,⁶ which has as yet little supporting evidence but is endorsed by leading international experts and is neuroscientifically credible. The costs of carrying out an outcome study of sensorimotor psychotherapy with current methodological constraints would be prohibitive. Somatic experiencing⁷ preceded sensorimotor psychotherapy as a body-based therapy for the resolution of traumatic experience and is widely used throughout the world. It also lacks the evidence base deemed necessary in those services for which rapid symptom reduction is the economically derived priority.

Both the National Institute for Health and Care Excellence (NICE) guidelines⁸ and a Cochrane review of psychological therapies for chronic PTSD in adults⁹ concluded that EMDR and trauma-focused CBT are effective in clinician-rated symptom reduction, although there was evidence of greater dropout in active treatment groups. The authors of both also considered the evidence available to them to be of low quality. A Cochrane review of psychological therapies for people with borderline personality disorder¹⁰ concluded that dialectical behaviour therapy (DBT) was effective in reducing anger and parasuicidality and in improving general mental health, but it did not appear to be more likely than treatment as usual to keep people in therapy. The authors considered that none of the treatments they studied for borderline personality disorder had ‘a very robust evidence base’.

Consequences of accepting ‘evidence-based’ as ‘evidenced’

If CBT and/or DBT were effective for 100% of patients with complex trauma sequelae there would be no need for additional therapeutic approaches. To illustrate our contention that this may not be the case, a relevant paper¹¹ recommended to us as methodologically sound has been selected. This helps to clarify the answer to the 100% resolution question in regard to CBT. In this paper by McDonagh and colleagues,¹¹ exclusion criteria were: use of medication with significant autonomic nervous system effects; dissociative identity disorder; current alcohol or drug misuse; presence of active suicidality or a history of two or more suicide gestures or attempts in the preceding year. Women were also excluded from the study if they were in a relationship with an abusive partner, a situation unfortunately all too common in this clinical population. Although the eventual study group had experienced multiple traumas, those who completed treatment were middle-aged, well educated and in employment. Many of the patients encountered in general psychiatric practice do not fit this profile. Many of those who present clinically with a history of complex PTSD have

been attempting to manage their distress through one – or more likely a combination – coping strategies, for instance self-harm, alcohol/drug misuse, eating disorders, or other behaviours designed to limit their sudden shifts out of the ‘window of tolerance’.¹² The efforts to achieve physiological regulation themselves then lead to further difficulties. Because treatment studies in general dislike comorbidity, the evidence on treatment approaches to multiple, coexisting and complex problems is limited.

As well as the exclusion of people who need therapy – such as those who are chronically suicidal as a result of early trauma – there was evidence of a problem with dropouts from the study. This was most evident with CBT (41%) and required the discharge of the random assignment process to get sufficient numbers into the CBT group. The post-treatment analysis applying intention-to-treat showed no significant difference in the numbers no longer meeting PTSD criteria: 28% for CBT ($n = 8$); 32% for present-centred therapy ($n = 7$); 17% for the waiting list ($n = 4$). So of the 200+ patients who met the criteria for complex PTSD following childhood sexual abuse, 74 were included in the study and 8 got better with CBT compared with 4 on the waiting list. This falls well short of a 100% recovery criterion which would support the restriction of training to CBT, and raises serious questions about CBT being the core treatment modality provided for complex post-traumatic presentations.

For the completers only (i.e. ignoring those who dropped out) both treatment groups improved significantly compared with the waiting list and both showed sustained improvements at 6 months. CBT therefore had clear and demonstrable benefits for some female childhood sexual abuse survivors. However, patients were more likely to stay in present-centred therapy, in which the therapists were required to be genuine, empathic and non-judgemental.

This is only one methodologically sound study of a selected population but it is of interest that the problem with the dropout rate has been previously observed for clinical practice in the ‘real world’,¹³ in which many psychologists trained in CBT were found to be reluctant to use imaginal exposure.¹⁴ There is a striking discrepancy between recommended best evidence-based practice for PTSD and actual clinical practice.¹⁵ The underlying reasons for this discrepancy are likely to be complex but may reflect the clinician’s view of the tolerability of the therapy for both patient and practitioner. Prolonged exposure may be necessary for some who prefer to spend the hours on slow adaptation rather than to go with the rapid information processing available in non-exposure treatment protocols such as EMDR.² However, EMDR cannot be applied in complex PTSD with strict adherence to the standard protocol used in non-complex PTSD without a high risk of increasing dysregulation. For the multiple traumatic events and experiences of the kind commonly encountered by victims of child sexual abuse, prolonged exposure is unlikely to work in the lifetime of the patient.

The context-dependent unhitching of stimulus and response can occur without any impact on the stored representation of the unconditioned stimulus.¹⁶ If the unconditioned stimulus involves a body memory from being raped at 3 years old, it may be possible to reduce the distress related to adult sexual activity without having any impact on the stored and readily triggered pain, rage, terror, shame, abandonment, isolation, worthlessness, hopelessness, helplessness or survival terror. Also unaffected will be the dissociative defences which helped the child to survive and continue with life, apparently unscathed. The therapeutic gains are therefore helpful, but limited.

Therapists engaged in the provision of prolonged exposure may be troubled by ‘feelings of helplessness’.¹⁷ So if the therapists feel helpless, they then need to spend more time in supervision, being exposed to their helplessness with a supervisor who presumably feels less helpless because he or she is supervising rather than treating. Subsequently, within systems there is then less time available to treat those patients who are willing and able to participate in the exposure therapy that even those supplying it dislike and prefer to avoid. It may also be the personal preference of clinical researchers to focus on the cognitive, as in restructuring, rather than be exposed to the realms of horror and terror, intense isolation and abandonment, excruciating pain and despair of the complex trauma survivor. If the therapist has unresolved residues of traumatic experience himself, the ability to convey the psychotherapy may be even more challenging; it is then much easier to focus on reappraisal and the reassurance that all present have survived and prospered.

Dropouts from DBT

Dialectical behaviour therapy provides techniques for safety and stabilisation of borderline personality disorders¹⁸ and some of its elements have been adapted for dissociative disorders.¹⁹ In DBT emotions are recognised as an important part of human experience and there is considerable emphasis on their regulation to reduce distress. So it is interesting to see that dropout rates from DBT in the UK can increase, from an already high 52% to 88% in those with more complex presentations.²⁰ Of course, not all patients with borderline personality disorder have a history of trauma or unresolved attachment and genetic and other factors may be present in some.²¹ However, between 40 and 70% of those with borderline personality disorder would also meet criteria for one of the major dissociative disorders in which trauma histories and disorganised attachment are major aetiological factors.²¹ It is surprising, but perhaps a reflection of what is considered treatable, that attachment trauma is often ignored, despite research specifying feelings of emptiness and problems in coping with abandonment as key features of borderline personality disorder.¹⁰ Treatment continuity may be interfered with by the behaviourist management of dissociation as a problem behaviour, which can be approached through desensitisation of present cues to past traumatic experiences.²¹ The structural dissociation model of van der Hart *et al*²² sees self-states that interfere with therapy as nevertheless based in the defence from the overwhelming effects of trauma. Therapists working with an ego state model in which the cooperation of aggressive protector parts is a prerequisite for continuing treatment (e.g. Paulsen²³) have identified and delineated strategies for achieving this. It would be interesting to know whether the disregard for the original survival functions of peritraumatic and structural dissociation contributes to the high dropout from DBT. A very testable hypothesis is that people who drop out from DBT are primarily those with significant but unrecognised dissociative disorders.

Prevalence of dissociative disorders

There is evidence that some of the complex post-traumatic disorders – including dissociative disorders – can have an impact on functioning equivalent at least to major psychotic disorders, and should be considered to be ‘serious mental illness’.²⁴ Studies of the general population find a prevalence rate for dissociative identity disorder at 1–3%, whereas in psychiatric patient populations the figure is 1–5%.²⁵ Those individuals are often not diagnosed as having dissociative identity disorder but receive treatment according to the most prominent signs and symptoms, and their response to treatment for depression, anxiety, panic disorder, eating disorder, substance misuse or somatoform disorders will inevitably be incomplete. Moreover, unreported or unrecognised trauma is common in psychiatric patients (details available from the authors on request). Unfortunately, in controlled trials in groups of patients presenting with these symptoms and syndromes the diagnosis of those who drop out is not reassessed. Ethical constraints would prevent attempts to acquire this information after a patient has dropped out, so there is a need to assess for the sequelae of complex trauma at recruitment. It could be predicted that some will have unrecognised major dissociative disorders, or significant secondary or tertiary dissociative symptoms. Treatment of comorbid conditions – or concomitant symptoms – is an inadequate response to a range of complex presentations aetiologically related to early trauma.

Therapy for severe complex PTSD and dissociative disorders

It could be argued that psychotherapy for the residual effects of trauma should start with the aim of helping those most severely affected. Chu *et al*²⁵ reviewed the treatment of the major dissociative disorders which are recognised to result from early attachment trauma often compounded by later sexual and/or physical abuse. The review argued that the economic cost of dissociative disorders was considerable and highlighted the priority needed for the development of effective treatments. However, dissociative disorders were frequently unrecognised as such, perhaps because of their polysymptomatic presentations, and therefore appropriate services were not provided. When treatment was adapted to address the consequences of dissociative defences to complex trauma, even those with severe disorders could improve. The lack of controlled or randomised outcomes studies for the psychotherapy of dissociative disorders is an effect of the complexity of the presentations and of the level of funding that would be required to properly evaluate treatment. The lack of evidence is not an indicator that particular approaches do not work – only that they have not been rigorously tested. Testing procedures understandably but unhelpfully prefer simple, measurable attributes for economy of scale.

Conclusions

Patients with many trauma-based disorders are not well served by existing therapies: they will often drop out of treatment at an early stage. PTSD is an inclusive term⁵ which has precipitated much research and clinical interest. However, this categorisation has dominated research and clinical services to the detriment of the range of disorders occurring after traumatic experience.²⁶ Disorders arising from extreme stress during the brain's development and maturation need a prolonged period for recovery. The first requirement is therefore to adopt an approach which will retain patients in therapy long enough for the therapist and patient to form a shared understanding of what is happening and to find a way of working together. This way must be found to be beneficial for the patient and sufficiently tolerable for the therapist so that the therapist does not avoid it.

We are grateful to Janina Fisher and Ron Schwenkler for comments on early drafts.

1.8.6 London's liaison psychiatry services: survey of service provision

Smitha Naidu Jim Bolton Jared Smith

Correspondence

Jim Bolton (jim.bolton@swlstg-tr.nhs.uk)¹

date

2015-4

Abstract

Aims and method To describe the liaison psychiatry services of all 30 general hospitals in Greater London and to determine whether services met national recommendations. The results were compared with a similar survey conducted 8 years previously to determine whether there had been significant service development.

Results We identified wide variations in service provision across London. Fifteen hospitals (50%) had 24-hour services and one had no service. There had been a significant increase in services that assessed older adults. Increases in the size of teams and consultant psychiatry staff were not significant.

Clinical implications Despite an increasing emphasis on the effectiveness of liaison psychiatry services, no London hospital had staffing levels consistent with national recommendations. Recent evidence for the cost-effectiveness of liaison psychiatry and an emphasis on parity between physical and mental health in National Health Service policy may provide further impetus for growth.

Liaison psychiatry is concerned with the management of mental disorder in general medical settings where there are high rates of mental health problems. Mental disorder accounts for 5% of emergency department attendances; 30% of hospital in-patients have comorbid mental illness.¹

A comprehensive liaison psychiatry service will address the following clinical needs:¹

patients presenting at the emergency department with mental health needs; comorbid mental and physical disorders; patients being treated for the physical complications of alcohol and substance misuse; where physical illness and its treatment is causing mental health problems; medically unexplained physical symptoms.

In addition, liaison psychiatry services have a role in the training of general medical staff in the recognition and basic management of common mental health problems.²

The benefits of a comprehensive liaison psychiatry service for a general hospital fall into four key domains:³

improved psychiatric and medical outcomes of patients
enhanced patient experience of medical care
increased patient safety
greater cost-effectiveness of medical services.

The National Health Service (NHS) Confederation highlighted the economic benefits of liaison psychiatry services, which are primarily achieved by decreasing the length of hospital stays and reducing the frequencies of reattendance and readmission.⁴ A subsequent economic analysis of a 24-hour liaison psychiatry service found that it generated considerable cost savings for the health economy, with a cost–benefit ratio of 4:1.⁵ The greatest cost benefit was found in service provision for older adults.

Following increased recognition of the clinical and economic benefits of liaison psychiatry services, the Academy of Medical Royal Colleges recommended the provision of 24-hour multidisciplinary liaison psychiatry services for emergency departments and in-patient wards.⁶ In addition, the need for specific liaison psychiatry service provision for older adults has been emphasised.^{7,8}

To meet a need for more explicit guidance on the provision of services for patients with mental health problems in general hospital settings, the Royal College of Psychiatrists⁹ updated its recommendations for the staffing of liaison psychiatry services (*Table 1*). These were reiterated in national commissioning guidelines.¹ The need for this guidance arose, in part, from the recognition of the wide variability in service provision.

In 2004, a survey of liaison psychiatry services in 29 general hospitals across Greater London identified wide variations in staffing, working hours and patient groups seen.¹⁰ Although half of services worked over 24 hours, all except one service fell short of national recommendations for service provision. Similar deficits have been identified in other areas of the UK.^{11–13}

Following a national focus on emergency care, there had been an expansion in liaison psychiatry services serving emergency departments. However, there was concern that *Table 1* Summary of liaison psychiatry staffing recommendations⁹, a Role Whole time equivalents Consultant psychiatrist 1.0 Trust grade doctor 1.0 Nurses 5.0 Clinical health psychologist 1.0 Administrator 1.5² services for other general hospital patients might be neglected as a result.

2

These recommendations are for a service operating from Monday to Friday, 09.00 h to 17.00 h, assessing and managing adults of all ages in a 650-bed general hospital. Psychiatric training posts are not included and are in addition to the staff above.

In light of recent recommendations for the establishment of robust liaison psychiatry services, this survey aimed to identify changes in service provision across London over the 8 years up to mid-2012, and to audit the staffing of these services against national standards.

Method

Greater London comprises 32 London boroughs and the City of London, and has 30 general hospitals with emergency departments. Information on bed numbers was obtained from hospital websites.

An email and telephone survey of liaison psychiatry services was carried out over the first 6 months of 2012. A senior clinician from each of the services was asked a list of predetermined questions. We enquired about the number and professions of clinical team members. Higher specialist trainees in psychiatry were not included in these figures as such posts are often supernumerary and may not continue beyond the current post-holder's attachment.

We established details of service delivery. Hours of work were categorised into services operating within core 'working hours' (09.00 h to 17.00 h, Monday to Friday), those delivering an extended-hours service and those operating 24 hours per day.

Comparison of the 2004 and 2012 profiles of the directly comparable liaison psychiatry services ($n = 27$)

Service variable	2004	2012	2004 v. 2012 <i>P</i>
Number of in-patient beds, mean (s.d.)	638 (232)	530 (242)	0.001
Number of whole time equivalent staff, mean (s.d.)	8.4 (6.0)	9.0 (5.7)	0.63
Hours of service, <i>n</i> (%)			
No service	0 (0.0)	1 (3.7)	
Working hours (09.00 h to 17.00 h)	5 (18.5)	6 (22.2)	
Extended hours	9 (33.3)	6 (22.2)	
24 hours	13 (48.1)	14 (51.9)	0.80
Staffing, <i>n</i> (%)			
Dedicated medical psychiatry staff	19 (70.4)	23 (85.2)	0.06
Dedicated consultant psychiatry staff	19 (70.4)	23 (85.2)	0.06
Patient groups seen, <i>n</i> (%)			
Older adults	17 (63.0)	26 (96.3)	0.01
Alcohol and substance misuse	21 (77.8)	23 (85.2)	0.55

The survey enquired about service provision for the following specific patient groups:

those presenting to the emergency department in-patients out-patients older adults those with alcohol and/or substance misuse those with perinatal mental health problems.

These groups were selected as being those most commonly served by a comprehensive liaison psychiatry service. Where specialist liaison teams existed to manage specific patient groups (e.g. older adults), these were included within the data collected for the overall liaison psychiatry service. Information was also collected on the organisations responsible for the funding and management of services.

//creativecommons.org/licenses/by/4.0/), which permits unrestricted re-use, distribution, and reproduction in any medium, provided the original work is properly cited.

The Authors own the copyrights to the individual articles.

The results of the survey were analysed using the Statistical Package for the Social Sciences, Release 19.0 (on IBM). Staffing levels were compared with the Royal College of Psychiatrists' recommendations (*Table 1*). Following reconfiguration of acute hospital services between 2004 and 2012, we judged that differences between liaison psychiatry staffing and service provision in these 2 years could be compared at 27 sites.¹⁰ Data from the two surveys were compared using the Wilcoxon Signed-Rank Tests for continuous variables and the McNemar (mid-*p*) test for categorical variables, which is appropriate for binary matched pairs data with small and moderate sample sizes.¹⁴ The criterion for statistical significance was set at $P < 0.05$.

Results

Hospitals

Information was collected from all 30 hospitals, of which 29 had a liaison psychiatry service. Between 2004 and 2012, 2 hospitals had closed and 3 new sites had opened; 27 hospitals were common to both surveys.

A comparison of the profiles of the 27 directly comparable services is given in *Table 2*.

Bed numbers

The mean number of in-patient beds for the 30 hospitals was 535 (range 200–1200, s.d. = 235). For the 27 comparable sites there was a significant decrease in bed numbers of 17% over the previous 8 years ($P = 0.001$).

Working hours

Six (20%) hospitals had services operating in core working hours (09.00 h to 17.00 h, Monday to Friday). Eight (27%) hospitals had extended-hours services and 15 (50%) had 24-hour services. At the 27 comparable sites, there was no significant change in the hours of work between 2004 and 2012 ($P = 0.80$).

In the 15 hospitals with either no liaison psychiatry service or where the service operated for less than 24 hours, out-of-hours cover by community mental health services was available at 13 sites (87%).

Patient groups

Table 3 describes the patient groups assessed by services and indicates where a particular group was managed by a specific specialist team within the overall liaison psychiatry service.

All of the 29 services assessed patients in the hospital's emergency department. One service only assessed patients of 65 years of age or over; younger adults were referred to community mental health services.

All of the liaison teams accepted referrals for older adults and 14 (48%) had a specific specialist older adults service. For the 27 comparable sites there was a significant increase in liaison psychiatry service provision for older adults between 2004 and 2012 ($P = 0.006$), but not for patients with alcohol and substance misuse ($P = 0.55$).

Staffing

The mean number of whole time equivalent clinical staff for all 29 teams was 8.7 (range 1–22, s.d. = 5.5). The mean numbers of staff for the various hours of service are given in *Table 4*.

With respect to the 27 directly comparable sites, there had not been a statistically significant increase in the mean size of teams ($P = 0.63$).

Three teams (10%) consisted solely of nursing staff, but had access to senior medical staff if required. Fourteen teams (48%) had at least one whole time equivalent consultant psychiatrist. Two teams (7%) had a whole time Table 3 Patient groups managed by liaison psychiatry services in London's general hospitals ($n = 30$) Patient groups Liaison psychiatry

(48) Alcohol and substance

misuse 26 (87) 10 (33) Perinatal 26 (87) 9 (30) Table 4 Staffing of London's liaison psychiatry services ($n = 29$) Whole

time equivalent number of staff, mean (s.d.) Hours of service Consultant

psychiatrist Other

medical Nursing Psychology Other Working hours ($n = 6$) 0.8 (0.5) 0.8 (0.7) 1.8 (1.0) 0.0 (0.0) 0.0 (0.0) Extended hours ($n = 8$) 0.5 (0.4) 1.3 (1.0) 5.1 (4.7) 0.3 (0.4) 0.2 (0.5) 24 hours ($n = 15$) 0.9 (0.7) 1.5 (1.4) 8.4 (2.4) 0.1 (0.2) 0.4 (1.1) equivalent psychologist and five more (17%) had regular psychology sessions.

At the directly comparable sites there had been an increase in the number of teams with dedicated medical psychiatry staff and specifically consultant psychiatry staff, but the differences were not statistically significant (both $P = 0.06$).

National staffing recommendations for liaison psychiatry services (*Table 1*) are for a working-hours service, although it is noted that an extended-hours service with additional staffing should be provided where there is local need. It is difficult to compare the services surveyed against these recommendations, because of the range of different hours of work. However, none of the services employed all of the recommended staff.

Funding and management

In total, 16 liaison psychiatry services (55%) were funded via a mental health trust, 6 (21%) via an acute trust and 7 (24%) were jointly funded. All services were managed by mental health trusts.

Discussion

This survey of London's general hospitals describes the level of liaison psychiatry service provision in 2012 and compares this with 8 years previously. As in 2004, the survey found a wide variation in staffing and hours of work. No hospitals had staffing levels consistent with national recommendations. Between 2004 and 2012 there was a significant increase in service provision for older adults. There was a non-significant increase in the number of liaison psychiatry teams with dedicated medical staff and consultant psychiatrists.

There continued to be considerable gaps in service provision, with one hospital having no liaison psychiatry service. Although community mental health services often provide psychiatric input where no liaison psychiatry service exists, this is likely to be a less clinically and cost-effective model of care.

The variation in service provision between hospitals has been found in surveys of other areas of the UK.^{11–13} As service provision in London has previously been found to be more extensive than elsewhere, this survey indicates that considerable development is required across the UK to fulfil national recommendations and achieve potential cost savings for the wider health economy.⁵

The increase in specific service provision for older adults might reflect the emphasis on providing such services following the previous survey.⁷ Subsequent evidence of their cost-effectiveness may provide further impetus for the growth of such services.⁵

There was an indication that psychiatric expertise within liaison psychiatry services may be increasing, including a growth in consultant numbers, although these findings did not reach statistical significance. This potential increase may reflect recognition of the need for robust clinical leadership and management, and of the specific expertise that psychiatry can bring to the management of complex cases.¹⁵

The decrease in mean bed numbers for London's hospitals may reflect the emphasis in health service policy for England and Wales on providing more services in the community. If this trend continues, it could have a significant impact on how liaison psychiatry services are delivered. One potential area of service development is the extension of liaison psychiatry expertise into primary care to support the management of patients with comorbid physical and mental illness and those with medically unexplained symptoms.^{15,16}

At the time of this survey, the principle of 'parity of esteem' between mental and physical health services was stated in England's NHS Mandate.¹⁷ NHS England's objective is to close the health gap between people with mental health problems and the population as a whole. The potential impact of this on liaison psychiatry has been articulated in a subsequent report, which recommends that commissioners need to regard liaison services as a necessity rather than an optional luxury, in order to provide an integrated approach to healthcare in acute settings.¹⁸

Potential changes in the funding and commissioning of liaison psychiatry services may also provide an impetus for service development. As indicated by this survey, most services in England and Wales are currently paid for from a mental health block contract.¹⁹ Separate funding of physical and mental health services is inappropriate for liaison psychiatry, which bridges the two areas.³ Work is underway to devise a sustainable model of funding that will provide more incentive for commissioners and providers of healthcare to establish comprehensive liaison psychiatry services.

Limitations

The survey was conducted in 2012, and several respondents indicated that local commissioners were considering an increase in liaison psychiatry service provision, often on a trial basis. Hence, although at the time of publication there may have already been an increase service provision in London, it will be several years before it can be determined whether this has been sustained. We anticipate that this survey will provide a baseline for a future survey to identify the effect of an increased focus on liaison psychiatry service provision in commissioning guidance.

The survey is likely to underestimate overall mental health service provision for adults in general hospitals. We did not include stand-alone specialist services that operated separately from the main liaison psychiatry service (e.g. neuropsychiatry, psycho-oncology, clinical health psychology). Also, we did not enquire about child and adolescent liaison psychiatry services, which usually operate separately from adult services.

Implications

The survey describes the persistent variation in liaison psychiatry service provision to London's general hospitals, with services universally falling below recommended standards. Since the survey was undertaken, a number of national reports have highlighted the clinical and economic benefits of liaison psychiatry and emphasised the importance of parity between physical and mental health services. As well as describing recent changes in services, the survey provides a basis for future research to determine whether current recommendations are translated into the commissioning of comprehensive liaison psychiatry services for all of London's general hospitals.

1.8.7 Children and Young People's Improving Access to Psychological Therapies: inspiring innovation or more of the same?†

Sami Timimi

Correspondence

Sami Timimi (stimimi@talk21.com)^{1,2}

date

2015-4

Abstract

In 2007 the UK Government announced a substantial expansion of funding for psychological therapies for those presenting with common mental health problems. This 'Improving Access to Psychological Therapies' (IAPT) project was widely welcomed, however, evidence backed, economic, and conceptual critiques were voiced from the start and the project remains controversial. In 2011, the UK government announced it was extending the IAPT project to encompass services for children and young people with the aim of 'transforming' the way mental health services are delivered to them. Here I critically reflect on the problems associated first with IAPT and then with CYP-IAPT and ponder whether CYP-IAPT is significantly different to the problematic adult IAPT project or more of the same.

 - *Conclusion*

Improving Access to Psychological Therapies (IAPT)

For those who believe that psychological therapies help people, there was much to celebrate in a plan to dramatically increase access to these therapies and decrease waiting times, allowing more people with common mental health problems, such as anxiety and depression, to recover. However, from the start IAPT has had a mixed reputation in professional circles, although this has not yet affected its continued expansion. Why did it become so controversial? One of the main reasons has been the 'fetishisation' of certain therapeutic modalities (particularly cognitive-behavioural therapy (CBT)) resulting from an adherence to a primarily technical understanding of the nature of mental health problems and their solutions. This stance marginalises the evidence base that points to the limitations of the technical paradigm, sets up an artificial hierarchy of desirability and efficacy for psychotherapies (and therefore psychotherapists), encourages medicalisation and leads to claims about efficiency that has not been matched by the available evidence.

The technical model assumes that: mental health problems arise from faulty mechanisms or processes of some sort involving abnormal physiological or psychological events occurring within the individual; that these mechanisms or processes can be modelled in causal terms and are not context-dependent; and that treatments can be designed and delivered in a manner that is independent of relationships, contexts and values.¹ Thus, like National Institute for Health and Care Excellence (NICE) guidelines, IAPT's foundational paradigm follows a pathway that assumes that a correct diagnosis (of mild to moderate depression for example) will enable the correct choice of a technical intervention to be made. In this linear formatting, process-driven protocols are central and relational and other contextual issues are of secondary importance – issues to be negotiated to enable satisfactory adherence with the required 'correct' treatment.

From a purely evidence-based point of view, this technical model for delivering mental healthcare has little to support it. Whereas factors outside of therapy (the real-life challenges and histories) have by far the biggest impact on outcomes, within treatment, the factor that has the biggest impact on outcomes is the therapeutic alliance (as rated by the patient) with matching treatment model to diagnosis having a small to insignificant impact.^{2,3} This relationship between the alliance and outcome seems remarkably robust across treatment modalities and clinical presentations.⁴ The search for the 'active ingredients' of a psychological therapy is anyway likely to be doomed to failure because it depends upon the false assumption that such ingredients are delivered by therapists in a uniform manner regardless of the state, requirements and input of the patient.⁵ After all, although the utterances of a patient may not have a direct impact on the chemical activity of a drug, they will in the two-way process of a well-delivered talking therapy. Thus we should not be surprised that attempts to find the active ingredients of, for example, CBT have failed, as studies have shown that most of the specific features of CBT can be dispensed with, without adversely affecting outcomes.^{6,7} Countless reviews and meta-analyses have found that no clear pattern of superiority for any one treatment model has emerged,^{8,9} a finding that extends into evaluations of NHS psychotherapy services, where non-specific factors such as the therapeutic relationship accounts for the variance in outcomes rather than the therapeutic model used.¹⁰

As a result, the IAPT process, which insists on one or two modalities, ends up limiting choice for patients, despite the lack of evidence supporting such a stance. It is possible, of course, that choice had to be sacrificed to maximise the efficiency that may come from standardisation, but the evidence here provides no encouragement either.

Not surprisingly, the IAPT project leaders have reported favourable results being delivered by their services;^{11,12} however, their reports do not include comparisons with the costs and outcomes achieved by non-IAPT services. The first independent evaluation of the initial IAPT pilot sites found little difference between the IAPT sites and comparator services. What differences there were in outcomes were not significant 4 months after treatment and had disappeared at 8 months, but IAPT treatments had cost more per patient, than those provided in neighbouring boroughs.¹³ According to reports compiled by the Artemis Trust,^{14,15} which evaluated data from the subsequent national roll out, the average number of patients achieving recovery for a fixed expenditure of £100 000, when treated by an IAPT service was far lower (49) than for pre-IAPT primary care counselling services (115) or voluntary sector counselling services (78). In addition recovery rates, as a percentage of patients referred, was lower for IAPT services than comparable services (pre-IAPT primary care therapy services, university counselling services and employee assistance programme counselling services).

This is a truly remarkable achievement. The government have spent large amounts of taxpayers' money creating an expensive service that provides little choice and has poorer outcomes than cheaper alternatives that were already in existence before IAPT. In terms of efficiency this has parallels with many large-scale government contracts, whether in information technology (we all know about the billions wasted trying to link up NHS information technology systems for example), building or procurement, where large amounts are put into monopoly contracts, that overcharge and deliver poor quality products that never quite work the way they were meant to.

Perhaps IAPT has helped reduce medicalisation? Again the answer is No. Prescriptions for antidepressants have continued to rise with little evidence that introducing IAPT has had any meaningful impact on these trajectories. Numbers of people claiming disability living allowance in the UK for a mental health problem has also continued to rise with psychiatric disorders as the reason for receiving disability benefits rising from 30.9% of claimants in 2000 to 44.8% in 2013, with the biggest subcategory (over 50%) being for people given a diagnosis of depression (information retrieved from <http://tabulation-tool.dwp.gov.uk>). If current national models of mental health service delivery were effective, we would not see this picture of steadily worsening long-term outcomes in parallel with steadily increasing expenditure.

We should again not be surprised by these findings. The technical model locates the challenges and dilemmas that people face in late capitalist neoliberal cultures as happening in people's heads rather than in the wider contexts of

their lived experience. The task of therapies such as CBT is that of helping the person adjust and learn to deal with the pessimistic thoughts that have come to dominate their life. Although I have no problem appreciating the usefulness of this approach for many people, the fetishisation and commodification of ‘suffering’ at the cultural/political level acts to create new markets for ‘treatment’ while simultaneously obscuring the brutal nature of our winner/loser culture through individualising people’s problems. An approach that fails to appreciate the social, cultural and political dimension of distress is thus unlikely to address the problem of the expanding medicalisation of suffering.

Children and Young People’s IAPT (CYP-IAPT)

As with the adult outcome literature, there is little evidence to support that matching a treatment model to a diagnosis differentiates which treatment is more likely to work and which is not in children and young people.^{16,17} It seems that ‘evidence-based’ treatments for youth tend to come out as superior to usual care, only if the ‘evidence-based’ treatment was developed by the researcher.¹⁸ Technical factors appear irrelevant. Thus, a meta-analysis of component studies found that the theoretically purported critical ingredients of CBT are not specifically ameliorative for child and adolescent depression and anxiety as full CBT treatments offered no significant benefit over treatments with only components of the full model.¹⁹

When real-life clinical outcomes from Child and Adolescent Mental Health Services (CAMHS) are examined the picture is even less encouraging. Research has found that 40–60% of youth who begin treatment drop out against advice.²⁰ Furthermore, although the effect size for outcomes in controlled studies is large, in traditional treatment in community CAMHS effect sizes are close to zero²¹ with little difference found in outcome between treated and untreated children.^{22,23}

Other evidence finds that service transformation projects including allocating extra resources have a negligible impact on outcomes. The Fort Bragg evaluation described the implementation, quality, costs, and outcomes of a \$94 million demonstration project designed to improve mental health outcomes for children and adolescents who were referred for mental health treatment. Outcomes in the experimental service were no better than those in the treatment as usual group, despite the considerable extra costs incurred.^{24,25} This finding was then replicated in the Stark County evaluation study where again there were no differences in outcomes when compared with care received outside the new system, despite the extra expenditure.²⁶

These are sobering findings suggesting that, just as with adults, traditional, medical/technical model approaches do not appear to provide much ‘added value’ in terms of improving the outcomes and efficiency of services.

Did the above findings have an impact on the design of the CYP-IAPT project?

In 2011 IAPT gave birth to the CYP-IAPT project. This upstart announced it was going to strike out in a new direction. But like many children who criticise their parents, the values they carry was already part of their histories, and the bold new direction they boasted about amounted to new directions in the scope of implementation without any recognisable change in the underlying paradigm. Indeed, CYP-IAPT decided to start by focusing on improving the skills of the existing CAMHS workforce and to achieve this by training staff in the manualised implementation of CBT or parenting management treatment (in phase 1). As far as the basics go CYP-IAPT was, therefore, no different to its parent IAPT project. However, another and more interesting objective of the CYP-IAPT project was that of ‘service transformation’. Here the plan was to influence the whole CAMHS team to use more feedback-informed approaches including use of session-by-session outcome ratings. Having been involved in a successful ‘service transformation’ project with my own team involving implementing session-by-session outcome monitoring and developing an outcomes database for the team, I was flattered to be invited to join the CYP-IAPT steering group. Perhaps CYP-IAPT was going to go in a new exciting direction after all. My resulting flirtation with CYP-IAPT proved to be a short lived, but fascinating, insight into how bureaucratisation happens when large monolithic programmes are attempted.

Instead of building on existing and successful service transformation projects that have been developed in other countries and in the UK¹⁶ (and I must declare a potential conflict of interest here – at present ideological rather than financial), the service transformation CYP-IAPT aimed for used the same expensive technological paradigm adhered to by the inefficient IAPT project. The millions given to this programme is being spent on sending CAMHS clinicians to train

in the delivery of manualised treatments (such as CBT or parent management). These clinicians' time then needs to be backfilled, and once trained they are to come back and deliver these therapies in diagnostic-based pathways. A course for managers and extensive implementation checklists have been developed adding greater complexity to service transformation while missing out on learning from whole service projects that have already demonstrated how you might achieve improved outcomes and efficiency. This choking bureaucratisation seems to happen whenever such national projects are attempted in CAMHS.

For example, the CAMHS Outcomes Research Consortium (CORC) has been operating as a UK national project since 2004 with the aim of instituting a common model of routine outcome evaluation and data analysis. However, return rates for second scores on the main patient-rated outcome measure have run at 10–25% or lower for years, thus no reliable and therefore valid outcome data has, at any point, been produced. No matter what they did they could not improve the return rate because the project failed to connect with the reality that front-line clinicians' face. Such national projects are at constant risk of morphing into ever more complex systems that offer little to help the daily practice of hard-pressed clinicians and therefore little to offer patients.

In my own service we have continued to develop an 'outcome orientated' approach¹⁶ drawing on the successful American 'Partners for Change Outcome Management Systems' (PCOMS) model.²⁷ Indeed, PCOMS is recognised as an evidence-based model by the USA 'Substance Abuse and Mental Health Services Administration' (SAMHSA) National Registry of Evidence-based Programs and Practices on the basis of sufficient randomised controlled trial research. Although it would be insulting and disrespectful to the diversity of opinions in our CAMHS service to claim our project has been a runaway success without immense and problematic aspects, what I can, I believe, claim is that drawing on and building on models that have already demonstrated improved outcomes, improved efficiency, improved recovery rates and decreased medicalisation; has engaged clinicians, proved cheap and efficient and built a database of outcomes for the whole service in under a year. I can tell you my own outcome data for open and discharged cases as well as the outcomes for the team I work with and our service as a whole. We have simple formats that provide our commissioners with the sort of whole-service outcome data they have never previously had. We did not need expensive formulaic trainings, just building on the existing skills of the workforce and providing a feedback mechanism that helps us focus on recovery and enhancing reflective practice.

Conclusion

The evidence from a variety of outcome studies provides important pointers for how we should design our services. Extra-therapeutic factors are by far the biggest factor influencing outcomes, which should help us have a little more humility about the task of helping people experiencing mental distress. When we deliver services, matching model of treatment to diagnosis is not only a waste of time (given its clinically insignificant impact on outcomes), but fetishising approaches denies patients choice and flexibility, leading to more potential for disengaging from treatment if the model used is not connecting meaningfully for them (a major problem in delivering our Western psychotherapies with marginalised groups such as ethnic minorities). It is clear to me, and an increasing number of psychiatrists, psychologists and researchers that our allegiance to the technical model for understanding mental distress and behavioural deviance is a big mistake. Meaningful transformations in mental healthcare are unlikely to come through projects like IAPT and CYP-IAPT that can not see this. Instead what we get when we go down the technical route is reduced potential patient choice, poor value for money, increasing medicalisation and bureaucracies that alienate clinicians.

I realise that in the face of powerful well-funded organisations, I am powerless to influence meaningful change. But given the overwhelming evidence and so many critics, perhaps together we can foment enough momentum to make possible a more informed national debate to take place that would lead to a more evidence-based approach and future reform of well-intentioned but misguided projects like CYP-IAPT.

1.8.8 Recognition of the neurobiological insults imposed by complex trauma and the implications for psychotherapeutic interventions†

Abstract

Considerable research has been conducted on particular approaches to the psychotherapy of post-traumatic stress disorder (PTSD). However, the evidence indicates that modalities tested in randomised controlled trials (RCTs) are far from 100% applicable and effective and the RCT model itself is inadequate for evaluating treatments of conditions with complex presentations and frequently multiple comorbidities. Evidence at levels 2 and 3 cannot be ignored. Expert-led interventions consistent with the emerging understanding of affective neuroscience are needed and not the unthinking application of a dominant therapeutic paradigm with evidence for PTSD but not complex PTSD. The over-optimistic claims for the effectiveness of cognitive-behavioural therapy (CBT) and misrepresentation of other approaches do not best serve a group of patients greatly in need of help; excluding individuals with such disorders as untreatable or treatment-resistant when viable alternatives exist is not acceptable.

The healing of emotional wounds is an endogenous, dynamic process which, fortunately, occurs spontaneously in most people whose traumatic experiences resolve over time. Just as the pain of grief diminishes as the body feelings become less insistent and perspectives change, so other adverse events can be processed naturally and emotional healing can occur. When a bereavement is traumatic, for whatever reason, the natural healing process may be blocked and the pain fails to resolve. This is echoed after other adversity: the distress and its associated body feeling, however subtle, continue to intrude on awareness and impair the capacity for positive affects. A failure to recognise the intrinsic homeostatic, emotional healing potential of the brain/mind leads to an overemphasis on techniques for regulation of distress and a denial of opportunity for resolution.

Simple protocols for PTSD, complex post-traumatic presentations and help-seeking

There are interventions available to treat established post-traumatic stress disorder (PTSD) that have been shown to be effective. Reviews of the literature and expert consensus have supported the use of trauma-focused cognitive-behavioural therapy (TF-CBT; especially treatment programmes involving imaginal and *in vivo* exposure), and eye movement desensitisation and reprocessing (EMDR).^{1,2} Moreover, the National Institute for Health and Care Excellence (NICE) guidelines on PTSD recommend that all individuals with PTSD should be offered TF-CBT or EMDR.³ However, psychotherapy studies for PTSD typically exclude for comorbidity and complexity and do not report adverse effects: it should not be assumed that therapy is either positive or, at worst, neutral. The wrong therapy, by the wrong therapist or with the wrong timing (or a combination thereof) may be psychotoxic. Reviews and guidelines present the evidence base for PTSD, but rarely overtly identify the dichotomy between the patients seen in research studies and those with the range of clinical presentations encountered after traumatic experiences, even though the evidence indicates that modalities tested in randomised controlled trials (RCTs) are far from 100% applicable and effective.⁴ The guidelines also do not readily apply to the nature and challenges of treating someone with complex PTSD, as opposed to single-event-related PTSD. The oversimplified misrepresentation of the evidence base leads to a constricted provision of services.

In most areas of medicine it is seen that the most severe damage can present the greatest challenges to the intrinsic healing potential of the body. The complexity of the wounding requires an integration of approaches from different specialties and disciplines. This applies not only to the acute interventions but to the painstaking rehabilitation work that may be required over many years to achieve optimal, if still less than full, functioning.

A pain clinic which ignored a history of severe body injuries with functional consequences – and the associated emotional factors – and offered only paracetamol on the grounds that there was good-quality evidence for its analgesic efficacy in many conditions, would fail to treat much intense and prolonged suffering. The psychotherapy often provided for complex PTSD includes no multi-modal approach and those who fail to benefit may then be considered to be treatment-resistant. For patients with complex PTSD the ineffectiveness of psychiatric treatment and subsequent labelling as treatment resistance can then be attributed to an underlying personality disorder, often without adequate assessment or corroboration. Patients who are told that their lack of response to treatment is due to long-standing differences in one or more of the following: their thinking, their emotional regulation, their behaviour, and/or their

interpersonal relationships, will feel further invalidation that confirms their inseparable differences from the rest of humanity. If everyone else can learn top-down regulation of distress in response to triggers, the failure to acquire these skills is held to imply deep-seated personality pathology.

Help-seeking: incentives and disincentives in asking for treatment

There is evidence that even those with non-complex post-traumatic disorders may be reluctant to seek treatment for their condition.⁵ Rates of help-seeking for PTSD are lower than for similar mental disorders such as depression⁵ and studies both internationally and in Northern Ireland have shown extended time to seeking treatment (12–22 years).^{6,7} Reasons given in the USA by those not in treatment who nevertheless recognised that they needed help included a perceived lack of effectiveness (it would not help or did not help in the past), dissatisfaction with services, stigma or fear of forced hospitalisation.⁵ If the wrong treatment paradigm has been offered or the individuals have felt labelled as treatment-resistant or as having a personality disorder, they will be less likely to present again for help and will either not seek any treatment or seek it elsewhere. A narrow approach focused on effortful regulation of distress will deter from contacting services those who believe they have been doing their best to manage their condition themselves.

Brain stem responses to traumatic experience may be stored and lead to dysfunction

The body awareness of defence responses

Trauma involving threat, whether physical or social, instigates impulses to defend oneself arising in the midbrain.^{8–10} These impulses may be aborted at an early stage or become active only to be ineffective. They may also be subject to top-down control through the ventromedial prefrontal cortex,¹¹ at which level the regulation may also be involuntary. The sequences of movement impulses associated with these responses can be stored ‘in the body’ to the extent that they are outside the ready awareness of working memory and unavailable to access through word-based interventions. Fight, flight, freeze, hide, avoid, attack, submit, despair and uncontrolled activation states have autonomic and motor accompaniments which can be triggered many years after the traumatic episode.¹² Striatal memory activated preferentially under stress is one mechanism implicating the basal ganglia¹³ in procedural (motor) rather than hippocampal (episodic) memory. Animal studies stress the role of the midbrain periaqueductal gray (PAG) and its connections with the hypothalamus for the full motor and autonomic components of the basic defence responses.^{14,15} It is often through specific motor tension patterns that trauma memories are accessed in body-based psychotherapy: these are the route to healing in somatic experiencing and sensorimotor psychotherapy. This suggests that the midbrain and the basal ganglia loops engaged by defensive movements, actual or thwarted, are instrumental in what is stored in the body following unresolved trauma. The profound impact of sensorimotor psychotherapy and somatic experiencing in survivors of trauma is a source of empirical data which demand thorough evaluation. Rigorous level 2 (case controlled trials, non-randomised) or level 3 (observational studies including surveys) evidence is frequently accepted in medicine when it would be difficult to apply RCT methods, either because of unrealistic statistical power demands or because of a likelihood of harm to patients assigned to a cohort which did not receive the active treatment; for example, the acceptance of psychological first aid after disasters where denying core elements of the approach would be unethical.

The body awareness of emotions

The animal work of Jaak Panksepp (e.g. Panksepp & Biven¹⁶) has accumulated over decades into a fundamental realisation that there are basic emotional systems in the mammalian brain. The seven basic emotional systems are: SEEKING/desire; RAGE/anger; FEAR/anxiety; LUST/sexual urges; CARE/maternal nurturance; PANIC/GRIEF/separation distress; and PLAY/physical social-engagement. The midbrain areas involved are the ventral tegmental area for SEEKING and PLAY; the dorsal PAG for RAGE and GRIEF/PANIC; the ventral and dorsal PAG for FEAR and LUST; and the ventral PAG for CARE. All of these basic affective systems are active in humans and are a fundamental part of being human. Many clinical researchers would add shame as a basic affect but the possibility of this being generated in the midbrain is difficult to study in laboratory animals (as discussed in Corrigan¹⁷). The emotional systems experienced as negative are all activated in various ways by traumatic experience. The aloneness, abandonment and shame

of GRIEF/PANIC/separation distress; the terror and dread of FEAR; the explosive energy of anger and RAGE: all of these are commonly encountered in treating PTSD. To treat them as only subcortical disturbances which must be properly managed by the re-trained cortex – or as manifestations of amygdala activation which can be re-learned through prolonged exposure – is to ignore the fundamental role of emotional response in a person's interaction with the environment. When the environment is hostile these responses facilitate survival: they are adaptive and based in trends that go far back in brain evolution. In therapy it can be through emotions that healing and lasting transformation are achieved.¹⁸

The understanding of the 'reptilian' brain as essential for human emotional life

The MacLean description of the triune brain¹⁹ provides a neat guide to the different levels of the central nervous system in relation to their evolution from organisms more primitive than humans. It is important, however, to appreciate that the 'reptilian' brain has evolved in humans to participate in complex functions that would not be available to reptiles. A human may not have as fast a tongue-flick as a lizard, but the human brainstem is supporting behavioural programmes with much greater autonomic and motor variability. A review of neuroimaging studies of the human PAG confirms the involvement of the PAG in many pain syndromes, including fibromyalgia and migraine, and during electroacupuncture.²⁰ There are demonstrable PAG responses during emotional experiences such as fear and dread, disappointment, social rejection, hearing aversive sounds, and stressful cognitive tasks. The imaging studies of the human PAG confirm much of what has been found in animal studies.

What is missing from evidence-based treatments that are not effective?

Patients with complex PTSD who cannot be held in a compassionate and non-judgemental therapeutic relationship will quickly revert to the survival behaviours which have kept them alive. They will default from a therapeutic interaction which carries some of the more threatening features of the ambivalent or disorganised attachment styles to which they may have been exposed from birth. These non-secure relationship templates amplify the impact of later traumatic experiences. Such patients are often exquisitely sensitive at an unconscious level to attachment conflicts. While craving normal attachments, like most humans, any ambivalence or disorganisation in the interactions can lead to an activation of defence response sequences established in early life. The associated survival behaviours will then interfere with the capacity to engage wholeheartedly with the treatments offered. Patients who understand and know the rules to abusive or traumatising interpersonal interaction need to be presented with contingencies to allow them to experience and learn how to have normal, non-traumatising interactions. The attunement with a therapist aware of the importance of attachment in early life experience is essential for the processing of early attachment disruption. The first opportunity some complex trauma patients will have for a stable and non-abusive relationship will be with the therapist. A non-challenging, validating and bounded therapeutic relationship may be able, eventually, to facilitate the feeling of safety and trust which has been lacking through most, if not all, of the patient's life.

The awareness of the body

Those who have disturbing body reactions to triggers reminiscent in some way of the original adverse/traumatic experience will have tried to think their way out of the problem themselves. They may also have been the recipients of common-sense solutions from friends and family. They will have almost certainly discovered the inability to influence through thinking the body sensations of traumatic experience: working memory and cognitive solution areas of the neo-cortex fail to influence the sensorimotor sequences programmed by the trauma. *Body-Centered Psychotherapy: The Hakomi Method*,²¹ first published in 1990, described mindful body awareness for the elicitation of core material, not necessarily of traumatic origin. This influenced the development of sensorimotor psychotherapy in which the mindful attention to somatic residues of traumatic experience promotes the resolution of these for clinical recovery.²² Somatic experiencing was developed by Peter Levine,²³ whose recent book carries the subtitle 'How the body releases trauma and restores goodness'.²⁴

The extant neurobiology also focuses on the body. For example, van der Kolk,²⁵ writing on approaches to the psychobiology of PTSD, included in the title of his chapter the evocative words: 'the body keeps the score'. Scaer, with

a perspective derived from an extensive experience in neurology, concluded that trauma, including preverbal trauma, could leave residues in the body to manifest in later years as clinical syndromes.²⁶ Patients with dissociative disorders have difficulty in being in the body experience and becoming safely embodied is a challenge for many.²⁷

The gulf between the body-based psychobiology and the talking treatments, evidence-based for PTSD but not for complex PTSD, has been bridged by sensorimotor psychotherapy, somatic experiencing, the Comprehensive Resource Model (CRM),²⁸ and other formalised approaches which provide extensive modality-specific training for trauma psychotherapists. Although these are widely used, the lack of RCT data means that they can be readily dismissed if authorities wish to do so: collation of level 2/level 3 evidence would cost much less and set standards for trainers and therapists in the promotion of safe practice. Anecdotally, dropout rate might be the first outcome criterion to employ when empirical studies do evaluate these psychotherapies. Patients who continue to attend because they find sessions helpful and relevant, especially when they have dropped out of other approaches, can provide naturalistic data of empirical value to a caring service.

The body awareness of safety

The 'safe place' is used in the preparation for EMDR to provide an imaginal resource for stabilisation if processing becomes too distressing.²⁹ It is also used as a screening tool for EMDR – a patient who cannot access an imaginal place of safety will not readily be offered active reprocessing. This is regarded as an important safeguard as those who have never felt safe have almost certainly suffered from attachment and other trauma from birth, and are likely to be highly dissociative. Calm or peaceful imagery may be used for those who cannot tolerate even the word 'safe', but this is fraught with difficulty as the lowering of vigilance may trigger switching to protective ego states or activate trauma-burdened memories. When hypervigilance has long been a default setting, the potential pursuit or creation of a 'safe place' or 'calm place' may be rejected as too triggering or activating, and alternative creative language will be required. In sensorimotor psychotherapy the attainment of a sense of safety in the body is considered of great importance for stabilisation. This leads to the proposition that it is only when the safe place is sufficiently strong to be experienced at a somatic level that it can be considered to be fully present. Safety resources that do not extend below the cortex are unlikely to have the required depth when processing becomes difficult. Conversely, being able to find the feeling of safety in the body²⁷ provides an anchor for processing material which would otherwise be overwhelming. Innovative approaches such as the CRM provide therapists with strategies to build internal resources; thus patients who would otherwise be rejected due to an inability to imagine a safe place can be resourced in alternative ways.²⁸

The understanding of dissociation as essentially neurobiological

Dissociation helps the individual experiencing trauma to survive by compartmentalising the responses to the event. It is then not overwhelming, either neurochemically or physiologically. Peritraumatic dissociation is probably best understood through animal models of stress-induced analgesia to which many neurochemicals contribute (e.g. Ford & Finn³⁰). However, it is clear from animal models that, when the trauma involves intense fear, endocannabinoids are released to prevent the overwhelming terror associated with unopposed glutamate, dopamine or acetylcholine transmission in the fear circuits. Riebe *et al*³¹ describe a spill-over effect which triggers the synthesis and release of endogenous cannabinoids. These then bind to presynaptic cannabinoid receptors to down-regulate the release of the fear-promoting neurotransmitters. The endocannabinoid system is active in the fear circuitry of the amygdala, hippocampus and prefrontal cortex, but also in the midbrain PAG where it mediates non-opioid analgesia.⁸ There is evidence that the learning of emotional responses is not confined to the corticolimbic system but occurs also in the midbrain – as would be expected from clinical observations in the treatment of PTSD, such as the resistance of the exaggerated startle response to extinction.

Endogenous opioids promote the analgesia accompanying the passive defence responses mediated by the ventral PAG;⁸ and modulation of these opioids can be used to study behaviour suggestive of terror in laboratory rats.³² Lanius³³ considers endogenous opioids to have a foundational role in dissociative responses to trauma. Whichever chemicals are primarily involved, peritraumatic neurochemical change may contribute longer-term to structural dissociation of the personality.

The awareness in the body of the level of activation related to trauma

Orientation to the occurrence of a traumatic event precipitates an immediate shift in the body's level of arousal. For example, being exposed to a direct gaze activates the midbrain in those who are suffering from the after-effects of complex trauma but induces a response at a primarily cortical level in a non-traumatised control group.³⁴ This activation readily precipitates a generalised arousal through brainstem nuclei for the release of monoamines and other neurochemicals. From brainstem structures such as the locus coeruleus there are ascending noradrenergic projections to the thalamus and cortex for general arousal as well as downward projections to the spinal cord. Ascending dopaminergic projections from the ventral tegmental area activate the ventral striatum and the substantia nigra. There are major ascending cholinergic and serotonergic projections from the brainstem. So alerting, arousing, activating stimuli – often involving different appreciation of pain levels – are exerting their influence through deeply subcortical structures.

The awareness in the body of the residues of attachment response patterns established in infancy

It is particularly easy for those working in the 'here and now' to scoff at the idea of working with body feelings left over from experiences of attachment disruption in early life. This is despite there being much description of the relevance of attachment in the development of affect regulation capacities (e.g. Schore³⁵) and evidence of the relevance of disorganised caregiving in the development of clinical syndromes (e.g. Lyons-Ruth *et al.*,³⁶ Hesse *et al.*³⁷). Attachment disorders can be dismissed as an easy default explanation when there is little evidence of other trauma to explain difficult-to-treat syndromes. However, if the conflicts are approached through body activations brought into awareness while grounded in the experience of specific situations, the patient, rather than the therapist's model, is leading the enquiry; the body's response will ground the experience in the 'here and now' (Schwenkler, May 2014, personal communication). If there are clear patterns of body response to the present-day relationship conflicts, these are the foundation for identification of cycles of obstruction of the attachment urge, followed by protest, despair, detachment, dissociation and sequences of defence responses. A simple here-and-now trigger, such as disproportionate rage to a partner's temporary absence, can reveal patterns established in early life. Scaer²⁶ sets out the arguments for procedural memory based in brainstem centres being established in infants with preverbal capacities for emotion and sensation. These action tendencies based in procedural memory manifest later as proximity-seeking, social engagement and defensive behaviours,³⁷ which may appear at odds with the here-and-now context.

Healing has no territory

We have argued that the evidence for particular approaches to the psychotherapy of complex PTSD indicates that so-called 'evidence-based' modalities – defined as much by those clinical cases excluded as those included – are far from 100% applicable and effective.⁴ Instead, we consider that psychotherapies which acknowledge the role of the somatic residues of traumatic experiences – provide techniques for their resolution – are necessary for the healing of the range of clinical disorders arising from severe and complex traumatic experiences during the brain's early development. Safety, compassion and patience are needed to counteract the long-term hypervigilance and other threat-based responses, so that the patient is internally resourced and treatment is not quickly rejected. Recognition, and evaluation, of non-RCT but still empirical data from widely used psychotherapies such as sensorimotor psychotherapy and somatic experiencing could widen the evidence base, guiding service development for those suffering in a way which cannot be treated by standard talking therapy.

A willingness to explore other/additional pathways to healing

Given the limitations of RCT-evidence-based CBT for complex post-traumatic conditions,⁴ it is essential to investigate other approaches consistent with the evolving understanding of the neurobiological underpinnings of traumatic experiences and reactions. In its standard format, EMDR cannot be readily applied in complex post-traumatic disorders but it can have adaptations for use in structural dissociative conditions (e.g. Paulsen³⁸). These modifications are often influenced by the many publications (over decades) of hypnotherapy experience of treating complex trauma disorders (e.g. Frederick & McNeal³⁹). Moreover, advances in psychotherapy such as Brainspotting⁴⁰ and the CRM²⁸ may be effective at a deep level of the psyche because they necessarily involve the midbrain.⁴¹ Psychotherapies such as sensorimotor psychotherapy and somatic experiencing, which work with emotions and defence responses and access these through awareness of the body and the sensations, movement tendencies and motor impulses ‘remembered’ from the time of the trauma, also work at multiple brain levels. Trauma release exercises⁴² for the discharge of muscular energy residual from adverse events will certainly recruit subcortical areas, as the intrinsic generators of tremor – central oscillators – are not in the neocortex.⁴³ Body-oriented breathing exercises stemming from the CRM²⁸ and yoga breathing cycles (e.g. Brown & Gebarg⁴⁴), based in the respiratory central pattern generators of the brainstem,⁴⁵ can be used clinically to augment affect regulation.

Russell,⁴⁶ asking why EMDR was not more available to US service personnel, explored the reasons for the dominant treatment paradigms being exclusive. Some of these were financial; some were theoretical or belief-based. Grand⁴⁰ advocates the view that ‘healing has no territory’: developments in therapy should always be encouraged and embraced, although it will inevitably mean that the techniques pioneered will be replaced. For example, the CRM has evolved from resource brainspotting to meet the needs of those individuals with complex trauma and dissociative disorders who require more resourcing than is provided by the safe, attentive and attuned presence of the brainspotting therapist working in a dual attunement frame.⁴⁰ Any important advance will change the field so much that other breakthroughs will follow; each is a temporary way station. No therapeutic paradigm should be allowed to become so dominant that it stifles clinical innovation, especially in the absence of compelling evidence of efficacy for complex disorders.

Implications for mental health services of fully engaging with the treatment of complex trauma, and research challenges

The high prevalence of trauma exposure and trauma-based disorders with severe consequences for physical and mental health raises the possibility of significant unmet need. Adults who have been exposed to four or more defined categories of adverse childhood experiences have higher risks for alcohol and substance misuse, depression, suicidality and poor physical health.⁴⁷ Childhood sexual abuse increases the risks in adulthood of depression, anxiety, suicidality, alcohol and illicit drug dependence, PTSD symptoms and poor physical health.⁴⁸ The lifetime prevalence of traumatic events and PTSD is high in those with severe mental illness⁴⁹ and there is evidence that trauma therapy can be effective even in this group.⁵⁰ The service implications of the epidemiological findings are that the provision of long-term trauma psychotherapy may be required, and this is expensive. It is considerably cheaper to downplay or ignore the role of trauma and constantly question any psychotherapy methods which have not yet acquired a gold standard RCT evidence base, even if they are expert led or neurobiologically informed. Indeed, services driven by waiting list targets have a disincentive to explore training in, and use of, psychotherapy interventions which require longer therapeutic contact. For dissociative disorders the treatment may require years, even with the best psychotherapy available,⁵¹ rather than the maximum of 20 sessions currently offered by many services.

If there is no cultural dissociation from the reality of the need for treatment of complex post-traumatic conditions, the consequence would be a caring health service providing treatment for a large number of patients who are only in ill health because they suffered trauma, loss or abuse at an early and critical age. If health service providers recognised the limitations of the RCT evidence base, they could promote training in internationally recognised models and conduct clinical research on those particular psychotherapeutic approaches. Moreover, psychotherapists who are better acquainted with the neurobiological underpinnings of psychological conditions and their implications for treatment and outcomes, may be less affected themselves by feelings of hopelessness in their long-term clinical endeavours.

NICE³ recommended chronic disease management strategies if trials of evidence-based therapies (TF-CBT or EMDR) were ineffective for PTSD; the guidelines did not differentiate the evidence base for PTSD from that for complex PTSD. As we have suggested, these treatments are likely to have been found ineffective for complex PTSD. A focus on sleep

hygiene, structured and supported activities as well as coping strategies for chronic problems will neither greatly assist the patient nor allow their therapist the satisfaction of seeing benefits from their skilled and compassionate intervention. Nothing else will be offered if services or systems continue to affectively dissociate from the clinical reality through the blinkered insistence that it is not really happening and that ‘apparently normal’ and ‘getting on with life’ perspectives are the only possible vision.

Research challenges

For clinical trial research to demonstrate real-world effectiveness of treatments for the range of post-traumatic conditions, the exclusion criteria need to be reduced. Comorbidity with PTSD is the norm, not the exception, yet trials do not reflect this. The measurement of treatment outcomes also needs to reflect more than just any change in PTSD symptoms and to include general functioning, intra- and inter-personal issues, and quality of life. Funding for complex interventions is expensive and a research programme is needed which does not rely on the single intervention for single outcome measure model: this would pose immediate difficulties within a phase-oriented structure for treatment. One intriguing question within the treatment of complex trauma is whether the resourcing required to allow re-processing of trauma experience and memory needs to be provided as a specific phase of treatment prior to any re-processing or whether it can be integral to each therapy session and therefore specific to the issue being reprocessed (as is suggested in the CRM²⁸). While discussions about the provision of expensive, innovative medical treatments have occurred, often in public, we are unaware of discussions justifying and limiting the access to long-term psychotherapy for complex disorders.

Education challenges

The need for outreach and education of referrers should not be underestimated. Evidence from a novel ‘screen and treat’ model after a high-profile terrorist incident showed that despite widespread advertising of the services, general practitioners (GPs) were found to refer few patients to trauma services specifically tasked with assessing and treating individuals in the aftermath of the incident.⁵² There is perhaps even less reason to expect referrals from GPs of individuals with complex post-trauma reactions originating in early development. Within general adult psychiatry the role of trauma may or may not be recognised, largely dependent on the clinician’s interest, knowledge or conceptualisation of cases; it may also perhaps reflect their pessimism about the availability of effective treatment. Potentially significant post-traumatic psychopathology in psychiatric patients⁴⁹ can go unrecognised when there is a failure to include trauma experience in treatment formulations. When this applies to the so-called ‘large T’ trauma causes, there is even less likelihood of the significant attachment disruptions inherent in developmental trauma being identified.

Conclusions

Within psychological services, the general public have been greatly served by improving access to psychological therapies (IAPT) in England and Wales and similar initiatives elsewhere. However, limited session provision and a dominant therapeutic paradigm that does not approach the needs of patients with chronic, comorbid and complex post-traumatic reactions, leaves those with the most severe symptoms without effective treatment. Patients unable to make use of time-limited cognitive-behavioural strategies may face rejection and labelling, feeling blamed for their non-improvement. In fact, they are victims again, this time of therapists trying to deliver a therapy for a quite different disorder, with managers who expect them to demonstrate consistently improving rating scale scores.

The strategy for the provision of psychological therapies needs to ensure that the most ill are not sidelined and blamed. Current drivers such as waiting list targets are vital to drive access to therapy. However, quality must also be brought to the fore: clinical governance demands the establishment of an environment that allows clinical excellence to thrive; excellence demands that the therapy provided is evidenced for the disorder being treated. In Scotland, there is a strategy for trauma-sensitive services including certain ‘at risk’ groups such as veterans of the armed forces. This is to be applauded. However, clinicians and managers should be educated to clinical need at all points on the trauma spectrum, not just those potentially responsive to CBT or those with combat-related disorders.

Systems that allow long-term trauma psychotherapy rather than time-limited, defined sessional input are needed. Treatment should be influenced by the major developments in affective neuroscience to proceed in a direction that is not affect-phobic. Individuals with highly polysymptomatic post-traumatic conditions, often with more Schneiderian first-rank symptoms than individuals with schizophrenia,⁵³ pose major difficulties when monitoring clinical trials. However, the inherent difficulties do not then demand an acceptance – as clinically sufficient – of those techniques validated for the reduction of particular symptoms or symptom clusters within non-complex PTSD. The search for the best treatments for the most traumatised individuals is being hampered by the exclusive acceptance of conditioning, cognitive or emotional learning models which dismiss the fundamental role of affective experience in response to the environment and are, therefore, dehumanising.

We are grateful to Janina Fisher, Ron Schwenkler and Catherine Shea for comments on earlier drafts of this paper and to the anonymous reviewer who made very helpful criticisms and comments.

1.8.9 Panic Disorder and Agoraphobia

Emma Barrow¹

Contents

- *Panic Disorder and Agoraphobia*

This text is part of the Oxford Psychiatry Library series and at about 80 pages there is nothing anxiety-provoking about its length. The authors make clear from the outset that this is a book designed to be user friendly in its approach and, with four independently referenced chapters, the reader instantly feels it will live up to this claim.

Published in the USA, the opening chapter on diagnosis refers to the (at the time of print) current DSM-IV and new DSM-5 diagnostic criteria. The main focus of diagnosis is, however, referencing the complex interplay between patients with panic disorder who frequently present with multiple and varied somatic complaints to a wide range of medical, surgical and psychiatric specialties. Of particular interest to this reader was the comprehensive table of medical conditions that can mimic panic attacks. Concise text is interspersed with useful boxes and tables, drawing the reader's eye to the key points and considerations. Three further chapters on aetiology, pharmacological treatment and non-pharmacological treatment follow a similarly structured pattern.

For those who are looking for a summary of the current research into these disorders the 'aetiology' section on neurochemistry will not disappoint. For those, perhaps from non-psychiatry-based disciplines, looking to jump to more practical management advice, the section on 'pharmacological treatment' contains a handy FAQ list.

This book is by no means exhaustive, but what it quite cleverly manages to do is educate and interest the reader while guiding them through the practicalities of treating patients with panic disorder and agoraphobia in clinical practice. The section on pharmacological treatments is not as detailed as, say, the NICE or Maudsley guidelines, but its handy

Abstract

Aims and method We compared findings of an audit of New Zealand’s version of the second opinion appointed doctor (SOAD) scheme with published information on the equivalent scheme for England and Wales, to consider what might be learnt from the different jurisdictions’ experience.

Results Strong similarities exist between the two schemes in the demographic profile of individuals subject to the SOAD process and rates of approval of compulsory treatment. The clearer legal framework for the English scheme and its supervision by an independent national agency may offer significant advantages in terms of consistency and transparency, compared with the informal, decentralised structure of New Zealand’s scheme.

Clinical implications Clinicians may not always favour greater formality or elaborate national structures for administering the Mental Health Act, but there are advantages in promoting clarity and consistency in a mandatory statutory process designed to protect compulsory patients’ rights.

In 1992, New Zealand adopted a modified version of the second opinion appointed doctor (SOAD) scheme into its mental health law. That scheme was first enacted for England (and Wales) by the Mental Health Act 1983 (UK). As in England, New Zealand law requires the proposals of the treating clinician to be approved by a second psychiatrist in two main situations – for longer-term use of medication, and for electroconvulsive therapy (ECT) – where a compulsory patient does not consent.¹ In England, this mandatory second opinion scheme has been managed, funded and periodically reviewed by a national agency, firstly by the Mental Health Act Commission (MHAC), then by the Care Quality Commission (CQC). In New Zealand, no equivalent national agency has existed to manage the scheme. Its administration has fallen on regional officials (usually senior psychiatrists) who manage the statutory process in the nation's 20 district health boards. Moreover, New Zealand's national guidelines on the Mental Health Act^{2,3} contain nothing like the detail of the English Code of Practice⁴ regarding conduct of the scheme. Instead, each local district health board uses its own systems and forms.

The English rules require SOADs to check the patient's legal status, speak to the patient in private, consult the treating clinician, consult two other professionals involved in the patient's care and provide written reasons for the decision. A national system of online forms is also used for SOADs to document these steps, state whether they approve the treatment in changed or unchanged form and specify the agreed treatment regime.⁵ No such prescriptive rules govern the New Zealand process. This paper compares the role performed by second opinion psychiatrists in New Zealand with that of SOADs in England and Wales. The term SOADs will be used to refer to the second opinion psychiatrists, of both jurisdictions.

Method

We audited the New Zealand scheme, for the first time, at three different centres. We reviewed documentation concerning SOADs' conduct of the treatment approval process, for both medication and ECT.⁶ We matched SOAD reviews of ECT with the two medication reviews nearest in time (ECT, $n = 146$; medication, $n = 292$; total, $n = 438$). Then we studied the progress in the following year of 11 patients at one centre whose treatment had not been fully approved by the SOAD.⁷ Finally, we compared our findings with published information and guidelines concerning the equivalent English scheme. The study was approved by New Zealand's Multi-Region Ethics Committee.

Results

Comparisons between the New Zealand and English SOAD schemes

We found intriguing similarities and important differences between the operation of the New Zealand and English schemes. There were strong similarities in the demographic profile of patients for whom treatment approval was sought for medication and ECT respectively. In both jurisdictions, in medication reviews, males outnumbered females by approximately 2:1, whereas that gender ratio was reversed for ECT; the mean age of patients undergoing medication review was significantly younger than for ECT; and the mean age of female patients under review was significantly older than males, for both medication and ECT.

These features seem to be associated with the different diagnostic profile of patients undergoing the different forms of treatment. In New Zealand, we found patients undergoing medication review tended to be male (62%), younger (mean age 44.8 years) and had a diagnosis of schizophrenia or schizoaffective disorder (64%), whereas patients being considered for ECT tended to be female (70%), older (mean age 56.9 years) and had a diagnosis of affective disorder (68%).⁶ Interestingly, Māori patients tended to be underrepresented in figures for ECT (6%) compared with their proportion in the general New Zealand population (approximately 15%).

In both jurisdictions, ECT reviews generally occur at an early stage in the Mental Health Act process. In England, Fennell, in a study conducted some years ago, found 60% of ECT approvals occurred within 7 days of the patient's detention under the Act, 18% on the very first day.⁸ In New Zealand, we found 60% occurred during the initial month's compulsory assessment under the Act.⁶ Medication reviews are only required by the legislation, of both jurisdictions, after the patient has been detained for a longer period of time.

In both jurisdictions, SOADs overwhelmingly approved the treatment sought, especially ECT. Non-approval, or significant change in the proposed treatment, was rare (*Fig. 1*).^{6,9–11} In England, there has been a recent trend towards less frequent full (or 'unchanged') approval of treatment plans for medication (81% in 2002–2007, falling to 68% in 2011–2012), though not for ECT.^{9,11}

Lack of consistency between New Zealand centres

In our New Zealand audit, we found little consistency in the conduct of the SOAD process at the different centres.⁶ There were marked differences in how SOADs were designated to review the treatment of individual patients; the number of clinicians who performed the SOAD role; their degree of independence from treating clinicians; the forms they completed; and the steps they took during the approval process, as documented in local forms or the patient's clinical record in the week before or after treatment was reviewed.

In New Zealand, the Mental Health Act authorises the Mental Health Review Tribunal to appoint qualified psychiatrists as SOADs, but there is no national agency managing the scheme.¹ Different methods are then used in the various regional district health boards to designate the particular SOAD who will review an individual patient's treatment. These methods include an administrator approaching SOADs on a roster system; the treating clinician sending an email request to all local SOADs, to see who responds; and the treating clinician directly approaching a SOAD with specialised knowledge in treating the particular patient's condition. In some services, treating clinicians personally decide which SOAD to approach.

At one centre, only a small number of appointed SOADs actually performed the task. At another, the work was shared widely among consultant psychiatrists. At a third, a single specialist considered almost all proposals for approval of ECT, then administered the course of treatment, if approved. The SOADs invariably worked in the same region as the treating clinician. They were not paid more to perform the SOAD role than their usual salary or given any particular relief from their usual workload.

Each district health board used different forms and systems for recording the SOADs' written opinions on treatment. The text of these opinions was remarkable in its diversity, ranging from a single word (the name of an alternative medication) to a three-page formal report. The depth of scrutiny given by SOADs to the treatment is indicated in part by this written record. It revealed great variation between New Zealand centres in the extent to which SOADs recorded having reviewed the patient's clinical notes, diagnosis or treatment plan, or recorded the patient's views on treatment. There was similar variation in the extent to which there was any record that SOADs had spoken to the treating clinician or provided a written *Fig. 1* Extent of approval of (a) medication and (b) electroconvulsive therapy (ECT) by second opinion appointed doctors (SOADs) in New Zealand (2003–2011) and England and Wales (2002–2012). Data from Dawson *et al* (2013),⁶ Mental Health Act Commission (2008),⁹ Care Quality Commission (2013).¹¹ Terms used in New Zealand: 'approved unchanged', 'partially approved' and 'not approved'. Terms used in England and Wales for both periods of time: 'approved unchanged', 'slight change' and 'significant change'. There were missing data for second opinions on medication (New Zealand 2003–2011, 2.4%, England and Wales 2002–2007, 7.6% and 2011–2012, 3.5%) and ECT (New Zealand 2003–2011, 0%, England and Wales 2002–2007, 8.2% and 2011–2012, 8.3%). justification for their decision. This diversity is illustrated in *Fig. 2*.

In short, there seems little consistency in SOADs' conduct of the process at different New Zealand centres. Moreover, different methods were used to store information generated during the process, and generally no adequate method was adopted for linking the information SOADs provided on the forms with any comments they made in the patient's notes, so the two could be read together.

No clear process where impasse

At one centre we evaluated the files of 11 patients whose treatment had not been approved, or only partially approved, by the SOAD,⁷ trying to determine how the disagreement had been resolved. We found that when the SOAD did not approve, or qualified, the treatment plan, intensive consultation usually occurred between the treating clinician, the SOAD and the regional administrator of the Act. Cases generating most correspondence concerned non-approval of ECT. In some cases, these written exchanges revealed significant dissatisfaction or disagreement on the part of the clinicians.

In England, the Mental Health Act Code of Practice says (para 24.67) there is 'no appeal' from the SOAD's decision to approve treatment or not.⁴ In New Zealand, the Act simply says that, for the proposed treatment to proceed, it must be approved by 'a' SOAD. This rule does not say the SOAD can veto the treatment proposed. Instead, it opens the possibility that another SOAD might approve the treatment, if the first SOAD does not. So it might be said that there is an appeal.

In 2 (of 11) cases of non-approval we followed, further second opinions were sought when the first SOAD declined. Nevertheless, some disagreement arose in these cases between the clinicians as to whether the initial SOAD's refusal to approve treatment was final. No clearly established process seemed to exist for resolving such disagreements, and no clear 'appeal' process was specified by the Mental Health Act guidelines² during the period studied.

Discussion

Main findings

Our findings show some clear similarities in the conduct of the SOAD schemes in England and New Zealand, although there is considerable inconsistency in the process followed at different New Zealand centres, along with uncertainties arising from the absence of a clear rule in New Zealand regarding the finality of a SOAD's decision not to approve treatment.

There are similarities in the characteristics of patients subject to medication and ECT reviews, in the stage patients have reached in the civil commitment process when undergoing these reviews and in the high rates at which SOADs approve the treating clinicians' plans. In sum, under the two schemes, SOADs seem to review similar patients, at similar stages in the Mental Health Act process, with similar results.

One can debate whether high rates of approval of treatment by SOADs are a good or a bad thing. Psychiatrists exercise considerable discretion in selecting appropriate treatment and, in doing so, must take many factors into account. Complete agreement between treating clinicians and SOADs on all occasions is therefore improbable. If it occurred, it would suggest 'rubber-stamping' and no exercise of independent judgement on the part of SOADs. That would seem to rob the process of any value. Yet high levels of disagreement between the two clinicians would also be a concern. It would seem to call into question the competence of SOADs, or the competence of treating clinicians whose plans would be regularly overruled. Alternatively, it would call into question the reliability of treatment decisions in psychiatry, if the two clinicians could rarely agree on a treatment plan.

A high but not complete level of agreement therefore seems satisfactory. It suggests that independent judgement is exercised by SOADs, but the two clinicians can usually agree on a treatment plan. The rates of approval, in both New Zealand and England, fit that pattern, even though the rates are not exactly the same.

Lessons learnt

At the New Zealand centres studied, there were notable inconsistencies in how SOADs were designated to review individual patients' treatment and in the degree of independence evident between SOADs and treating clinicians. There also seemed to be little consistency in the range of people SOADs consulted or in the information they considered (including the frequency with which they consulted the treating clinician, considered the patient's views about treatment and provided a written justification for their decision) – as judged from their written comments on the forms or in patients' notes. Likely explanations for this diversity include the lack of detailed national guidelines stipulating a process to follow, lack of specific training or funding for SOADs who perform the role, and absence of decisions of New Zealand courts reviewing the SOADs' conduct against legal standards of procedural fairness.

A notable feature of the New Zealand situation is the absence of a 'no appeal' rule. In cases where SOADs declined to approve treatment, intense consultation usually occurred, but this did not always produce agreement between the SOAD and treating clinician on an amended treatment plan. Approval from another SOAD might then be sought, on the premise that treatment could proceed if 'a' positive opinion was obtained.

The 'no appeal' rule in England is more final and certain. It may encourage SOADs and treating clinicians to negotiate an amended treatment plan to permit some form of agreed treatment to proceed, when the patient is detained for treatment under the Act. It is interesting that the MHAC and CQC publish no figures on cases in which SOAD approval is declined. They report only cases in which the treating clinician's plan was approved 'unchanged', 'slightly changed', or 'significantly changed'. There is in fact no space on the current CQC form for English SOADs to say they decline. Presumably they could simply decline to sign the form and – if there was 'no appeal' – that would seem to mean the treatment could not proceed.

This does not mean that all disagreements in England between treating clinicians and SOADs are happily resolved. The 'no appeal' rule may confer sufficient authority on SOADs to secure amendment of the treatment plan, in most cases, and conferring such authority on SOADs may be more readily justified where – as in England, but not New Zealand – senior psychiatrists are selected, trained, funded and supervised by an independent national agency to perform the task. But it is not wholly obvious why one SOAD should have final authority to approve the treatment or not, and some treating clinicians are no doubt left aggrieved by the SOAD's decision. The SOAD does not carry continuing responsibility for the patient's care, and the treating clinician may have far more knowledge of the patient and be a specialist in treatment of the patient's particular condition. So why should the treating clinician be overruled by another clinician, with no right of appeal?

Greater knowledge on the part of the treating clinician should, of course, be taken into account by the SOAD when making their decision. But a case can be made for the New Zealand position: that treatment should be permitted provided 'a' SOAD approves. This produces something like an appeal from the first SOAD's decision. Any appeal process should be clearly specified, however, and should not be capable of manipulation by the treating clinician.

The new New Zealand guidelines regarding the Mental Health Act, issued in 2012³ after closure of the period we studied, address the matter more fully. They suggest (at para 10.2.2) that, where the first SOAD declines to approve, the regional administrator of the Mental Health Act (although not the treating clinician) may 'direct that another approved psychiatrist provide a second opinion'. So the process of obtaining another SOAD's opinion is to be managed by a senior psychiatric administrator, not by the treating clinician. One can imagine such a process being managed in England by the CQC.

Nevertheless, through this 'appeal' process the first SOAD's view can be trumped. So then we may ask: why should the second SOAD's view be preferred to the first, and will 'shopping around' for opinions somehow occur? In the end one might conclude that the practical advantages of finality justify accepting the first SOAD's view, and support the 'no appeal' rule.

Other changes to the New Zealand scheme might be made to try to capture some advantages of the English superstructure. The new guidelines in New Zealand suggest SOADs should consider, before approving treatment: the history of the patient's illness and prior pharmaceutical regime; the risks and benefits of potential treatment approaches; the patient's views, as far as they can be ascertained; and whether the treatment is of maximal benefit to the patient and appropriate to their condition.³ This provides some guidance on the process to follow. But the guidelines could go further, to specify clearly the degree of independence required between SOADs and treating clinicians, and the information

SOADs should record. The Ministry could promulgate a system of online forms to be used nationally. Completion of the forms would confirm the necessary steps have been taken, and the forms could be used to collate data, publish statistics and make the process more transparent, as has occurred in England with reports from the MHAC and CQC.^{9–11}

Limitations

The shortcomings of this study must be acknowledged. The retrospective data collection for our audit was based on written forms and clinical notes. It is a study of documented steps and is likely to underestimate the intensity of treatment review SOADs conducted. Our general audit only covered the process at 3 New Zealand district health boards (out of 20) and our substudy covered a small number of non-approved cases at a single board. The audit discovered significant diversity in practice between district health boards, so generalising to other boards may be inappropriate.

Implications

In our audit, 438 examples of the SOAD process were studied at the three sites. These related to both medication and ECT, and the results show clear parallels between the operation of the New Zealand and English schemes. Our substudy of non-approved cases is, we believe, the first of its kind. In conclusion, the inconsistencies revealed in the conduct of the process at different New Zealand centres should encourage clinicians in England and Wales to value their clear national guidelines and forms. It shows the benefits of the structure, training, funding and reporting provided by the MHAC and CQC. Clinicians may not always value greater formality or elaborate structures for administration of the Mental Health Act. But, in light of New Zealand's experience, we suggest that central administration of a SOAD scheme can confer advantages in terms of clarity and consistency that are particularly desirable in a mandatory process designed to protect compulsory patients' rights.

1.8.11 Age inclusive services or separate old age and working age services? A historical analysis from the formative years of old age psychiatry c.1940–1989

Claire Hilton Correspondence to: Claire Hilton (claire.hilton@nhs.net)

date

2015-4

Abstract

The Equality Act 2010 made it unlawful to discriminate in the provision of services on the grounds of age. This legislation is open to interpretation, but it is affecting the way older people's services are defined and provided. Historical evidence indicates that, since the 1940s, apart from psychiatrists working in dedicated old age services, most were unenthusiastic about working with mentally unwell older people and unsupportive of those who chose to do so. A historical analysis might shed light on current dilemmas about 'all age' or 'old age' services and inform decision-making on future mental health services.

 - *Discussion*

The Equality Act 2010¹ made it unlawful to discriminate in the provision of services on the grounds of chronological age, but precisely how the Act can be brought into effect to produce appropriate services for older people is unclear. The Act has led to reconsideration of whether dedicated services for older people, or ‘all age’ services, are clinically most appropriate and legal, and to the Royal College of Psychiatrists Old Age Faculty proposing new criteria to define their specialty.² Key themes in public health policy and practice recur and are re-addressed by each generation.³ Some reiteration of themes is inevitable and sensible in the context of material changes in society and new medical discoveries. But attitudes in society can be slow to change and some deep-seated cultural beliefs endure, which, although not reproduced identically at different times, provide antecedents of public resistance to health innovation. Historical analysis can help clarify this process⁴ and may facilitate rational decision-making. This is particularly important for new policies as ‘policy makers are constrained from behaving rationally in many ways’: they, like the rest of society, are not value-free and they are faced with influences of past policy that may restrict options.⁵ This paper derives from a historical study concerning the formative years of the specialty of old age psychiatry until it was recognised by the Department of Health in 1989. It would be difficult to undertake a reflective historical analysis of the years 1990–2014, partly because of its recency and also because of methodological difficulties such as accessing government documents under the ‘30 year rule’. Historical evidence from the formative years may nevertheless help inform current decision-making on planning mental health services for older people.

The very beginning: the 1940s

There was little enthusiasm for working specifically with older mentally ill people in the 1940s: ‘After all, they had to consider the medical personnel as well as the patients’⁶ one psychiatrist commented at a psychiatry conference. Geriatric medicine was new, and contrary to cultural beliefs that emphasised inevitable decline in old age, the early geriatricians demonstrated that age-appropriate specialist treatment could reverse much physical impairment.⁷ Birth rates had been falling and infant mortality increased at the beginning of the Second World War.⁸ Population projections were that one in six of the population would be of pensionable age by 1961. Welfare planners were not to know that this was a significant overestimate. The government prioritised supporting families and young children and William Beveridge’s plan for the welfare state gave older people less priority.⁹

Joseph Sheldon’s study of older people noted their ‘mental vigour and “guts”’, and concluded that ‘living in the environment they are used to, of having something to do, and of being still able to feel necessary to the world’ were important for their well-being.¹⁰ This was an innovative message for health and social care authorities, who tended to focus on the minority who needed intense support, rather than the well majority. Such evidence challenged widespread negative assumptions,¹¹ including in the medical profession that tended to neglect mentally ill older people.¹²

The first old age psychiatry services c.1950–c.1970

In the 1950s, dedicated old age services were almost nonexistent. A report in the *Guardian* commented that mental hospitals ‘should be regarded as treatment centres for the mentally ill and not as depositing grounds for the senile for whom nothing can be done’.¹³ The very presence of older people in mental hospitals was deemed, by some psychiatrists, to undermine care for those ‘more in need of active treatment, having to be denied admission’,¹⁴ i.e. younger people. Brice Pitt (later professor of old age psychiatry) said: ‘The hospital... was like a castle, a good registrar would fend off the elderly, as those who got in were bound to stay, bound to be dumped by their family’.¹⁵

Once admitted, older people mainly by-passed the assessment wards and were admitted directly to long-stay back wards.¹⁶ Potentially reversible physical and psychiatric disorders often remained undiagnosed.¹⁷ Grudging medical attention given to older people¹⁸ contrasted with that given to younger people on forward-looking wards that became hotbeds of intervention with new treatments¹⁹ and rehabilitation.²⁰ Emil Kraepelin’s influential opinion prevailed: most old age psychiatric disorder was irreversible senile dementia,^{21,22} the ‘result of the natural wear and tear of the body’.²³ This stereotypical view of the inevitability of decline undermined proactive approaches to treatment. Evidence from geriatric medicine about treatment, rehabilitation and support for families²⁴ had not permeated mental hospital practice. Psychiatrists working across all ages offered little to older people.

In the early 1950s, at Crichton Royal Hospital, Dumfries, rather than admitting older people directly to back wards, in order to improve outcome, all patients regardless of age began to be admitted to acute admission wards. This all age approach failed: the admission wards filled with older people. Their needs were different: different presentations of the same illnesses, different sensitivities to medication, slower rehabilitation and negative staff expectations of recovery could undermine treatment. Also, mixing older, frail, restless and confused people with acutely disturbed younger people was not conducive to safety or well-being.^{16,25} In response, at Crichton Royal in 1958, Ronald (Sam) Robinson established a dedicated comprehensive old age psychiatry service, a successful prototype for others to emulate.²⁶

In 1959, the medical committee at the Bethlem-Maudsley psychiatric teaching hospital in south London analysed recent publications about the needs of older people (see, for example, National Old People’s Welfare Council²⁷). Several consultants were consulted in this analysis, but Felix Post, the only consultant working specifically with older people, was not.²⁸ Reasons were not given, but perhaps an old age psychiatrist’s opinion was not considered relevant, implying that the really important clinicians worked with younger people. This mirrored leaving out geriatricians from a British Medical Association committee in 1954 when planning geriatric services²⁹ and later events at the Royal College of Psychiatrists.³⁰ The Bethlem-Maudsley committee concluded that better services for older people would relieve ‘pressure caused by aged and infirm people’ in mental hospitals: this would give more scope for treating younger patients. Post repeatedly tried to improve services for his patients during the 1950s and 1960s, an impossible challenge for a lone psychiatrist advocating for older people. The Bethlem-Maudsley’s prioritisation of younger people and ambivalence towards older people persisted. It included proposals to reduce beds in the old age wards and re-designate them to other departments,³¹ and seemed to perpetuate an inferior share of resources for older people.

Elsewhere, there was also ambivalence among general psychiatrists towards treating older people. At Claybury Hospital, Essex, in 1966, some general consultants wanted to keep their older patients with treatable conditions, but hand over those thought to be incurable: ‘the general psychiatrists were dead keen to get us to take their old schizophrenics’ recollected Pitt. Others wanted to keep their caseload of older people perceived as needing little clinical input: it conveniently boosted their numbers.

In all age services, where no old age psychiatrist effectively advocated for older people, they were treated inequitably; similar happened at policy level. For example, the Worcester Development Project, a feasibility study of comprehensive community and district general hospital mental health services to replace a local psychiatric hospital, did not automatically include older people.³² In Northern Ireland, in 1970, the Ministry commented that older people ‘often have to go through the general admission unit, to the distress of younger patients and the detriment of the service’.³³ It did not mention that older people might be distressed by younger patients, or that the NHS was meant to be universal.

Old age services begin to increase: 1970s

In the 1970s, there was a tendency to plan for younger before older mentally ill people. *Hospital Services for the Mentally Ill*, in 1971, mentioned ‘psycho-geriatric’ assessment but did ‘not deal with services for elderly patients whose mental illness symptoms are the result of ageing or physical disease or both’. It promised further guidance.³⁴ The mental health charity MIND and the Royal College of Psychiatrists were disappointed by the exclusion.^{35,36} Not mentioning older people did not necessarily exclude them, but left ambiguities rather than a sense of direction and responsibility for provision. It conveyed that their particular needs were unimportant and discouraged the development of specific services, despite increasing clinical evidence of benefits from active interventions.^{37,38}

A geriatrician noted that psychiatric hospitals were becoming ‘silted up’ with older mentally ill people, at least partly because psychiatrists ‘do not wish to treat’ them.³⁹ Tony Whitehead, an old age psychiatrist, commented that psychiatrists should stop ‘pretending that the old were not their concern’.⁴⁰ The logical course to avoid competing with younger people was to provide dedicated, resourced services.⁴¹ In 1972, the Department of Health and Social Security’s (DHSS) *Services for Mental Illness Related to Old Age*, based on recent clinical experience in a few places, recommended appointing a psychiatrist with ‘special responsibility’ for older people in each health authority catchment area.⁴² Progress was slow.⁴³ The DHSS acknowledged that ‘old people are almost inevitably neglected among the competing demands of acute work with younger people’^{44,45} and, in 1976, reiterated the need for ‘at least one consultant in each district’ to lead clinically and to develop services for older people.⁴⁶

The Royal College of Physicians of London suggested reasons for underprovision of dedicated services for geriatric medicine that were equally applicable to old age psychiatry. They included the need for adequate resources and ‘fundamental changes in society’s attitude to old people’.⁴⁷ The general psychiatric leadership of the Royal College of Psychiatrists made disparaging comments about old age psychiatry: it might create ‘a vacuum for unsuitably qualified people’ and ‘It was necessary to preserve standards and maintain some unity’.⁴⁸ These comments implied their view that ‘psychogeriatrics is a dead end job for which no psychiatrist in his right mind applies’.⁴⁹ Their stereotypical attitudes revealed prejudices about working with older people.

Older people accumulated in mental hospitals. In 1978, in England and Wales, people over 75 years old occupied 20 000 mental hospital beds (25%),⁵⁰ but that age group accounted for only 5.6% of the total population.⁵¹ To some degree, the need for institutional care reflected age-related degenerative disorders and the needs of ageing long-stay patients with illnesses dating back many years. Other factors affecting bed use were less justifiable: clinically unnecessary admissions; low expectations of recovery; patients remaining in hospital when they no longer required treatment and they could have been better supported elsewhere; limited provision of domiciliary services and community residential care; unsupported families being unable to cope with the care of older people;⁵² and potentially curable conditions such as depression remaining undiagnosed.⁵³ In addition, they were given less opportunity than younger people for community and rehabilitation services, probably at least partly related to their perceived low economic value,⁵⁴ a yardstick of success in Western society.

Into the 1980s

Attitudes to illness and disability in old age did not generally improve, at least not sufficiently to influence service provision widely. A joint geriatric, psychiatric and nursing report in 1987 noted that ‘the low worth of old people and their therapeutic potential still persist despite the dramatic evidence to the contrary’.⁵⁵ Attitudes outside old age specialties were often derisory, in contrast to the rewarding nature of the work experienced by staff doing the job.^{56,57} A lecturer at a nursing conference in 1982 commented: ‘the thought of being permanently posted to a psychogeriatric ward fills newly qualified nurses with dread’.⁵⁸ The president of the Royal College of Psychiatrists, Thomas Bewley, commented: ‘it was quite difficult to discover what percentage of a psychiatrist’s sessions were spent on caring for old people, part of the problem being that the general psychiatrist might have fears about being labelled as a psychogeriatrician’.⁵⁹

In some places, general psychiatrists were unwilling to share resources with those taking responsibility for older people;⁶⁰ resources might have been even less for older people if no one was specifically advocating for them. For example, the admired old age psychiatric service at Redruth, Cornwall, which hosted numerous visiting dignitaries, including Prime Minister Edward Heath and teams from abroad, consistently faced ‘half-hearted understanding rather than fervent support’ from the local general psychiatrists.⁶¹ The precise level of resources was probably less important

than local colleagues' willingness to offer a commensurate share of existing resources. The problem of providing adequately for older people meant that old age psychiatrists' roles included: 'occasional militancy... to gain a fair share of scant resources, to put them to best use, to make do with too little while wheeling, dealing, and fighting for more'.⁶² As in earlier decades, meetings about old age psychiatry service development took place without old age psychiatrists and risked overlooking older people's mental illnesses.^{63,64}

There were few formal studies comparing clinical effectiveness of old age and all age psychiatric services. One study conducted in 1985/6 compared 'specialised' and 'non-specialised' services treating older people with mental illness. Despite difficulties in the sampling method, which were likely to minimise differences, it indicated outcomes 'in favour of the specialised services', such as for teaching, research and having beds in general hospitals rather than in psychiatric hospitals,⁶⁵ suggesting that dedicated services provided more forward-thinking services. Methodologically ideal randomised studies were lacking, and even well-designed studies risked creating artificial environments of case selection, staffing levels and case-load.⁶⁶ Comparative studies often did not state clinical outcomes,⁶⁷ although some noted better outcomes for depression treated by old age services.⁶⁸ Better outcomes could irritate colleagues of equal status who do not like to be told by others that they can do the job better: challenges to professional skills are linked with ambivalence towards emerging new specialties,⁶⁹ risking undermining developments.

General practitioners (GPs) mentioned advantages of having old age psychiatric services 'closely allied' to primary healthcare, but this was sometimes almost synonymous with shortage of resources.⁷⁰ Where dedicated old age mental health services existed, GP referral rates of older people increased significantly: at Crichton Royal, between 1974 and 1984, a 16% increase in the population over 65 was associated with a 150% increase in referrals,⁷¹ suggesting that GPs valued the interventions provided.

Discussion

'Age' can be measured in different ways.⁷² Usually in health service planning, 'chronological age' was used. A 'chronological' retirement age is arbitrary, but men's retirement and pension age, 65 years, was socially acceptable to define and establish services for older people.⁷³ In clinical work, staff knew the limits of their responsibilities and it could constructively guide GPs to refer patients to the appropriate psychiatric team. Chronological age cut-offs remain inseparable from certain services. They are used at both ends of life for administrative matters such as for leaving school or receiving a state pension or to enable population needs to be estimated and plans implemented. Age-related physiological and social factors affect illness in old age and may interact, requiring a distinct body of clinical knowledge and skills to permit optimum treatment. Illnesses in childhood and adolescence also present differently from in adulthood with different diagnostic and treatment implications. Not all adolescents reach 'maturity' at the same chronological age, and not all older people age at the same rate. In childhood and adolescence, separate services based on chronological age are acceptable. Similarly, old age services may be necessarily and appropriately different, rather than bearing overtones of negative discrimination.

An alternative definition of age is 'cultural age', combining chronological age with aspects of function ('functional age'), degree of independence and capacity for self-care, coupled with the understanding of old age within a community's value system.⁷⁴ It relates to society's expectations of outcome of treatment and priorities about providing health services. Those factors are not neutral and might affect providing and planning services for older people.

How best to ensure non-discriminatory services for older people remains unclear. In line with their understanding of the Equality Act, the Royal College of Psychiatrists' Old Age Faculty has proposed criteria for services based on 'cultural', rather than 'chronological', age.² This might, however, be discriminatory, given the subjective implications of the former, and since it raises issues of whether it could reliably provide appropriate services for people who need them. Who would decide on robust clinical grounds, for example, which patients should be referred to which service? Ambiguous lines of responsibility for older patients might contribute to undermining treatment for them.

Negative attitudes towards treating older people persist widely in the NHS and there is evidence that older people are still unwelcome in hospitals.⁷⁵⁻⁷⁷ Times have changed, legislation has changed, but attitudes appear similar. The World Psychiatric Association recently noted that combating ageism was part of the remit of services for older people;⁷⁸ taking that perspective might be difficult for those also advocating for younger people, especially where there are resource constraints. This reflects the historical evidence that services improved where dedicated old age psychiatrists advocated for their patients and were listened to.

General psychiatrists have repeatedly demonstrated a lack of interest and desire to work with older people and excessively low expectations of health improvement for them. Clinicians, managers and NHS planners overlooked their needs when creating services and allocating resources. A survey of health service commissioners in 2010 identified a disconcerting pattern of government response: ‘Governments and commissioners have shown a surprising failure to realise the significance of the ageing population, adopt best practice and make service development for older people a national priority’.⁷⁹

Services for older people lag behind those for younger people (see, for example, Hilton⁸⁰). Since the 1970s, policies for older people have appeared after those for younger people, reinforcing the idea that the needs of older people are less pressing. The National Service Frameworks for mental health in 1999 and for older people in 2001⁸¹ are more recent examples. Two years might seem little, but in the context of this being a repeated pattern, with reluctance to provide for older people, and in the context of economic downturns, including the financial crisis beginning in 2008, this has probably cumulatively undermined service development. A recent government strategy for mental health stated: ‘we will use the word “people” to encompass infants, children, young people, working-age adults and older people’.⁸² Age-equality is welcome, but has the anti-discrimination agenda become so all-encompassing and the policies so inclusive and watered down as to be meaningless? Will this pattern prevent real differences from being recognised? All age government strategies, however, have the potential to enhance equality in terms of planning services and allocating resources to all age groups simultaneously. By contrast, evidence of negativity towards older people by general and all age psychiatrists reinforces the importance and appropriateness of clearly defined, chronologically age-based, separate services to ensure reliable, dynamic, enthusiastic and effective psychiatric provision in old age.

Thanks to Tom Arie, Dave Jolley and Pat Thane for their comments.

1.8.12 Understanding Medical Education: Evidence, Theory and Practice (2nd edn)

Brian Lunn¹

Contents

- *Understanding Medical Education: Evidence, Theory and Practice (2nd edn)*

Why should a jobbing psychiatrist be interested in a medical education textbook? Simply put, it is that we have shifted from an era of ‘See one, do one, teach one’ to one where an evidence base is available for education, not just for treatments. This is particularly the case for medical education, where the need to evidence pedagogic practice for regulators has been a priority for many years and has driven research to support and drive practice. This is an increasingly important issue. The General Medical Council, in *Recognition and Approval of Trainers*, has set out the standards it requires for clinicians to be trainers, with an implementation date of 31 July 2016, and a similar standardised approval process is well underway for undergraduate teaching.

Understanding Medical Education is a good place to start for those wishing to build their knowledge of the evidence base to inform their teaching. With a strong cast of the ‘usual suspects’ in the field, it delivers a broad range of chapters covering the breadth of educational topics. The book is set out in themed sections allowing selection of topics of interest. For the determined reader, read sequentially they build from basic foundations through strategy and assessment to research and finally, a ‘Staff and Students’ section that covers issues related to learners and teachers. This all finishes with an excellent chapter on educational leadership.

This should not be seen as a book targeted at the academic community. Even though one or two chapters may not affect most doctors’ teaching practice (e.g. the chapter on curriculum design), they will nonetheless enhance understanding of the choices that went into learning and teaching strategies.

So at the end of this, a reasonable question might be, ‘Is it worth my time buying/borrowing this book?’ If you already have a strong background in pedagogic theory, then it gives up-to-date monographs collected together in one place but perhaps nothing new, so it may be one you borrow rather than buy (and this is not a criticism). If you are developing your knowledge or wish a reference to support your teaching, whether undergraduate or postgraduate, then the answer is indubitably ‘Yes.’

1.8.13 *Bulletin* comment: Ever-expanding empires†

- *Bulletin comment: Ever-expanding empires†*

The development of policy and governmental decisions at the highest level ought to be based on sound information, research or expert advice. Further, once change has been implemented and new practices set up there needs to be ongoing assessment, monitoring and reflection on the relative merits of the situation. Depending on the findings it might be necessary to make further changes: sometimes these alterations may even result in a complete reversal of the newly implemented practice.

The plan to increase the availability of psychological therapy for individuals with the more common mental disorders was clearly a good one. However, in practice the evidence for its effectiveness failed to materialise; research originating from two pilot sites was flawed giving an unbelievable impression of it doing good. Hopes of returning thousands of people with mental health issues to full-time employment were also unmet. Incredibly, the response to such an unconvincing success has been the further expansion of the service into the provision of talking treatments for children and young people experiencing a wide range of psychological problems.

No one can argue against the expansion of psychological services so that much needed appropriate treatment can be given to people with genuine problems. However, any plan consuming millions of public money ought to show convincing effectiveness on all fronts before it is blindly expanded.

1.8.14 Skydiving for Beginners: A Journey of Recovery and Hope

Femi Oyebode¹

date

2015-6

Contents

- *Skydiving for Beginners: A Journey of Recovery and Hope*

This book will surprise you, shock you, and intrigue you but ultimately it will fill you with admiration and respect for the author. It is the personal memoir of Jo McFarlane, a woman who was born into adversity but who has triumphed, very much against the odds. She is that rare human being: sensitive, thoughtful, positive, driven and without bitterness. A living example of what resilience means in practice.

Her life started in ‘virtual squalor with dry rot and gaping holes in the floor’. She goes on: ‘Ours was a dirty, freezing home infested with vermin’. As if the utter material deprivation was not enough she experienced sexual abuse at the hand of both her father and brother and the circumstances were unspeakable: ‘The politics of my parents’ sex life was played out openly among the children. We knew that he wanted it all the time and that she hated it. This was an enduring source of tension in their marriage and they often embroiled us in the drama [...] One of her avoidance strategies was to have me sleep in their bed between them. I soon became an outlet for his sexual frustration’. The whole family were subjected to her father’s unpredictable moods which ‘like flames could blaze at the slightest provocation and burn for hours; at other times they were extinguished in a breath [...] So unpredictable were his rages that the atmosphere was like a bomb ticking towards its inevitable climax’.

This deprived and abusive childhood formed the backdrop of her psychiatric history in adulthood. Her account of her many admissions, treatments, suicide attempts, and relationships with psychiatrists, nurses and social workers is written with candour. It is an unsparing honesty with which she describes her own behaviour with unswerving clarity and objectivity. There is no sentimentality, self-pity or excuses here. It is an analytic mind that is on display, one that is eloquent and self-assured in how it handles language and ideas. She says of one of her depressive spells: ‘A military metaphor is the most apt I can think of to describe the war zone in my head. It was not a benign melancholy but a splintering of faculties, a torture even to exist. The rapid gunfire of destructive thoughts supplanted my will to survive’. Again, ‘I was so paranoid I thought Kathryn had hidden cameras in my flat, that they were all watching and laughing at my distress, that they could hear what the voices were saying to me and were using them to drive me to suicide. I felt I had to get away from the Royal Edinburgh as far as possible and I boarded a night bus for London. The journey was hell because of my mental state’.

The depiction of life on psychiatric wards, of good relationships with psychiatrists, of the exemplary quality of the interactions with some nurses, and of the kindness and generosity of many people underlines what is admirable and exceptional in mental health services. But, sadly, there are many examples of abuse, of disinterest, of perfunctory interactions, of gross neglect and of errors of judgement. What is impressive is that Jo McFarlane takes the good and the ugly in her stride and she emerges as an astonishing human being.

This memoir stands alongside the great memoirs of Daniel Schreber, Janet Frame, William Styron and Kay Redfield Jamison. It sheds light on the intersections of disrupted attachment in early life, of traumatising abuse and of biological vulnerability to psychosis. It reveals the unheard but real voice of a fragile self that is masked by serious illness. And McFarlane's own ambition in writing this book is to be 'an invitation to others, through encouragement and example, to embrace their talents with pride and joy'. I think she has succeeded marvellously.

1.8.15 Clinical Guide to Obsessive Compulsive and Related Disorders

Ijeoma E. Onuba¹

date

2015-6

Contents

- *Clinical Guide to Obsessive Compulsive and Related Disorders*

This book gives an overview of obsessive–compulsive disorder (OCD), hoarding disorder, body dysmorphic disorder, excoriation (skin picking) and trichotillomania, all listed in DSM-5 under 'obsessive–compulsive and related disorders'. The authors have also included hypochondriasis and tic disorder as some of the related disorders.

The book is divided into three parts. The first part gives a general overview and evaluation of the disorders. The second part discusses each disorder in detail, focusing on the clinical description, diagnosis, comorbidity, course and prognosis, differential diagnosis and treatment. Scales that can be used in monitoring treatment are included in the appendix at the end of the book. The final part is titled 'special clinical considerations' and addresses areas such as treatment resistance, treatment of children and people with intellectual disability, and alternative treatments. This part also mentions neurosurgery for OCD and the ethical dilemmas associated with this approach. The appendices have a list of suggested further reading and contact details of organisations and treatment centres.

A useful resource for trainees and students is a table in the first chapter, which shows types of obsessions and compulsions with good examples. I also like the way the authors describe how to differentiate the symptoms associated with each disorder and normal behaviour. The book also gives practical advice on how to screen for these disorders. The response rates to treatments are discussed and some chapters also mention research work.

There is a table summarising pharmacological treatment for each disorder when managing children and I wished a similar table was done at the end of part two, which could be used as a quick reference guide. The book's title may mislead readers who are looking for information on hypochondriasis and tic disorder.

I would recommend this book for health professionals, students and even patients and their carers. It is well written, concise and easy to follow.

1.8.16 Gregory O'Brien MB ChB MA MD FRCPsych FRCPCH FRANZCP

Tom Berney

date

2015-6

Contents

- *Gregory O'Brien MB ChB MA MD FRCPsych FRCPCH FRANZCP*

Formerly Professor of Developmental Psychiatry, Northumbria University and the University of Queensland; Consultant Psychiatrist and Associate Medical Director, Northumberland, Tyne and Wear NHS Foundation Trust; Senior Psychiatrist with the Queensland Mental Health Assessment and Outreach Team of Disability Services.

Greg O'Brien, who died recently aged 59 years, played a major part in developing the character of the speciality of the psychiatry of intellectual disability, first in the UK and then in Australia.

Greg entered intellectual disability psychiatry in the 1980s at a time when its role and future were being questioned. Over the next 30 years, he helped develop its clinical and academic character. Within the Royal College of Psychiatrists, he was elected Chair of the Faculty of Psychiatry of Intellectual Disability in 2002 and appointed Associate Dean in 2006, an office that gave him a wider opportunity to develop psychiatric education. He was appointed to the academic chair in Developmental Psychiatry at Northumbria University in 2004. Martin Bax drew him into the Society for the Study of Behavioural Phenotypes and the Ronnie MacKeith group where he was able to focus on autism and epilepsy. These various worlds had in common a clannish, crusading nature, which Greg explored with energy and ebullience, fermenting ideas through encounters that included long journeys, long lunches, research meetings and conferences. His numerous publications reflect a wide range of concepts and approaches to clinical practice. In particular, he was the senior editor of *Behavioural Phenotypes*, the first textbook published on this subject.

The College gave Greg a further forum which he relished, enjoying its influence on psychiatric training and service development. Like others, he had set out to be a child psychiatrist, only to be drawn into the fast-changing, multi-disciplinary adventure of intellectual disability. Both locally as a medical director and nationally as the faculty chair, he was effective in steering professional and service development through the surf of repetitive reconfiguration that characterises the NHS. His apparent confidence in doing this was achieved only by careful preparation.

An unfashionable speciality, Greg made sure the Faculty of Psychiatry of Intellectual Disability would be a significant source of support for many isolated members. Its growth inevitably brought some loss of informality and intimacy. Greg's antidote was to foster the inclusive, all-are-welcome ethos that was the Faculty's hallmark. He started the tradition of after-dinner music at Faculty meetings, the sessions extending through the night and becoming, for some, the highlight of the programme.

While still at the height of this career, he left the UK in 2010 to move to Queensland, where he succeeded in recapturing the pioneering spirit that had inspired him in the UK, developing a new service and its academic base. Appointed Senior Staff Specialist on the Mental Assessment and Outreach Team of Disability Services and to the chair in Developmental Psychiatry at Griffith University, he set about a similar campaign to convince the Royal Australian and New Zealand College of Psychiatrists not only that there were powerful intellectual challenges in neurodevelopmental psychiatry but also that this could become the most human and clubbable of the psychiatric specialties.

Greg grew up in Paisley, where his family and school (St Aloysius College) left him with the strong sense of social justice that would underpin his life. His father, Jack O'Brien, was a Glasgow trade unionist. After graduating from Aberdeen Medical School, Greg entered psychiatry in Newcastle. There he met Barbara, who was to become a specialist in paediatric intensive care, and whom he later married. The O'Briens moved to Cambridge in 1986, where Greg took up a post as lecturer in the Department of Psychiatry, specialising in intellectual disability. In 1991, he returned to Newcastle to become a consultant at Northgate Hospital. There, with Ken Day as his mentor, he focused on forensic psychiatry and medical management. At the same time, he completed his MD and set about fostering academic development in

his specialty, directing the regional training programme, organising research, editing a series of books and managing the politics of a professorial chair.

Throughout his career, Greg remained a clinician, seeing, treating and learning from individuals, their families, friends and carers. He had an intense enthusiasm combined with the strong sense of humour that carried him through his career. Behind the jollity and extravagance of manner was a keen awareness that he was lucky to have such congenial employment. He was always ready to help colleagues with advice that was not only intelligible but also constructive. He was a great confidant, recognising the normality of imperfection. For Greg, however, the real world was rooted in his family and friends whose own lives were shaped by his warmth and humanity.

His illustrated life on Facebook, written from Australia, was about fun, friends and family (blithely ignoring the cancer that developed a year after his arrival) and he lived life to the full, right up to the point when he wrote a dignified letter of farewell to the Australian College (<https://www.ranzcp.org/Membership/Subspecialty-groups/Interest-Groups/Intellectual-Developmental-Disabilities/SIGPIDD-Newsletter-May-2014.aspx>). He returned to Newcastle and made arrangements for his disposal (a funeral mass at the cathedral, a crowded wake and then, on the following day, a more private cremation).

Greg O'Brien died of cancer on 13 July 2014 at his home in Newcastle upon Tyne. He is survived by his wife, Barbara, and their children, Áine and Daniel.

2015-6

Abstract

Aims and method This paper intends to analyse the number of applications, trainee demographic and approval rate of those applying for out of programme training (OOPT) or out of programme research (OOPR) between January 2008 and April 2013 using the committee's anonymised database. We also describe the process of application and approval by the Quality Assurance Committee.

Results There were 90 applications, including 10 resubmissions during the 64-month period. Most applicants (77%) were higher trainees; 53% of applicants were from the London deanery; 60% of applications were for research posts and higher degrees (OOPR). Overall, 64% were approved by the committee: 70% for OOPRs and 53% for OOPTs.

Clinical implications This paper shows with transparency the breakdown of applications to the Quality Assurance Committee. Around two-thirds of applications to the committee are supported (64%). Relatively few psychiatry trainees (2.5%) have applied for an OOPT or an OOPR over the past 5 years.

 - * *Implications*

The Quality Assurance Committee at the Royal College of Psychiatrists includes a group of consultants across all specialities, a lay member, carer and trainee representative. The committee leads on the review and college approval of trainee's out of programme training (OOPT) or research (OOPR). Trainees seeking for their OOPT or OOPR to count towards part of their psychiatric training and therefore certificate in clinical training (CCT) apply prospectively to the committee via a structured application form. In this article we will review the process of applying, the outcomes of those that apply, the common pitfalls and problems for those that are unsuccessful and review the demographics of applicants.

Method

We analysed the numbers of applications, trainee deanery and ethnicity and approval rate of those applying for OOPT or OOPR between January 2008 and April 2013 using the Quality Assurance committee's anonymised database. We also describe the process of application (see *Box 1*) and approval by the Quality Assurance Committee.

Results

The Applicants

There were 90 applications to the Quality Assurance Committee between January 2008 and April 2013, a 64-month period. This included 10 resubmissions. The descriptive data on core and higher trainees; approval rates; and applications by deanery is described in *Table 1*.

Approval v. non-approval

Of the 90 applications, 58 (64%) were approved and 32 (36%) not approved on the first application. Of the 32 applications not approved, 10 (31%) trainees resubmitted additional evidence or information with 8 (80%) successful in gaining approval. Of the 10 resubmitted, 1 application required minor changes and was approved after personal correspondence between committee members between meetings. Nine (90%) were reviewed at the subsequent committee meeting following resubmission.

Core v. higher trainee applicants

Overall most applications were from higher trainees; 77% (70/90). Core trainees included those who were core trainees at the time of applying. These trainees may be applying for OOPT or OOPR in their next post, which may be a higher training post. This may have had an impact on the actual proportion taking OOPT or OOPR in their higher training.

Box 1 The application process

Trainee applies for a specific training or research opportunity not part of their programme. Trainee starts deanery/LETB process for applying for local approvals; leading to signed LETB form usually by educational supervisor, training programme director and dean or head of school. Trainee looks at website: <http://www.rcpsych.ac.uk/training/qualityassurance.aspx> for timeline of next quality assurance committee meeting. If trainee does not want to have OOPT/OOPR to count towards CCT, the trainee need not apply to the Quality Assurance Committee at the College. If trainee wants some or all of the OOPT/OOPR to count towards their CCT they then apply to the Quality Assurance Committee using the structured application form on the website in the area on quality assurance of training (<http://www.rcpsych.ac.uk/training/qualityassurance.aspx>) before starting the new post (i.e. prospectively). The trainee includes a covering letter, copy of the signed local approval, the Quality Assurance Committee application form and all the recommended supporting evidence. The Committee meet quarterly and review all of the applications. The applications are not anonymised so any members who know the trainee or have a conflict of interest leaves the room. The Committee then recommend approval, request for further information or non-approval by letter to the applicant. This includes the number of weeks to months to count towards CCT. Those that are not approved are given the reasons for the decision. The approved applications are then forwarded to the General Medical Council for final approval and a letter is sent to the applicant with their amended CCT date. Applications that required minor further information are usually reviewed in between meetings online. Applications that require resubmission or are less minor are reviewed at the following quarterly meeting. A letter to the applicant, advising the result, is sent by email and post within 1–2 weeks of the quarterly meeting.

The numbers and success rate of core and higher trainees applying for out of programme training (OOPT) and out of programme research (OOPR) by deanery (local education training board)

Not able to say from College data.

Applications by deanery or local education training board

We analysed the 90 applications across deaneries, now local education training boards (LETBs). The largest deanery in the UK is London in terms of psychiatry trainee numbers. The London deanery applicants made up 53% of applicants (48/90) with the other deaneries making up the remaining. We found that OOPT and OOPR applications were at the same rate in the London deanery (2.5%) as in the overall trainee sample (2.5%); during 2008–2013 the London deanery had 1918 trainees. As a result of the relatively small numbers applying from deaneries outside London, data from all other deaneries was combined for statistical analysis. These data were compared with data from the London deanery. Results from chi-squared analysis ($\chi^2(1, n = 89) = 0.94, P = 0.33$) indicates that there was no significant difference in the likelihood of success on an application based on deanery location (London *v.* outside London). This supports the transparency of the application process by deanery.

The diversity data

The Quality Assurance Committee reviewed trainee's ethnicity against application approval for all declared ethnic groups. This was as part of the committee's process to ensure there was no discrimination as part of the approval process. Declared ethnicity is available for all applications since January 2009. The database includes 76 applications; 95% ($n = 72$) of trainees declared their ethnicity on the OOP application. *Table 2* shows that across trainees that declare their ethnicity, 33% (19/57) of White trainees did not have their applications supported v. 40% (6/15) of Black and minority ethnic trainees. Data was statistically analysed to see if self-declared ethnic group (White or non-White) was significantly related to the likelihood of success for OOPT and OOPR applications. Chi-squared analysis ($\chi^2(1, n = 72) = 0.23, P = 0.63$) indicates that there was no significant difference in the likelihood of success based on ethnicity. This supports the transparency of the application process by ethnicity.

OOPT v. OOPR

The majority of trainee applications 60% (54/90) were for OOPR. The remaining were for OOPT 36% (32/90) and 4% (4/90) were unclear from College databases. A total of 16 of the 54 (30%) OOPR applications were not approved to count towards training or CCT (this included resubmissions). Of the OOPR applications, the majority were for research posts, PhDs and research fellowships. Some diverse applications were approved including a 12-week research post in Ghana and an MSc that counted towards CCT.

Of the 32 OOPT applications to the College, 15 (47%) were unsuccessful in gaining college support towards a CCT. Of the successful 17 applications, 4 (24%) were for forensic training including 3 forensic child and adolescent *Table 2* Applications for out of programme training (OOPT) and out of programme research (OOPR) by ethnicity (White and Black and minority ethnic) Ethnicity Groups Core trainee, n Higher Trainee, n Applied for OOPT or OOPR, n Supported OOPT or OOPR, n Unsupported OOPT or OOPR, n White (any origin) 907563573819 Black and minority ethnic (any origin) 12768051596 Total 21831368724725 psychiatry and a medium secure forensic training post. A total of five (29%) posts were approved for work overseas including South Africa (one), Ghana (two) and Australia (two). Five (29%) fellowship posts were approved in areas as diverse as medical education, quality improvement, healthcare policy and practice fellowships. The remaining posts included working in London at the Maldives High Commission Drugs Policy Unit, clinical lecturer and clinical posts in the UK.

Reasons for non-approval

For the 16 OOPR applications not approved, 8 (50%) required further necessary information. For example not including the requested supporting information, not stating how psychotherapy competencies in core training would be met as part of the post or not including previous information on posts. For the remaining rejected applications, reasons for non-approval of core trainees related to issues such as taking OOP too early in core training (contrary to *The Gold Guide*¹) (one); taking additional OOPS in core training when already on an academic clinical fellow (ACF) scheme with a 75% clinical post (one). Pitfalls for higher trainees included requesting multiple OOPT or OOPRs to count towards training (three), clinical lecturer posts whose timetables did not meet the clinical training requirements (one), overseas posts that did not meet the curriculum, or trainees who had already completed 24 or more months training at the time of application (two).

For 15 OOPT applications not approved, 6 (40%) were posts in Australia. The main reasons for unsuccessful applications included a lack of evidence particularly around work-based assessments or documenting how assessments would take place. Other reasons for non-approved applications included the following.

Retrospective and did demonstrate coverage of the curriculum. One was for an infant mental health post (children aged 0–3), which is not part of the UK higher training child and adolescent mental health services (CAMHS) curriculum. One

was for a post at a House of Commons Committee that did not map to the curriculum. One was for a post overseas where the duties appeared too junior for equivalence of a higher trainee. One post overseas did not demonstrate how the curriculum competencies would be met. One had an incorrectly completed application form. One was a core trainee before core trainee year 3 (CT3) who had not completed 2 years of core training prior to an OOPT as recommended by the Gold Guide. The remaining two required further information to support their application.

Trainee psychiatrists v. other colleges trainees

Of the current psychiatry trainees 90 out of 3606 (2.5%) core and higher trainees in psychiatry have applied for OOPT or OOPR. Following request to the other Royal Colleges for comparative data, we have three returns with some information. The responses were from the Royal College of General Practitioners (RCGP), the Royal College of Obstetrics and Gynaecology (RCOG) and The Royal College of Pathologists (RCPath).

The RCGP confirmed that they have no OOPT or OOPR approved to their knowledge. They report that as general practice is a short training programme of 3 years, which includes a mix of training opportunities there is no need to do OOPT. Of those that take time out, for example to work overseas, it is usually recorded as a career break (OOPC) and therefore is dealt with at deanery/LETB level. In terms of OOPR, GP trainees have the opportunity to apply for an academic clinical fellow (ACF) scheme and therefore do not require OOPR during the training period.

The RCOG report that, in 2012, 26 of their trainees had OOPR or OOPT and 62 in 2011. The RCPath report that since 2003, 20 trainees have applied for OOPRs and 7 trainees applied for OOPT and 100% of trainees were approved to count towards training and their CCT. Both colleges did not supply the numbers of trainees in total to compare the rates of OOPT and OOPR with psychiatry

Discussion

Out of programme training and research remains a fairly uncommon experience with just 2.5% of psychiatry trainees applying for a training or research experience outside of their programme to count towards their CCT. The reasons for this may be that relatively few trainees spend time in out of programme experiences (OOPEs) outside of their programme in psychiatry. However, it may be that, similar to the GP vocational training scheme (VTS) programme, many trainees take time but do not apply for their OOPE to count towards their CCT. Reasons may be that the training programme is relatively short (6–7 years depending on endorsements). It is noted that there are relatively low competition ratios in psychiatry at CT1 and specialty trainee year 4 (ST4) entry over the period analysed. It may be that many trainees do not feel the need to develop their curriculum vitae in this way through research and OOPT. Qualitative analysis could explore the reasons why in future studies.

A further possible explanation is that trainees do not have an awareness of the process and role of Royal College of Psychiatrists in signposting and supporting applications for OOPT or OOPR. It may be that on a practical level out of programme opportunities and processes within the college and deaneries need to be more actively promoted.

The analysis shows that about two-thirds of trainees (64%) who apply for OOPT or OOPR are successful in getting approval by the Quality Assurance Committee. The Committee noted that a proportion of approvals were incomplete and required further information or evidence of mapping to the curriculum or training programme. We have simplified the application system by creating a form that prompts trainees to complete all of the required information. This went live in October 2012 on the College website. The updated guidance document is available on the College website.

There are relatively low numbers of OOPR applications (54 over 64 months). This suggests that there is a relatively low interest in research opportunities outside of the academic clinical fellow scheme; just 1.5% (54/3606) trainees have had the opportunity to be actively involved in a full-time research opportunity as OOPR. This suggests that relatively few trainees will have exposure to practical research experience, which may be of some concern to academics and the profession. Medicine and allied health sciences is based on the principles of evidence-based practice, where current best evidence is utilised in making decisions about the care of individual patients, therefore research is critical to developing psychiatry's evidence base and practice.²

It is noted there are relatively high numbers of applications from the London deanery (53%), compared with all of the other deaneries. The data demonstrate that London, compared with the UK as a whole, has the same rate of uptake of OOPT and OOPR, when taking into account the total number of psychiatry trainees in the deaneries. Despite a large number of applications from London, applications were not significantly more or less likely to be approved. This supports the transparency of the application and review process. This was also found for ethnicity supporting issues around equal opportunities and diversity. The larger number (not rate) of OOPTs and OOPRs in London suggests that there may be a culture there that encourages trainees to develop their expertise through OOPTs or OOPRs, which is not the case in other regions to the same extent. However, it may be because a large proportion of the research and training opportunities available out of programme are in London as a result of the high number of expert centres and universities. It may be that there is a supportive 'hidden curriculum' in London; led by supervisors with explicit links to these centres in signposting, promoting and supporting trainees in research and additional training.

Implications

Overall, although only a small proportion of trainees apply for OOPT or OOPR. Our analysis indicates that the process of its quality assurance is transparent in terms of applicants by ethnicity or deanery. The majority of applications overall are successful. Future research should examine how psychiatry compares with other specialisms in more detail and the reasons why low percentages of psychiatry trainees are applying for OOPT or OOPR. However, there is a lack of easily accessible comparative data making generalisations across specialisms difficult.

We wish to thank the Quality Assurance Committee for their input.

1.8.18 Investigating the usefulness of a metacognitive training group programme for schizophrenia

Lorna Jane Howe Ian D. Brown

Correspondence

Ian Brown (ian.brown@sheffield.ac.uk)¹

date

2015-6

Abstract

Aims and method To examine the usefulness of a cognitive-behavioural therapy-based group intervention, metacognitive training for schizophrenia (MCT), in a 'real-world' clinical setting. In total, 164 participants completed 327 questionnaires at the end of MCT group sessions; rating the perceived usefulness, helpfulness to recovery, change in knowledge and anxiety. Non-parametric statistical tests were used to analyse the data.

Results Participants indicated positive responses in terms of perceived usefulness, helpfulness to recovery and increased knowledge following group attendance. Significant positive correlations were found between: (a) usefulness and helpfulness to recovery, and (b) helpfulness to recovery and change in knowledge. There were significant negative correlations between: (a) usefulness and anxiety, and (b) helpfulness to recovery and anxiety.

Clinical implications The results suggest that MCT is a useful and effective evidence-based psychological intervention. It supports the use of cognitive-behavioural interventions in the treatment of individuals experiencing psychosis, although further evaluation is needed.

¹ Lorna Jane Howe is a Clinical Psychologist at Cambian Healthcare. Ian D. Brown is a Clinical Psychologist and Honorary Researcher at the University of Sheffield.

 - *Discussion*
 - * *Limitations*
 - * *Clinical implications*
 - *Questions on the evaluation form*

The need for psychological interventions for psychosis is increasingly recognised¹ and cognitive-behavioural interventions have emerged as potentially effective approaches that should be considered in the treatment of schizophrenia.² The rationale for such approaches stems from mounting evidence that cognitive biases may trigger or maintain symptoms in schizophrenia, especially rigidly held unusual beliefs, frequently described as delusions within the literature.³ Individuals with the diagnosis may show evidence of attributional biases, jumping to conclusions, bias against disconfirmatory evidence, overconfidence in errors and problems with theory of mind.⁴ In light of these findings, an evidence-based group cognitive training programme has been developed called metacognitive training for schizophrenia (MCT)⁵ (metacognitive can be defined as thinking about one's own thinking). The programme aims to provide psychoeducation on cognitive biases to help alter individual's current problem-solving repertoire and prevent relapse.^{5,6} Research has confirmed the feasibility of MCT and provided support for its efficacy in reducing positive symptoms and cognitive biases related to schizophrenia in 29 countries including Germany^{7,8} and Switzerland.^{9,10}

However, although there is already support for the efficacy of MCT^{7,8} exploring its effectiveness within the local service was deemed important and, if necessary, adapting the service on the basis of feedback. This was reinforced by a health trust-wide initiative to promote clinical effectiveness through service-user feedback. It was considered important to examine individual sessions/modules as well as the broader programme experience (collapsing across attended modules). The open nature of the programme was such that participants could enter the programme at different points in the cycle: comparison of individual modules would show whether different entry-points to the programme were seen to be similarly useful/effective and identify particular foci for improvement. Three specific aims emerged from local service needs: to (a) explore the perceived utility and effectiveness of each MCT module, (b) explore the overall perceived utility and effectiveness of MCT group attendance (collapsing across sessions attended), and (c) examine the interrelationships between post-session ratings of perceived group utility, effectiveness and self-reported anxiety.

Method

Participants

Flyers inviting individuals to attend MCT sessions were disseminated to potentially suitable participants through professionals within the local community mental health team and acute in-patient ward. There were 164 participants; 105 attended only one session and 59 attended multiple sessions (mean 3.8 sessions, range 2–17). The mean age of participants was 42.7 (range 16–85); excluding 18 participants who did not give their age. Seventy respondents indicated they were male (43%) and 82 female (50%). Participants were not asked for details of their diagnosis in order to ensure the sessions were as non-invasive as possible.

Procedure

At the end of each session, participants were given a questionnaire to rate the utility and effectiveness of the programme. Throughout eight cycles (64 sessions) of the group, 327 questionnaires were completed.

Measures

The questionnaire was developed by the group facilitator (a clinical psychologist) based on the questionnaire used by the authors of MCT.⁵ It took approximately 5 min to complete and covered demographic information, questions that created a unique anonymised code to track participants through the programme and questions providing quantitative data on either a five-point or ten-point Likert scale (*Appendix*).

Description of the programme

The MCT programme consisted of eight sessions on a weekly basis lasting approximately 45 min, facilitated by a clinical psychologist. There were different modules each week, which consisted of familiarising participants with the Table 1 Programme content¹¹

Module title Target domain Overview of exercises

Module 1a & 1b: Attribution – blaming and taking credit

Self-serving bias v.

depressive attributional bias Different reasons for positive and negative events are contemplated.

Explanations that account for various causes are preferred to single

explanations

Module 2a & 2b:

Jumping to conclusions

Jumping to conclusions/ liberal acceptance/bias

against disconfirmatory evidence Situations leading to rash decisions are discussed and disadvantages are emphasised. Disjointed pictures are shown that ultimately display objects

Module 3a & 3b: Changing beliefs

Bias against disconfirmatory evidence Cartoon sequences are shown in backward order. Individuals learn to

withhold strong judgements until adequate evidence has been collected

Module 4a & 4b: To empathise

Theory of mind Incomplete cartoon strips and pictures of human faces are presented, and participants are asked how the people depicted might feel. The first

intuition is often wrong, showing that relying solely on facial expression

can be misleading and multiple cues should be used

Module 5a & 5b: Memory Overconfidence in errors Factors that may promote or impair memory acquisition are discussed.

Complex scenes are displayed with two typical elements each removed.

Participants learn to differentiate between false and correct memories

by their vividness Module 6a & 6b:

To empathise II Theory of mind/need for

closure Different features guiding theory of mind are discussed. Cartoon sequences are presented, and the perspective of one of the characters is considered Module 7a & 7b:

Jumping to conclusions II Jumping to conclusions/

liberal acceptance Similar to module 2, the disadvantages of hasty decisions are outlined.

Paintings are also displayed, and the correct title must be inferred from

four options Module 8a & 8b:

Self-esteem and mood Mood and self-esteem Causes, symptoms, and treatment of depression are discussed. Typical depressive cognitive patterns are presented. Strategies to help enhance

self-esteem and improve mood are also discussed target domain (for example jumping to conclusions, attributional style), using everyday examples and illustrations projected from a computer screen. Two cycles of the programme were available; each cycle involved the same targets but with different group exercises. It was an open group that individuals could join at any time. The manual, modules and other resources were downloaded cost-free from www.uke.de/mct. Table 1 outlines the content of the group programme.¹¹

Results

Data was not normally distributed, therefore, non-parametric tests were used and the median and interquartile ranges (IQR) are reported throughout.

Utility and effectiveness of each module

Table 2 shows the descriptive statistics for each module of the group programme; 266 out of 327 participants' completed questionnaires were included; 61 were excluded because of missing data. Mann–Whitney *U*-tests were used to compare differences between ratings given for parallel sessions within each module. No significant differences were found; therefore, the two cycles of the programme were considered equivalent and the data was pooled.

As Table 2 shows, ratings for each module seemed fairly positive in terms of usefulness, change in knowledge and helpfulness to recovery. A Kruskal–Wallis test was conducted to investigate whether there were any significant differences in perceived utility and effectiveness between Table 2 Median (interquartile range) ratings by module *a*

Median (IQR) Module *n* Usefulness Knowledge – prior Knowledge – post Change in knowledge Helpfulness

to recovery Anxiety

(1.75–8.0)² modules. No significant differences were found on usefulness ($H(n = 154) = 2.738, P = 0.908$), change in

2

n represents the number of participants providing ratings for each module. Usefulness was rated on a five-point scale anchored at: 1, 'unhelpful' and 5, 'very helpful'; knowledge, helpfulness to recovery and anxiety were all rated on a ten-point scale anchored at 1, 'none at all' and 10, 'a great deal'.

Copyright Notice

Articles published from BJPsych Bulletin are open-access, published under the terms of creative commons Attribution licence (<http://creativecommons.org/licenses/by/4.0/>), which permits unrestricted re-use, distribution, and reproduction in any medium, provided

knowledge ($H(n = 157) = 11.558, P = 0.116$), and helpfulness to recovery ($H(n = 154) = 5.057, P = 0.653$). To ensure that each rating was independent, only the first observation from each of the 59 individuals who attended more than one session was taken, and some individuals were excluded because of missing data. This suggested that ratings for each module were comparable and it was concluded that evaluating the group as a whole to evaluate the remaining aims of this paper was justifiable.

Overall utility and effectiveness of group attendance

Subsequent analyses collapsed data across sessions to produce individual-level summaries. Thus, each unit of observation represents a separate individual, and each data-value represents the average score for that individual, across the sessions that they attended. In this way, all observations are independent and comparable, facilitating descriptive and inferential analyses of aggregated individual-level data that reflect the overall impact of group attendance.

On average, participants reported that sessions were fairly useful (median 4) and helped towards their recovery somewhat (median 4.5). Wilcoxon Signed Ranks tests were conducted for individual-average ratings of change in knowledge. Participants reported a highly significant increase in knowledge from pre-group (median 4.5) to post-group (median 5.5), $z = -5.79, P < 0.001$.

Although there were overall (sample-level) changes in knowledge, inspection of individual change-scores seemed Table 3 Spearman's rho correlations for overall group ratings ($n = 150$) Helpfulness to recovery Change in knowledge Anxiety $rPrPrPU$ Usefulness $0.288 < 0.001 - 0.0530.514 - 0.301 < 0.001$ Helpfulness to recovery $0.2060.010 - 0.1940.018$ Change in knowledge $-0.0400.625$ to show that some individuals reported no change or negative change between pre- and post-group. Specifically, 20% (32/159) reported zero or negative changes in knowledge. It was not possible to compute accurate reliable change estimates¹² for knowledge items, as available estimates of test-retest reliability are conflated with intervention effects. Those who showed zero and negative changes would not be able to demonstrate reliable improvement in any analysis of reliable change.

Interrelationships between group utility, effectiveness and self-reported anxiety

The Spearman's rank order correlation coefficient (i.e. Spearman's rho) was performed to explore the interrelationships between group ratings (Table 3). The Spearman's rho revealed significant positive correlations between (a) usefulness and helpfulness to recovery and (b) helpfulness to recovery and change in knowledge. Furthermore, there were significant negative correlations between (a) usefulness and anxiety and (b) helpfulness to recovery and anxiety.

Discussion

Participants indicated positive responses towards MCT in terms of perceived usefulness and helpfulness to recovery. Changes in outcome measures revealed an overall increase in knowledge following group attendance, although at an individual level some individuals did not report any increase in knowledge (this is discussed further in the Limitations section).

No particular sessions were perceived as more useful or effective than others. This supports the clinical application of all components of the programme and could be seen to support the open format of the group, since all entry-points are generally comparable in terms of utility.

It seems that the more useful participants found the group, the more they found it helpful towards their recovery – and vice versa. In keeping with the aims of the group, helpfulness to recovery was also positively correlated with change in knowledge. By increasing an individual's awareness of cognitive biases and providing corrective experiences, it could be expected that an individual would report an increase in knowledge and related recovery (in terms

the original work is properly cited.
The Authors own the copyrights to the individual articles.

of decreased symptoms).⁵ However, it is acknowledged that ‘recovery’ is a complex term and, although recovery from clinical symptoms can be seen as an outcome, individuals may continue to experience psychological distress while achieving ‘personal’ and ‘social’ recovery.^{13,14}

Interestingly, self-reported anxiety was negatively correlated with perceived usefulness and helpfulness to recovery. This suggests that the more anxious participants were, the less useful and helpful towards their recovery the group was – and vice versa. This may have important clinical implications for future practice, which are discussed below.

Limitations

Despite participants’ responses supporting the utility and effectiveness of MCT, which met various criteria for statistical significance, a number of limitations must be noted. The frequency of zero and negative individual-level change-scores suggests that some participants did not demonstrate knowledge improvements. From the available data it is unclear why this may be. It could be hypothesised that because the programme was an open group, establishing group cohesion was difficult. Therefore, although some individuals may have benefitted from the social processes of the group, some may have found the situation unhelpful and possibly anxiety-provoking. This may have had an impact on their ability to process and retain the information.

As participants were not specifically asked about their diagnosis, individuals who did not experience psychosis may have been included. As such, the programme content may not be suitable for those individuals and they may not have benefited from the group. Nevertheless, it is suggested that individuals with various mental health difficulties may benefit from MCT as the focus is on providing a neutral ‘common ground’ for discussing thinking styles, rather than individual symptoms.¹¹ However, this remains to be investigated and was beyond the scope of this paper.

It is also noted that some participants only attended the group once or a few times. This may be a behavioural indication that the intervention was not working. On the other hand, it may indicate that individuals were in the process of recovery and felt they no longer needed MCT. There are also contextual issues to consider; for instance, those participants who were in-patients may have been discharged and reluctant to return to the group because they were feeling better or a desire to disassociate with the hospital environment.

The service-developed questionnaire also had a number of shortcomings that may have affected the results. Change-scores were based on retrospective measures that may have resulted in inaccurate estimates, or participants may have felt obliged to respond in accordance with perceived demand characteristics. Furthermore, the items do not map onto the specific targets of MCT, including the expected reduction of positive symptoms and cognitive biases. In addition, it was difficult to establish what ‘recovery’ meant to respondents and how they evaluated this. As mentioned above, recovery is a very complex and individual experience and the quantitative data did not capture this.

Clinical implications

Despite the limitations, the results address the aims of the paper and suggest that MCT can provide a useful and effective evidence-based psychological intervention to participants within a local service. In addition to meeting local service needs, this paper contributes to the broader evidence base for MCT and supports the use of cognitive-behavioural interventions in the treatment of individuals experiencing psychosis.^{2,7,8}

The results have provided some important insights that may help to inform future clinical practice. Correlations suggested that individuals may need support to manage their anxiety in order to facilitate the processing of programme content (for example using relaxation and ‘ice-breaker’ exercises at the beginning of sessions). It may also be useful for the group facilitator to have an open dialogue with participants about the effects of the group and recognise that not everyone may benefit from MCT. Furthermore, as some individuals did not appear to benefit from the group, more selective inclusion criteria may be needed (for example ensuring only individuals with a diagnosis of schizophrenia/psychosis are included). It may also be useful to implement the recently developed individualised MCT programme on a one-to-one basis with some clients who may not benefit from a group format.¹⁵

The MCT programme showed promising results in promoting knowledge and was helpful for recovery and therefore further evaluation of the MCT group programme is needed in the future. There were various design limitations of the

questionnaire that would need to be addressed in order to improve future evaluation: (a) some participant demographics should be collected, including diagnosis, (b) measures of change should be taken before and after sessions in order to overcome problems with retrospective accounts, (c) items should map more tightly to the theoretical targets of MCT and could include objective tests (for example multiple-choice questions) v. subjective items that are more open to bias, (c) space for qualitative data should be provided under each question – particularly in relation to ‘recovery’ and what participants found helpful/unhelpful, and (d) questions about the impact of the facilitator’s style of delivery. This would allow exploration of what influences on outcomes relate to programme content or facilitator’s presentation skills.

Questions on the evaluation form

How much knowledge did you have on the topic being covered prior to this session?									
1	2	3	4	5	6	7	8	9	10
None at all									A great deal
How much knowledge do you feel you have now on this topic?

- *Learning about Emotions in Illness: Integrating Psychotherapeutic Teaching into Medical Education*

Reading *Learning about Emotions in Illness*, I found myself reflecting on my emotional response to the book – I was moved, and surprised at being moved. Partly, it reminded me of my own time as a medical student participating in the student psychotherapy scheme, which gave me my first opportunity of being useful as a trainee doctor, as opposed to being someone in the way. The supervision group was a wonderful and constant haven in which to reflect within the busyness and ever-changing landscape of medical training. Partly, I was simply moved by some of the accounts of people who as students had participated in either of the schemes described in the book, as they grappled with their own and their patients' emotional responses, especially to physical illness.

The book describes two approaches aimed at helping students learn how psychotherapeutic understanding can help them with their patients: the student psychotherapy scheme and student Balint groups. There are accounts of the scheme both from its supervisors and from participants, and there is also a chapter on research into the two schemes. The University College London student psychotherapy scheme has a long pedigree, having run for over 50 years and surviving various organisational changes. It has spawned other schemes such as in Bristol and Heidelberg. The scheme allows medical students to take on a patient for psychotherapy for a period of about a year. At its inception, allowing untrained students to practise psychotherapy was an audacious move. However, patients are carefully selected and the process is well supervised, and studies seem to indicate that patients have a good outcome. For students, the scheme often leaves an indelible mark, with a number of people citing it as a highlight of their medical training.

By its nature the psychotherapy scheme can only take on a limited number of students, and numbers wanting to participate outstrip the available places. Modified student Balint groups were introduced at University College London as an alternative. These meet in small groups for a period of 11 weeks and are used to reflect on students' emotional responses to patients they have seen, to help foster, in Balint's terms, a patient-centred rather than an illness-centred approach.

Participants in the scheme seem more likely to become psychiatrists – a point to be noted given the recruitment shortage. However, the real value of these schemes is in helping to develop doctors who can tolerate difficult emotions that arise in patient–doctor interactions and to be alive to the often unspoken emotions that our patients communicate. In other words, regardless of specialty, to make better doctors.

1.8.20 Testimony of Experience: Docta Ignorantia and the Philadelphia Association Communities

- *Testimony of Experience: Docta Ignorantia and the Philadelphia Association Communities*

R. D. Laing and others founded the Philadelphia Association (PA) in 1965. The PA provides community households where people with emotional difficulties can live with others. The first ‘official’ community was the infamous Kingsley Hall, a ‘counterculture’ centre in the East End of London, which after 5 years was largely trashed and uninhabitable. In retrospect, Laing admitted that it was not a ‘roaring success’ (*Conversations with R. D. Laing*, B. Mullan). Nonetheless, despite the commonly perceived demise of ‘anti-psychiatry’, with which Laing was associated, the PA has survived nearly 50 years and still runs two community houses. In this book, Bruce Scott, a member of the PA, where he did his psychoanalytic psychotherapy training, offers the testimonies of 14 people who have lived in a PA household. These were obtained mostly by face-to-face interviews or by questionnaire.

Scott sees the PA communities as providing true asylum, in the sense of an ‘inviolable place’. There is no discussion, however, about whether such asylum is possible if the person is detained under the Mental Health Act 1983. My guess is Scott would say not. He makes a case for *docta ignorantia* or the doctrine of learned ignorance, a concept used by Nicolas Cusanus in the 15th century to recognise the limits of knowledge. For Scott, this is a path to health practised by the PA communities. However, there is little discussion about whether such neutrality is attainable. I am uncertain whether Scott’s search for an ‘anti-method’ is anything more than being pragmatic. The testimonies commonly mention the lack of structure in the households. I have no problem with mystery and perplexity and I totally agree with an anti-materialistic stance for dealing with mental distress. The PA rightly wants to avoid the objectification of people with mental health problems. Helping them find their own way is not easy.

This book describes the tension between ‘going to pieces’ and being helped to ‘come back together again’. Regression and psychosis can be mechanisms of healing and re-adaptation, as noted by Donald Winnicott among others. The PA continues to explore these areas, as does this book, but it may be increasingly difficult to find space for them in a bureaucratic society.

1.8.21 Services for adults with ADHD: work in progress†

: Commentary on ... Specialist adult ADHD clinics in East Anglia

Abstract

Magon and colleagues highlight a number of relative strengths and weaknesses very reminiscent of those we have seen over the years in the development of similar services for children and adolescents. It is clear that we all have a lot of work to do to improve our approach to the transition from child to adult services. There was clear evidence that adult services can adapt to manage ADHD, but there is also a clear need for increased upskilling of clinicians in the practical management of medication and other treatments. I disagree with Magon and colleagues about the role of primary care and believe that treatment initiation and ongoing monitoring should, for the time being, remain in secondary care and that, because of the volume of work that will come our way, this will need to become a core rather than specialist task. As with other aspects of psychiatric care, there is a clear role for specialist nurses in delivering a significant proportion of the core care.

 - * *A new way of delivering services*

Magon and colleagues ¹ are to be congratulated for conducting what I believe is the first evaluation of the National Institute for Health and Care Excellence (NICE) recommendations on services for adults with attention-deficit hyperactivity disorder (ADHD). Their audit highlights several of the important, and sometimes controversial, issues that face commissioners, practitioners and patients.

This is a field of clinical work that is constantly evolving. Many of the changes that we are seeing mirror those that have taken place over the past two decades within child and adolescent mental health services (CAMHS). It will therefore be important that the lessons learnt there are not ignored. However, there are also many differences between the needs of people still experiencing ADHD and its related impairments as adults and those that they had while growing up and these too need to be respected. It is an important starting point to acknowledge that ADHD does not arise *de novo* in adulthood. There are of course some individuals with ADHD who were provided with ample scaffolding and support at home and school during childhood and adolescence and whose ADHD-related impairments may only have become clear when they left home and/or moved to less supported educational or work situations in early adulthood. But for most, their ADHD will have been causing significant problems throughout life and will have had an impact throughout their lives on their educational achievements, ability to form and sustain relationships, personality development and mental well-being.

ADHD diagnosis rates in the UK

Unfortunately, in the UK at least, many of those with ADHD will not have received a diagnosis or any treatment during childhood or adolescence. Recent figures from Scotland suggest that despite increases in recognition over the past 20 years ADHD is still significantly under-diagnosed. Even in the regions with the highest rates of recognition only around one in five of those with ADHD are currently being diagnosed. ² There is also very significant variation between regions and in the most densely populated areas of Scotland the rates of recognition are even lower, with diagnosis and treatment rates running between 6 and 13% of the epidemiological prevalence. ² This same situation, both with respect to under-recognition and regional variability, is almost certainly replicated across the rest of the UK.

As a consequence, it seems very likely that those individuals who are being identified, diagnosed and treated are those with the most severe symptoms and impairments. They are also the group that is most likely to need continuing services

and the greatest support during transition. It comes as no surprise to me to hear that transition was generally not well managed in either of the services covered in the audit and I recognise many of the comments in the discussion about the problems of transition only too well from my own clinical experience. From the CAMHS perspective it is often difficult to have the conversation about what the young person should expect from adult services when you are fully aware that in reality this depends a great deal on who picks up the case. It is much easier to hold on to cases well past the official transition date but this is neither good clinical practice – the needs of young adults are different and deserve to be treated by adult-oriented services – nor a good way to develop these much needed services.

Guidelines for service transition

Acknowledging the challenges of developing these, essentially new, services, we have produced guidance for the establishment of transition services.³ These built on NICE recommendations⁴ and include suggestions that:

a planned transfer to an appropriate adult service should be made if the young person continues to have significant symptoms of ADHD or other coexisting conditions that require treatment; transition should be planned in advance by both referring and receiving services; transition between teams should be a gradual process, e.g. lasting a minimum of 6 months; clear transition protocols should be developed jointly by commissioners, CAMHS/paediatric services, adult mental health services (AMHS) and primary care to facilitate transition and ensure that standards of care are maintained during the transition period; pre-transition: young people with ADHD should be reassessed at school-leaving age by the service managing their care; they should be informed of the outcome of this assessment and transitioned according to need; during transition, child and adult services should ideally have a joint transition appointment; during these meetings both services must ensure the needs of the young person will be appropriately met, which may involve further discussion and collaboration with educational and/or occupational agencies; post-transition: a comprehensive assessment should be carried out by the receiving service and this should include a reassessment for comorbid conditions; shared-care arrangements between primary and secondary care services for the prescription and monitoring of ADHD medications should be continued into adulthood.

Admittedly, these may seem to be relatively demanding recommendations, but the ongoing burden will be considerably lessened if they are underpinned by good-quality commissioning and planning. Getting the transition arrangements right should help to set the right tone for broader service planning. It should also strengthen the relationships between the child and adult services and facilitate joint learning, protocol development and planning.

ADHD pharmacological treatment: competence issues

In contrast to the clear issues hindering transition, it was very encouraging to see that both audited services were generally doing very well with respect to the assessment of not only the core ADHD symptoms but also the physical needs and coexisting conditions as well as in the initiation of medication treatment. This clearly indicates that it is possible for adult services to develop the required skills and integrate them into day-to-day practice. Although I do not believe this was ever in doubt, it is not uncommon to hear colleagues say that they feel out of their depth when dealing with these patients. There are now increasing opportunities for training in the assessment and management of adults with ADHD. In particular, the UK Adult ADHD Network (UKAAN; www.ukaan.org) has developed, and can deliver, high-quality training within the UK and has produced a helpful handbook for clinicians.⁵ There are also recently updated guidelines from the British Association of Psychopharmacology.⁶

It has become clear in recent years that the pharmacological management of ADHD is a skilled task and that whereas the basic principles of treatment are relatively simple, it is not so easy to ensure that treatment is first optimised and then continues to work well over time.^{7,8}

Primary- v. secondary-care management

Various opinions have been proposed about why it is difficult to maintain treatment results over time, but it would seem that continuing to provide ongoing high-quality care may be one important part of the puzzle (e.g. see Langley *et al*⁹). This certainly seems to be the case in our own clinic and has led to us developing a nurse-led clinical pathway that focuses on providing high-volume, high-quality continuing care.¹⁰ This highlights the one area where I think I may disagree with Magon *et al*. I do not believe that primary care services in the UK have yet acquired the skills to manage ADHD independently of specialist services. I certainly fully support the use of shared-care arrangements whereby (post-stabilisation) prescribing and possibly some physical monitoring is managed in primary care. I strongly believe, however, that symptom monitoring, monitoring of impairment and functioning and monitoring of comorbid conditions should at present remain within secondary care. These are skilled tasks and take time to do properly, and even if general practitioners (GPs) acquire the skills they are unlikely to be able to spend enough time to ensure outcomes are optimised.

Specialist ADHD management teams: (not) a perfect approach?

Although I do not currently support primary care-led services, it is still an open question as to which secondary care service model is best suited to the delivery of services for adults with ADHD in the National Health Service (NHS). Several different models have been put forward, ranging from all-age specialist teams, through specialist services limited to adults (such as those described in Magon *et al*'s audit), to services using a standardised protocol to deliver care via general AMHS. It is easy to see the allure of specialist teams, whether they be all-age or separate teams for children and adolescents and adults. There are, however, risks with this specialist team model. These include continued marginalisation of ADHD with specialist teams being seen as elitist and allowing those who are sceptical about ADHD to continue to ignore it as a valid clinical entity. Indeed, within such a model even those who may be somewhat interested but have not been placed on the team will often feel deskilled and left out.

Specialist teams often depend on a small group of individuals often centred around a charismatic and motivated leader. This makes them vulnerable when someone retires or leaves for another post. If successful, such teams will need to either become very big or only manage a small area. If they are large they can be very difficult to manage, if small one often gets postcode prescribing. On the other hand, expecting all adult psychiatrists to accept and manage ADHD alongside their other duties from the outset is almost certainly unrealistic and would be very likely to result in a huge variability in services. It would therefore seem parsimonious to accept that, as recommended by NICE, specialist services for adults with ADHD should be encouraged in the short to medium term, but that in the longer term it should be expected that managing ADHD will become a core skill for adult psychiatry, as it has over the past 20 years for child and adolescent psychiatry.

A new way of delivering services

While the optimal configuration of services is still being debated, I strongly support the use of multidisciplinary skills in the delivery of care. It is certainly not the case that all clinical care needs to be delivered by a doctor. In Dundee we have successfully developed a pathway that is primarily delivered by trained nursing staff, most of whom are not prescribers. These skilled nurses run parallel clinics, often as many as five at a time, supported by a senior medical staff member (usually a consultant), who works as a 'floating doctor' across the clinics providing support as required and overseeing changes in medication. I am aware that several adult services have also been successful in adopting a similar nurse-led service model and believe this is the way forward for ADHD services across the age range. Clinical psychologists, occupational therapists, dieticians, a range of psychological therapists and voluntary sector staff can also play a very important role in providing holistic care and their involvement should be encouraged wherever possible. It is not essential, or often desirable, for everyone to be part of a physical team and there can be great benefits from adopting a 'virtual team' approach with a clear and shared clinical pathway.

Another important point raised by the audit is the current difficulty accessing non-pharmacological treatments. It is true that we do not yet have a solid evidence base for non-pharmacological approaches to the management of ADHD in adults, nevertheless I believe that NICE was correct to highlight the potential importance of broader approaches to

treatment. As pointed out by Magon and colleagues, there are now a range of psychological therapies, most of which use a cognitive-behavioural therapy (CBT) approach. The problem seems to be getting those with the skills to deliver such programmes actually interested in doing so. Similar problems have arisen in effectively delivering behavioural parenting approaches. Here one solution has been to engage partners from outside the healthcare spectrum, often third-sector voluntary agencies, in delivery. It is not yet clear how this will work out for adult services. It may be the case that we have to wait until more clinical psychologists and/or appropriately trained nurse practitioners are ready to step up to the plate and start to provide a sound base of practice skills from which work can expand. Or it may be that, as suggested by Magon and colleagues, opportunities will arrive through the development of stronger and more active local ADHD support groups working in partnership with the voluntary sector.

The last point I would like to pick up on is that there were quite a few instances where the practice of the two audited services differed considerably. This is in line with the clear geographic differences in provision of services to children and young people. However, even though some degree of variability between services is of course inevitable, in ADHD very high levels seem to be the norm. Some of this variability will represent historical differences based on individual or service-level beliefs about the validity of ADHD and the use of medication to treat it and will have predated the provision of clear clinical guidelines. However, the introduction of guidelines does not seem to have led to increased uniformity in service delivery for child services^{2,11} and I suspect it will take a lot of hard work to ensure greater uniformity in the development of services for adults. Audits such as this are a good starting point and I again thank Magon and colleagues for getting the ball rolling.

schizophrenia’² and Ian McEwan’s *Enduring Love*,³ to Mersey Regional Health Authority’s implementation of care in the community and books, including *I Want a Christian Psychiatrist*⁴ and *Uncommon Psychiatric Syndromes*:⁵ now out of print, the paperback fourth edition is currently available from online sellers, second-hand, for over £1000.

The spectrum of today’s search results for this 88-year-old emeritus consultant psychiatrist of Royal Liverpool University Hospital, fellow of the Royal College of Psychiatrists, member of its Council for over 20 years and Court of Electors for 8, due shortly to publish his autobiography, offers just a glimpse of the diverse tales Dr Enoch might relate, should you be lucky enough to meet him.

Waziristan

With a surname meaning ‘he who walks with God’, Morgan David Enoch was a sixth-form student due to read theology at the end of World War II. David’s mother, who worried about his sister attending a hairdressing course in Swansea, 8 miles from the family home, was shocked when, after a letter from the King of England, he was soon serving with the British army in India’s north-west frontier, ‘facing the forces of the Faqir of Ipi at the very place where fighting has been heaviest for the [past] 10 years’, aged 18. Later, following a War Office Selection Board, he trained at the Indian Military Academy, ‘the Sandhurst of India’ at Dehra Dun, was commissioned into the Royal Artillery and posted to the second Indian (Sikhs) Field Regiment in 1947.

During this time, he says ‘while angry with God for obstructing my chosen path, I had four exciting years in India. I heard Jawaharlal Nehru and Mohammed Ali Jinnah address vast crowds: I witnessed the birth of two great nations and the process of India’s violent partition’. Playing rugby for the British Army in India, David returned to Woolwich Arsenal on leave, expecting to continue playing but was indignant to be ordered back to India to complete his outstanding months’ National Service. He says the physical and mental suffering he observed during his army career is what called him to medicine. After eventual military discharge, he ‘went around the London teaching hospitals and liked St Thomas’ Medical School. I think the uniform helped at interview’.

Medical training

Qualifying in 1954, following house jobs Dr Enoch returned to Wales to work at St David’s Mental Hospital, Carmarthen, as his father, ‘a hewer of coal in 2 feet 9 inches’ was dying of silicosis. Of his first years in psychiatry, he recalls the routine use of the hypnotic paraldehyde at night, prescribing ‘quite effective’ Drinamyl (amobarbital and dextroamphetamine, later known as ‘purple hearts’), deep insulin coma therapy and, for the first time, an antipsychotic: chlorpromazine.

Following his father’s death in 1958, he returned to London, then ‘the supreme place to train’, obtaining a medical registrar post at University College Hospital, working for Professor Baron Max Leonard Rosenheim, Dr Roger Tredgold and Dr Desmond Pond, later president of the Royal College of Psychiatrists. In the mid-fifties, after the Institute of Psychiatry course and obtaining his Diploma in Psychological Medicine, Dr Enoch witnessed the introduction of antidepressants, beginning with imipramine and amitriptyline. He later obtained a senior registrar post divided between the London Hospital (now the Royal London Hospital) and Runwell Mental Hospital, Essex, which opened after World War II in response to shell shock – the last mental hospital built in Britain.⁶

Dr Enoch recalls Runwell’s physician superintendent, Dr Rolf Ström-Olsen, as ‘one of the best physicians I ever met. He was Norwegian, abrupt and highly intelligent’. He recollects Runwell’s units divided into neurosis and psychosis, conferences clouded in cigarette smoke, treating patients for the first time with out-patient electroconvulsive therapy and the introduction of newer antipsychotics, like haloperidol. This dynamic clinical, educational and research environment was to prove instrumental in inspiring his future writing, yielding a lifelong dedication to evidence-based improvement in clinical practice.

Uncommon Psychiatric Syndromes

Dr Enoch recalls presenting a patient at Runwell Hospital, whose complaint was that ‘my wife’s an impostor’. Phrases began to occur to him describing the psychodynamic processes at work: ‘His wife was “the fallen idol”, hence the delusion of doubles. How do you resolve loving and hating someone at the same time? By splitting. Is apperception not a wonderful word? To perceive with feeling. That is the essence of Capgras psychopathology.’

After further research, Dr Enoch’s paper on Capgras syndrome won the bronze medal and prize of the Royal Medico-Psychological Association in 1962 and was published in *Acta Psychiatrica Scandinavica* in 1963,⁷ the same year he won the Gaskell Prize. He developed an increasing interest in rare presentations, from De Clérambault’s syndrome, to folie à deux, Tourette’s and more, which yielded his first book. The first edition of *Some Uncommon Psychiatric Syndromes*, a bestseller, was published in 1967, with further editions in 1979, 1991 and 2001. Dr John Pollitt, President of the Section of Psychiatry of the Royal Society of Medicine, predicted that it ‘well deserves to be placed as a classic’;⁸ it has been translated into French, German, Turkish and Japanese.

Dr Enoch expected his ‘uncommon syndromes’ to remain rare and was surprised by their later *cause célèbre* status. ‘I never thought, for example, that patients with Munchausen syndrome by proxy would become so important. They became huge’. The diagnosis was questioned publicly, after several child killing convictions were overturned, including that of lawyer Sally Clark. In these cases, the diagnosis was used inappropriately for paediatric assessment, without involvement of a psychiatrist. By contrast, high-profile cases incorporating psychiatrist assessment, such as that of nurse Beverley Allitt, now detained at Rampton Secure Hospital, demonstrated the contemporary relevance of the diagnosis.

To this day, Dr Enoch receives telephone calls from readers of *Uncommon Psychiatric Syndromes* from around the world; he remains fascinated by delusional disorders. ‘I’d like to know far more about emotions. How can feelings affect thought? Psychodynamics remain all important. This book has been lived’. Although he never met Ian McEwan, who referenced the text in *Enduring Love*, Dr Enoch ‘approved’ of the novel, unlike the film *Fatal Attraction* (1987, director A. Lyne), which did not depict true De Clérambault’s syndrome, because ‘the protagonists had an initial affair: usually there is no contact’.

After the success of *Uncommon Psychiatric Syndromes*, Dr Enoch wrote other well-received books, including *Healing the Hurt Mind: Christian Faith and Psychiatry*.⁹ Now in its 11th edition, its title was inspired by a patient’s letter, kept to this day, stating that ‘Dr Enoch was the first person who listened to me and asked me how I am. Healing began for me today’. In the most recent, *I Want a Christian Psychiatrist*,⁴ he returns to his theological roots. ‘You don’t necessarily need a Christian psychiatrist: you need a competent psychiatrist who must respect your faith’.

Clinical career

Dr Enoch recalls obtaining his first consultant post at Shelton Hospital, Shrewsbury, after debating Ganser syndrome with Professor Sir William Trethowan, foundation chair of psychiatry at the University of Birmingham, at interview. He would later invite Trethowan to contribute to the chapter on Ganser syndrome and Dr John C. Barker that on Munchausen syndrome, in the first edition of *Uncommon Psychiatric Syndromes*.

It was at Shelton Hospital that Dr Enoch introduced regular teaching, therapeutic communities and care in the community. He recalls meeting Enoch Powell, then expounding de-institutionalisation as minister of health. He worked with Barbara Robb on a national campaign for elderly care in hospitals, contributing a chapter to her book, *Sans Everything: A Case to Answer*.¹⁰ He remembers ‘feeling encouraged’ at the time by the *Sunday Times*’ article series on care in the community by Marjorie Wallace, who later founded the mental health charity SANE, with telling photographs by Lord Snowden.

Dr Enoch was later head-hunted to take on the new post of consultant psychiatrist and senior clinical lecturer at the new Royal Liverpool University Hospital’s ‘superb’ department of psychiatry, later including beds at Rainhill Mental Hospital. He is still remembered as a dynamic and enthusiastic teacher, as evidenced by Dr Gamal Hammad’s description of him as ‘a charismatic guru, a wonderful mentor and a visionary’.¹¹

Fig. 15: Dr Enoch at his home in Cardiff, March 2014.

He always enjoyed encouraging the next generation of psychiatrists and made a point of involving students and nurses in ward rounds: 'I wanted the doctors and students to see the full range of psychiatric disorders. I used to remind them, "Rare things rarely occur".' At the opening of Shelton Hospital's replacement, the Redwoods Centre, in 2011, his second wife, Anne, a retired headmistress, recalls him being treated 'like a celebrity... they'd all read his book'.

Above all, Dr Enoch strove to teach and practise psychiatry as a holistic discipline, examining each and every patient: 'I liked psychiatry because it deals with the whole person: their body, mind and spirit. I wanted to do something exciting while staying true to my faith. A good psychiatrist is prepared to listen, know their stuff and gather it all together into a diagnostic formulation. It doesn't mean you have all the answers, but the diagnosis is the first step to management and treatment.'

On psychiatry

Dr Enoch is a staunch supporter and advocate of psychiatry as a compelling specialty with much still to be discovered: 'It's a new frontier of medicine... We know so little about the human brain: the heart is a pump, but you love with the hypothalamus. We thought that scans would give us clear-cut answers but they have not. What is consciousness? I have thirty books on it but no one can say where, how, what. It is remarkable what can arise from the unconscious. I thought that fMRI would locate jealousy, De Clérembault, because those syndromes are so specific: monomanias with one delusion. The fact that we cannot locate them suggests that the brain's connections hold the answers. But can this brain really have the capacity to understand itself?'

The specialty remains compelling for Dr Enoch, even after more than 50 years; he continues to advocate keeping psychiatric wards within medical hospitals: 'Psychiatry is the most intriguing of all specialties: you deal with the whole Meeting the Royal College of Psychiatrists' Pathfinder Fellows, January 2014. person. You must be a first-class physician: I have picked up lung cancer, brain tumours, pernicious anaemia, cardiac lesions, thyrotoxicosis. We are physicians of psychological medicine. Recalcitrant cases not medically understood are referred to us. You listen and discover things other doctors miss.

Patients come to you broken psychologically and emotionally, intent on suicide, and get better. Is there anything more helpful in society than to heal pain: physical and psychological? Psychiatric illness is an illness like any other: treatable and curable despite what even doctors may think. You need maturity to choose something so difficult, though. You will need hope, positivity and graciousness.'

On reflection

Having seen his last patient on 31 December 2012 and survived a coronary artery occlusion of '99%', Dr Enoch remains active, lecturing at Cardiff University Medical School until recently. In addition to his forthcoming autobiography, a book of Welsh essays is due for publication in 2014, with several exploring the relevance of the Ten Commandments today. Although he never did complete that theology degree, he has continued to preach from age 16 until today, in between spending time with his wife, son and four grandchildren. Considering his rather uncommon life, he reflects that: 'I have been greatly blessed. I am very grateful for a very exciting life; it's still exciting. I have enjoyed psychiatry's riches in helping people in great depth.'

When we last met, Dr Enoch was looking forward to meeting recipients of the Royal College of Psychiatrists' Pathfinder Fellowships, considering the next generation with excitement – and a little envy: 'this is going to be the century of the brain'. Above all, it is the pursuit of learning which he most fervently advocates for us all: 'I spent 65 years in the game, to realise how little I know. I would love to be starting again, with the knowledge I have now'. His wife adds, 'He is as enthusiastic today as when he was twenty'. All taught by Dr Enoch, exposed to this enthusiasm, may count themselves truly fortunate. His last piece of advice? 'Gather your materials from everywhere, but be your own architect.'

1.8.23 Mental health clustering and diagnosis in psychiatric in-patients

date

2015-6

Abstract

Aims and method This paper investigates the relationship between cluster (Mental Health Clustering Tool, MHCT) and diagnosis in an in-patient population. We analysed the diagnostic make-up of each cluster and the clinical utility of the diagnostic advice in the Department of Health's *Mental Health Clustering Booklet*. In-patients discharged from working-age adult and older people's services of a National Health Service trust over 1 year were included. Cluster on admission was compared with primary diagnosis on discharge.

Results Organic, schizophreniform, anxiety disorder and personality disorders aligned to one superclass cluster. Alcohol and substance misuse, and mood disorders distributed evenly across psychosis and non-psychosis superclass clusters. Two-thirds of diagnoses fell within the MHCT 'likely' group and a tenth into the 'unlikely' group.

Clinical implications Cluster and diagnosis are best viewed as complimentary systems to describe an individual's needs. Improvements are suggested to the MHCT diagnostic advice in in-patient settings. Substance misuse and affective disorders have a more complex distribution between superclass clusters than all other broad diagnostic groups.

 - * *Limitations*

A set of needs-based clusters were originally developed as a classification system to aid service improvement in secondary care mental health services.¹ There are a total of 21 clusters grouped into three superclasses: non-psychosis, psychosis and organic. Each cluster describes a particular type, combination and severity of needs. This Care Pathways and Packages approach (www.cppconsortium.nhs.uk) was subsequently adopted as the heart of a move away from block contracts towards a new mental health payment system.

The first 12 scales of the Mental Health Clustering Tool (MHCT) are Health of the Nation Outcome Scales (HoNOS) items.² The HoNOS tool was originally developed by the Royal College of Psychiatrists' Research Unit as an outcome measure. The Care Pathways and Packages Project developed the remaining six MHCT scales to support the classification of patients based on their level of need.¹ The *Mental Health Clustering Booklet* provides likely diagnoses for each cluster. Added to version 3.0 of the booklet were unlikely diagnoses for each cluster based on the ICD-10 classification system used in the National Health Service (NHS).^{3,4}

Aims

The study had two aims. The first was to analyse the diagnostic make-up of each cluster from an in-patient population and to investigate the clinical utility of the advice in the MHCT booklet regarding likely and unlikely diagnoses. The second aim was to investigate the distribution of diagnoses across both superclass cluster groups and individual clusters.

Method

All discharges from working-age adult or older people's in-patient services in Northumberland, Tyne and Wear NHS Foundation Trust (NTW) between 1 April 2012 and 31 March 2013 were included in the study (each discharge refers to one treatment episode rather than one patient). Working-age adult services included psychiatric intensive care units (PICUs), acute adult and rehabilitation wards. Older people's wards included functional, organic and long-term/complex need wards.

The cluster on admission was taken as cluster assigned on date of admission or up to 3 days after admission, or nearest cluster prior to admission. Cluster superclass groups used are those given in the MHCT booklet: non-psychosis clusters 1–8; psychosis clusters 10–17; and organic clusters 18–21. Patients were assigned to cluster 0 if they were not adequately described by another cluster but required secondary care services.

We considered the diagnosis on discharge because diagnosis is more likely to be recorded on discharge and is more likely to be related to the current episode than diagnosis on or prior to admission. The ICD-10 code was sourced from electronic patient records. The broad diagnostic groups used were F00–09 (organic and dementia), F10–19 (substance misuse), F20–29 (schizophrenia and related disorders), F30–39 (affective disorders), F40–48 (neurotic, stress-related and somatoform disorders), F60–69 (personality and behaviour disorders), and 'other' diagnoses. 'Other' diagnoses included F50–59 (behavioural syndromes associated with physiological disturbances and physical factors), F70–79 (mental retardation), F80–89 (disorders of psychological development), other developmental disorders, G00–99, H00–95, R00–99, S00–T98 and Z00–99. The next diagnostic level used to analyse the data was at the 'three character' level, for example F32 depressive episode or F33 recurrent depressive disorder. Within affective disorder the four-character level was used to distinguish conditions with and without psychosis.

To empirically validate the MHCT 'likely' and 'unlikely' advice, a threshold of 65% was set for the cumulative proportion of discharges in a cluster which were attributed to the 'likely' diagnoses. In other words, all of the 'likely' diagnoses for a cluster should account for 65% or more of discharges. An acceptable threshold of 10% was set for the 'unlikely' diagnoses, meaning that all 'unlikely' diagnoses for a cluster should not account for more than 10% of discharges. Diagnoses not in the likely or unlikely groups were put in the 'other' group.

All analysis of the data was performed using SPSS version 19 for Windows and Microsoft Excel.

This study was part of a service evaluation of clinical activity in NTW which focused on the use of in-patient services across the trust. This was within the Transforming Services Programme which had approval of the trust board and included ongoing work to evaluate the use of MHCT within the trust. Data were provided by the trust informatics department. We used routinely collected data for this study.

Results

In total, there were 2830 discharges between 1 April 2012 and 31 May 2013. Primary discharge diagnosis was available for three-quarters of these ($n = 2094$): half were accounted for by affective disorders ($n = 552$, 26%) and schizophrenia and related disorders ($n = 533$, 25%). The remaining diagnostic groups were: personality disorders ($n = 283$, 14%); alcohol and substance misuse ($n = 260$, 12%); neurotic, stress-related and somatoform disorders ($n = 253$, 12%); dementia and organic disorders ($n = 131$, 6%); other ($n = 82$, 4%).

Over 90% of discharges ($n = 2570$) had an admission cluster. Of those, almost half (45%, $n = 1145$) were non-psychosis clusters 1–8, 42% ($n = 1091$) were psychosis clusters 10–17, 11% ($n = 287$) were organic clusters 18–21 and 2% ($n = 47$) were cluster 0.

There were 1937 discharges with both a cluster on admission and diagnosis on discharge. The diagnostic make-up of clusters 1, 2 and 21 was not analysed due to low numbers. In 11 of the remaining 17 clusters, the likely diagnoses made up more than 65% of the cases. This figure was highest for clusters 13, 16 and 17 where the likely diagnoses accounted for more than 80% of the cases. In 6 of the 17 clusters the likely diagnoses accounted for less than 65% of the cases and made up half or less of cases in clusters 3, 4, 10, 15 and 18. These same five clusters had high rates of ‘other’ diagnoses.

In the majority of clusters the ‘unlikely’ diagnoses made up around 10% of cases. In four of the clusters in the psychosis superclass (clusters 11, 12, 15 and 16) the ‘unlikely’ diagnoses accounted for between 11 and 17%.

Highlighted in *Table 1* are five clusters which have low numbers of ‘likely’ diagnoses and relatively high numbers of ‘other’ diagnoses. There were a number of unexpected diagnoses for some clusters, particularly within non-psychosis clusters. Alcohol misuse was the primary diagnosis in more than 10% of those in clusters 3, 4 and 5. Personality disorder was the primary diagnosis in more than 10% of cluster 3; similar figures were found for recurrent depression in clusters 6 and 15, and organic disorders (F04–09) in clusters 18 and 19. More than a third of those in cluster 15 had an F20–29 diagnosis. Alcohol and substance misuse was the primary diagnosis for a fifth of cluster 10, whereas depression accounted for 10%.

Table 2 shows the distributions of broad diagnostic groupings among the cluster superclasses. There was a significant relationship between cluster and diagnosis: F00–09 largely falling within the organic superclass; F20–29 largely falling within the psychosis superclass; F40–48 and F60–69 largely falling within the non-psychosis superclass.

Substance misuse and affective disorders were split between the psychosis and non-psychosis superclass clusters. *Table 3* shows a significant relationship between different types of substance misuse and superclass. Two-thirds of F10 diagnoses fell in the non-psychosis supercluster and nearly half were classified as having alcohol dependence (F10.2). In contrast, 67% of the F11–18 diagnoses fell within the psychosis supercluster. Multiple substance misuse diagnoses were equally split between these two superclass clusters.

A marked distinction between mania and bipolar disorders and the remaining affective disorders was observed (*Table 3*). There was a non-significant trend towards clustering bipolar disorder in the psychosis clusters, regardless of whether the patient exhibited psychotic symptoms or not. Patients with depression were significantly more likely to be assigned to non-psychosis clusters than to psychosis clusters. The only exception to this was depression with psychosis (*Table 3*).

Discussion

The results show that the diagnostic advice in the clustering booklet holds true for ‘likely’ diagnoses in 11 of the 17 clusters analysed and in 13 clusters for ‘unlikely’ diagnoses. In five clusters (3, 4, 10, 15 and 18) the ‘likely’ diagnoses accounted for half or less of discharges from hospital and there were particularly high rates of other diagnoses.

Discharges from each cluster and the percentage in the likely, unlikely and other diagnoses from the Mental Health Clustering Tool advice. Individual clusters with low rates of ‘likely’ diagnosis and high rates of ‘other’ diagnoses in bold

	$\chi^2 = 1622.7$, d.f. = 14, $n = 2523$, $P < 0.001$				

Caution must be taken when interpreting some of these findings due to low sample numbers in some of the clusters. Further analysis in both in-patient and out-patient populations is necessary. Our findings indicate that the diagnostic advice holds true for the majority of clusters. However, the low rates of ‘likely’ diagnoses among a few clusters suggest that the current advice for those clusters does not hold true for a subsection of the in-patient population. These findings are supported by previous research which found high rates of mismatch between ICD-10 diagnoses and clusters 3, 4, 15 and 18.⁵

Clinical practice issues could partly explain these findings, but if further in-depth analysis in other trusts reveals similar trends, then changing the ‘likely’ diagnosis advice will increase the MHCT booklet’ clinical usefulness. Our results indicate that the following diagnoses could be added to the ‘likely’ diagnoses group: alcohol misuse for clusters 3 to 5; recurrent depression for cluster 6 and 15; Table 3The distribution of F10–19 substance misuse and F30–39 affective disorder diagnoses across the non-psychosis and psychosis superclass groups. Cluster 0 and organic superclass are not shown separately, but are included in total numbersMHCT groupsICD-10 diagnostic groupTotal cluster 1–8Total cluster 10–17TotalF10–19 alcohol and substance misuse128 (56%)93 (40%)230 (100%) F10 alcohol80 (67%)31 (26%)119 (100%) F11–18 opioids, cannabinoids, sedatives, stimulants etc.7 (29%)16 (67%)24 (100%) F19 multiple drug use41 (47%)46 (53%)87 (100%)² = 20.41, d.f. = 2, $n = 221$, $P < 0.001$ F30–39 affective disorder255 (49%)254 (49%)517 (100%) F30–31 mania and bipolar disorder49 (20%)192 (78%)245 (100%) F32–33 depression196 (76%)59 (23%)259 (100%) F34–39 persistent mood disorders, other mood disorders and mood disorders unspecified10 (77%)3 (23%)13 (100%)² = 162.22, d.f. = 2, $n = 509$, $P < 0.001$ F31 bipolar

There were two diagnostic areas that are worth discussing further. The first was personality disorder. A number of diagnoses of personality disorder were found in cluster 8. However, there were also some found in other non-psychosis clusters including clusters 3 and 4. It may be that these were incorrectly diagnosed or clustered. Alternatively, it may be that those with complex and severe personality disorders are allocated to cluster 8 whereas those with simple personality disorders are clustered lower down within the non-psychosis superclass.⁶

A further area of concern was the high proportion of ‘other’ diagnoses in cluster 10, a substantial proportion of which were alcohol and substance misuse diagnoses. This is at odds with the finding that the prevalence of drug-induced psychosis is relatively low in England.⁷ It may reflect a reluctance of some early intervention psychosis services to give a formal diagnosis early on in an individual’s contact with services.⁸

Whereas dementia and organic disorders, neurotic and stress-related and somatoform disorders, and schizophrenia and related disorders aligned to one superclass cluster group, affective disorders and substance misuse disorders did not. At one diagnostic level down, depression mainly fell within the non-psychosis superclass while mania and bipolar disorder fell within the psychosis superclass. The only exception to this was the diagnosis of psychotic depression. Local trust policy, in line with Royal College of Psychiatrists advice, was to cluster patients with bipolar disorder to the psychosis clusters, regardless of whether psychotic symptoms were present.⁹

Department of Health guidance currently being drafted suggests that patients with bipolar disorder diagnoses may be allocated to either psychotic or non-psychotic clusters depending on presenting needs,¹⁰ supporting the view that cluster and diagnosis should best be viewed as complementary. These findings also have implications for the proposed reorganisation of services. If there is to be a division between psychosis and non-psychosis, it is evident that both teams will require expertise in the management of affective disorders.

Further analysis showed that F10–19 alcohol/substance misuse accounted for 14% of all clusters 2–8 and was largely uniform across each cluster individually. This highlights that patients with a primary diagnosis of alcohol/substance misuse experience a wide range of problems and have varying levels of need. This can be seen as supporting the previous decision to disaggregate the original generic substance misuse cluster 9.¹¹

Limitations

There are a number of limitations of this research which need to be highlighted. First, the accepted thresholds used for ‘likely’ and ‘unlikely’ diagnoses were set by the research team. No previous research was available in which to benchmark against. Second, only in-patient discharges were included, but the MHCT was developed for use in both community and in-patient services. To acquire a fuller understanding of the cluster–diagnosis relationship, the research should be extended to community patients. Third, for low-need non-psychosis and organic clusters in particular, there were low numbers, meaning that reliable and valid conclusions could not be drawn. Fourth, it is important to note that during the first analysis, we grouped together all ‘likely’ diagnoses and did not separate out the relative contributions of each diagnosis. It is possible that a ‘likely’ diagnosis occurred rarely and was offset by a more frequent one. Fifth, audits established that cluster accuracy for the period from January to June 2012 was at 68% (CAPITA, personal communication, 2013). However, assignment to superclass cluster was highly accurate; only one service user (2%) was assigned to the wrong supercluster. It is important to note that this audit was conducted using 63 patients who had been clustered to a psychosis cluster only. This suggests that findings of associations at the superclass level are likely to be more robust than at the individual cluster level. Finally, we used clinical diagnoses and due to the nature of the study it was not possible to check accuracy or interrater reliability.

This paper provides further information on the relationship between cluster and diagnosis in an in-patient setting. It supports the notion that cluster and diagnosis are best seen as complementary systems to describe an individual’s needs,

rather than there being a 1:1 relationship. This particularly applies to affective and substance misuse disorders. The data identified different skill sets required for the management of in-patients in the psychosis, non-psychosis and organic clusters if services are to further specialise in these areas. Results suggest some of the interventions that would need to be delivered within these services. Future work should extend this research into community teams.

1.8.24 The neurology–psychiatry divide: a thought experiment†

Thomas J. Reilly

Correspondence

Thomas J. Reilly (t.reilly@nhs.net)^{1,2}

date

2015-6

Abstract

Diseases of the brain are generally classified as either neurological or psychiatric. However, these two groups of illnesses cannot be readily separated on the basis of pathophysiology or symptomatology. It is difficult to rationally explain to someone with no prior frame of reference why we have the split between neurological and psychiatric illness. This demonstrates that the division is untenable, which has implications for training in both psychiatry and neurology.

Contents

- *The neurology–psychiatry divide: a thought experiment†*
 - *Convention*
 - *Neuropathology*
 - *Symptomatology*
 - * *The biopsychosocial approach*
 - *Conclusion*

Can the distinction between psychiatric and neurological illness be explained to a Martian? This hypothetical Martian has come down to Earth and wants to know about our classification of diseases pertaining to the brain. Let us suppose our Martian has similar anatomy and biology to humans, except he has no concept of illnesses relating to the central nervous system; he does not experience psychiatric or neurological disease. The Martian is curious as to why most organs (such as lungs, kidneys, hearts and eyes) are treated by a single medical specialty, whereas the brain is divided between neurologists and psychiatrists.

¹ Thomas J Reilly BSc MBChB is an academic foundation doctor at the University of Glasgow and NHS Greater Glasgow and Clyde, UK.

Convention

Perhaps a reasonable place to start would be to define neurological illnesses as those treated by neurologists and psychiatric illnesses as those treated by psychiatrists. You might take the Martian to a neurology ward and declare that all patients here have neurological illnesses. Or explain that the people seen by community psychiatric nurses are those with psychiatric illness. Of course, this is circular reasoning and does not stand up to much scrutiny. The Martian would surely not be satisfied by this explanation; he has no prior knowledge of the history, development or social implications of psychiatry *v.* neurological disease. Therefore, to him, the division is not self-evident.

Neuropathology

You might, therefore, go a little deeper and start to think about what characterises each type of illness. The Martian recognises the notion of pathology and can relate this to other aspects of disease – for example, pulmonary fibrosis causing restrictive lung disease, which we categorise as a respiratory disease. By comparison, you might argue that neuropathological lesions cause neurological disease, whereas psychiatric illness is more to do with abnormal function of the brain. This seems sensible and certainly holds for well-characterised neurological disease such as multiple sclerosis. Demyelination of neuronal axons is the neuropathology, which results in a patient's symptoms. However, it becomes less tenable as the underlying disease processes are less well characterised. Epilepsy was once regarded as a psychiatric disease. As its neuropathology was better understood, we now regard it as a neurological illness.¹ Similarly, we now know of pathological processes in diseases such as schizophrenia. These processes, while not localised lesions, are evident when comparing brain imaging of people with schizophrenia to healthy controls and are present before the illness manifests clinically.²

The final nail in the coffin of classifying brain diseases by their pathology is the case of conversion disorder, or neurologically unexplained symptoms. By definition, this disorder cannot be explained by underlying neuropathology.³ It is, presumably, a result of psychological and social factors and is more a 'functional' disorder of the central nervous system. And yet it is not treated by psychiatrists but by neurologists. Attempting to categorise brain disease by pathology is clearly troublesome so perhaps we should focus on dividing illnesses based on their symptoms.

Symptomatology

You could try explaining to the Martian that there are 'neurological symptoms', weakness, tingling and seizures, for example. By contrast, 'psychiatric symptoms' would generally be regarded as dysfunction of higher functions of the nervous system, disturbance in mood, delusions, hallucinations and so forth. Of course, there is some overlap but neurological symptoms would generally signify neurological disease which would interest a neurologist more than a psychiatrist. This holds true for conversion disorder which, although not involving lesions of the nervous system, certainly presents with symptoms more familiar to neurologists.

Unfortunately, it would take little time for our Martian friend to pick holes in this argument. He could point to anti-*N*-methyl-*D*-aspartate receptor encephalitis, which can be clinically indistinguishable from the first episode of schizophrenia, though it has a well-defined 'neurological' pathophysiology.⁴ This disease was only recently discovered, making it difficult to estimate how many patients presenting with psychiatric symptoms actually have neurological diseases. Similarly, psychiatric symptoms are common in traditionally neurological disorders: hallucinations in Parkinson's disease⁵ and depression in multiple sclerosis⁶ are just two examples.

The biopsychosocial approach

It could be argued that psychiatrists are specifically trained to have a biopsychosocial approach to disease, paying more attention to psychological and social aspects.⁷ This is important, as these factors influence the presentation and course of psychiatric illness. However, as previously stated, psychological and social factors also underpin traditionally neurological conditions such as unexplained neurological symptoms and non-epileptic attacks. Indeed, there is a spectrum of psychosocial components to all diseases. Having a biopsychosocial approach to illness is required not just for psychiatrists and neurologists but for all doctors. In an ideal world, our approach to all illness would include consideration of psychological and social factors, and would be indistinguishable between neurologists and psychiatrists.

Conclusion

There is no defining line between neurology and psychiatry. Furthermore, I contest that it is impossible to justify the separation of neurological and psychiatric illness on a rational basis. To a Martian, or anyone looking at the situation with a fresh pair of eyes, it is impossible to explain how we put brain disorders into either neurological or psychiatric boxes. This is because current classification is based on convention, tradition and quirks of history.

To our Martian, it would probably seem rational to have a degree of overlap in training between neurologists and psychiatrists. It would seem desirable that neurologists be competent in the management of psychiatric disorders, and *vice versa*. Unfortunately, this is not the case. In the UK, it is perfectly normal to train in one of these specialties with no exposure to the other, unlike in other European countries.⁸ Nature does not respect our arbitrary categorisations and neither do our patients. It would surely benefit both specialties to integrate training pathways, as has been suggested by others.⁹

1.8.25 *Bulletin* comment: What is wrong with the likes of Rolf Harris?

- *Bulletin comment: What is wrong with the likes of Rolf Harris?*

The revelations about the perverse activities of high-profile celebrities such as Rolf Harris, Jimmy Savile and Max Clifford continue to cause shock, bewilderment and voyeuristic intrigue. It seems the scourge of abuse is so prevalent that it extends into all institutions previously held in high regard; from the county councils, to the Catholic Church, and further to the Houses of Parliament.

For mental health professionals (as well as any other keen observer of human behaviours), such disturbing disclosures often lead to discussions about why any individual might act this way: considerations of personality disorders may be had. The extreme arrogance, the lack of regret and absence of profound feelings of guilt, in the context of lifelong careers in the media or entertainment industries or positions of importance in society, point towards cluster B difficulties, with elements of both antisocial and histrionic disorders.

News reports inevitably pay most attention to the wrongdoer and the calls for enquiries into the institutions, organisations or official bodies that have essentially been supportive or at least responsible for passively allowing the abuse to continue.

Ultimately, the revelations lead to thoughts about the trail of destruction left in the wake of such behaviours. Extensive research has repeatedly linked child sexual abuse with mental health difficulties of later life. Severe depression, anxiety problems, post-traumatic stress disorder and long-term inability to adjust to adult life: some studies have found life prevalence rates of up to 80% in victims of sexual abuse.

Although the media focus is on the activities of celebrities or society leaders, they are clearly responsible for only a tiny fraction of all childhood and adult sexual abuse cases. This high prevalence in the community setting places the problem fairly and squarely in the realm of public health. And as such, it should be the focus of effective education programmes and community-based treatments for sex offenders. The instruction of children and adolescents on human sexuality and the importance of interpersonal skills needed to build satisfying and healthy intimate relationships needs to be emphasised and funded.

Incarcerating the likes of Rolf Harris might satisfy the public's desire for justice or their need for prurient stimulation, but in reality it does little for primary prevention of a continuing societal scourge.

1.8.26 Relationship between timeliness of contact and length of stay in older and younger patients of a consultation-liaison psychiatry service

Rebecca Wood Anne P. F. Wand Glenn E. Hunt

Correspondence

Rebecca Wood (rebecca.wood@sydney.edu.au)¹

date

2015-6

Abstract

Aim and methods The aims were to determine whether the timeliness of contact with a consultation-liaison psychiatry (CLP) service is associated with shorter lengths of stay (LOS), whether this relationship persists for stays greater than 4 days and whether this association varies with age. The length of stay was correlated with the time from admission to contact with the service (the referral lag (REFLAG)), and the REFLAG's proportion of length of stay (REFLAG/LOS) for all 140 in-patients, those with stays greater than 4 days, and for those under and over 65 years.

Results The length of stay was significantly correlated with referral lag and logREFLAG/logLOS for all patients and for patients with stays greater than 4 days. The correlations remained significant for both age groups, but were stronger in the younger group.

Clinical implications Timeliness of contact with CLP was associated with shorter length of stay, particularly in younger patients. Psychiatric factors influencing length of stay in older patients should be studied by CLP services.

Consultation-liaison psychiatry (CLP) has not consistently demonstrated evidence of cost-effectiveness, which is partly related to the difficulty of conducting studies with robust methodology that reflect the real-life operation of CLP services.¹ Some recent studies have demonstrated the effectiveness of intensive psychiatric consultation services with the specific brief of reducing length of stay (LOS).^{2,3} In contrast, studies of services with a traditional model of accepting referrals from a treating team, have found that earlier contact with CLP is associated with reduced lengths of stay.⁴⁻¹¹ Most of these studies have compared length of stay with the proportion of the referral lag (i.e. REFLAG: the time from admission to patient contact with the CLP service) of the length of stay (i.e. REFLAG/LOS).^{4-7,10} This avoids directly comparing lengths of stay with the referral lag, as these are related variables. In support of this, REFLAG/LOS has been found to be independent of length of stay, if the stay is longer than 4 days.¹⁰ The primary aim of this study was to examine if the timing of contact is associated with length of stay for all patients referred to a CLP service, particularly when those with a stay less than 4 days were excluded. Furthermore, CLP services see many frail and complex older patients who utilise proportionally greater resources.¹² Older in-patients with, or who develop, mental conditions while in hospital have been found to have longer lengths of stay.¹³ A secondary aim of this study was to compare the relationship of timeliness of referral and length of stay for patients under and over 65 years old.

Method

Participants

The study was conducted at a 215-bed acute metropolitan general hospital in Sydney, Australia. The CLP service at this hospital consisted of a part-time staff specialist psychiatrist (0.6 full-time equivalent) and a full-time psychiatry trainee. The hospital also employs mental health liaison nurses (0.9 full-time equivalent) who directly manage some ward referrals instead of the CLP service. The CLP service was referred 1.03% of all hospital in-patients during 2012, which is in keeping with previous studies.¹⁴ All consecutive in-patients referred to the CLP service, excluding those referred from the obstetrics and gynaecology department, from 1 January to 31 December, 2012, were included in the study. This exclusion was made because of a difference in referral pathway, as these patients had usually been seen on an ongoing basis during their out-patient antenatal care.

Data collection

Data were collected for patients referred to the CLP service from the routinely used service referral forms and the medical record. Data collected included demographic information, admission date, date of first contact with CLP and number of contacts, length of stay, referring team, referral reason, medical diagnosis, psychiatric diagnosis, Karnofsky score on contact with the CLP service and at discharge. The Karnofsky score was recorded by the CLP team at initial contact and on discharge. This score was devised to quantify ability to carry out normal activities and self-care, and is rated from 0 (dead) to 100 (normal, no complaints, no evidence of disease) and has been established as a valid and reliable score of global functioning.¹⁵

Length of stay was calculated as the whole number of days from admission to the day of discharge from the hospital and if these were the same day this was counted as a length of stay of 1 day. The psychiatric diagnosis was made using the DSM-IV-TR criteria,¹⁶ and multiple psychiatric diagnoses were recorded with identification of the primary diagnosis relevant to the episode of care. This study was approved by the Human Ethics Committee for Sydney Local Health District (RPAH zone).

Statistical analysis

Distributions were described as mean, standard deviation and range. The referral lag was calculated as the whole number of days between admission and first contact by the CLP service and this parameter was used to calculate the proportion of referral lag over length of stay (REFLAG/LOS). Thus, a REFLAG/LOS of 0.5 indicated that a patient was referred halfway through their admission and a REFLAG/LOS of 0.25, at the first quartile of the admission. Logarithmic transformations ($\log\text{REFLAG}/\log\text{LOS}$) were required because the data were positively skewed and logging the values made the data more normally distributed, consistent with previous studies.⁴⁻⁷ These variables were compared with the lengths of stay for all in-patient referrals, and then specifically in groups according to age ('younger' – defined as under 65 and 'older' – 65 years or more). Group differences were determined using one-way ANOVAs and Spearman's correlations were used to assess associations between variables if any of the variables were not normally distributed. All data analyses were performed using SPSS version 17 for Windows. All *P*-values were two-tailed and significant differences between groups were determined using $P < 0.05$.

Results

There were 174 in-patient referrals to the CLP service in 2012. Of these, 34 were in-patients of the obstetrics service who were excluded from the analysis. The demographic profile, referring team, Karnofsky score and number of contacts by the CLP service of the remaining 140 patients are presented in *Table 1*. Patients 65 years and older were more likely to be born overseas, require an interpreter and have more contacts (reviews during admission) than younger patients. In total, seven (5%) in-patients died; four of these were less than 65 years old.

The most common referral reasons for all referrals were depression (45, 32%) and self-poisoning (18, 13%), followed by confusion (16, 11%) and medication review/past psychiatric history (14, 10%). For the two most common referral reasons, there was the greatest discrepancy in the age groups. There was a greater proportion of patients 65 years and older referred for depression (37, 41%) compared with those under 65 years of age (8, 16%); and a greater proportion of those with self-poisoning in the younger group (13, 26%) than the older group (5, 6%).

The most common medical diagnostic categories for all referrals were respiratory (21, 15%), oncological (18, 13%), related to self-poisoning (16, 11%) and neurological (15, 11%) conditions. Between the age groups the largest differences in percentage terms were for self-poisoning (12, 24% for the younger group and 4, 4% for the older group) and urosepsis (0, 0% v. 13, 14%).

The psychiatric diagnoses for both age groups are also presented in *Table 1*. There was a significant association between psychiatric diagnoses and age groups ($\chi^2 = 14.804$ (d.f. = 4), $P < 0.005$). When the four diagnostic groups were assessed individually, it was noted that patients 65 years and over were more likely to have a diagnosis of a mood disorder than younger patients ($\chi^2 = 5.20$ (d.f. = 1), $P = 0.23$), whereas younger patients were more likely to have other diagnoses (*n*

= 14, 28%), such as anxiety or adjustment disorders ($\chi^2 = 7.59$ (d.f. = 1) $P = 0.006$) compared with older patients ($n = 9$, 10%).

The average length of stay for all patients was 19.6 days, whereas the average hospital in-patient stay over the same time period was 3.5 days. The length of stay, referral lag and related parameters are detailed in *Table 2*. The lengths of stay for older patients was significantly longer than those patients who were under 65 years old ($F(1,138) = 6.17$, $P = 0.014$). There was also a significant age group difference for referral lag ($F(1,138) = 4.80$, $P = 0.030$) and logREFLAG/logLOS ($F(1,124) = 4.41$, $P = 0.038$).

When contact with the CLP service occurred during a 1-day admission (LOS = 1) or on day 1 of a longer admission (REFLAG = 0), this introduced a mathematical error in calculating the REFLAG/LOS and the logarithmic transformation of REFLAG/LOS. As the logarithm of zero is undefined and the logarithm of one is zero, these cases resulted in an undefined value for logREFLAG/logLOS. Therefore, these patients ($n = 14$) were not included in some analyses. There were no significant differences between the older and younger groups of patients in terms of the number of these cases.

The correlations between length of stay and the parameters related to referral lag are shown in *Table 3*. There were significant correlations between length of stay and all the referral lag parameters for all patients, which included the correlation between length of stay and referral lag when the values were logarithmically transformed (logREFLAG/logLOS, $r = 0.38$, $P = 0.001$). These relationships were more strongly correlated in patients under 65 years old. A total of 38 patients had a lengths of stay of 1-4 days. The positive correlation of the timeliness of referral and length of stay was only maintained for the REFLAG/LOS with logarithmic transformation ($r = 0.242$, $P = 0.02$) and the referral lag itself ($r = 0.547$, $P = 0.001$) when the 38 patients with a shorter length of stay were removed (*Table 4*).

Other diagnoses included: anxiety disorders, adjustment disorder, borderline personality disorder, somatoform disorders, substance misuse disorders, eating disorders and bereavement.

Discussion

It is acknowledged that the average length of stay of patients with psychological comorbidity is much longer than the overall average length of stay.¹⁷ This is consistent with the results of this study where CLP-referred patients had a greater mean length of stay compared with the length for all patients at the studied hospital. It is therefore important to investigate factors that may relate to this disparity in stay length, which could then become targets of interventions to reduce healthcare costs. In this study, there is a significant association between early contact with CLP services and shortened stays for all patients referred to the CLP service. The association was strongest for patients under 65 years of age. The relationship was maintained for those patients with stays greater than 4 days.

The results regarding timeliness of contact with CLP services are in keeping with most previous studies.⁴⁻¹¹ Only one study, which focused on patients with organic brain disorder referred to a CLP service, did not find that earlier referral predicted a shorter length of stay.¹⁸ Only two previous studies have separated out those patients with stays greater than 4 days.^{3,10} It could be argued that in a hospital stay less than 4 days, the impact of a CLP service is likely to be minimal given the frequently delayed response to psychiatric interventions, both pharmacological and psychological, and the multiple other factors that are involved in a patient's readiness for discharge. Furthermore, it is particularly important for CLP services to demonstrate reduction in lengths of admissions in more complex long-term patients; where there is greater potential cost saving through shorter hospital stays.

None of the studies that have previously examined the impact on the length of stay of the proportion of the referral lag of the length of stay have specified the number of cases that have not been calculated because of the mathematical errors in those cases with a stay of 1 day, or who are referred on the same day of admission.⁴⁻⁷ This is not as important for those cases with a 1-day stay as there is no possibility that a CLP service could reduce this further. However, the necessity to not include those cases that are referred as early as possible does potentially reduce any positive effect demonstrated by CLP services using this measure. Thus, the number of cases that result in mathematical error should be reported in future studies.

Differences between the two groups

There was a significant but comparatively weaker correlation between length of stay and timing of referral in older patients compared with the younger group, which was a disappointing finding as this is a large and important target group for CLP services. This result is in contrast to the study of the rapid assessment, interface and discharge integrated model (RAID), which found that most of the service's cost savings were achieved through reduced lengths of stay and fewer readmissions in the geriatric wards.² The authors suggested these outcomes were related to educating general hospital staff about mental health problems and efforts to link patients to appropriate pathways for community care.² The difference in strength of correlation of the association found in the study presented here may be because of the inherent differences Table 2 Comparison of length of stay (LOS) and referral lag (REFLAG) related parameters by age group Mean (s.d.) rangenAge 64 or younger

(*n* = 50) Age 65 or older

between the two age groups, including the need for an interpreter. The study hospital serves an ethnically diverse population with 48.1% of the hospital's catchment population born overseas, which explains the high level of utilisation of interpreters by this CLP service.¹⁹

The higher number of contacts with the CLP service received by the older group is likely reflective of the longer length of admission. This correlation has been found previously.¹⁰ It is unsurprising that patients who are in hospital longer will see CLP services on a greater number of occasions. In support of this, there was no significant difference between the two age groups in the average number of contacts/day after initial contact with CLP services, despite the greater need for interpreters in the older age group.

Surprisingly, the Karnofsky scores were not significantly different between the older and younger groups of patients, which would suggest that disparity in functional status does not account for the difference in the correlation results. This may reflect the limitations of this scale as it is most applicable to non-hospital-based supportive care settings, such as palliative care, rather than acute in-patient treatment.²⁰

Previous studies have found factors that predict later referral to CLP services, such as higher social vulnerability,¹² referral for depression and psychiatric diagnoses of adjustment disorder and delirium and no psychiatric diagnosis.⁵ Therefore, the profile of psychiatric diagnosis between the younger and older patients may also have contributed to the difference in impact of CLP on length of stay between the two groups. The older patients were more likely to be diagnosed with a mood disorder but, Table 4 Spearman's correlations between referral lag (REFLAG) related parameters and length of stay (LOS) when patients with a length of stay <4 days (*n* = 38) were excluded

Variable *n* Length of stay, *r* *P* Age 1020.090 NS Referral lag (REFLAG) 1020.5470.001 REFLAG/LOS 97a –0.087 NS Log(REFLAG)/log(LOS) 97a 0.2420.02^{7,8} unexpectedly, there was no difference for the diagnoses related to organic brain disorders between the two age groups. There are two possible explanations for the relatively low frequency of referred patients diagnosed with cognitive disorders. First, the study hospital has been found to have low rates of recognition of cognitive disorders by referring teams.²¹ Second, a concurrent delirium-prevention study took place at this hospital that improved staff knowledge and confidence and reduced the occurrence of delirium, which may have reduced the overall number of individuals with cognitive disorders referred.²²

² NS, not significant.

³ Data for seven patients could not be calculated because of consultation on day of admission (REFLAG = 0).

⁴ Data for 14 patients could not be calculated because of a REFLAG = 0 (*n* = 7) or LOS = 1 (*n* = 7).

⁵ Data for seven patients could not be calculated because of consultation on day of admission (REFLAG = 0).

⁶ Data for 14 patients could not be calculated because of a REFLAG = 0 (*n* = 7) or LOS = 1 (*n* = 7).

⁷ NS, not significant.

⁸

Data for five patients could not be calculated because of consultation on day of admission (REFLAG = 0).

There was a greater proportion of patients referred for, and diagnosed with, self-poisoning in the younger group of patients compared with the older group, which may have influenced the difference seen in the two age groups. Psychiatric input is almost universal in patients who are admitted with self-harm as the reason for the consultation is immediately obvious and this may be reflected in earlier referral of these patients by the treating team⁵ and arguably therefore, greater influence of the CLP team on management and discharge planning.

There were other significant differences in the older group of patients in this sample in terms of length of stay and referral lag. The fact that there was a longer length of stay in older patients referred to CLP is not surprising and is in keeping with previous reports.¹³ Three in-patients, all older than 65 years of age, had stays greater than 100 days. These outliers were included in the final statistical analysis but did not significantly influence results when removed. The longer admissions may have been because of factors such as waiting for residential care placement or rehabilitation, and greater medical comorbidity, which are less common in younger patients. Arguably, there is limited scope for CLP to influence lengths of stay when these factors are active.

The longer referral lag for the older patients is somewhat surprising for this service, which has a liaison attachment with the aged care and rehabilitation department. This department referred only 24% of all older (65) CLP patients; a greater proportion of older patients were referred instead by general medical teams (40%), which carry a larger total patient load. However, the longer referral lag in the older patients may also reflect other differences between the younger and older patient groups that influence timing of the referral from the teams. For example, proportionally more older patients were born overseas and required an interpreter. It is possible that delays in accessing interpreters precluded early referral to CLP.

Limitations

This study was conducted in a district hospital with a representative sample of CLP patients. It did not involve alterations to the established CLP service or its referral patterns and was conducted retrospectively, which eliminated the possibility of the Hawthorne effect. Therefore, although based on small numbers, the results are generalisable to most CLP services, which are not designed as specialised acute intervention teams focused upon reducing lengths of stay.

The data collected included many of the parameters that may have contributed to the differences in effect of CLP contact on length of stay of the two groups. However, the re-admission rates of the two groups were not known and this has been suggested as an important potential consequence of reducing length of stay, although this is contested by some studies.²³ No other study that has examined the timeliness of CLP contact has included this parameter,^{4-7,10} but it has been included in other cost-effectiveness studies with different methodology.² This would be an important point for inclusion in future studies of timeliness of CLP contact and lengths of stay.

The limits of interpretation previously discussed regarding the association of timeliness of referral with lengths of stay also apply to this study. The demonstrated relationship between the time to referral and stay length cannot be assumed to be causal and it remains possible that the association is a result of unmeasured factors. These factors may include those associated with the request for consultation or also that the direction of the inference may be reversed.²⁴ Thus, it is not possible to state that this CLP service directly shortens lengths of stay if there is greater proportional involvement in a patient's admission, except to state that a positive association between these two variables has been demonstrated.

Implications

Timeliness of referral was associated with shorter lengths of stay, including for those with stays of more than 4 days. This correlation was weaker for older than for younger patients. There are multiple and complex factors that likely lead to this result, particularly the greater likelihood of the older patients requiring an interpreter and being born overseas, as well as a greater delay in contact with CLP services and a longer length of stay when compared with younger patients. Given the ageing population, further exploration of these factors should be a priority for CLP services, as this is a group where CLP could have a considerable impact and cost-benefit. It is important to evaluate whether better outcomes achieved through hospital-wide education about mental health problems and emphasising clear pathways for community care can be replicated.²

1.8.27 Black Rainbow: How Words Healed Me – My Journey Through Depression

- *Black Rainbow: How Words Healed Me – My Journey Through Depression*

Black Rainbow is Rachel Kelly's story of depression and recovery. It is an eloquent description of her experience of two severe depressive episodes, both with marked anxiety symptoms, and with a strong emphasis on the 'striking physicality of the illness'.

During her first episode, she focuses on the biological nature of her illness, becoming frighteningly dependent on her husband and mother and an attentive psychiatrist, and obsessively preoccupied with her medication. Although this persists in the second episode, she develops a wider interest in factors that may have contributed to her illness, and seeks lifestyle changes and therapy to reduce her vulnerability. She recognises in particular her traits of sensitivity and perfectionism, and the difficulties inherent in combining motherhood with a high-achieving career.

Kelly gains much solace from words, including poetry and prayer, during her prolonged recoveries. Her familiarity with poetry from childhood may underlie this and her accounts of her life when depressed describe a return to a childlike state, where she is cared for by her devoted husband and mother. Her own role as a mother is temporarily lost, something she reflects on later with a sense of shame and failure.

Although she does not spare herself, it must be acknowledged that her experiences are different from most, given her level of privilege. A full-time nanny cares for her children, her psychiatrist visits her at home every couple of days, and she gives up work without obvious financial pressure, assuming a prolonged sick role. Interestingly, she herself questions the value of this and explores the difficulty of needing to be seen as either fully ill or well, and the possibility, often denied, of secondary gain. But her recovery is allowed to be unusually gentle, with a gradual and vividly recounted reawakening of senses dulled by depression, something not always possible for those less fortunate.

More personally, having also experienced depression, I found this a beautiful book. I remain unconvinced that poetry can cure depression (Kelly does not claim this), but it can provide much needed comfort and sets it within the human experience. In W.H. Auden's words from *Musée des Beaux Arts*, 'About suffering they were never wrong, The Old Masters'.

1.8.28 Do psychiatry and neurology need a close partnership or a merger?†

Michael Fitzgerald

Correspondence

Michael Fitzgerald

(profmichaelfitzgerald@gmail.com)^{1,2}

date

2015-6

Abstract

Advances in neuroscience in recent years have blurred the boundaries between psychiatry and neurology. They now have more in common than what divides them and this signals a return to their origins. Many have called for a merger of the two disciplines, which would offer a more holistic approach, whereas others vigorously reject such a move. Limiting neurology to the study of the nervous system and psychiatry to the social brain or affect and its disorders is no longer sustainable. The ongoing separation of the disciplines has had an impact on diagnosis and treatment, on professional isolation and on funding psychiatric research.

Contents

- *Do psychiatry and neurology need a close partnership or a merger?†*
 - *History of the relationship between neurology and psychiatry*
 - *Why are psychiatry and neurology separate?*
 - *Why bring neurology and psychiatry together?*
 - *Professional isolation from medicine*

The relationship between psychiatry and neurology remains a controversial topic, with strong voices opposing a merger, whereas others point out that the future lies with the neurologist/psychiatrist or neuropsychiatrist. ¹ Either way, it highlights the growing disparity in how the disciplines are currently defined and the many areas of overlap.

¹ Michael Fitzgerald was Henry Marsh Professor Of Child And Adolescent Psychiatry at Trinity College, Dublin.

History of the relationship between neurology and psychiatry

The term ‘neurology’ originated with English physician Thomas Willis following his study of brain anatomy in the 1660s, according to Millon.² Subsequently in 1808, Johann Christian Reil, a German physician and philosopher, gave us the term ‘psychiatrie’. However, the two disciplines had common origins. Krishnamoorthy³ points out that the ancients, including Hippocrates, believed that all psychopathology arose in the brain and that this is clearly reflected in writings well into the nineteenth century. On the other hand, this was not a universally held view and some of the ancients believed that hysteria was because of a wandering womb. Even so, the 1845 seminal work on mental illness by Wilhelm Griesinger in *Mental Pathology and Therapeutics* still has a modern ‘ring’ to it in the 21st century. He was a major clinical and academic researcher in a number of hospitals in Europe at the time. The one-time unity of the disciplines was also reflected in the title of the journal Griesinger founded in 1867, *Archives of Psychiatry and Neurology*. For Griesinger, mental diseases were essentially brain diseases, according to Millon.

Over the years there has been considerable opposition to Griesinger. In an interview with Poole,⁴ William Alywn Lishman was severely critical of Griesinger because he ‘tried to make the whole of psychiatry brain science’. I would concur with Lishman that Griesinger went too far and especially ignored environmental influences. I believe the biopsychosocial model of psychiatry can only operate via the brain and Johansson⁵ is correct in his assertion that all mental life will eventually be mapped onto ‘a neuronal substrate’. The split between medicine and psychiatry was lamented by Silas Weir Mitchell as early as 1894. He expressed the view that when the ‘treatment of the insane’ passed completely out of the hands of the profession at large and ‘into those group of physicians (psychiatrists) who constitute a sect apart... what evil this has wrought, what harm it has done to us’, as noted by Andreason.⁶ This split became even more pronounced in the USA between 1935 and 1975, when psychoanalysis largely took over psychiatry there, further increasing the gap between neurology and medicine generally. Ironically, psychoanalysts are now trying to reconnect with neurology through neuropsychology, according to Solms.⁷

The advent of diagnostic imaging has brought a certain degree of clarity to the field. Kandel points out that had imaging been available in 1895 when Freud wrote *Project for a Scientific Psychology* he might have directed psychoanalysis along very different lines, keeping it ‘in close relationship with biology as outlined in that essay’.⁸ It is worth noting that Freud was a superb neuropathologist and neurological scientist, as evidenced in the very ambitious but highly relevant *Project for a Scientific Psychology*.⁹ However, the work also signalled his subsequent move away from traditional science.

Why are psychiatry and neurology separate?

Many views have been expressed on why psychiatry and neurology are separate. In response to White *et al*’s¹⁰ assertion that it is time to end the distinction between mental and neurological illnesses, Ikkos points out that neurology’s expertise is the nervous system and its disorders, whereas psychiatry’s expertise is affect and its disorders.¹¹ Furthermore, he argues that, conceptually, neurology is necessarily at a different level of abstraction from the nervous system. This argument, however, is not the least bit persuasive to me. Miller notes that ‘psychiatry was neurology without physical signs’,¹² whereas Holmes points out that ‘only psychiatry can encompass the social brain’.¹³ There is absolutely no reason why neurologists cannot embrace the social brain and indeed many do today. I believe the split between neurology and psychiatry is in fact artificial.

The chorus of disapproval against neuropsychiatry has certainly grown. Pies argues that psychiatry and neurology cannot simply merge because they use ‘significantly different narratives or... discourses’.¹⁴ He also claims that psychiatry is grounded in human subjectivity and existential concerns and is a ‘discourse of interlacing and multi-layered meanings’ and a ‘narrative about narratives’. Neurology, on the other hand, he believes is fundamentally ‘a discourse of neuroanatomical and neurophysiological relationships’. When a neurologist examines a patient with symptoms not corresponding to known neurological pathways, which Pies sees as ‘functional, supratentorial or psychogenic’, then the patient should be deferred or referred to the psychiatrist. Essentially, Pies’ description of psychiatry has echoes of psychoanalysis. For example, he asserts that psychiatry’s discourses should be understood as a dialectic between a text and a presumed subtext – ‘not unlike the dialectic between *p’shat* and *d’rash* in Talmudic exegesis. That is, beneath the literal words or surface meaning of a biblical text (*p’shat*), there lies a realm of figurative, allegorical, and mystical meanings that must be explicated (*d’rash*)’.¹⁴ Indeed, his description of psychiatry relates to that of the mid-nineteenth century, in my view.

An editorial by Baker *et al* in the *BMJ* in 2012 stated that it is time to tear down the wall between neurology and psychiatry advances in neuroscience.¹⁵ In response to this editorial, Bailey *et al* presented the orthodox psychiatric reaction. They point out that most mental disorders, given our current state of knowledge, have no unequivocal biomarkers and classification has to rely, however imperfectly, on clinical signs and symptoms.¹⁶ They were against a merger of neurology and psychiatry, but in favour of a close working relationship.

The advances in neuroscience prompted Stone & Sharpe to pose a key question: will greater understanding of neuroscience mean that psychiatry will simply follow neurology in abandoning the patients that fail to fit into a reductionistic paradigm?¹⁷ However, I believe that if there were a merger, patients would be less likely to fall through the ‘cracks’. Excessive specialisation is the greatest reason for bringing neurology and psychiatry together. Indeed, even at a research level progress is more likely to occur at the interfaces between specialties and subspecialties. One reason for the lack of progress in psychiatric research in recent years has been because of the excessive specialisation and subspecialisation.

Why bring neurology and psychiatry together?

One of the most compelling arguments for bringing the two disciplines together is that their boundaries are becoming increasingly blurred. Ramachandran observed this fact and declared it was only a matter of time before psychiatry becomes just another branch of neurology.¹⁸ I would dispute that aspect of the argument; there is no question of one discipline ‘swallowing’ up the other. Instead it would be a merger of two equal partners: neurology and psychiatry. If it were to occur, both disciplines would enrich each other enormously.

The separation of the two disciplines has had a somewhat negative impact on diagnosis and treatment. Kanner points out that, in neurology, the separation from psychiatry has led to comorbid disorders being underrecognised and undertreated.¹⁹ In effect, the separation of neurology from psychiatry has led to a separation of the brain from the mind – the physical from the mental – which has been unhelpful for both disciplines. If a merger did occur, the neuropsychiatrist could provide a more holistic approach to the diagnosis and treatment of a patient. In fact, all neurologists and psychiatrists practise basic counselling and brief therapy to varying degrees. It is noteworthy that there are similar brain changes after the treatment of obsessive-compulsive disorder with either medication or behaviour therapy. This increases the link somewhat between neurology and psychiatry.

Aarli points out that psychiatry and neurology have a common route and both share a common basis in neuroscience.²⁰ He also notes that there is much more that unites neurology and psychiatry than divides them. Neurobiological conditions like epilepsy, autism, dementia, delirium, Tourette syndrome, intellectual disability, dyspraxia, speech and language problems are all overlapping. Between neurology and psychiatry Henningsen favours overcoming ‘dualistic’ and often ‘irrational splits’ in the classification and in the practice of medicine.²¹ He agrees with the idea of subsuming mental disorders under ‘disorders of the brain’ because this gives greater clarity and simplicity. Kandel finds it useful to consider that psychiatry and psychoanalysis work at the level of individual nerve cells and their synaptic connections.⁸ Neurology and psychiatry are simply two ‘sides of the same coin’. Certainly in the area of neural plasticity, neurology and psychiatry overlap.

The overlap is also evident in medical journals relevant to the disciplines. In a study of papers published in *Neurology* and the *American Journal of Psychiatry*, Price²² found that less than 5% of papers in the *American Journal of Psychiatry* were on meningitis, epilepsy and headache and that less than 5% of papers in *Neurology* focused on schizophrenia, panic and mania. The proportions for attention-deficit hyperactivity disorder were 23% in *Neurology* and 77% in the *American Journal of Psychiatry*; for autism 30% in *Neurology* and 70% in the *American Journal of Psychiatry*; for ‘mental retardation’ 70% in *Neurology* and 30% in the *American Journal of Psychiatry*. As one can see, there is considerable overlap. Similarly, Raja showed that neurological disease affected 13.05% of acute and 68.9% of chronic psychiatric patients.²³

Professional isolation from medicine

The question of professional isolation has also emerged. The separation of psychiatry from neurology has led Levine to comment that, over the past 30 years, psychiatry has become professionally, geographically and managerially separate from the rest of medicine.²⁴ In many places this isolation has seriously damaged psychiatry and caused major recruitment and funding problems.

In a paper entitled 'Wake-up Call for British Psychiatry', Craddock *et al* were concerned about the evolution of unclear responsibility in psychiatry, which reduces medical student interest because of not being 'proper doctors', and modern psychiatry, diminishing the value of careful diagnosis and reducing psychiatry to a 'nonspecific psychological support'.²⁵ Combining neurology and psychiatry would reduce these problems. It is well-known that medicine and psychiatric illness are closely allied. The merger of neurologists and psychiatrists would improve the care of the patient at the interface and moreover may reduce stigma. Bullmore *et al*²⁶ believe that the merger would reduce stigma, however Jorm & Oh²⁷ did not find that brain *v.* social aetiology affected stigma in their formal study. Read *et al*,²⁸ in their review paper, said that biological psychiatry increases stigma, whereas Bullmore *et al*²⁶ suggested the opposite. This issue remains controversial and opinions as described vary.

There is a great deal of similarity in the training of neurologists and psychiatrists from medical school onwards. At the present time, all psychiatrists are required to spend a minimum of 6 months to a year working in neurology and vice versa. Joint training in neurology and psychiatry would be helpful. These individuals would be dual trained and would require both Royal Colleges to come together to produce this dual-trained neurologist/psychiatrist, as happens in the USA and Germany. Indeed, it may be easier to recruit this neurologist/psychiatrist in the future. In a study of trainers and trainees in psychiatry/neurology, Schon *et al*²⁹ found that psychiatrists were even keener on links between neurology and psychiatry training than neurologists, with psychiatric specialist registrars significantly more in favour.

In conclusion, psychiatrists should return home to neurology and medicine and leave non-medical interventions to non-medical practitioners, for example in relation to specialist or long-term psychotherapy. Neurologists and psychiatrists need to merge into neuropsychiatry or some acceptable title. The merger would admittedly not be easy, but it would be beneficial to both fields in the long term and to patients at a clinical level.

1.8.29 Specialist adult ADHD clinics in East Anglia: service evaluation and audit of NICE guideline compliance†

and adolescent mental health to adult ADHD services. Comprehensive treatment programmes addressing psychological, behavioural, educational and occupational needs were not well developed. Deficiencies were observed in conducting recommended physical examinations. Substance use was prevalent in almost half of ADHD patients.

Clinical implications Greater attention is needed in delivering better transitional arrangements and comprehensive treatment programmes for adult ADHD. More structured training with emphasis on ADHD-specific psychological interventions, physical examination and treatment of complex cases, especially with comorbid substance misuse, should be offered to clinicians.

Attention-deficit hyperactivity disorder (ADHD) is the most common neurodevelopmental disorder. Symptoms of ADHD persist into adulthood and 10-20% of children with a diagnosis of ADHD still meet diagnostic criteria in adulthood. ¹ The National Institute for Health and Care Excellence (NICE) guideline makes clear recommendations for assessment and management of ADHD in adulthood. ² An increasing number of mental health trusts in the UK are implementing this guideline and offer services for adults with ADHD. ³

The Adult ADHD Research Clinic in Cambridge (with a satellite clinic in Peterborough) is a joint venture between the Department of Psychiatry at the University of Cambridge and Cambridgeshire and Peterborough NHS Foundation Trust (CPFT); this tertiary referral centre provided a diagnostic and treatment advice service for East Anglia until it was temporarily suspended in August 2011. In January 2013, a new National Health Service (NHS)-funded adult ADHD service was started by CPFT. Adult ADHD clinics of the Hertfordshire Partnership NHS Foundation Trust (HPFT) are part of secondary mental health services for adults in Hertfordshire providing comprehensive assessment, diagnosis and treatment. Patients stabilised with drug therapy are referred back to their respective general practitioner (GP) through a shared care agreement.

Method

The study was conducted to measure compliance of current practice in two adult ADHD centres with recommendations in the NICE guideline and to further inform service development.

We audited the case notes of 150 patients who were referred to our adult ADHD clinics in Cambridgeshire and Hertfordshire in 2010–2011 against NICE standards using an adapted version of the ADHD (adult) audit support tool.⁴ The percentage of patients was calculated for whom selected relevant NICE standards were met. As a part of the audit, data on patterns of substance use in the ADHD population were also collected. The project had formal approval from both participating trusts.

Results

There were a total of 150 ADHD adult patients selected consecutively for this audit from the two trusts (CPFT $n = 100$, HPFT $n = 50$).

Demographics

The study sample (*Table 1*) was predominantly male (77%), young (66% were 18–30 years old) and White (84%). Ethnicity was not recorded in the case notes of 64 adult ADHD patients. Less than a third of the sample ($n = 46$) was in regular employment, with 51 patients in the unemployed category; the rest were in education ($n = 41$). Employment status was unknown for 12 patients. Fifty-seven ADHD patients had a forensic history.

Transitional arrangements

There was failure in transition to adult ADHD services in 34 out of 53 (64%) cases known to child and adolescent mental health services (CAMHS) with an established ADHD diagnosis (*Table 2*). The reason quoted for non-transition in some cases was receiving treatment from abroad (6 cases); one patient did not want to continue the drug treatment and one patient was having difficulty with the drug treatment. The reason for non-transition in the remaining 26 patients was not known.

Diagnosis and treatment

Good compliance was observed in using (and documenting) diagnostic criteria (DSM-IV and/or ICD-10)^{5,6} across both trusts (89% at CPFT and 100% at HPFT) and assessing psychosocial impairment along with patients' needs, physical health history and coexisting conditions.

Drug treatment was the first line of treatment recommended for 80% (80/100) of the patients at CPFT and 94% (47/50) at HPFT. In HPFT, methylphenidate was the first drug tried in 79% (37/47) of cases and there was 100% compliance in initiation and titration of the methylphenidate and monitoring of side-effects. Before starting the drug treatment, a full mental health and social assessment was carried out for all patients. However, a full physical assessment prior to drug treatment was performed only in 11% of cases (5/47); some physical examination was carried out in 72% (34/47). Risk assessment for substance misuse and drug diversion was performed in the majority of cases (HPFT 94%; CPFT 100%). Of the patients taking methylphenidate, 10% (4/47) received routine blood tests. Antipsychotic use was observed in 3% of patients (5/150); none of these patients carried a diagnosis of psychotic disorder; one patient suffered with a comorbid tic disorder and indication of antipsychotic use in four other patients was not documented in case notes.

A medical or family history of serious cardiac disease, a history of sudden death in young family members or abnormal findings on cardiac examination was reported in only 7 patients, but an electrocardiogram (ECG) recording was performed for 14 patients.

A comprehensive treatment programme including drug treatment and addressing patients' psychological, behavioural, educational or occupational needs was recommended by CPFT for 95% of adults with ADHD. However, drug treatment formed a part of comprehensive treatment programme in only 25% (12/47) of adults receiving treatment in HPFT, where a diagnostic and treatment service is established.

Psychological intervention

Group or individual cognitive-behavioural therapy (CBT) to address the person's functional impairment was considered Table 1 Study sample demographics Age group, years 18–30 31–65 Female 21 13 Male 78 38 Ethnicity White British 72 Other White and Black background 9 Other mixed background 1 Asian 2 Other ethnic background 2 Unknown 64 Employment status Regular employment 46 Unemployed 51 Student 41 Unknown category and other 12 for 15% (15/100) of the service users attending CPFT and 10% (5/50) of service users in HPFT. Psychological treatment was considered in the context of persisting functional impairment or patients' choice as an alternative to drug treatment.

Alcohol and substance misuse

Almost half of the sample diagnosed with ADHD used illicit or licit substances (45%; 67/150). Alcohol (19%; 28/150) and nicotine (17%; 26/150) were the most commonly used drugs. Patients also used caffeine (13%; 19/150); cocaine (10%; 15/150); cannabis (7%; 11/150); amphetamine (4%; 6/150); ecstasy (3%; 5/150); hallucinogens (0.6%; 1/150) and heroin (0.6%; 1/150). All adults with ADHD and comorbid substance use received treatment by clinicians with expertise in both ADHD and substance misuse management (HPFT) or were referred to the drug and alcohol team with a recommendation for starting ADHD drug treatment after the substance misuse management (CPFT). Overall, 85% (57/67) of patients using substances were offered drug treatment for ADHD and 15% (10/67) were referred or signposted to the drugs and alcohol team for treatment of alcohol dependence ($n = 9$) and opiate dependence ($n = 1$).

Person-centred care

Written information about the illness and on the treatment and care was given, along with information on the availability of NICE guidance to the majority of patients (148/150).

Organisational service

Organisational support in terms of training programmes covering diagnosis and management was present at both trusts. Local shared care arrangement between primary and secondary care was present at HPFT only. Under the shared care arrangement, a range of responsibilities from drug prescription to physical health monitoring and annual reviews is transferred when the specialist and the GP agree that the patient's condition is reasonably predictable and the treatment regime has been specified. If the GP is not confident about undertaking this role, then they are under no obligation to do so. In such an event, the total Table 2 Audit standards based on the NICE guideline and trust compliance Compliance with standards % Standards HPFT CPFT Smooth transition for young people with ADHD receiving treatment and care from CAMHS 67 **24*** Diagnosis should meet the diagnostic criteria in DSM-IV or ICD-10 100 89 Diagnosis process should include an assessment of the person's needs, coexisting conditions, social, family and educational or occupational circumstances and physical health 100 100 Drug treatment should be the first-line treatment 94 80 Drug treatment should be started only under the guidance of a psychiatrist, nurse prescriber specialising in ADHD, or other clinical prescriber with training in the diagnosis and management of ADHD 100 * Before starting drug treatment for adults with ADHD: 100 100 • A full mental health and social assessment should be performed • ECG if there is medical or family history of serious cardiac disease, a history of sudden

death in young family members or abnormal findings on cardiac examination 100 (overused in 7 cases) * • Risk assessment for substance misuse and drug diversion should be performed 94 100 • All recommended physical examination **11** (34 received some physical examination) * Drug treatment for adults with ADHD should always form part of a comprehensive treatment programme that includes psychological, behavioural and occupational needs **25 95** (standard recommended on assessment*) Antipsychotics should not be used for the treatment of ADHD in adults 90 100 Methylphenidate should be the first drug tried in adults with ADHD 78 * People taking methylphenidate should not have: * • Routine blood tests 90 • ECG 100 During the titration phase, symptoms and side-effects should be recorded at each dose change by the prescriber 100 * Adherence to NICE guidelines on methylphenidate use 100 * Group or individual CBT to address the person's functional impairment should be considered **10 15** Drug treatment for adults with ADHD who also misuse substances should only be prescribed by an appropriately qualified healthcare professional with expertise in managing both ADHD and substance misuse 100 * Specialist ADHD teams should jointly develop training programmes for the diagnosis and management of ADHD for mental health, social care, forensic and primary care providers and other professionals who have contact with people with ADHD 100 100 Are there local shared care arrangements in place between primary and secondary care? 100 *³⁴⁵ clinical responsibility for the patient remains with the specialist in secondary care.

Discussion

Overall, this first audit of adult ADHD services in East Anglia established good compliance with NICE guidance for assessment and treatment. This confirms that the implementation of NICE guideline recommendations for adults with ADHD is feasible and should therefore be rolled out and evaluated on a broader scale.

There was a failure in smooth transitional arrangements from CAMHS to adult ADHD services. Different reasons were quoted for non-transition in some cases, but for most patients the reasons were not known. The 2010 TRACK study, which looked into the transition policies, procedures and outcomes in Greater London,⁷ found that neurodevelopmental disorders such as ADHD did not come under the eligibility criteria for transfer from CAMHS to adult mental health services. These young people are either retained at CAMHS or referred to GPs or voluntary organisations. For patients with a childhood diagnosis of ADHD there should be a clear transitional arrangement that takes into account the fact that adolescents are the most critical group of patients and that lack of treatment during the transitional period typically results in increased morbidity in adulthood.⁸ Clear communication and transitional pathways between specialist adult ADHD services, CAMHS, community paediatricians and GPs are essential to ensure continuity of care for individuals with ADHD from adolescence to adulthood. Currently, HPFT has a policy and CPFT is developing a transitional pathway, with the aim of improving transitional arrangements.

NICE has explicitly expressed the need for full mental health and social assessment and full history and physical exami-

³ ADHD, attention-deficit hyperactivity disorder; CAMHS, child and adolescent mental health services; CBT, cognitive-behavioural therapy; CPFT, Cambridgeshire and Peterborough NHS Foundation Trust; ECG, electrocardiogram; HPFT, Hertfordshire Partnership University NHS Foundation Trust; NICE, National Institute for Health and Care Excellence.

⁴ Standards for recommended therapeutic interventions were not applicable due to the limited service model (assessment and treatment advice only) at the time of the audit.

⁵ Highlighted low compliances (in bold) are discussed in the paper in detail.

nation prior to the drug treatment.² In our study good compliance was observed in using (and documenting) diagnostic criteria (DSM-IV and/or ICD-10) and assessing psychosocial impairment. A full mental and social assessment prior to starting the ADHD drug was carried out, but deficiencies were observed in conducting (or delegating) recommended physical examination. Interestingly, there was an overuse of ECG investigations. Such discrepancy in practice can be overcome by structured training on adult ADHD with emphasis on physical examination and the use of ECG. This can be complimented by filing a physical examination checklist in the patient file and developing a local protocol for the indication of ECG use in adult ADHD patients with a history (or family history) of cardiovascular problems.

Drug treatment was the first line of treatment in the majority of cases. However, attention is needed in delivering more comprehensive treatment programmes addressing psychological, behavioural, educational and occupational needs. Adult ADHD patients are commonly referred to existing psychological services embedded in local community mental health teams or Improving Access to Psychological Therapies (IAPT) services, which have limited expertise in managing ADHD symptoms and associated impairments. The main issues that affect adults with ADHD include poor skills in prioritising and organising workloads in the workplace and home environment, occupational and educational underachievement, poor interpersonal and social skills and low self-esteem.⁹ Although good evidence of the effects of psychotherapy in adulthood is sparse,¹⁰ new research supports the use of CBT programmes in adults with ADHD.^{11–13} In the UK, the Young–Bramham Programme¹¹ provides an integrated approach for understanding ADHD, adjusting modules to the diagnosis and developing skills to cope with symptoms and associated impairments. The programme offers techniques based on psychoeducation, motivational interviewing, cognitive remediation and CBT.¹¹

Use of antipsychotics was seen in 3% (5/150) of patients referred for ADHD assessment, despite the fact that NICE has ruled out the use of antipsychotic drugs in treatment of core symptoms of ADHD.² The finding highlights the need for more effort in educating clinicians about safety and effectiveness of antipsychotics in ADHD. More comprehensive treatment programmes that address psychological, behavioural, educational and occupational needs should be established and encouraged through the development of local ADHD support groups and in partnership with the voluntary sector. These include anger management, occupational therapy, ADHD life coaching, inter-agency liaison and working with voluntary sector providing employment support and counselling services.

Several longitudinal studies of children and adolescents with ADHD have demonstrated an increased risk of developing substance use disorder compared with matched controls.^{14,15} Factors such as novelty-seeking personality traits, increased impulsivity, self-medication for ADHD symptoms¹⁶ and comorbid disorders such as conduct disorder^{14,17} and bipolar disorder¹⁸ increase the risk of developing substance use disorder in this population. Adults with ADHD are more likely to be past or current users of substances and use these substances in greater amounts. They are also more likely to receive treatment for previous alcohol and drug use disorders.¹⁹

In our sample, substance use was prevalent in almost half (45%) of the ADHD patients. Patients with substance use disorder were appropriately referred to the addiction team and/or managed by clinicians with expertise in treating both ADHD and substance misuse as per the NICE guideline. It is important that mental health professionals receive appropriate training in assessment and management of ADHD with comorbid substance use disorder. Magon & Müller²⁰ discuss treatment studies in this area and provide a treatment algorithm to guide clinicians in the management of adult ADHD comorbid with different forms and severities of substance use disorders.

The national Prescribing Observatory for Mental Health (POMH-UK) launched a new Quality Improvement Programme (QIP) in 2013 focusing on prescribing for ADHD in children, adolescents and adults (www.rcpsych.ac.uk/pomh). The baseline audit on prescribing for ADHD was concluded and results published in a report in September 2013; the report is not available externally, but more information can be obtained by contacting POMH at pomh-uk@rcpsych.ac.uk. The QIP project will generate UK-wide data on prescribing for adults with ADHD and help to identify gaps in service provision.

1.8.30 The borderline of bipolar: opinions of patients and lessons for clinicians on the diagnostic conflict

Emma Richardson Derek K. Tracy

Correspondence

Derek Tracy (derek.tracy@oxleas.nhs.uk)¹

date

2015-6

Abstract

Aims and method It has been observed that some individuals self-diagnose with a bipolar affective disorder and many are later diagnosed with a borderline personality disorder. There is a background context of clinical and neurobiological overlap between these conditions, and fundamental debates on the validity of current diagnostic systems. This qualitative study is the first work to explore the views of patients caught at this diagnostic interface. We predicted that media exposure, stigma and attribution of responsibility would be key factors affecting patient understanding and opinion.

Results Six core illness-differentiating themes emerged: public information, diagnosis delivery, illness causes, illness management, stigma, and relationship with others. Individuals did not ‘want’ to be diagnosed with a bipolar disorder, but wished for informed care.

Clinical implications Understanding patient perspectives will allow clinical staff to better appreciate the difficulties faced by those we seek to help, identify gaps in care provision, and should stimulate thought on our attitudes to care and how we facilitate provision of information, including information about diagnosis.

‘Someone call the doctor,
Got a case of a love bipolar’
– Katy Perry, ‘Hot N Cold’

Diagnosing mental illness can be clinically challenging. The publication of DSM-5¹ and the surrounding debates have raised long-standing arguments about the fundamental validity of classification systems and their potential to variously stigmatise and disempower, or clarify and facilitate treatment and research.² In parallel, neuroscientific research is increasingly moving towards the concept of ‘pathway’ illnesses³ with complex interactions between many risk genes and the environment, and fuzzier boundaries between conditions lying on a spectrum of phenotypes.^{4,5}

Given the difficulties that trained professionals can experience, it is scarcely surprising that patients can have problems self-identifying psychiatric phenomenology and diagnostic labels, and indeed seeking expert help to establish a diagnosis has always been an important part of all healthcare. It has been noted recently that a growing number of individuals are presenting to mental health services having self-diagnosed with bipolar affective disorder (BPAD).⁶ In our experience, many are ultimately diagnosed with a borderline personality disorder (BPD).

Although there are obvious clinical similarities between the two conditions, notably mood cycling between pathological extremes, and a growing literature comparing them, to the best of our knowledge no one has previously tried to explore the opinions of those caught in this diagnostic dilemma. We hypothesised, fitting with the discussion piece by Chan & Sireling,⁶ that a complex combination of factors including stigma, causality and blame, celebrity culture, treatment (and treatability) and perception of staff attitudes would influence patient thinking regarding diagnosis. Furthermore, we anticipated that a better understanding of these issues would afford us greater insight into those we treat, with reflection for how this might positively affect our clinical practice in better communication, making and discussing diagnoses, and developing rational care plans.

Method

Participants

The study recruited eight individuals over a 3-month period in the London Borough of Bromley. All had self-diagnosed with BPAD, but were subsequently diagnosed with BPD. Four had no previous contact with mental health services and had been referred by their general practitioner (GP) to secondary mental health services for assessment due to their concerns that they had BPAD. Four had been within mental health services for varying periods of time (3-32 years): differing diagnoses had been suggested to them at different times, but a diagnosis of BPD had only been made for the first time in the month prior to interview and in the context of the patient having advocated for a diagnostic review in the belief they had BPAD. All participants were White women (7 British, 1 American), although this was not intended through study design, and were aged between 27 and 56 years old (median 35).

Materials

A semi-structured interview was designed following a narrative review of the literature on the presentation and treatments of both BPAD and BPD. This was used to explore participants' opinions on the similarities and differences between the two disorders in six areas: symptoms; the cause of the difficulties; public understanding; availability of clinical information; treatment; and stigma and attitudes. Participants were encouraged to express their thoughts on any topic they felt was important, including any not covered, or not fully covered, by the semi-structured interview.

Procedure

The study received ethical approval through Oxleas NHS Foundation Trust. The London Borough of Bromley's primary care liaison 'intake' team and the home and day treatment services were approached to identify eligible individuals. A letter of introduction outlining the study rationale was sent to 15 potential participants: 8 responded, were screened and deemed eligible, and provided informed consent to take part. All interviews were conducted jointly by both researchers and lasted between 36 and 75 minutes. They were transcribed verbatim (by E.R.) and processed Table 1 The major themes for both diagnoses identified by participants Theme Bipolar affective disorder (BPAD) Borderline personality disorder (BPD) Public information on the illnesses Highs and lows; euphoria; more predictable;

public awareness; positive celebrity exposure;

more internet resources and support groups Quicker mood changes, more exhausting; highs 'not really enjoyable'; unknown to the public; harder to

diagnose Delivery of the diagnosis Given more time by staff; taken seriously Mental health staff less knowledgeable; being kept

in the dark; staff hesitancy; being dismissed; might

present as clinically well; services geared towards

the 'most unwell' rather than people with BPD Illness causes More genetic; brain 'wiring' or 'chemical' problem More affected by the environment, especially early

life traumas; inconsistent parenting Illness management Medications efficacious; psychology has less of a role; established protocols; a more

passive process; staff better trained Primary psychological management but treatments

have limited effectiveness; never recover; needed

more self-awareness and self-management; become

one's own therapist; a difficult process to effect

personality change; symptoms mitigate against

recovery; staff 'anti-medication' even where it

worked Stigma and blame De-stigmatised by public exposure; received

sympathy; outside one's control; people

might fear you Reinforced by perceived staff attitudes and lack of

information; staff hopelessness; personal fatalism;

the name implies blame; responsible for being

unwell; lack of sympathy; receiving a diagnosis

could help remove some self-blame and provide

better self-understanding Relationships with others Supported by friends, family and colleagues;

can be concealed; infrequent nature would

make it less troublesome Insidious destruction and sabotage of relationships;

the need for a good therapeutic relationship;

sabotage professional care offered; seek out

conflict; ever-present and cannot be concealed

from relationships through thematic analysis using the software package NVIVO v.10 for Windows.

Results

Six main themes emerged: public information on the illnesses; delivery of the diagnosis; illness causes; illness management; stigma and blame; and relationships with others. Participants' comments are summarised in *Table 1*.

Public information on the illness

The largest theme to emerge was on 'public information': what these disorders 'looked like' and how one could find reliable information about them. All participants said they had more preceding knowledge of BPAD, primarily from mainstream media sources; most said they had never heard of BPD before being diagnosed and all thought the public at large would be quite ignorant of this diagnosis. With the hindsight of having been diagnosed with BPD, participants thought the two conditions were quite similar, with prominent problematic mood swings occurring more rapidly with a personality disorder. Several clinically delineating factors were suggested, fitting with the literature on the topic:⁷⁻¹⁰ 'self-loathing' was noted to be a core feature of BPD but not BPAD; a couple of participants opined that the rapidity of mood swings made BPD a more 'exhausting' illness, whereas four participants stated the 'highs' in BPD were not the pleasurable or euphoric type they imagined one might experience with BPAD:

'With borderline personality it all happens within sort of minutes, rather than a few months and elated mood for a period of time and then the depression, within the space of an hour you can be down again... which is pretty exhausting.'

Most participants had made attempts to find information prior to and after accessing healthcare, most commonly though the internet. All had found useful information on BPAD, though with the caveat that this is what they initially supposed themselves to have, but only one participant said she found a useful online resource on BPD after being diagnosed. However, this finding, which was the subjective view of the small number of participants interviewed, can be challenged and there are certainly numerous professional and peer websites providing information, support and advice. Putatively, the sense of there being 'less information' might be a better reflection of the celebrity culture that was cited by seven participants as informing their views specifically of BPAD, and no participants could think of parallel examples of hearing about BPD:

'[The public] haven't a clue, never heard of [BPD]. If you went out now and took a questionnaire, a very simple yes/no questionnaire: "Have you heard of?", I bet you would get 90% "no" as a response.'

Delivery of the diagnosis

An interesting finding to emerge was that not one of our sample 'wanted' to 'be bipolar', with all regarding this as a serious illness with no degree of 'social desirability'. The label of bipolar disorder had been self-affixed as a means of trying to understand the difficulties they faced, with a sense that it seemed a 'best fit'. Three of those already in mental health services said they had an awareness that (at least some) staff disagreed with their self-diagnosis, but that they were not offered any alternative. Most said that when the BPD diagnosis was first put to them they did not have enough time to ask questions about this or talk through what it meant, and several used the word 'abandoned' in this context. Several participants initially challenged the diagnosis of BPD, but only in the context of feeling they were being dismissed or pejoratively judged by staff. One recalled a staff member saying 'there's nothing we can do for you', whereas another said she was told, post-diagnosis 'oh well, yeah, that's a personality disorder, so we can't really help that'. Several thought this was because staff 'don't know as much' about BPD as they do about BPAD, and might 'cover their ignorance' through dismissive attitudes. Six participants acknowledged it might be more difficult for professionals to reach the diagnosis of BPD; that BPAD might 'look more obvious'; and that the labile nature of BPD meant their presentations might be erratic – including individuals presenting as clinically well – which might confuse staff. One participant had been seen intermittently for varying durations by mental health services over a period of 30 years before

a diagnosis of BPD was put to her. The discussion arose when she inadvertently saw the phrase on her psychiatrist's computer screen:

'It also makes me angry, not because I have got [BPD], but angry because I have been seen by mental health professionals over the years and no bugger has mentioned anything about this.'

All eight participants stated that when time and care were taken to explain what a personality disorder was, why it might occur, how it might manifest for different people, and how one might try to manage ensuing difficulties that the diagnosis of BPD 'made sense'. In fact, the majority of patients described a sense of relief at having had a long-term difficulty named and contextualised, allowing them to think of how they might prospectively deal with it. Two participants said that they felt sufficiently strongly that the appropriate discussion of diagnosis with patients was so critical a professional training need that they were happy to volunteer time to speak to staff groups about this:

'I felt absolutely over the moon because I had a real thing with a real name and I wasn't being told I was just hysterical and imagining it... so yes, to find out is a huge relief, and it is not that I am a complete bloody arsehole... it wasn't me being obnoxious or out of control as a person.'

There was unanimity in feeling that anyone diagnosed with BPAD would be given more time by staff to talk through the illness implications for them and their family, and that in such discussions professionals would be far less reticent and 'take it seriously'. However, not all help-seeking interactions with staff were reported in negative terms: one participant recalled a very supportive one-to-one session with her key worker, shortly after she had received her diagnosis:

'[He said] "it's something like having blue eyes, it's nothing you can help and it's nothing to be ashamed of, it is just the way you are and it's treatable", and he was very nice about it you know... it made me feel better'.

Illness causes

The literature supports an important role for environmental factors, particularly early life trauma, in both BPD¹¹ and BPAD,¹² although sexual abuse rates may be greater in those with BPD.^{13,14} Twin studies have shown a high degree of heritability for BPD,¹⁵ although this is still less than that of BPAD.¹⁶ Fitting with this there was reasonable unanimity among participants that BPAD was 'more nature' and BPD 'more nurture', with BPAD seen as variously a brain, neurological or chemical disorder that one was more likely to inherit and BPD a condition that developed in light of environmental stressors and traumas, with particular emphasis given by most (5) participants to the notion of inconsistent or unloving parenting:

'I have always thought that bipolar [disorder] was mainly a chemical imbalance of the brain and that to me it didn't seem that it was... environmentally affected. Borderline [personality disorder] seems to me as less of a chemical problem and more of a behaviour problem or reaction to environment and experiences.'

Illness management

Participants' comments on illness management were, in the main, in line with the principles encapsulated in national guidelines.^{17,18} Most considered that medication was the cornerstone of treatment for bipolar affective disorders. In this way treatment for those with a bipolar illness was seen as a more passive process, wherein one could 'just take the medication and get on with it':

'The way I look at it is, if someone is diagnosed with bipolar [disorder] and... you get to a stage where you work out what medication suits them, I am therefore assuming they would operate as a normal functioning human being. Now there isn't a pharmacological proposition for the likes of us, then we have to carry on in our own world and have to just get on with it, so we can't reach that level of normality, can we?'

Six participants expressed frustration that although they did not think medication was the primary treatment of BPD, staff had very negative views of issuing them any medication, certainly when compared with patients with BPAD:

‘I know you have this thing about why are people with [borderline personality disorder] given all this strong medication. From my experience I needed that to bring me down and keep my feet on the floor, because I was so impulsive and if I didn’t have that medication I probably wouldn’t be here as I would’ve jumped off a bridge or in front of a car.’

Participants thought that psychological engagement was more of a critical factor for BPD than BPAD, although interestingly five believed that the very nature of symptoms experienced in BPD mitigated against good outcomes: a labile mood could make it hard to predictably and consistently engage with therapy; and individuals might demonstrate impulsive sabotaging acts against those trying to help them that would ‘prove’ their worthlessness. One participant thought people with personality disorders could become ‘defensive and stubborn’ when offered advice, whereas another thought them ‘very sensitive’ to perceived criticisms compared with those with BPAD, and expressed her own general sense when speaking to staff that ‘I’ve tried everything and none of it works... it’s hard to imagine someone else can tell me how to deal with this’. Participants thought that individuals with BPAD were ‘more predictable’, whether having low or high mood, which would make it easier for the patient and clinician to engage and treat them.

Stigma and blame

All participants thought that significant stigma surrounded all mental illnesses: individuals with both BPD and BPAD were seen as likely to experience prejudice, with, in broad terms, neither disorder clearly ‘better’ or ‘worse’, although there is a body of literature to suggest that BPD carries a particularly strong sense of stigma.¹⁹ The commentary by Chan & Sireling⁶ noted the potential role of public exposure, celebrity discussions and TV programmes in portraying BPAD in a positive light and our work reflected this nuanced aspect, with most participants saying such public discussions had helped de-mystify BPAD:

‘It is quite uplifting, you look at someone like Stephen Fry, because if he has got it and he is still getting out and about and having a career, it’s not so bad for a person, I know... but borderline, I mean I don’t know.’

Although the point was not explicitly raised by any participant, and indeed denied by several, it remains possible that this ‘celebrity culture’ and media portrayal of BPAD might have imbued this condition with an implicit degree of social desirability and association with positive attributes such as artistic creativity, and therein account for the fewer negative comments accrued when compared with BPD. Staff attitudes were also seen to more negatively impinge on BPD, with the lack of discussion leading to a sense that ‘there’s something wrong with [borderline personality disorder]’. The very term borderline personality disorder was described by four participants as being demeaning, with one noting that it felt like a judgement on her life even though ‘there are aspects of my personality which are lovely, you know, I can be quite funny and humorous’. In 2003 the Treatment and Research Advancements National Association for Personality Disorders (TARA-APD) campaigned to change the name and designation of borderline personality disorder in DSM-5; more recently an internet survey of 646 individuals diagnosed with BPD noted that a considerable percentage thought this should be renamed in DSM-5, potentially to include the terms ‘emotion(al)’ and ‘(dys)regulation’.²⁰

A final delineating aspect with regard to stigma was a sense of attribution of blame: seven participants felt that they, staff and the public at large would regard someone with BPAD as a ‘victim’ of a serious mental illness, whereas those with BPD were more likely to be perceived as ‘perpetrators’ or creators of their problems, enhancing feelings of guilt, shame and self-loathing. Nevertheless, several participants noted that confirmation of the diagnosis of BPD had alleviated some of this self-blame, with a sense that they had ‘a real problem, like other people had’.

Relationships with others

In discussion of the relationships with friends and family as well as professional staff, all participants felt this was a more difficult issue for those with BPD than for those with BPAD. Interestingly, in both cases participants felt blame could at least in part be attributed to those with a BPD, as well as to prejudicial attitudes:

‘they would be more understanding [of BPAD]... with borderline it is just these personality traits that are very difficult to live with... it is just a lot of work and you have to understand and I don’t think people can be bothered to try and understand other people.’

‘I seem to have this dependence on the therapist or psychiatrist... sometimes I would get really angry and lose my temper with people who are caring for me, I understand why professionals would dread [individuals with BPD] more than [those with] bipolar [disorder].’

In general, BPADs were seen as something that might be more easily concealed from others, whereas a personality disorder was too pervasive for this:

‘Nobody at her work knew [my friend] had bipolar. It has never been discussed, never been an issue, why? Because there has not been any abnormality of behaviour. But [people who have a borderline personality disorder] are doing it all the time.’

Discussion

Both BPD and BPAD are common mental health conditions, affecting 4–12% (BPD)²¹ and 1–4% (BPAD)²² of the population, and of course they can occur comorbidly.²³ For professionals there are apparent similarities between them, and several recent systematic reviews have explored this topic.^{13,24,25} As well as an overlap in symptomatology there are interesting data indicating that both conditions demonstrate some similar neurobiological changes, especially to the limbic system and in frontolimbic connectivity – although with differences in amygdalar and hippocampal alteration – and to serotonergic and dopaminergic neurotransmitter systems. Nevertheless, most work supports the concept that these two disorders are fundamentally distinct conditions.^{7,13,26–28} Despite this broad literature, to the best of our knowledge no previous work has explored the opinions of those caught in the diagnostic dilemma on the similarities and differences between the two disorders.

Study limitations

Our study included only eight participants, all women and from a single London borough, and this may hinder the generalisability of our data. Furthermore, there might be a responder bias, and the opinions of the seven potentially eligible participants who declined to consider taking part might have been quite different. No clear differences in response were noted between those newly referred to mental health services and those already receiving care for some time, and the latter did not ‘know more’ about BPD. None of our participants were continuing to question their diagnosis of BPD, and all had had some time to contemplate it before the interview. There were more negative comments expressed about BPD, even if participants said they did not think this was a ‘worse’ condition. We did not identify, and are not aware of, any patients presenting with concerns that they have BPD only to be diagnosed with BPAD: this may be less likely due to the identified issue of public awareness. No viewpoints of those with BPAD on the difference between the disorders were obtained.

Implications

Our study suggests that people do not ‘want’ to be diagnosed with bipolar affective disorders; they are looking for information and clear communication with professionals. Whereas previous work has qualitatively explored the thoughts and feelings of those diagnosed with BPD (and BPAD), none has evaluated a diagnostic interface and prior knowledge of the disorder. One cannot receive appropriate treatment for something one is unaware of, and there must be many individuals suffering psychological distress and the symptoms of BPD without being aware of the nature of their illness and struggling to define their difficulties.

At the broadest level, there are interesting questions about the role of the mental health professions and professional bodies such as the Royal Colleges of Psychiatry and Nursing and the British Psychological Society in the UK, third-sector organisations and the media in the discussion of mental health disorders. Such organisations, and many others, continue to roll out worthy campaigns to target stigma and discrimination in mental health. Information on specific mental health difficulties, including BPD, is available, including a leaflet produced by the Royal College of Psychiatrists and designed to be read by non-professionals (<http://www.rcpsych.ac.uk/healthadvice/problemsdisorders/personalitydisorder.aspx>). However, a critical question is how could one look for what one does not know exists? Most participants noted that their information about mental ill health came, at least initially, from general media and in particular from awareness of celebrities whose mental health difficulties had been well documented. Stephen Fry was held out as a particularly positive role model by most of our participants: his willingness to talk publicly and openly was cited as being both inspiring and informative, and had a marked impact on participants’ conceptualisations about their own problems, including influencing their thoughts on their diagnoses. A perhaps unanswerable question is how to achieve a similarly positive and educational context for BPD. Whether campaigns such as that by TARA-APD have significantly raised the profile of BPD remains uncertain.

Nevertheless, the challenge to mental health staff faced with patients in this diagnostic dilemma is clear. Our patients are asking us for information, for time to think about and question what we say, and for the respect of being treated honestly in such discussions. A recent review by Gask *et al*⁹ noted the critical importance of hope, optimism and an accessible ‘trusting relationship with an open, non-judgemental manner’ when managing personality disorders.

Diagnosis is part of healthcare, and while important debates about the validity of our existing models continue – and the British Psychological Society expressed concern in 2011 about the potential medicalisation of what might be considered normal variation in behaviour²⁹ – a diagnosis can help conceptualise difficulties and instigate appropriate and evidence-based care. Although professionals can be circumspect about making a diagnosis too rapidly (and many psychiatrists have been traditionally taught not to diagnose a personality disorder on first assessment), there is a very real danger that failure to do so can hinder care and mean that individuals receive no, or inappropriate, treatments that might not help, and indeed that might cause harm. If we are withholding or being unduly circumspect and hesitant about diagnosis, then we must ask ourselves why, and consider how our (in)actions might make a patient feel. Failure to openly discuss diagnostic thoughts risks perpetuating stigma and self-blame that can already be a common part of BPD. All our participants stated that having an accurate diagnosis was a hugely important step in self-reflection and understanding, and in considering their future, even if it came with other negative aspects.

In our sample several participants acknowledged that the diagnosis of a BPD might be hard to make; that the inherent lability could make it difficult to accurately assess the mental state and risk; and that the very nature of the symptoms suffered could make it challenging to consistently engage with a therapeutic programme and the staff providing care. There are real professional dangers of negative counter-transference in such situations and of projecting our frustrations or disappointments – current or historically accumulated – on those we treat, potentially furthering a sense of abandonment and rejection. Trust and the therapeutic alliance is a critical component of the relationship and process of our engagement with all patients, even if not addressed explicitly, and seldom more so that those with BPD,³⁰ many of whom have had a significant history of past abandonments. We must be careful in suppositions that people are ‘choosing’ or ‘want’ diagnoses to ‘escape’ or deny a personality disorder: our data would not support such a hypothesis.

We believe there are many positives for patients and staff to take from this work. The debates on diagnostic systems and the neuroscientific research will continue, but what is being asked for is freely available: open and honest discussion, respect and information. Disagreements are part of clinical life and outcomes are not always as optimal as one would like: however, these factors can only be worsened by not listening. Our attitudes and self-reflection are vital: it is an interesting fact that BPAD is often conceptualised as a ‘serious mental illness’, but BPD is not, when the evidence

suggests functioning and prognosis can be as bad in the latter.²⁴ Few staff working in mental health can be unaware of the frequency and often profound severity of BPD, but there is a critical issue of perception: of allowing those we try to help to see our concerns, and making them feel listened to in clear dialogue. Borderline personality disorder was initially named as it was felt to ‘border’ on a psychotic state, but perhaps bordering on a bipolar one would be more apposite.

We are grateful to those who gave their time to talk openly and thoughtfully about the difficulties they have faced. We hope they will derive some satisfaction from the fact that this may help the care of others.

1.8.31 Early Psychosis Intervention: A Culturally Adaptive Clinical Guide

- *Early Psychosis Intervention: A Culturally Adaptive Clinical Guide*

This book is written by multidisciplinary pioneers in early psychosis intervention in South-East Asia and is a product of two decades of development in this rapidly growing region, a cultural mosaic. In the foreword, Professor Patrick McGorry highlights that the essence of such intervention is to bring maximum recovery for young people with psychotic experiences.

The book is unique and attempts to connect early psychosis with transcultural psychiatry. The first part describes service structures of early psychosis programmes in Hong Kong, Singapore, Japan and Korea. The authors define early psychosis afresh by introducing the culturally adaptive translation in Chinese, *sijueshitiao*, meaning imbalance of thinking and perception. The second part discusses the cultural issues in management of early psychosis. The authors tactfully compare and contrast different Asian beliefs of mental illness including Islam (unbalanced lifestyle), Hindu (bad karma), Buddhism and Taoism (attacks by ghosts) and Christianity (demonic possession). The local cultural beliefs may increase duration of untreated illness because patients and families often consult their traditional healers instead of medical practitioners.

The authors present interesting data on public misconceptions about psychosis. They highlight salient points in early psychosis treatment such as recommended dose of each antipsychotic drug, topics to be covered in peer support groups, strategies for family work and medication adherence. I personally found the chapter illustrating the state-of-art information technology and database design very interesting.

I highly recommend this book to mental health professionals who are keen to establish early psychosis intervention services in other parts of Asia, Africa and South America. The authors carefully insert clinical vignettes throughout the book and enrich its clinical relevance. Mental health professionals working for well-established early psychosis

2015-2

Abstract

Aims and Methods The UK's Driver Vehicle Licensing Authority (DVLA) requires individuals to report if they have a medical condition such as alcohol dependence. General Medical Council guidance indicates that medical practitioners should ensure patients are aware of their impairment and requirement to notify the DVLA.

Results In a survey of 246 people with known alcohol dependence, none were aware of advice on driving given by medical practitioners and none had self-reported. In addition, 362 doctors, either attending a college symposium or visiting a college website, were asked about their knowledge of DVLA regulations regarding alcohol dependence: 73% of those attending the symposium and 63% of those visiting the website answered incorrectly. In Scotland, over 20 000 people have alcohol dependence (over 1 million people with alcohol abuse), yet only 2548 people with alcohol problems self-reported to the DVLA in 2011.

Clinical implications If the DVLA regulations were implemented, it could make an enormous difference to the behaviours of the driving public.

The dangers of driving while under the influence of alcohol are well known. Alcohol remains a significant public health risk and has been identified as the most important factor contributing to the occurrence of severe to fatal automobile crashes. ¹ Acute alcohol intoxication affects the behavioural and coordinating functions necessary for driving. ² Alcohol consumption at lower levels also interferes with performance on neurological and psychological tasks, ³ which include

a wide variety of cognitive processes, ⁴ affects immediate memory span and short-term memory ⁵ as well as motor speed and coordination. ⁶

Driver licensing in Great Britain is governed by the third European Commission Directive on the Driving Licence. ⁷ Annex III of the directive provides the minimum medical standards for driving expected across all member states. It states: 'Driving licences shall not be issued to, or renewed for, applicants or drivers who are dependent on alcohol or unable to refrain from drinking and driving. After a proven period of abstinence and subject to authorised medical opinion and regular medical check-ups, driving licences may be issued to, or renewed for, applicant or drivers who have in the past been dependent on alcohol'. ⁷ The persistent misuse of drugs or alcohol, whether or not misuse amounts to dependency, is a relevant disability in the Motor Vehicles (Driving Licences) Regulations 1999.

Guidance from the Driver and Vehicle Licensing Agency (DVLA) states that persistent alcohol misuse requires licence revocation or refusal until a minimum 6-month period of controlled drinking or abstinence has been obtained, with normalisation of blood parameters. Alcohol dependency requires licence revocation or refusal until a 1-year period free from alcohol problems. ⁸ Abstinence will normally be required and medical reports from the driver's general practitioner (GP) are necessary, usually in conjunction with an independent medical report.

The aim of this study was to ascertain the knowledge of 'recovering alcoholics' of the DVLA regulations related to driving a car while still 'actively drinking' and whether they could recollect whether their health professional had given them appropriate advice. In addition, a total of 362 senior doctors, either attending a Royal College of Physicians (Edinburgh) symposium or visiting a Royal College of Physicians (Edinburgh)/Royal College of Psychiatrists (Scotland) website, were asked about their knowledge of DVLA regulations and alcohol dependence. The terms 'recovering alcoholics' and 'actively drinking' are recognised and regularly used by Alcoholics Anonymous. ⁹

Method

Patients

In total, 246 'recovering alcoholics' attending five different Alcoholics Anonymous (AA) meetings in Ayrshire, Scotland were surveyed during 2011. The individuals surveyed had all previously been heavy consumers of alcohol (> 100 units/week). They had attended AA meetings regularly for over 6 months and by self-report had been free of any alcoholic intake for at least this period. Membership of the Fellowship of AA is described in Tradition 3: 'The only requirement for A.A. membership is a desire to stop drinking'. ⁹ (Traditions and 'Steps' are the foundation of AA.) Of the sample, 194 (79%) were male and the ages ranged from 21 to 80 years, median 57 years. As anonymity is a very important aspect of AA, further demographic detail was not collected. All individuals questioned were in possession of a current driving licence and had the willingness and apparent capacity to provide consent for participation in the survey. They were asked to complete a brief, anonymous questionnaire (unsupervised) about their knowledge of DVLA regulations and about the information that they had been given by health professionals. Those involved in any drink driving offences were excluded. The survey was undertaken with the full knowledge of Fellowship of AA. However, as according to the AA Tradition 6: 'Our groups ought never endorse, finance or lend our name to any related facility or outside enterprise, lest problems of money, property and prestige divert us from our primary purpose', ⁹ the work was conducted independently of the Fellowship. The questionnaires were distributed to members for completion before or immediately after AA meetings (*Table 1*).

Participant survey results

Question	Yes, <i>n</i> (%)
1 Are you a recovering alcoholic?	246 (100)
2 Do you have a driving licence?	246 (100)
3 Do you drive a car?	246 (100)
4 Did your problems with alcohol lead you to see your GP?	185 (71)
5 Do you recollect your GP giving you any advice about driving?	0
6 Have you ever been admitted to hospital due to your alcohol problems?	137 (56)
7 When you were in hospital do you recollect getting any advice about driving?	0
8 Do you recollect if your GP or a hospital doctor have ever asked you/told you to stop driving?	0
9 Have you ever informed the DVLA that you have/had a problem with alcohol?	0
10 Do you think that it would be sensible/reasonable to be told not to drive if you still had an active problem with drinking?	223 (91)
11 Have you ever driven a car knowing that you were under the influence of alcohol/were over the limit (including the morning after)?	246 (100)
12 Have you ever driven a car when you were withdrawing from alcohol?	194 (79)
13 Did you ever stop driving or think of not driving while still actively drinking?	103 (42)

GP, general practitioner.

Doctors

There were nine questions posed to doctors at the symposium and online: three were based on alcohol-related problems, three on cardiology, two on psychiatric issues and one on diabetes. Of the physicians who attended the Royal College of Physicians (Edinburgh) symposium, 292 took part in the survey and 70 doctors did so online.

The alcohol and driving question stated: 'If a patient is admitted to hospital with an alcohol dependence problem (requiring benzodiazepine treatment for withdrawal symptoms) the patient must be advised to inform the DVLA, who will revoke their licence for a year'. Respondents could answer that this was true, false or that they did not know the answer.

Results

The 246 'recovering alcoholics' answered all 13 questions (*Table 1*). All 246 had a driving licence and drove a car; 185 (71%) went to see their GP with an alcohol problem and 137 (56%) were admitted to hospital with alcohol problems. None recollected their GP or a hospital doctor asking them to stop driving. In addition, none had informed the DVLA that they had a problem with alcohol.

At the symposium, 73% physicians answered the question incorrectly and on the website 62% of physicians and psychiatrists gave an incorrect answer; 9% of those at the symposium indicated that they did not know the answer. With regard to questions on alcohol-related seizures and alcohol misuse, 64% and 62% respectively answered incorrectly. The other non-alcohol related questions demonstrated a higher level of knowledge among the symposium audience (13–42% incorrect).

Discussion

This study has shown that awareness of individual responsibility among recovering alcohol-dependent individuals is low and recollection of discussion with health professionals about driving is non-existent. The people we surveyed were regular attendees of AA meetings. This is likely to be a group who have developed a high level of understanding and insight into their alcohol problem and would be willing to engage in open discussion with doctors. A few specialist alcohol services in Scotland provide written information to newly referred patients alerting them to their responsibilities regarding the DVLA, but it is not known whether patients recall this (in the short or long term) and clearly very few act on the advice. It is also probable that a significant proportion of health professionals are not aware of the advice that they should be giving in relation to driving and alcohol dependency and alcohol misuse. These small but significant doctor surveys reflect that knowledge of alcohol-related DVLA issues is poor among hospital doctors. The Royal College of General Practitioners (Scotland) was invited to participate but declined this opportunity. General practitioners form a key professional group regarding health issues and driving. This lack of knowledge in 'recovering alcoholics' may reflect a number of elements, including lack of knowledge in health professionals, lack of willingness of health professionals to discuss the issue or lack of recollection from the individuals themselves. In addition, it is possible that health professionals who are aware of the appropriate advice are unwilling to discuss the topic in case it would adversely affect their relationship with the patient.^{10,11} In particular, there may be a reluctance to raise the issue of driving in case this becomes a disincentive for patients to be open about their drinking.

The DVLA guidelines⁸ give advice on a number of medical conditions that may affect driving, including diabetes mellitus, epilepsy, sleep apnoea, dementia, psychiatric disorders, as well as alcohol misuse and alcohol dependency. If a patient is admitted with a 'first' seizure, most doctors and health professionals would know to advise the patient that they may not drive for a year.¹² In addition, if a patient is started on insulin therapy, then most doctors and health professionals, particularly those associated with the management of diabetes,¹³ would know that they should advise their patient to inform the DVLA.

The definition of alcohol misuse used by the DVLA – 'A state which, because of consumption of alcohol, causes disturbance of behaviour, related disease or other consequences, likely to cause the patient, his/her family or society harm now, or in the future, and which may or may not be associated with dependency'⁸ – is helpful but can be difficult to interpret in the context of dealing with patients in an acute medical setting. The definition of alcohol dependence used by the DVLA – 'A cluster of behavioural, cognitive and physiological phenomena that develop after Table 2 Notifications to DVLA on UK licence holders with alcohol misuse or alcohol dependence from all sources, 2006–2011

Year	2006	2007	2008	2009	2010	2011

difficulties in controlling its use, persistence in its use despite harmful consequences, with evidence of increased tolerance and sometimes a physical withdrawal state'⁸ – is much clearer and, particularly in relation to alcohol withdrawal, much easier to implement clinically. If more hospital doctors were aware of the DVLA repercussions of making the diagnosis of alcohol dependence or misuse, it may make the use of alcohol withdrawal regimens more problematic. For example, the Clinical Institute Withdrawal Assessment – Alcohol (CIWA–A) scale¹⁴ is commonly used in alcohol withdrawal situations in medical wards. Perfunctory attention to the history and frequent overreliance on unsubstantiated alcohol use can lead doctors to the inappropriate use of CIWA–A, which could have significant consequences on lifestyle and driving advice they give their patients.¹⁵

The responsibility for ensuring that the patient informs the DVLA lies with the licence holder. The guidelines for fitness to drive are available on the DVLA website (www.dvla.gov.uk) and are revised every few months. The website states that the General Medical Council (GMC) has issued clear guidelines to doctors with regard to their responsibility to the DVLA:¹⁶ 'the DVLA is legally responsible for deciding if a person is medically unfit to drive. They need to know when the driving licence holders have a condition, which may, now or in the future, affect their safety as a driver'. It also states that if a patient has such a condition, the doctor should 'make sure that the patients understand that the condition may impair their ability to drive' and 'explain to patients that they have a legal duty to inform the DVLA about their condition'. In addition, it states that doctors can 'suggest that the patient seek a second medical opinion, and make the appropriate arrangements for the patient to do so' if the patient is unwilling to accept the diagnosis (personal communication, DVLA freedom of information request responses 2010/2011). Patients who fail to notify the DVLA of a medical condition without reasonable excuse are guilty of an offence. Failure to notify the DVLA also invalidates their motor insurance cover. Current notification levels of alcohol misuse and alcohol dependency received by the DVLA are very low (*Table 2*). A small number are also reported through a third party (which may be family, friend, health professional, etc.).

Situation in Scotland

In the Scottish population, the estimated prevalence of alcohol dependence at 4.9% and of harmful and hazardous use at 27.9% indicates around 20 000 people with dependence and over a million with harmful or hazardous use.¹⁷ A high proportion of these are likely to be driving licence holders since approximately 86% of the UK adult population has a driving licence of some sort, with 73% being full UK licences.¹⁸ Most licence holders obtain their licence in young adulthood, before alcohol dependence develops. Therefore it is not unreasonable to estimate that there may be in excess of 150 000 licence holders with alcohol dependence in Scotland alone and a further 700 000 licence holders with harmful or hazardous use of alcohol. This represents an enormous cohort of people who should be reporting their alcohol problems to the DVLA. The Department for Transport report on the attitudes of health professionals giving advice on fitness to drive (including for people with alcohol and drug misuse and dependency) contains a series of recommendations for improving such advice.¹⁹ Key among these are recommendations on the inclusion of a question on fitness to drive in the exit examination for all relevant medical specialties, the creation of clear, well-signposted guidelines for use in general practice and the production of a clear flowchart for common medical conditions to which healthcare practitioners can refer.

Limitations

There were some limitations to the study. The questionnaires had not been externally validated but the questions were simple, straightforward and easy to understand. We accept that the group of ‘recovering alcoholics’ questioned involved only a limited number of adults in Ayrshire. AA meetings provided a venue where motivated individuals who had recognised their problem with alcohol were present; it might be considered that their recall of advice would be greater than that of those who chose not to attend AA. Alternative methods for assessing recall of medical advice, such as surveying patients at addiction clinics, could have suffered from bias as the clinic staff became aware of the study. A presumption was made that none of the attendees experienced alcohol-related brain damage or other memory loss syndrome and could recall accurately the discussions that they had had with their medical advisers about their drinking. The study demonstrated non-existent knowledge of the DVLA regulations relating to alcohol dependence and misuse among a group of ‘recovering alcoholics’ plus a poor level of knowledge in a group of senior doctors. Very importantly, the figures obtained from the DVLA indicate very low levels of self-reporting. During the 2011/2012 period there were 38 737 alcohol-related hospital discharges in Scotland²⁰ and almost 97 830 alcohol brief interventions completed,²¹ which give numerous opportunities for alcohol advice. If the DVLA regulations were implemented, it could make an enormous difference to the understanding and behaviours of the driving public.

1.8.33 Personal experience: Suicide and psychiatric care – a lament

Jeremy Holmes

Correspondence

Jeremy Holmes (j.a.holmes@btinternet.com)¹

2015-2

Abstract

A personal bereavement from suicide prompts a critique of current mental healthcare. Fragmentation, lack of long-term attachment to a tenured professional, the dearth of family therapy, and professional ambivalence are identified as weaknesses in current provision. Implicit is the case for change in UK psychiatric services, both structural (need for long-term therapies) and cultural (need for a mentalising rather than protocol-driven, ‘choice’-led ethos).

Recently, a close relation of mine died, through suicide. An intelligent, beautiful, creative young woman, for nearly 20 years she had suffered from bipolar disorder, for which she had received intermittent psychiatric care. Although the scale of my grief is minuscule compared with that of her immediate family, the poignancy was magnified, because I am, or was, a psychiatrist.

Inevitably, as one vainly tries to elude the irreversibility of time and loss, I have replayed in my mind the story of her illness and last days. Inescapably, too, I have felt on her behalf and that of her family a degree of guilt, anger and regret. Surely things could have been done differently, I think to myself. I look back on the patients with bipolar disorder I have treated over the years – those who have survived, and those unforgettable few, who, like my relative, took their own lives. I think of lessons learned, and not learned.

Although many aspects of psychiatric services have undoubtedly changed for the better (e.g. patient empowerment, multidisciplinary teamwork), there are also ways in which current psychiatry lets down its patients, especially when suicidal. What follows is perhaps yet another ultimately futile, counterfactual ‘if only...’ narrative that typically haunts the bereaved. But for all that, it may contain some validity.

Death and psychiatry

There can be few psychiatrists who have not at some point been faced with the death by suicide of a patient under their care. ¹ Although psychological autopsy and critical incident review are unexceptionable, hospital authorities react very differently to death by suicide as compared with other deaths. Compared with the acceptance of the inevitable mortality associated with chronic physical illness, when a patient with a psychiatric illness takes their own life there is invariably an undercurrent of blame. ² Bipolar disorder, major depressive disorder and schizophrenia have a 20% mortality rate, ³ comparable with multiple sclerosis ⁴ or many forms of cancer, but the reactions they evoke are very different. This is reflected in the way that death by suicide is classified and recorded. Bipolar disorder, schizophrenia or borderline personality disorder are not in themselves ‘causes’ of death to be determined by a coroner. Suicide is grouped with the other stigmatised ‘-icides’, alongside homicide and infanticide.

Changing classification might well be desirable, but stigma-reducing biomedical attributions of ‘illness’ will still fail to capture the essence of the psychological pain with which the survivors are inundated. It is hard to accept that we can be so helpless in the face of unconscious forces over which we appear to have little control. The challenge to our sense of omnipotence and sense of freedom is overwhelming. There must, it seems, be an explanation, a narrative – someone or something to blame.

Changes in psychiatric care – and their consequences

Official enquiries into untoward deaths usually end up with bland banalities such as ‘poor communication’ and ‘failure of adequate risk assessment’. ⁵ But these gloss over the negative consequences of the many changes that have overtaken psychiatry in the past few decades.

The first is fragmentation of care. In the UK an ill patient is likely to be ‘looked after’ by at least three different groups in the course of her illness: the in-patient team, the assertive outreach team, and the continuing care team, each staffed by different people with differing philosophies, skills and limitations. Each team will be keen to get their job done and then pass the patient on, leading to eventual discharge. There is rarely one single individual who holds the patient in mind through all the phases of their illness, in sickness and in health. No ‘risk assessment’ protocol can substitute for this intimate knowledge, built up over time, of patients’ unique vagaries, strengths, weaknesses, vulnerabilities and inner workings.

This role could be, but so often is not, occupied by a senior tenured clinician – consultant psychiatrist, nurse-specialist, psychotherapist or clinical psychologist, supplemented by other members of the team. For this to happen there would need to be a move from short-termism and quick-fix problem-only therapies to long-term care for chronic illness. This

would entail recognition that, as in Germany, long-term therapy, despite its cost, is economically efficient and can be available as part of comprehensive universal healthcare. ⁶

Attachment theory: Refuge

Attachment theory provides a possible scientific underpinning for this perspective. The distressed – and what is suicide if not the ultimate manifestation of distress? – are psychobiologically driven to seek out a secure base in the hope of alleviating their mental pain. ⁷ In the absence of a secure base an abyss of despair and terror gapes, to which the illusory comfort of death may appear to provide a modicum of comfort.

Secure attachment is based on sensitive and responsive knowledge of the care-seeker, backed by ‘allo-parents’ ⁸ who augment and temporarily substitute, but can never fully replace, the primary attachment figure. The prevailing ‘customer-provider’ ethos, postmodern suspicion of inequalities in power relationships, and an underlying cost reduction imperative, are used to justify the current model. There is scant acknowledgement that the idea of ‘choice’ makes little sense in the context of severe mental illness. A commercial-type ‘contract’ anticipates, and tries to shape, the consumer’s needs, but is essentially non-‘mentalising’. ⁹ It does not take account of the uniqueness of attachment relationships or attend to the inner world of experience that drives external behaviours.

Understanding a person’s inner world is not a recipe for vague psychological theorising, but can be intensely practical. A mentalising parent is able to plan effectively, take account of her own states of mind, and make sensible guesses about what is going on in her child’s mind. Similarly, a primary ongoing psychiatric attachment figure offers not just support and therapy to her patient with bipolar disorder, but, based on a shared journey through the vicissitudes of illness, gauges the need for medication, and helps the patient regulate the basic parameters of life – sleeping, eating, working, relating. ¹⁰

Long-term care has benefits

Soon after my relation died I dreamt I was in charge of her care; ‘You are going to stay in the ward, sectioned if necessary, until you are really well, even if that means staying here for a year!’, I said in my dream narrative. In reality this could, and probably should, be no more than a dream. In-patient beds are vanishingly scarce; ward culture inimical to long-term care; sectioning a highly articulate and plausible patient increasingly problematic. The idea of a hospital as an asylum, of therapeutic communities in which people with mental illness live and learn together, seems little more than a nostalgic memory. But in a psychiatric world without walls, the need for long-term care based on enduring relationships becomes all the more important, not least because the developmental experiences of those who suffer from mental illness are typically characterised by disorganised and disrupted attachments. ¹¹ The current climate tends to reproduce and reinforce rather than mitigate these adverse developmental experiences.

The importance of family therapy

Finally – whatever happened to family therapy? From an attachment perspective family members – parents, spouses, siblings – however stressed, possess a unique sensitivity to the inner world of their loved ones. They have a lifelong baseline of normality against which to judge the subtle signs of relapse. They are an indispensable resource in which indefatigable altruism, based on the care-giving dynamic, can be taken for granted. Mental health professionals have often not yet fully thrown off their own adolescent rebellion, and too easily slip into excluding or even blaming the family, in part no doubt as a way of coping with the stresses of working in the beleaguered field of psychiatry. One consequence of ‘community care’, so called, is that families are relatively unsupported in their struggle to help their mentally ill relation, or cast as the ‘cause’ of the problem, and kept in the dark about professional formulation and planning.

Faced with the huge trauma of mental illness, the world typically becomes split into good and bad. When patients were detained for longer periods in psychiatric units, its staff at times became the necessary ‘bad object’, Rey’s ‘stone Mother’, ¹² a paradoxically safe container for all that was painful and destructive about mental illness. Hope and

recovery were associated with discharge and resuming the ongoing connections represented by friends and family. Today, without the secure base function of the hospital, the family itself is too easily scapegoated, while professionals take refuge behind ‘confidentiality’ as a rationale for excluding family members. Skilled family therapists are a rarity, despite robust evidence that family intervention prevents relapse in serious mental illness.¹³

Carrying on

Of course none of this call – for an attachment perspective, for more long-term therapy, for reviving therapeutic communities, for training family therapists – can reverse the horror of the loss one iota. When someone dies, from whatever cause, especially if young, a web of meanings, hopes and connections is severed. Restoration of meaning entails a painful recapturing and reworking of the past. The totality of the patient’s being – strengths, delights, loves, achievements, as well as suffering and pain – has to be sought and re-found. A similar task faces today’s psychiatric profession – to value the past, mourn what is irrevocably lost, reclaim what can be salvaged. In suicide, echoing Tennyson, a lifelong mourner,¹⁴ ‘much is taken’, but ‘much still abides’. This lament is a plea, when faced with suicide, for psychiatrists, alongside patients and their families, to ‘strive, to seek, to find, and not to yield’ – to fashion, finance or fatalism.

1.8.34 Anti-N-methyl-d-aspartate receptor encephalitis: review of clinical presentation, diagnosis and treatment

Abstract

Anti-N-methyl-d-aspartate (NMDA) receptor encephalitis is a form of encephalitis occurring primarily in women and associated with antibodies against NR1 or NR2 subunits of the NMDA receptor. As a potentially treatable differential for symptoms and signs seen in neurology and psychiatric clinics, clinicians practising across the lifespan should be aware of this form of encephalitis. Common clinical features include auditory and visual hallucinations, delusions, behavioural change (frequently with agitation), impaired consciousness, motor disturbance (ranging from dyskinesia to catatonia), seizures, and autonomic dysfunction. We present a review of the literature on the disorder, including its clinical presentation, differential diagnosis, epidemiology, treatment and prognosis.

- *Summary and implications to clinical practice*

Anti-*N*-methyl-d-aspartate (NMDA) receptor encephalitis was first described in 2007 by Dalmau and colleagues,¹ who identified 12 patients presenting with prominent neuropsychiatric symptoms. All were confirmed to have serum or cerebrospinal fluid (CSF) antibodies to the NMDA receptor.¹ In a subsequent case series of 100 patients, 77 initially presented to psychiatric services.² Although patients with anti-NMDA receptor encephalitis exhibit high rates of psychiatric disorder, psychiatrists may not be fully aware of the diverse presentation of this disorder. Given the high mortality rate (up to 25%), the likelihood of presentation across the age range and the potential for treatment, a high index of suspicion is warranted by clinicians.

Epidemiology

Epidemiological studies suggest that anti-NMDA receptor encephalitis may be the most common cause of autoimmune encephalitis after acute demyelinating encephalitis.³ While to date there are no estimates as to prevalence rates, more than 500 cases have been reported.⁴⁻⁶ Between September 2007 and February 2011, the California Encephalitis Project examined referrals of 761 patients presenting with encephalitis.⁷ Of the cases of identified aetiology, anti-NMDA receptor encephalitis was the leading entity (32 of 79 cases) within the cohort and was identified four times as frequently as herpes simplex – type 1, West Nile virus or varicella zoster virus.⁷ In another study, Steiner and colleagues examined 121 individuals with schizophrenia for diverse NMDA receptor antibodies. Approximately 10% ($n = 15$) were found to be positive for anti-NMDA receptor antibodies, two of whom had the specific immunoglobulin G (IgG) NR1a antibodies of anti-NMDA receptor encephalitis.⁸ Zandi *et al*⁹ observed NMDA receptor serum antibodies in approximately 6% (3 of 46) of patients with first-onset schizophrenia. The true rate of anti-NMDA receptor encephalitis in the population generally and among individuals with psychosis is thus not yet fully clarified.

Pathophysiology

Encephalitis and psychosis have a long association, with a viral aetiology of psychosis hypothesised as early as the 19th century. The influenza epidemic in the early 20th century led Karl Menninger to conclude that ‘dementia praecox is at least in most instances a somatopsychosis, the psychic manifestations of an Encephalitis’.¹⁰ While the dopaminergic model of schizophrenia has been the leading neurochemical hypothesis of psychosis for many decades, hypofunction of the NMDA-type glutamate receptors provides an alternative model to understanding the pathogenesis of schizophrenia. It is well described that antagonists of NMDA receptors (e.g. phencyclidine (PCP)) produce a clinical syndrome that closely resembles negative symptoms of schizophrenia and induce neuropsychological and sensory processing deficits that are very similar to those observed in schizophrenia.¹¹

The prominent psychotic symptoms, catatonia and indicators of dopaminergic involvement (orofacial dyskinesias) are all consistent with the effects of PCP,¹¹ which is well recognised to also replicate many aspects of the presentation of schizophrenia. NMDA receptor antagonists are believed to function by blocking the NMDA receptor in the presynaptic gamma-aminobutyric acid (GABA)-ergic neurons of the thalamus and frontal cortex, leading to a disinhibition of postsynaptic glutamatergic neurons and subsequent glutamatergic and dopaminergic dysregulation in the frontal cortex.

It has been observed that nitroprusside completely abolishes the behavioural effects of PCP in animal models.¹² Hal-lak and colleagues¹³ administered a sodium nitroprusside infusion to 20 patients with a diagnosis of schizophrenia, with a resultant rapid improvement in symptoms. They hypothesise that in addition to generating nitric oxide in the brain and increasing cAMP production, nitroprusside may also modulate NMDA receptor activity. In addition, reductions in plasma and brain glycine, D-serine and glutathione levels provide additional mechanisms underlying NMDA dysfunction.¹⁴

The neuropsychiatric presentation of these cases of anti-NMDA receptor encephalitis thus provides important support for the NMDA receptor hypofunction hypothesis for psychosis.^{15,16} Explanations for the proposed NMDA receptor hypofunction in schizophrenia are varied and may involve altered recycling of NMDA receptors.¹⁷ However, the possibility that autoantibodies to the NMDA receptor subunits may be causal in psychotic presentations is novel.

Acute psychosis in anti-NMDA receptor encephalitis is associated with serum and CSF IgG antibody titres against the NR1a subunit of the receptor. However, antibodies against different antigens (e.g. the NR2a and NR2b subunits) have been described in cases of limbic encephalitis and systematic lupus erythematosus,^{18,19} and psychiatric symptoms may not be exclusive to the NR1a subunit. Steiner *et al*⁸ examined the serum of 459 patients admitted with schizophrenia ($n = 121$), major depression ($n = 70$) and borderline personality disorder ($n = 38$) for a variety of antibody subtypes in order to determine whether antibody subtypes overlap with or are distinct from those in anti-NMDA receptor encephalitis. They identified NMDA antibodies in 9.9% of patients with schizophrenia. Diverse NMDA receptor antibodies, including those specifically found in anti-NMDA receptor encephalitis, were found primarily in those with an initial diagnosis of schizophrenia; two patients initially diagnosed with a disorganised or catatonic schizophrenia were subsequently diagnosed with, and treated for, anti-NMDA receptor encephalitis.⁸

Potential causes for the behaviour, learning and memory difficulties in anti-NMDA receptor encephalitis have been postulated by Iizuka and colleagues,²⁰ who noted reversible predominant frontotemporal atrophy, an area in which NMDA receptors are present in high density, therefore suggestive of an immunological cause to the atrophy.

Anti-NMDA receptor encephalitis is associated in some cases with ovarian pathology, in particular teratomas. It is considered that the antibodies to the NR1–NR2 subunits of the NMDA subtype of glutamate receptors develop in response to this abnormal tissue.

Clinical presentation

Presentations can be variable, thus posing a challenge to clinicians in neurology and psychiatry settings. With symptoms and signs ranging from psychosis to mania to catatonia, clinicians may be prompted to consider primary mental health aetiology. Dalmau *et al*⁶ have proposed a staged presentation. Maneta *et al*⁵ summarise these into early, middle and late symptoms, initially involving a prodrome, followed by more overt psychiatric manifestations and later physical symptoms.

Clinicians should be aware that the presentation of anti-NMDA receptor encephalitis includes several characteristic features.

A non-specific prodrome: in one series of 100 individuals with encephalitis, 86% had headache, low-grade fever or a viral-like illness (headaches, respiratory or gastrointestinal symptoms) in the weeks prior to acute presentation.² In our series of five cases, we identified a prodrome in four, with symptoms including poor concentration, anorexia, insomnia and slurred speech.⁶ Psychiatric symptoms are prominent: agitation, bizarre and disinhibited behaviour, delusions and auditory and visual hallucinations.² In our series, the psychotic phenomena observed were markedly fragmented in comparison with those typically found in functional psychoses, with delusions being poorly formed and non-systematised.⁶ Cognitive dysfunction: short-term memory loss can also be a presenting feature, as can concentration difficulties. Formal neuropsychological testing in the presence of psychosis and/or behavioural disturbance may present difficulties in clinical practice. Motor dysfunction: in addition to typical epileptic seizures, patients often develop dyskinetic movements, including orofacial dyskinesias (grimacing or lip smacking), which may be mistaken for seizures. These abnormal movements, especially orofacial dyskinesia, may present from an early stage and are often a clue to the diagnosis. Autonomic instability: autonomic instability and hypoventilation can also occur (41 of Dalmau's series² had one or both of these features), as can cardiac dysrhythmias often necessitating intensive care unit management.² Dissociative responses to stimuli during have been noted, including resistance to eye opening while

displaying no response to painful stimuli, a combination that may lead to diagnostic confusion.^{20,21} Association with known pathology: an association with ovarian pathology has also been identified. Dalmau and colleagues reported that in 59% of cases, the diagnosis was associated with ovarian tumours, primarily ovarian teratomas.² However, Irani and colleagues identified tumours in only 26% (9 of 34) of cases.²² Children under the age of 18 are unlikely to have an associated tumour.

Diagnosis

Confirmation of the clinical diagnosis of anti-NMDA receptor encephalitis requires a positive serum or CSF sample screening for antibodies to the NMDA receptor subunit. There is ongoing controversy as to whether serum or CSF is best tested. Dalmau recommends testing of both,⁶ whereas Irani & Vincent,²³ by contrast, report that serum levels of anti-NMDA receptor antibodies were similar or higher to those of CSF. The clinical symptoms of this disorder correlate well with antibody titre.² The test for anti-NMDA receptor encephalitis, although currently somewhat slow, is relatively cheap, and therefore should be considered in any patient presenting with an acute onset of psychiatric symptoms with atypical features or unusual movements.

CSF abnormalities have been described in approximately 80% of cases and include a mild lymphocytic pleocytosis, normally or mildly increased protein concentration, and CSF-specific oligoclonal bands.^{2,24}

Brain magnetic resonance imaging scans have been reported as normal in 70% of cases.⁴ In the remainder, hyperintensities in a variety of regions may be evident (implicated areas include the hippocampi, cerebellar and cerebral cortex, basal ganglia, brainstem, frontobasal and insular regions).²⁵

Typically, electroencephalograms (EEGs) may show non-specific slowing or slow continuous rhythmic activity during the catatonic phase of illness.²⁶ An EEG is very helpful if one is trying to distinguish between encephalitis and a primary psychiatric disorder, as the majority of patients (90%) with anti-NMDA receptor encephalitis have evidence of non-specific slowing at some stage during the illness.⁴

While not at present likely to support clinical practice, other investigations have been reviewed. Positron emission tomography has shown variable findings, with some evidence of cortical hypometabolism.²⁷ This contrasts with findings from other investigators, suggesting subcortical hypermetabolism.²⁸

Differential diagnosis

The condition may present in the domain of either the neurologist or the psychiatrist, depending on whether psychiatric symptoms precede the neurological features, as is often the case.

Neurological

Neurological differential diagnosis tends to include viral encephalitis, cerebral vasculitis or other forms of autoimmune encephalitis and encephalitis lethargica.²⁹ Dyskinetic movements may be mistaken for seizure activity or tardive dyskinesia. Patients can also have bizarre stereotypies. Repetitive stereotypies and orofacial dyskinesia can be mistaken for seizures.³⁰ The seizure-like dyskinetic movements may also be misdiagnosed as status epilepticus, a diagnosis that is reported in 6% of cases.³⁰ Dericioglu and colleagues³⁰ report two cases where status epilepticus was suspected but video EEG was indicative of encephalopathy, thus avoiding aggressive treatment with intravenous anaesthetics. Caution therefore is advised in interpreting these movements, unless clarified by video EEG, when status epilepticus is suspected.³⁰

Psychiatric

Psychiatric differential diagnoses are usually the primary differential in the initial phase of illness. New-onset psychosis is typically recorded in the literature as the most common initial diagnosis because of the presence of delusions, hallucinations and catatonic features. Recent studies explore the possibility that this disorder, or indeed other similar autoimmune conditions, may present with a more typical schizophrenia picture and be responsible for as much as 5–10% of first-onset psychosis.^{8,9} Zandi and colleagues⁹ screened a 46-patient cohort of first-episode psychosis patients in a prospective study for NMDA receptor antibodies and only 2 tested positive. The authors state that there were no clinical features to differentiate these individuals from other individuals with psychosis in the cohort.

Cases of ‘postnatal psychosis’ in association with ovarian pathology that bear remarkable similarity to anti-NMDA receptor encephalitis have also been described.³¹

The presence of rigidity and altered consciousness, which are common in anti-NMDA receptor encephalitis, may also lead to consideration of a diagnosis of neuroleptic malignant syndrome, particularly when antipsychotic medications are prescribed. This may present both a diagnostic dilemma and a management challenge in clinical practice, as these diagnoses are clearly not mutually exclusive.

Treatment options

It is important to note that treatment must target both the cause and the clinical consequences of the encephalitis (the behavioural and psychotic symptoms). With respect to the former, first-line treatment is immunotherapy, typically corticosteroids, intravenous immunoglobulins or plasma exchange, in addition to the removal of any identified teratomas. Titres are effectively reduced by immunomodulatory treatments, including high-dose steroids, intravenous gamma globulin and plasmaphoresis.

Behavioural disturbance can be a marked obstacle to initiation of treatment, often requiring patients to be sedated for administration of plasma exchange.

Second-line immunosuppression may be necessary using rituximab or cyclophosphamide.

These are often required in individuals who receive a delayed diagnosis or those without a tumour.²⁶ Liba *et al*³² report use of alemtuzumab in an 8-year-old child with a positive outcome.

Treatment is generally thought to be more effective in patients who have an underlying tumour removed. Cases of ovarian teratomas discovered years after initial onset of symptoms have been described, particularly in patients who experienced a slow recovery.²⁰ Peery and colleagues describe a case where oophorectomy was performed despite negative scan results and on postoperative biopsy an occult teratoma was revealed, with subsequent improvement in clinical symptoms.³³

With respect to the immediate management of behavioural and psychotic symptoms, both typical and atypical, antipsychotics have been utilised. It must be noted that use of antipsychotics can complicate the picture, particularly prior to definite antibody diagnosis. The development of autonomic instability and rigidity may be mistaken for neuroleptic malignant syndrome. In addition, use of corticosteroids may result in confusion with a steroid-induced psychosis. Clonidine, trazadone and benzodiazepines have been used successfully for reversal of sleep disturbance.³⁴

Catatonic symptoms are typically treated with benzodiazepine medication. Doses of up to 20–30 mg of lorazepam daily have been used to manage symptoms in catatonia, although little has been published on its efficacy in anti-NMDA receptor encephalitis.³⁵ Electroconvulsive therapy (ECT), though the gold standard for treatment of catatonia in the absence of a response to benzodiazepines, is little studied in the area of anti-NMDA receptor encephalitis. Case reports of catatonic symptom response in anti-NMDA receptor encephalitis have been described.³⁶ Interestingly, in animal models of ECT action, an elevation of messenger ribonucleic acid (mRNA) of the NMDA subunits NR2A and NR2B has been demonstrated, leading to an up-regulation of the NMDA receptor.³⁷

Prognosis

According to Dalmau's original case series, approximately 75% of patients with NMDA receptor antibodies recover or have mild sequelae; the other 25% have severe deficits or die.² Subsequent studies have identified a 12–24% risk of relapse.^{9,34,35} Mortality of 7% at 24 months has been noted.⁴ Other studies have noted that approximately 25% of patients at diagnosis give a history of one or more similar symptom episodes in the months preceding diagnosis, indicating a more relapsing and remitting course of illness than initially described.²⁶

Titulaer *et al*⁴ in a cohort study of 577 patients noted that first-line immunotherapy resulted in an improvement in 53% of patients in the first 4 weeks of treatment, 97% of whom showed a good outcome at 24 months. In the 47% of patients who did not respond to first-line treatment, those who received second-line immunotherapy (i.e. rituximab, cyclophosphamide or both) had better outcomes than those who continued first-line treatment or received no further immunotherapy.⁴

Several prognostic factors are implicated. With respect to duration of illness and treatment outcome, Finke and colleagues³⁸ demonstrated a better cognitive outcome in a small cohort of adult patients with anti-NMDA receptor encephalitis who were treated with immunomodulatory therapy within 3 months of disease's onset compared with those who were treated at a later stage or not at all. The authors proposed that a delay in treatment may lead to permanent hippocampal damage,³⁸ yet the optimal time frame from onset of symptoms to treatment has yet to be determined.

Other identified predictors of outcome include: lower severity of symptoms, not requiring ICU admission, prompt initiation of immunotherapy and tumour removal where present.^{4,39}

Summary and implications to clinical practice

Anti-NMDA receptor encephalitis is a relatively newly identified and potentially treatable cause of psychiatric symptoms in both adults and children. Several hundred cases have been reported since its identification in 2007; however, clinicians may be unaware of developments in this field. It is vital for psychiatrists working across the age spectrum to be aware of this condition and to engage in timely liaison with our neurology colleagues, thus facilitating early screening and diagnosis.

There are a wide range of presenting symptoms and signs. Patients may present with prodromal features, followed by psychiatric and perhaps later physical manifestations. As outlined, anti-NMDA receptor encephalitis is easily diagnosed using a blood or CSF test. This presents the opportunity for early treatment, and a low index of suspicion should be considered for any patient presenting with a constellation of symptoms.

To date, the recommendation for screening has advised testing of those patients, particularly females, with an atypical new-onset presentation of psychosis with motor features. However, recent studies have questioned how readily this disorder is distinguishable from those where patients receive a purely psychiatric psychotic diagnosis.

It is clear that early identification and treatment may have serious prognostic implications. Delay to treatment with immunosuppressive therapy probably results in worsened outcomes, with evidence for permanent hippocampal damage.³⁸ Management may prove clinically challenging, from the perspective of treating both the cause and the symptoms. Initiation of antipsychotic treatment is not without risk in these patients and behavioural management may prove challenging.

Anti-NMDA receptor encephalitis is a potentially treatable form of psychiatric illness that is illuminating our understanding of the neuropathophysiology involved in some individuals who present with symptoms of psychosis.

1.8.35 The cardiovascular safety of the empirical measurement of the seizure threshold in electroconvulsive therapy

Lindsay Mizen Charles Morton Allan Scott

Correspondence

Lindsay Mizen (lmizen@nhs.net)¹

date

2015-2

Abstract

Aims and method The Royal College of Psychiatrists' Committee on Electroconvulsive Therapy (ECT) and Related Treatments advises the measurement of initial seizure threshold in all patients undergoing ECT if possible. The subconvulsive electrical stimulation inherent in this process is thought to increase the risk of bradycardia and therefore asystole. Our aim was to establish the prevalence of asystole (no heart beat for 5 or more seconds) during empirical measurement of seizure threshold in patients who had not received anticholinergic drugs, as we were unable to find any published reports of bradycardia or asystole prevalence under these conditions. The electrocardiogram traces of 50 such consecutive patients were analysed later.

Results Asystole occurred in 5% of stimulations. Each episode of asystole resolved spontaneously with no adverse outcomes. Contrary to expectations, asystole was no more prevalent in subconvulsive stimulations than in convulsive stimulations.

Clinical implications There was no evidence that the empirical measurement of the seizure threshold added to the cardiovascular risk of ECT.

Contents

- *The cardiovascular safety of the empirical measurement of the seizure threshold in electroconvulsive therapy*
 - *Method*
 - *Results*
 - *Discussion*

The electrical stimulus of electroconvulsive therapy (ECT) may have effects other than the induction of cerebral seizure activity. It was recognised soon after the introduction of ECT that the stimulus could affect the heart, usually causing a bradycardia resulting from the electrical stimulation of the motor nucleus of the vagus nerve and nucleus ambiguus, within the medulla oblongata. ¹ This bradycardia can be severe and as long ago as 1978 the American Psychiatric Association (APA) stated that the bradycardia might even be prolonged enough to cause cardiac arrest. ² Although no references were given to support this concern, asystole and cardiac arrest have been reported since. ³ The APA recommended the routine intravenous administration of an anticholinergic drug to reduce the risk of severe bradycardia, but this never became routine anaesthetic practice in the UK. The Royal College of Psychiatrists recognises that 'severe bradycardia can usually but not invariably be prevented by pre-treatment with anticholinergic agents' and that such vagolytic drugs are sometimes used to attenuate bradycardia, but it does not specifically recommend the routine administration of an anticholinergic drug. ⁴

Evidence from case reports has been taken to mean that severe bradycardia is more likely after subconvulsive electrical stimulation; that is, stimulation that does not lead to generalised cerebral seizure activity. ^{1,2,4} This is because seizure activity has an opposite effect on the heart, leading to tachycardia, whereas in subconvulsive stimulation the vagal effect is unopposed. ¹ Subconvulsive stimulation was uncommon in traditional ECT practice because fixed, high doses of

¹ **Dr Lindsay Mizen** is a Clinical Research Fellow at the University of Edinburgh and an honorary ST5 trainee in the psychiatry of intellectual disability in the South East Scotland Deanery who was based at the Royal Edinburgh Hospital while conducting this study. **Dr Charles Morton** is a consultant anaesthetist, Royal Infirmary of Edinburgh. **Dr Allan Scott** is now retired, but was a consultant general adult psychiatrist at the Royal Edinburgh Hospital while conducting the study.

electrical charge were delivered. Contemporary ECT machines can deliver adjustable doses and it is now recommended that the dose is titrated for the individual patient, particularly for bilateral ECT.⁴ The convulsive dose depends on the seizure threshold for the individual patient. This is measured empirically by stimulation with repeated, increasing doses of electrical charge at the start of the course of ECT. In contemporary practice, the vast majority of patients receive at least one subconvulsive stimulation at their first treatment in a course of ECT. The APA now notes that not all anaesthetists routinely use anticholinergic drugs, but also states that the bradycardia after subconvulsive stimulation is of 'graver' concern, and that many anaesthetists routinely administer such agents at treatments in which the measurement of seizure threshold is planned.⁵ Some ECT practitioners simply do not undertake empirical measurement of the seizure threshold in patients with a known history of cardiac disease.⁶

We aimed to investigate the prevalence of asystole during empirical measurement of seizure threshold in the absence of anticholinergic drugs.

Method

We analysed the printed paper record of the electrocardiogram (ECG) taken during the first treatment of 53 consecutive patients referred for a new course of ECT at the Royal Edinburgh Hospital between 12 February 2008 and 5 March 2010. An individual patient was included only once. Three of these patients are not included in the present report because the anaesthetist administered an intravenous anticholinergic drug before ECT; in all cases this was because of previous excessive salivation during ECT. The present sample therefore consists of 50 from 53 consecutive referrals for ECT. The intravenous induction agent was etomidate in 38 patients and propofol in 12 patients. Muscle relaxation was always achieved by intravenous suxamethonium, after precurarisation with 5 mg atracurium. The vast majority of patients ($n = 47$) were treated with bilateral ECT; the remaining 3 received right unilateral ECT.

All treatments were administered using a Spectrum 5000M ECT machine, which has an inbuilt two-channel electroencephalogram (EEG) facility to measure cerebral seizure activity. The protocol for the empirical measurement of the seizure threshold at the first treatment was as follows: the first stimulation was with 4% (46 mC), and if cerebral seizure activity did not ensue, then a second stimulation was given with 7% (81 mC). In patients prescribed an anti-epileptic drug, the first stimulation was with 9% (104 mC) and if no cerebral seizure activity ensued, then a second stimulation was given with 18% (207 mC). For both groups of patients the protocol included doses for third and subsequent stimulations, when necessary. The flow chart presented in *Fig. 1* shows the number of patients receiving one or more stimulations.

Our clinic participates in the Scottish national audit of ECT practice, coordinated and reported by NHS National Services Scotland. This paper includes demographic, episodic and treatment data routinely recorded and reported. The only change made to our routine data collection was to print a paper record of the ECG. These paper records were given a coded number by the ECT consultant (A.S.) and then stored outside the ECT clinic until they were read by an independent rater (L.M.); clinical and treatment information was masked to the rater. We used ECG lead II and the paper record ran at 25 mm/s.

The point when bradycardia becomes asystole is arbitrary. The criterion that 5 s (125 mm on the paper record) without a QRS complex constitutes asystole is taken from a previous report.⁷ Its authors also conducted a secondary analysis of patients in whom the asystole lasted as long as 7 s and so we also considered a secondary analysis with this definition of asystole. The analysis of the paper records was standardised by discussion among the present authors before analysis. The electrical stimulation led to a characteristic type of artefact on the paper record (*Fig. 2*) and the time from the end of this artefact (that is, the end of electrical stimulation) to the time of the first QRS complex was measured. The morphology of this complex had to be the same morphology as complexes before electrical stimulation, which meant ectopic beats were disregarded. If the independent rater was uncertain about the measurement of this time, she consulted C.M. and the time was agreed between these raters; patient details remained masked to L.M., and C.M. was shown only the paper record and any other clinical or treatment information was masked. The results were analysed using Microsoft Office Excel 2007 and StatsDirect Version 2.7.9 for Windows. As the inter-subject variance (between different patients) was *Fig. 1* Numbers of patients in the sample receiving one or more ECT stimulations. *Fig. 2* ECG with electrical stimulus artefact followed by a period of asystole. likely to be higher than the intra-subject variance (multiple stimulations in one patient), each electrical stimulation was considered as an independent measure. Convulsive and subconvulsive stimulations were compared using Fisher's exact test and the 'exact' or 'Clobber-Pearson' method

was used to calculate 95% confidence intervals of proportions.⁸ The episodes of asystole in different stimulations were compared using paired *t*-tests.

It is the policy of NHS Scotland to withhold from publication data that may identify individual patients.⁹ This report respects this principle.

Results

As shown in *Table 1*, the sample consisted of 37 women and 13 men (mean age 57.4, range 22–87 years). The most prevalent primary psychiatric diagnosis was severe depression with ($n = 18$), or without ($n = 16$), psychosis; 6 patients had moderate depression and 7 were diagnosed with other types of depressive disorder. Six of the total group of patients with depression had bipolar affective disorder. Schizophrenia was the primary diagnosis in 2 patients.

The majority of patients ($n = 38$) were prescribed a combination of psychotropic drugs, including tricyclic antidepressants ($n = 6$) and lithium carbonate ($n = 7$); 8 patients were prescribed monotherapy, 6 with an antidepressant drug, 1 with lithium carbonate and 1 with diazepam; 4 patients were not prescribed any psychotropic drug treatment. Five patients were prescribed a beta-blocking drug for hypertension. Of the 8 patients who experienced asystole, 3 were anaesthetised with propofol and 5 with etomidate. None of these 8 patients were on anti-epileptic medication and so they received the standard electrical stimulation protocol (rather than the higher doses administered to patients on anti-epileptics).

Table 2 shows that the time to first R-wave ranged from 0.04 to 9.12 seconds. Because of the nature of the titration procedure, most patients ($n = 47$) did not have a convulsion after the first stimulation and so experienced more than one electrical stimulation.

The data were analysed with each stimulus measured as an independent variable and the total number of stimulations given in the study was 172. Most patients ($n = 49$, 98%) experienced cerebral seizure activity (CSA) in this study and the one patient who did not underwent 5 electrical stimulations with no seizure. This patient did not experience asystole. The mean number of stimulations before experiencing CSA was 2.5. Our primary analysis was with asystole defined as 5 s without a QRS complex. With this definition, asystole occurred in 4/124 (3%) subconvulsive stimulations (95% CI 0.89 to 8.05%) and 5/48 (10%) convulsive stimulations (95% CI 3.47 to 22.66%). The number of subconvulsive stimulations is considerably higher than that of convulsive stimulations because, from the second stimulation onwards, the patient has experienced previous subconvulsive stimulations, but for convulsive stimulations the patient has not experienced any previous convulsive stimulations. Of the asystolic events, 6 occurred after a second electrical stimulation and the other 3 occurred after a third stimulation. Only one patient, a 70-year-old female with severe depression, experienced multiple episodes (2) of asystole, which were after her second (non-convulsive) and third (convulsive) electrical stimulation. The average age of the 8 patients who experienced asystole was 69.9 years and only 1 of them was male. Six of these patients were prescribed a combination of psychotropic medications and one was not prescribed any psychotropic drugs. Six of these patients had no documented history of cardiovascular disease.

Secondary analysis carried out using a definition of asystole of 7 s without a QRS complex reduced the number of episodes of asystole to 2. One of these followed a convulsive stimulation in a 72-year-old female with severe depression and a history of hypertension and ischaemic heart disease with previous stent insertion. She was the only patient (of three) taking a beta-blocker (atenolol) to exhibit asystole. The other episode of asystole lasting longer than 7 s was in a 70-year-old female with severe depression without a history of cardiovascular disease. It followed a second non-convulsive stimulation, lasted 9.12 s and was therefore the longest period of asystole noted.

A two-tailed Fisher's exact test, comparing convulsive and subconvulsive stimulations, did not reach statistical significance ($P = 0.12$), but the odds ratio was 3.46 (95% CI 0.71 to 18.27) suggesting that a patient was more likely to have an episode of asystole after convulsive rather than subconvulsive stimulation. We compared the first and second stimulations in patients who had two or more subconvulsive stimulations, using a paired *t*-test, and found that the mean time to the first QRS complex was statistically longer after a second subconvulsive stimulus ($P = 0.04$, 95% CI -1.72 to -0.04). We then compared the first and second stimulations in all patients who had two or more stimulations, regardless of whether they experienced Table 1 Demographic of the study sample Asystole No asystole Whole sample Total n 8 42 50 Demographics , , , Male, n (%) 1 (12.5) 12 (28.6) 13 (26.0) , , , Female, n (%) 7 (87.5)

post-stimulation was significantly longer after a second stimulation ($P = 0.03$, 95% CI -1.09 to -0.05). We also compared the time to the first QRS complex after second and third stimulations in all patients who underwent three or more stimulations, using a paired t -test, but did not find a statistically significant difference ($P = 0.36$, 95% CI -0.66 to 0.96).

All episodes of asystole in this study resolved spontaneously without medical intervention.

Discussion

Asystole (5 s without a QRS complex) occurred in 9 of 172 stimulations in this study (5%; 95% CI 0.02 to 0.10). As each episode of asystole resolved without medical intervention, our findings suggest that the empirical measurement of seizure threshold does not add to the cardiovascular risk of ECT, nor is there a need to routinely administer an anticholinergic drug. Contrary to expectation, asystole was more prevalent after convulsive than non-convulsive stimulation. We have also shown that time to the first QRS complex post-stimulation was longer in patients who received two subconvulsive stimulations rather than one. As increasing doses of electricity are given on subsequent stimulations when titrating up to seizure threshold, this could suggest that time to the first QRS complex simply increases together with the dose of electricity. This is supported by the fact that none of the episodes of asystole occurred after a patient's first electrical stimulation and that the comparison of first and second stimulations, regardless of whether or not seizure activity ensued, showed a statistically significant difference between the times to first QRS complex ($P = 0.03$, 95% CI -1.09 to -0.05). On the other hand, there was no statistically significant difference between second and third stimulations ($P = 0.36$, 95% CI -0.66 to 0.96). This may be because the effect of increasing doses of electricity and/or absence of seizure activity is lost after a certain threshold, or because neither the electrical dose nor presence or absence of seizure activity are factors influencing the risk of asystole and the effect seen at previous stimulations may be due to small sample size. Further studies with a larger sample size would help to delineate this.

Our results support those of Burd & Kettl,⁷ who found that although asystole was common in elderly patients undergoing ECT (364/1146, 40.1%), routine use of atropine was unnecessary because brief asystole was not associated with adverse outcome. Burd & Kettl studied patients throughout ECT treatment courses, not just during stimulus titration, which may explain the difference in incidence of asystole observed in our study. They also refer to reports of asystole lasting up to 7 s and so we attempted to conduct a secondary analysis using a definition of 7 s without a QRS complex. However, in our sample there were only 2 episodes of asystole which exceeded 7 s (1 in a convulsive stimulation and 1 in which no convulsion was stimulated) and so no statistical analysis of these episodes could be performed. In 1996, McCall *et al*¹⁰ used an even more conservative definition of asystole (10 s of ECG electrical silence) in an attempt to capture only pathological asystolic events. Using this cut-off there were no patients in our study who experienced asystole, again supporting the idea that the periods of electrical silence in our study were not pathological. Furthermore, only one of the patients in our study suffered more than one episode of asystole, which suggests that, for a given individual, one episode of asystole does not generally predict further similar events. A limitation of our study was that it was not possible to statistically analyse the other factors that could prolong the time to the first QRS complex, because of the small number of patients. Larger prevalence studies will be needed to further investigate these factors.

We thank Fiona Morrison, medical secretary supervisor, for her help with the production of the manuscript.

- *Voicing Caregiver Experiences: Wellbeing and Recovery Narratives for Caregivers*

In this easy-to-read book, ten authentic carer stories of different styles have been collected. Each has different themes, many of sadness and loss, and they describe the roller-coaster ride that most have had to endure until eventually finding stability and some acceptance of the situation in their own and their loved ones' lives. Tips between carers are shared, especially those of encouraging and steering others towards empowerment both in managing their own, often ignored, needs and to negotiate the fragmented, bewildering and inconsistent care delivery arrangements.

The most notable theme is that of hope. The stories demonstrate the process of finding hope, not a superficial denial of the challenges that lie ahead, but something worthy of respect. This hope is borne in adversity, is effortful and those who do find it have to overcome years of difficult associations to have future positive expectations.

Another theme is that of the care triangle between service users, carers and professionals. Many speak of how devastating some professional attitudes and practices can be, leaving wounds that take years to heal. Many also speak of positive relationships with professionals that have the capacity to become pillars of strength.

These stories are of heroes, and their own contribution to their relative's wellness is often under-recognised, overlooked and underestimated. In addition, their own care needs are often ignored as their caring role becomes engulfing. Many require active encouragement and permission to attend to their own wellness. When we as professionals see carers presenting as fraught or distressed, we should honestly ask ourselves 'What would we do?' After reading these stories, I am doubtful any of us, even experienced clinicians, would know what it takes to manage some of the situations described, let alone find the peace than many carers achieve.

1.8.37 Providing free heroin to addicts participating in research – ethical concerns and the question of voluntariness

Abstract

Providing heroin to people with heroin addiction taking part in medical trials assessing the effectiveness of the drug as a treatment alternative breaches ethical research standards, some ethicists maintain. Heroin addicts, they say, are unable to consent voluntarily to taking part in these trials. Other ethicists disagree. In our view, both sides of the debate have an inadequate understanding of 'voluntariness'. In this article we therefore offer a fuller definition of the concept, one which allows for a more flexible, case-to-case approach in which some heroin addicts are considered capable of consenting voluntarily, others not. An advantage of this approach, it is argued, is that it provides a safety net to minimise the risk of inflicting harm on trial participants.

- *Providing free heroin to addicts participating in research – ethical concerns and the question of voluntariness*
 - *Two concepts of 'voluntariness'*
 - *Why the circumstances of heroin addicts might undermine the voluntary nature of their consent*
 - *Voluntary consent and risk-minimising ethical analysis*
 - *Conclusion*

In the bioethics literature, there has been considerable debate as to whether giving heroin addicts legal access to free heroin in connection with research on the effectiveness of heroin prescription as a treatment alternative constitutes a breach of ethical research standards. The ethical issue here is that the researcher must obtain the informed consent of the study participants. For their consent to be valid, individuals must give it voluntarily. The question is whether consent can be said to have been given voluntarily if the person has heroin addiction (we are assuming, of course, that they are neither intoxicated nor experiencing withdrawal symptoms at the time of giving consent). Those who claim that it cannot argue that it is in the nature of heroin addiction for individuals to lose their ability to resist their desire for heroin. Since a loss of ability means heroin addicts cannot refuse offers of free heroin, neither can we presume that they can give voluntary consent to take part in research that involves giving them a choice of free heroin. ¹ According to those who maintain that consent given by heroin addicts can be valid, this argument is flawed. Several studies show that financial concerns, fear of arrest, values regarding parenthood and many other factors influencing decisions in general often persuade a person addicted to heroin to cease their drug-oriented behaviour. ² That heroin addicts frequently respond to such incentives means that they cannot have lost the ability to resist their desire for heroin. We can presume, therefore, that heroin addicts have the competence to give voluntary consent to take part in trials involving the drug.

We want to argue that both sides in this debate are mistaken. Although it is plausible that many – perhaps even most or all – heroin addicts have the ability to resist their desire to take heroin, the degree to which their consent is voluntarily given greatly depends on the wider social and psychological circumstances under which they choose whether to consent or not. Focusing on these circumstances rather than universal and hard-to-verify claims about abilities of resistance allows for a more flexible, case-to-case approach, one that does not rule out the possibility that while some heroin addicts might be competent to give voluntary consent, some might not. One advantage of this approach compared with the alternatives is that it provides a safety net to minimise the risk of inflicting harm on the individuals who participate

in these kinds of studies.

Before presenting our argument, a note of caution is in order: we do not want to claim that the answer to the ethical question raised by research on heroin prescription as a treatment alternative is alone sufficient to determine whether or not such research should be carried out. Even if the issue of voluntary consent in heroin trials was problematic, it does not follow that prescribing heroin as a treatment alternative should necessarily be banned. If, for example, the risks to the participants were small or non-existent while the benefits outweighed such risks, strategies that circumvent the normal standards of consent should indeed be considered. One such strategy could be to appoint some surrogate authority who is not involved in the study (e.g. a family member) to ensure the best interests of the participant, or perhaps to relax competence-defining criteria.¹ Whether prescribing heroin therapeutically is an effective way of treating heroin users needs to be determined empirically and will not be discussed here.

Two concepts of ‘voluntariness’

What does it mean to say that a consent is voluntary? In the bioethics literature it is widely agreed that a person acts voluntarily if he or she wills the action (performs it intentionally) without being under the controlling influence of another person or condition.³ Controlling influences are divided into ‘external’ and ‘internal’ depending on whether they are caused by the intentional actions of other persons (such as different forms of coercion or manipulation) or lack of internal self-control, an incapacity typically associated with mental illness. Although this characterisation of voluntary action is both plausible and, no doubt, helpful in many situations in which clinicians have to assess a person’s capacity, we believe it is ill suited to explaining how certain social circumstances and the beliefs they inform might sometimes constrain choices. This is because the circumstances and beliefs might exert a controlling influence on the person, causing them to feel pressured into performing certain actions (like enrolling in clinical trials, for example), without necessarily removing their internal capacity for self-control. In fact, we believe research on the effectiveness of heroin prescription as a treatment alternative provides an illustration of this, as we try to show in this article. First, however, we need to introduce another concept of ‘voluntariness’ that comes from political and legal philosophy.⁴ This will allow us to explain how social circumstances and the beliefs they inform could deprive a person of their voluntariness without removing their internal capacity for self-control. We introduce it here with a view to suggesting an alternative – and, we believe, important – perspective on the effects addiction might be thought to have on the voluntariness of heroin addicts’ consent that has been largely ignored in the debate about this issue. It is worth noting that it relies on a consequentialist ethical theory, which some readers may have objections about. We cannot provide a full conceptual defence of this notion or its ethical foundations here. Consequentialism, however, is a widely used approach in much ethical analysis in the field of healthcare.

Very briefly, this alternative concept of voluntariness begins by distinguishing between three types of options in terms of ‘acceptability’, where the standard for the acceptability of options is an objective standard of well-being. First, there are options that one strongly dislikes, which one holds to be ‘unacceptable’ in the sense that they bring one’s well-being below a certain threshold. These are options that are thoroughly bad because they involve losses it would be unreasonable to expect anyone to bear. Second, there are options that are undesirable but not thoroughly bad, which one holds to be ‘acceptable’ in the sense that they bring one’s well-being above a certain threshold. These are options that have sufficient value to be choiceworthy. Finally, there are options that bring one’s well-being up to a high level and that one likes so much that one chooses them. Consider then the following plausible definition of voluntary choice: a choice is voluntary if it is not made because no other acceptable alternative options are available. This negative definition implies the existence of two types of situations in which a person makes a voluntary choice. First, there are situations in which she has at least two acceptable options and chooses one of them because, all things considered, she prefers one option to the other. Second, there are situations in which she has at least one option that she likes so much that she chooses it because of that, whether or not there are any acceptable alternative options. In neither of these cases is her reason for making her choice not having other acceptable alternative options. One implication of this concept of voluntariness is that whether a choice is voluntary or not depends not just on the person’s internal capacity for self-control, but crucially also on her *beliefs* about her options and hence actual motivation for making the choice. As we argue in the next section, we cannot rule out that the social circumstances typical of many chronic heroin addicts affect their beliefs about their options in a way that undermine the voluntariness of their consent even if they retain their capacity for self-control (for an extended version of this argument, see Henden, 2013).⁵

Why the circumstances of heroin addicts might undermine the voluntary nature of their consent

To determine whether heroin addicts are able to give voluntary consent, assuming the understanding of voluntariness just outlined, we need to know something about their beliefs about their options. Of course, one difficulty is that heroin addicts are not all alike. Their individual circumstances including social and personal resources are likely to differ, and their beliefs about their options are therefore likely to differ as well. That being said, there is widespread consensus that heroin treatment is suited to a minority of heroin users as a second-line treatment for those individuals who do not respond to methadone or buprenorphine treatment delivered under optimal conditions.⁶ Thus, heroin trials have essentially sought to determine the therapeutic value of prescribing heroin to high-risk heroin users for whom such benefits cannot be expected or achieved by existing treatment options.⁷ When discussing the competence of heroin addicts to consent to participation in heroin trials we should therefore focus primarily on chronic addicts with a history of repeated treatment failure. The prevalence of health and social problems in this group of addicts is widely acknowledged.⁷ Major psychopathological studies of heroin users report rates of comorbidity that far exceed those of general population estimates. In addition to having high rates of comorbidity, it is well known that many individuals with chronic heroin addiction lead marginalised, impoverished lives, often associated with criminal activity, anxiety and high levels of risk. Can it be ruled out that such circumstances might create situations of constrained choice? We believe that it cannot. To see how such a situation could arise, consider first the option of obtaining heroin from the street. Many individuals reach a point in their chronic heroin addiction history in which their current lifestyles do not seem to them to be sustainable any longer; evidence of this is that many eventually seek help for their addiction. Presumably the costs of maintaining this lifestyle begin to exceed the benefits. Put in the terminology introduced in the last section, we might say that they come to consider a life centred on the procurement of heroin to be ‘unacceptable’ in the sense of no longer bringing their well-being above a certain threshold. Consider next the option of abstaining from heroin. For an action to be an acceptable option, it is not sufficient to have the ability or power to perform it. One must also *believe* one has that ability or power. There are many studies showing that mood disorders such as depression and anxiety lower belief in the person’s capabilities or perceived self-efficacy.⁸ Since there is a strong correlation between mood disorders and chronic heroin addiction, it is reasonable to assume that many heroin addicts harbour a low sense of self-efficacy and lack confidence in their ability to abstain from heroin.⁹ Chronic heroin addiction is associated with hopelessness about the future and a sense of powerlessness to influence the direction one’s life is going – reinforced by a history of failed attempts to abstain. Now, a lack of belief in one’s own ability is clearly detrimental to one’s will. Thus, according to a standard philosophical view, intentions involve plans of action and such plans, in order to be rational, require the belief that one has an acceptable chance of changing the world in ways one believes are for the better.¹⁰ Given this view, it would not be rational to form intentions one believes one is not going to carry out. The implication is that individuals with heroin addiction who have little belief in their capacity to abstain are likely to find it extremely difficult to form the intention to abstain. That is, since they believe they are going to fail if they try, they are likely to lack the will to abstain. Consequently, their commitment to changing their way of life may be low. Since believing one has reasons not to make an effort to exercise an ability (since one thinks it is futile) is not equivalent to lacking the ability, the problem here is not a lack of ability. The problem rather is an impairment of rational will due to a lack of belief in self-efficacy. It cannot be ruled out that such impairments of the will may lead some chronic heroin addicts to falsely believe abstinence is a non-option.

If this is correct, everything depends on the option of taking part in research. Will a person with chronic heroin addiction consider this option to have a high value, not just as an acceptable way of avoiding the hassle on the street or to get free heroin from a legal source, but as a way of improving their well-being so much that they choose it *because* of that? In fact, there appears to be little reason to think so. Many heroin addicts actually refuse to take part in these studies. In heroin trials in Switzerland, only a third of participants decided to take part when given the choice.¹¹ One reason, presumably, is that they find the costs of keeping regular appointments with healthcare professionals too high. Chronic heroin addicts who do consent must judge these costs as less important than the benefits associated with obtaining free heroin. Presumably, they consider the value of obtaining free heroin to be sufficient to make participation in research acceptable, even if they do not consider the combined value of obtaining free heroin and taking part in research to be very high.

To sum up, it cannot be ruled out that many chronic heroin addicts for whom the problems of procuring the drug on the street are unacceptable, but for whom abstinence is not an option, believe they have only one option, which is to consent to research involving the medical provision of heroin. Since there is evidence to suggest that they might choose this option not because they like it very much, but because they have no acceptable alternative options, their consent

could be construed as non-voluntary. What constrains their choice is not their desire for heroin, but the wider social and psychological circumstances of their heroin addiction and the beliefs about the options these circumstances create.

Our reasoning here is, of course, hypothetical. We have no empirical evidence of the contents of the decision-making processes in individuals with heroin addiction (nor do we know whether any such evidence exists). However, if it is a plausible reconstruction of what these processes might look like given the situational constraints and our current state of knowledge, it suffices, we believe, for our current purpose, to provide a reason why we should not take the voluntariness of their consent for granted.

Voluntary consent and risk-minimising ethical analysis

As we have argued, given a certain plausible conception of voluntariness, we cannot rule out that the beliefs held by individuals with heroin addiction about their options and hence their motivation for action might undermine the voluntariness of their consent even if they have the ability to resist their desire for heroin. One important reason for this is that the wider social circumstances typical of many such individuals may shape their beliefs about their capacity to make choices (such as making abstinence seem impossible) and these beliefs (which may be false) could then impair their will to abstain from heroin use. This suggests that paying special attention to these circumstances should form an integral part of the assessment of whether or not the person's consent is voluntary. However, the argument may perhaps strike some as overly philosophical. On what basis can we decide between different conceptions of voluntariness? Let us end with some more general considerations in favour of the view we have presented.

According to the World Medical Association's declaration on ethical principles for medical research involving human subjects (the Helsinki Declaration), the participation of human subjects in research requires the voluntary consent of individuals who are considered competent to give their consent (www.wma.net/en/30publications/10policies/b3/). What makes it so ethically challenging to assess whether, in the case of heroin research, a person is competent to give their consent voluntarily is, of course, that we have no uncontroversial concept of voluntariness that applies to the specific circumstances of heroin addicts, and we have no direct access to the mental processes of the consenting individual to accurately appraise whatever conception we lean towards. This means that judgements about voluntary consent will always involve uncertainty. How can we best deal with this uncertainty? An ethical way of justifying why one approach is chosen over another might be to compare the potential harm these approaches may inflict on the research participants. Such an overall account of harm will have to reflect the inherent uncertainty of the assessment and also include considerations of harm potentially caused by a flawed assessment.

In this article we have identified three different approaches to consent in individuals with heroin addiction:

a person's desire for heroin rules out any ability to choose freely between receiving heroin or not, hence we should presume that no heroin addict can voluntarily consent to medically prescribed heroin; heroin addicts have the ability to choose freely between receiving heroin or not, hence we should presume that all heroin addicts can voluntarily consent to medically prescribed heroin; the social and psychological circumstances of some individuals with heroin addiction might be such that we cannot presume that they can voluntarily consent to medically prescribed heroin.

Which of these approaches would minimise the harm inflicted on the person if they were used to inform an assessment of their competence to give voluntary consent?

Consider (a). There may be circumstances in which it might be better for some individuals with heroin addiction to receive free heroin under medical supervision than getting it on the street. That is, the harm inflicted on these addicts by obtaining heroin on the street might greatly exceed the potential harm resulting from participation in heroin trials, because of mistaken assumptions about valid consent. Thus, these addicts might end up worse off than if (a) had not been used as the basis for an assessment of voluntary consent. Ironically, the protective safety net of the ethical standard of valid consent breaks down in this case, and in fact inflicts more harm than if the standard were ignored. Next, consider (b). The circumstances of many individuals addicted to heroin might suggest that they have some chance of succeeding in abstinence-based drug treatment programmes. However, this option of trying to achieve a life free of heroin is effectively ruled out if they receive heroin medication on a regular basis. Consequently, the harm these individuals may suffer could be considerable if their consent is accepted as valid without further questioning. Again, they could end up worse off than if we had not used (b) as the basis of the assessment of voluntary consent. Finally, consider (c). This approach differs from (a) and (b) by focusing on the particular person's social and psychological

circumstances (including motivating beliefs) as the basis of the assessment, rather than on universal and hard-to-verify claims about abilities of resistance of persons with heroin addiction. It therefore allows for a more flexible, case-to-case approach, one that neither rules out competence to consent voluntarily nor rules it in. This option would minimise the risk of inflicting more harm than if (c) had not been applied. Consequently, the potential of inflicting harm by assuming this approach is smaller compared with (a) and (b).

Conclusion

Philosophy and medicine are inherent to mental healthcare. Clinical assessments of mental non-observable categories rely on adequate philosophical conceptualisations. Since the adequacy of these conceptualisations cannot be settled *a priori* and uncertainty will always be involved whenever attempts are made to confirm or reject their appropriateness *a posteriori*, philosophy offers a means of identifying the most apt conceptualisation according to a risk-minimising ethical analysis. An assessment of capacity for voluntary consent in individuals with heroin addiction should be based on an approach that minimises the risk of harming them more than if the approach were not applied. According to our argument, focusing on addicts' social and psychological circumstances (including motivating beliefs) as the basis of an assessment rather than their abilities of resistance is the most apt approach in this regard. We therefore suggest that this approach to the assessment of participant consent should guide and inform an ethical practice of including and excluding heroin addicts in research on heroin provision.

1.8.38 Reforming the culture of healthcare: the case for intelligent kindness

Penelope Campling

2015-2

Abstract

There has been increasing interest in the culture of healthcare in the light of the two reports by Robert Francis into the care at Mid Staffordshire. This editorial encourages a comprehensive exploration of the conditions that promote a benign caring culture and make outbreaks of cruel neglect and abuse of patients less likely. Creating and sustaining such a culture is dependent on being honest and realistic about the forces that threaten to undermine it. The editorial argues that being able to confidently articulate the positive values that should define healthcare culture is particularly important at this time. The case is made for a conscious focus on the concept of intelligent kindness.

- *‘Intelligent kindness’*
- *Conclusion*

Robert Francis’ two reports into the Mid Staffordshire scandal, ^{1,2} other inquiry reports such as Winterbourne View ³ and, most recently, Julia Neuberger’s inquiry into the Liverpool Care Pathway ⁴ face us with the reality that healthcare organisations and the healthcare workers within them are capable of neglectful and abusive behaviour that can justifiably be described as cruel. The outrage presses towards sackings and resignations, to a ‘never again’ attitude, or, in various quarters, towards further denigration of the National Health Service (NHS) as a public enterprise. The determination to do something directs us towards yet more regulation and hundreds of other initiatives. Many of these actions may make a difference, but there is a risk that they will become yet another ‘programme’ of activity, on top of an already toppling tower of initiatives, and vulnerable to becoming a mechanical activity rather than keeping their purpose (securing kindness and compassion) in mind.

There has been a general call to address the culture of the NHS. Again, there are signs that this will become another programme – split off from or, at best, sitting alongside, others like the drive for efficiency, promoting choice, etc., rather than a comprehensive consideration of the totality of the conditions in which the NHS works, a genuine exploration of how the NHS culture promotes kindness, or cruelty.

As part of this enterprise, this editorial makes the case for a more conscious and active focus on the concept of intelligent kindness in all parts of the healthcare system. It starts, however, by exploring the forces that create perverse dynamics that can pull in the opposite direction.

The emotional task

Why do seemingly caring staff behave unkindly? This question can be looked at from many perspectives, starting at the level of the individual. ⁵ While it is clearly important to think carefully about recruitment criteria and to encourage people to think clearly about their motivation to work in healthcare, studies suggest that the majority of healthcare students are motivated by the wish to make things better, but during their training become more distanced from patients and less empathic. ^{6,7}

Raymond Tallis, British philosopher and retired professor of geriatric medicine, comments on the enormity in the history of civilisation of the imaginative and moral step involved in engaging with the realities of illness. ⁸ He describes a challenging process of cognitive self-overcoming on the part of humanity and reminds us that humans found it easier to assume an objective attitude towards the stars than towards their own inner organs. This self-overcoming – surely one of humanity’s greatest achievements – has to be done on an individual level by thousands of NHS staff every day as they muster the will, the necessary balance of kindness and professional detachment, to perform the most intimate tasks imaginable. It is easy to forget the appalling nature of some of the jobs carried out by healthcare staff day in, day out – the damage, the pain, the mess they encounter, the sheer stench of diseased human flesh and its waste products.

Contact with emotional distress and disturbance can be equally, if not more, harrowing. Existential questions about identity, suffering, madness and death are raised and may put people in touch with extreme feelings of confusion, pain and loss. ⁹ The struggle with feelings of helplessness and hopelessness in the face of suffering cannot be avoided, and individuals, depending on their personality and past experience, protect themselves in different ways from the emotionally traumatic environment. ¹⁰ Psychological defence mechanisms are evoked frequently. Problems can arise if staff are exposed to frequent emotional trauma, without space to process their feelings. Defensive styles of coping

then become entrenched. ¹¹ As defensive walls build up, feelings of vulnerability and sadness become more deeply buried and the capacity for empathy recedes.

Problematic team-working

Attachment to a well-functioning group can help to contain disturbed feelings and facilitate a healthy focus on the emotional task, but groups can also be the scene of disturbed – often unconscious – dynamics. ¹² There is evidence that the quality of the team one is working within makes a lot of difference to staff experience, can buffer the effects of a wider dysfunctional organisation ¹ and enhances functioning generally. ¹³ Unfortunately, many hospital teams are not highly evolved in their functioning as teams. They tend to have unclear boundaries and conflicting objectives, with different professions approaching the task from different perspectives and tensions sometimes arising between professional and organisational hierarchies. In addition, many staff are on rapid training rotations or can be moved without consultation to cover shortages in other teams. The breakdown of close-knit medical ‘firms’ means patients often complain that they see a series of junior doctors and do not know the name of their consultant. Many staff, particularly senior staff, have a peripatetic role and belong in many different ‘teams’. Although most hospital staff say they belong to a team, Borrill *et al* ¹⁴ show that more than 60% are in what they call pseudo-teams, with no obvious cohesion or boundary. Responsibility-shifting, driven by fending off anxiety between team members or between teams in wider system, is a particularly prevalent dynamic in health and social care. ^{15,16}

Problematic organisations

Menzies Lyth’s famous study of nurses in the 1950s sought to understand why nurses resigned from their profession in such high numbers. ¹⁷ It showed that the stresses of nursing, and the intimate relationship it demanded with patients, made an impact on the organisation of care, leaving those closest to patients exposed to emotional pressures that most senior staff and managers were defended against. Menzies Lyth felt that the work of nursing – what she called the objective situation – because it involves physical and emotional contact with illness, pain, suffering and death, arouses feelings and associated thoughts linked to the deepest and most primitive levels of the mind. She proceeded to show how the organisation of the hospital can be seen as consciously and unconsciously structured around the evasion of this anxiety.

Menzies Lyth proposed that the success and viability of a social institution are intimately connected with the techniques it uses to contain anxiety. In the intervening years, these ideas have been developed, looking at the goodness of fit between organisation structures on the one hand, and the emotional demands of healthcare work on the other. There is little sign that the system as a whole has developed effective structures to support frontline staff process the emotional disturbance inherent in their interactions with sick patients; in fact, evidence from the annual staff surveys suggests the opposite (www.nhsstaffsurveys.com). Moreover, there is little understanding or attempt to contain the primitive anxieties that pervade the system and affect all involved, including decision makers at government level. If anything, there is more disconnection between the policy level of the organisation and the emotional reality of clinical encounters. ¹⁸

Whereas much of Menzies Lyth’s 1959 study could be describing the health service of today, there is one important difference. Menzies Lyth noted the resistance to change in the NHS of the 1950s and saw it as a significant part of the social defence system. I suggest here that it is the uncritical promotion of constant change and imposition of new ideologies that is the main social defence system in the modern health service, ¹⁹ overloading and fragmenting the system and distracting from the task of caring for the sick and dying. ²⁰⁻²³

Perverse dynamics

The health service sits within a broader society that shapes its rules, agreements and unconscious social pacts. The spirit of cooperation that was around in the immediate aftermath of the Second World War provided a fertile value base for implementing the NHS, but has been steadily encroached upon by individualism, consumerism and the hegemony of market forces. Susan Long describes and gives evidence for this in her book *The Perverse Organisation and Its Deadly Sins*.²⁴ A basic premise of her book is that there has been a move in society generally from a culture of narcissism to elements of a culture of perversion. Perversion flourishes where instrumental relations have dominance – in other words, where people are used as a means to an end, as tools and commodities rather than respected citizens. It is these relations that Long sees predominating increasingly. Her book considers large private corporations rather than the public sector. However, the fashion to idealise large private sector corporations and the subsequent corporatisation of the public sector means much of the thinking in her book is relevant to the modern health service.

It is important to realise that Long's emphasis is on perversity displayed by institutions rather than by their leaders or members. There is no suggestion that individual NHS workers, as people, are any more perverse than workers in any other organisation. Nevertheless, in reality, an organisation and its members are entwined: the decisions and actions of individuals are influenced by organisational culture and, in turn, reinforce it, for good or ill. The concept of perversion sheds light on frankly exploitative behaviour, helps explain how many people in positions of trust end up abusing those positions and how people may be collectively perverse despite individual attempts to be otherwise.

Corrupting forces?

There appear to be four closely intertwined processes at work. None of them is perverse in itself, but separately and together they can create perverse dynamics in the context of healthcare. The first is the active promotion of a competitive market economy, on the basis of a commodified view of need, skills and service. Such an economy works against the idea of an integrated service that prioritises the needs of vulnerable patients, and can insidiously affect the attitudes, feelings and relationships of staff.^{25,26} The second is the process of industrialising healthcare.^{27,28} This enterprise has the potential to undermine healthcare as work undertaken by skilled individuals in relationships with patients and to turn it into the mechanical delivery of processes and systems. The third is the framework and currency of specification, regulation and performance management. How services are specified, monitored and evaluated – and funded – has a profound effect on the day-to-day clinical work.^{29–31} The fourth is the inexorable rise of consumerism and the promotion of patient 'choice'. These four elements are of course interrelated and, some would say, reflect inevitable trends in society at large. But of particular concern is the way these processes have taken hold without proper debate and understanding of the unintended consequences for the system as a whole.

Focusing on compassion and kindness

In the light of the present crisis in the culture of our healthcare system, it is particularly important to be able to talk in terms of positive values, to have a clear vision of how we would like to see our organisations function, how we wish to encourage society – and the organisations that serve society – to relate to the sick and vulnerable. The NHS was founded at a particular point in history when there was a strong motivation to create a better future based on the idea of the common good – a concept that may be out of fashion but is still enshrined in the NHS constitution.³²

If our public organisations are to flourish, we need to be able to articulate our aspirations in ways that resonate with today's citizens. A number of writers and philosophers have attempted to address the worrying narrowing of the moral universe in organisational life: Paul Ricoeur refers to the loss of ethical intention in public life;³³ Onora O'Neil talks about the growing culture of suspicion linked to increasingly excessive accountability regimes and urges us to free professionals and their public services to serve the public;³⁴ Michael Sandel talks about the squeezing out of altruism and argues that we put limits on the current encroachment of market thinking into every sphere of life;³⁵ and Tony Judt made an appeal before he died that we rediscover a language around which we can be motivated collectively, whether on the issue of justice, inequality, cruelty or unethical behaviour – a language that will bind us together.^{36,37}

There has been a focus recently on compassion in healthcare.^{38,39} Although the popular press tends to see this as a nursing issue, there is wider acknowledgement that creating a more compassionate culture will need a systemic

approach. There has been a growing interest more generally in compassionate leadership and the ‘compassionate organisation’ (www.compassionateleadership.com; <http://instituteforcompassionateleadership.org>).⁴⁰

It is clear – and understandable from an evolutionary perspective – that if a person is feeling under threat, it is likely that the compassionate components of the mind are turned off and instead the mind has a pattern of motivation and ways of feeling that are about protecting oneself from danger. This is of obvious relevance to the NHS workforce and points to the creation of a culture that feels safe and affirming rather than unsettled and threatening.⁴¹

Clearly, there is a large overlap between the concept of compassion and the concept of kindness. Both words are defined in relation to other people: compassion literally meaning ‘suffering with’ whereas kindness is linked to the concept of kin and kinship. Kindness is a word very commonly used by patients. Many people’s stories about their experience of healthcare centre around the degree and quality of kindness they have (or have not) experienced. Often these accounts are complaints about the absence of kindness, the thoughtlessness, the lack of humane care. Sometimes they describe the power of small, but highly relevant, acts of kindness to transform an otherwise miserable experience of suffering (www.patientopinion.org.uk).^{42,43}

Kindness is a word with an interesting history. It is also a word that needs rescuing for it can evoke mixed feelings in the modern world and easily become a mere synonym for individual acts of generosity, sentiment and affection, for a general fuzzy ‘kindliness’. The warping and obscuring of what kindness is about have been extensively discussed by psychoanalyst Adam Philips and historian Barbara Taylor in their recent book, *On Kindness*.⁴⁴ They explore the way in which a philosophy and culture of competitive individualism and the pursuance of self-interest has challenged the value, and negatively influenced the meaning, of kindness. Kindness, they say, is not a temptation to sacrifice ourselves, but to include ourselves with others – kindness is being in solidarity with human need. They describe a process in which what had been a core moral value, with a subversive edge, at centre stage in the political battles of the Enlightenment, became something sentimentalised, marginalised and denigrated through the 19th and into the early 20th century.

‘Intelligent kindness’

Kindness has its roots in the Old English word *cynd* – meaning nature, family, lineage – kin. Kindness implies the recognition of being of the same nature as others, being of a kind, in kinship. It implies that people are motivated by that recognition to cooperate, to treat others as members of the family, to be generous and thoughtful. The word can be understood at an individual and at a collective level, and from an emotional, cognitive, even political point of view. Adding the adjective ‘intelligent’ signals, first that it is possible to think in a sophisticated way about the conditions for kindness, and second that clinical, managerial, leadership and organisational skills and systems can be brought to bear purposively to promote compassionate care. Intelligent kindness, then, is not a soft, sentimental feeling or action that is beside the point in the challenging, clever, technical business of managing and delivering healthcare. It is a binding, creative and problem-solving force that inspires and focuses the imagination and goodwill. It inspires and directs the attention and efforts of people and organisations towards building relationships with patients, recognising their needs and treating them well. Kindness is not a ‘nice’ side issue in the project of competitive progress. It is the ‘glue’ of cooperation required for such progress to be of most benefit to most people.

To illustrate how such behaviour is nurtured in the wider system a virtuous circle is envisaged, where there is not only a compassionate connection between the clinician and the patient, but the potential for something to happen in the wider system (*Fig. 1*).

There is a body of evidence that supports this virtuous circle, cited elsewhere.⁴⁵ Simply put, the more attentively kind staff are, the more their attunement to the patient increases; the more that increases, the more trust is generated; the more trust, the better the therapeutic alliance; the better the alliance, the better the outcomes. The result of all this is a reduction in anxiety, improved satisfaction (for staff and patient), less defensiveness and improved conditions for kindness. This system will flourish if individuals and the system as a whole are driven by a sense of kinship. This can be expressed as simply as seeing oneself in the patient – or as the King’s Fund put it, seeing the person in the patient and delivering the sort of care you would like for your family and friends.⁴⁶ This sense of kinship will promote the feeling and expression of kindness which then directs attention, and so on.

These dynamic processes can also contribute to productivity, a key challenge for all health services. A useful concept in the industrial model is that of ‘getting it right first time’ as a key driver for eliminating waste – of *Fig. 1* Intelligent

kindness: a virtuous circle. time and resources. All stages and the combined effect of this cycle contribute to such effective activity. The more work is founded on kinship, motivated by kindness and expressed through attentiveness and attunement to the patient's needs, the more it is likely to be timely and 'right first time'.

Conclusion

Kindness rooted in kinship is a powerful concept – ethically, politically, socially and clinically – in the project of improving healthcare. It increases patient satisfaction, staff morale, clinical effectiveness and efficiency. But virtuous circles are vulnerable and we know from history how quickly a benign culture can become malignant. The first part of this editorial described some of the difficulties inherent in the healthcare task that make a benign culture difficult to sustain if they are not properly understood and managed.

Menzies Lyth's work on social defence systems in healthcare was published over 50 years ago. In general, though, there has been a failure to create organisations that are fit for purpose and able to facilitate the emotional work that is such an important component of the healthcare task. There has been a failure to acknowledge and get to grips with the way overwhelming anxiety – largely unconscious – can unhelpfully drive and undermine the system. Moreover, it is suggested that some of the changes in society over this time period have had an impact on the health service in a way that has amplified the amount of anxiety in the system, pulling the culture in a direction where perverse behaviours become more likely. Many would say the system has already become a vicious circle where so-called 'solutions' involve overloading the system and creating ever more dangerous levels of anxiety. Virtuous circles unravel so easily; vicious circles, on the other hand, are extremely difficult to break.

It is more important than ever to have an explicit value base underpinning the work of both individual staff members and healthcare organisations, and to understand what that value base looks like 'in action'. The virtuous circle described here earlier could provide a basis for thinking about this, strengthening relationships between colleagues and with patients, and counteracting the pressures to adopt instrumental attitudes to the work that are all too prevalent at the present time. The possibility emerges of a kinder culture developing as all aspects of the NHS – evidence, skill, new technologies, where money is spent, how people are managed – are scrutinised in terms of how they support this virtuous circle.

At an anecdotal level, individuals report that the concept of intelligent kindness properly embedded in reflective practice has 'reconnected them to their altruism'; and teams from ward to board level have found the virtuous circle a helpful focus when thinking about culture change. There is scope for adapting the model for research and audit purposes, building on the evidence base for relational science to influence the organisation of healthcare delivery and outcome.

- *Our Encounters with Self-Harm*

When I was working as a junior doctor in accident and emergency, one of my favourite jobs was suturing. A pleasant break from the constant decision-making, an opportunity to do something practical and almost artistic, and most of all a chance to just sit down and chat with the patient as I stitched. Despite this, one of my least favourite tasks was patching up those who had self-harmed. Something about the sight of the self-inflicted wounds upset me far more than the most horrendous accidental injuries; I tried to still be warm and not allow the distress and disgust I felt show, but I did not know what to say and we would often sit in silence as I worked. I had never been taught about non-suicidal self-harm, what it serves, how to approach it, anything. It was not until I began my psychiatric training that I began to understand it, and became retrospectively frustrated with how I had felt and responded to it earlier in my career. I now ensure I cover this subject in some depth with my medical students, to try to avoid them feeling about self-harm the way that I used to. Alternatively, I could just make them read this book.

Our Encounters with Self-Harm is made up of 37 pithy chapters by different authors. The majority are written by those who have, or still do, self-harm, and others are by family members and professionals (the last of which I found the least educational; an interesting reminder not to dismiss personal accounts in an era where quantitative research often feels the only thing that counts). Most take the form of a piece of prose about the writer's personal experience, followed by a short bullet-point list of thoughts that they would like the reader to take away from it.

These pieces are brave, articulate, occasionally harrowing, and frequently illuminating. Since it is an anthology, unsurprisingly there is a certain amount of repetition within the book. This is no complaint; it serves to reinforce the most common themes such as: accept that this is my coping mechanism, find out what it means to me, look beyond the act of self-harm to treat the person behind it with kindness. Meanwhile, the divergences remind us of other key points such as not making assumptions and remembering that 'everyone who self-harms is an individual, so everyone's self-harm has individual meaning'.

Buy this book and force every medical and nursing student you encounter to read a chapter from it. I suspect it would significantly improve in the future the care that patients presenting to accident and emergency with self-harm receive. While you are at it, share it with your psychiatric colleagues; a reminder of empathy and a deepening of our understanding of our patients can never go amiss. As one of the contributors writes, 'whatever you learn, get it out there, you never know who might benefit from your own experiences'.

1.8.40 Anti-NMDA-receptor encephalitis presenting with catatonia and neuroleptic malignant syndrome in patients with intellectual disability and autism

Abstract

We report anti-*N*-methyl-d-aspartate (NMDA) receptor encephalitis in two patients with autism and intellectual disability presenting with neuropsychiatric symptoms of catatonia and neuroleptic malignant syndrome. Case reports such as these help raise awareness of this clinical issue. By paving the way for earlier diagnoses they ultimately maximise the potential for curative treatments and prevention of long-term complications.

 - * *Differential diagnoses*

Anti-*N*-methyl-d-aspartate (NMDA) receptor encephalitis is a recently recognised syndrome, which can be mistaken for psychiatric disorders. It is potentially reversible with appropriate treatment. It is usually idiopathic but can be associated with tumours, particularly ovarian teratomas in female patients. Surgical excision of the tumour (if present) and immunotherapy are currently considered optimum treatment for anti-NMDA-receptor encephalitis.

An increasing recognition has been given to the aetiological role of the immune system in the pathogenesis of various psychiatric disorders and early diagnostic tests have been recommended to rule out autoimmunity.¹⁻³ Anti-NMDA-receptor encephalitis is one of the recently described autoimmune encephalitides⁴ with a prominently psychiatric presentation.⁵ It is important to diagnose and treat anti-NMDA-receptor encephalitis. Untreated, it can lead to cognitive deficit and death.⁶ Definitive diagnosis relies on the detection of anti-NMDA-receptor antibodies, using a highly specific and sensitive assay, yielding no false positives as yet.⁷ The reduction in NMDA-receptor antibodies with clinical improvement supports the pathogenic role of antibodies in anti-NMDA-receptor encephalitis.⁸

A publication in the *British Journal of Psychiatry* describes four cases of anti-NMDA-receptor encephalitis initially presenting with signs and symptoms suggestive of a psychiatric disorder.⁹ We report two cases of anti-NMDA-receptor encephalitis presenting with catatonia and neuroleptic malignant syndrome (NMS) in individuals with autism and intellectual disability.

Case studies**Case study 1**

A 32-year-old single woman with a diagnosis of mild intellectual disability, autism and Larsen's syndrome presented with social withdrawal and a persistently low mood. Subsequently, her sleep and oral intake deteriorated. A preliminary diagnosis of depression was made and she was put on an antidepressant. Unfortunately, her skills deteriorated further and her parents had to attend to her basic needs. She then showed objective evidence of hallucinations when she would shout incoherently or burst into laughter for no apparent reason. She was therefore started on a low-dose antipsychotic medication but then developed incontinence, muteness and rigidity. She maintained a sedentary position

The Authors own the copyrights to the individual articles.

and needed a wheelchair to be moved around. There were classic catatonic signs and symptoms such as negativism, echolalia and posturing. At this stage NMS was suspected as the patient had low urine output, low-grade fever, clammy skin and fluctuation of blood pressure. Her psychotropic medication was stopped and she was urgently admitted for further assessment. Investigations revealed a normal creatine kinase (CK) level and no evidence of infection or metabolic imbalance. With many presenting symptoms being of a psychiatric nature, an initial diagnosis of functional catatonia was thought most appropriate. Consequently, treatment with psychotropic medication was reinitiated targeting the psychotic and mood symptoms. Despite this, her condition continued to deteriorate. She then had at least two episodes of non-convulsive seizures (with inter-ictal electrocardiogram (EEG) not showing any evidence of epileptiform activities) and several episodes of what were initially thought to be breath-holding attacks. A referral to the respiratory department ruled out bronchomalacia reported in Larsen's syndrome. As her oxygen saturation and chest X-ray were normal, these episodes were first thought to be behavioural in nature. She later developed a rabbit-like movement of the lips, which lasted for 2 weeks. Magnetic resonance imaging (MRI) scans of the head and spine were normal.

Anti-NMDA-receptor encephalitis was suspected in view of her complex presentation and normal investigations. A serum sample later on in the course of illness was strongly positive for anti-NMDA-receptor antibodies. Following diagnosis, a thorough investigation was undertaken to rule out the presence of an underlying tumour, particularly an ovarian teratoma, which has been reported in a considerable number of cases of anti-NMDA-receptor encephalitis in females.^{10,11} Abdominal and pelvic ultrasound, brain MRI and chest, abdominal and pelvic computed tomography (CT) scans, blood tests for tumour markers and other autoimmune disorders revealed no abnormalities. By the time she received intravenous methylprednisolone, she had started to show improvement and this gradually continued with the second course.

During recovery she suffered mild amnesia. She would often be searching for something that she was actually holding in her hand, for instance a mobile telephone or spectacles. Owing to a prolonged period of immobility, she developed a flexion contraction in her upper and lower limbs, which improved partially with physiotherapy. Six months later, she had completely recovered with no evidence of psychosis or cognitive deficit and all her skills, apart from ability to walk, returned to a pre-morbid level. She is now awaiting orthopaedic intervention to facilitate her mobility.

Case study 2

A 42-year-old single man with moderate intellectual disability, autism and a history of affective psychosis in remission presented with urinary retention requiring catheterisation. This was attributed to anticholinergic side-effects of his psychotropic medications. These were therefore stopped. He later developed sepsis and needed to be treated with intravenous antibiotics. At this point, his estimated glomerular filtration rate had reduced dramatically (27 ml/min) and his urea and creatine increased (13.3 mmol/l and 240 umol/l respectively); as he also was on lithium, this had to be stopped to avoid toxicity. Following treatment, his kidney function tests came back to normal but his condition deteriorated and he displayed aggressive outbursts and insomnia. Given his recent history of urinary retention/renal failure, extreme aggression and a history of affective psychosis, he was subsequently treated with a new generation antipsychotic, aripiprazole, but this could not be continued because of allergic skin rashes. A few days following the cessation of aripiprazole he appeared vacant and confused, unable to communicate, and was rolling on the floor while kicking out in the air. Owing to extreme agitation, he needed benzodiazepine agents and intensive two-to-one support to ensure he did not sustain injury. The floor and walls of the room were covered with soft mattresses to prevent any skin breakdown due to friction on the floor. He had speech and language therapy input to prevent aspiration but soon stopped oral intake completely. With a working diagnosis of acute delirious state, he underwent extensive investigations including blood tests, lumbar puncture and brain scan, which all were reported as normal. His EEG at this stage reported generalised low-amplitude slow-wave activities in line with a mild diffuse cerebral dysfunction.

Since all investigations were within normal range, the clinical picture was attributed to a rapid withdrawal of his psychotropic medications and therefore a low dose of olanzapine (2.5 mg daily) was started. However, he deteriorated and his vital signs started to fluctuate. Blood investigations revealed extremely raised CK level (5369 iu/l). His white blood cell counts, kidney and liver function tests, however, were within normal range. Olanzapine was stopped and a working diagnosis of NMS was made. He received intravenous bromocriptine but even after CK level came back to normal, he did not show any improvement. During this time he presented as non-responsive, with decreased level of consciousness and some repetitive swinging movements of his arms and legs. All the investigations, including brain

MRI scan, lumbar puncture and numerous blood/urine tests came back as normal. Swallowing difficulties with a high risk of aspiration resulted in the requirement of a radiologically inserted gastrostomy. He subsequently developed pneumonia and was placed on positive airway pressure for a short time. Treatment with intravenous antibiotics resulted in recovery of pneumonia but he developed severe diarrhoea owing to *Clostridium difficile*.

At this stage it was felt that his condition could not be explained simply by a change in his medication or NMS and further investigations revealed positive anti-NMDA-receptor antibodies. Various investigations, including tests for other autoimmune encephalitides, tumour markers and chest, abdominal and pelvic CT scans were carried out to rule out an associated neoplasm, which has been reported to co-occur with anti-NMDA-receptor encephalitis in male patients,¹² but the results came back negative. He was treated with methylprednisolone, after which he started to improve cognitively; however, he continued to go through latter stages of the disease and developed seizures and orofacial dyskinesia. He had another course of methylprednisolone and gradually, over a period of a few months, started eating and walking.

Discussion

These two cases of anti-NMDA-receptor encephalitis, in individuals with intellectual disability and autism, presented with signs and symptoms of NMS and catatonia. In both patients the diagnosis was made with delay owing to the complexity of their presentation.

One of the characteristic features in Case study 1 was the presence of autonomic dysfunction which manifested with clammy skin, low-grade fever, persistent sinus tachycardia and fluctuation in blood pressure. These were unrelated to an underlying infection or dehydration. The patient also had short-lived episodes of central apnoea which confusingly presented itself similar to breath-holding attacks, which were first thought to be behavioural in nature. Autonomic instability in Case study 2 presented with episodes of urinary retention necessitating frequent catheterisations. Both patients developed frequent urinary and chest infections, muscle atrophy and contractures needing a multi-agency approach and intensive skin care to prevent pressure sores. During the first few months of their illness, both patients required two-to-one staffing support on a daily basis. In spite of intensive multi-agency support provided by the health and social care services, the experience was overwhelmingly traumatic and stressful for the families who had to cope with witnessing the patients going through a life-threatening and debilitating illness.

Differential diagnoses

Anti-NMDA-receptor encephalitis can be mistaken for psychosis¹³ or catatonia.^{14,15} Concerns have been raised that catatonia is underdiagnosed. One study¹⁶ found that in Scotland the prevalence of catatonia varied depending on the diagnostic criteria used, ranging from 1.3 to 32%. In that study the prevalence of psychiatric patients demonstrating any catatonic signs was at least 7.9–19.1%. The most common catatonic signs were marked underactivity, echolalia, palilalia, marked overactivity and *gegenhalten*. In those with catatonic signs, the most common diagnoses were schizophrenia, schizoaffective disorder, dementia and non-psychiatric disorders (1.5%).

Malignant (lethal) catatonia presents with clouding of consciousness, autonomic instability, mutism, refusal to eat and drink, rigidity, waxy flexibility and posturing, and can be mistaken for NMS. Raised creatine kinase-skeletal muscles isoenzyme and leukocytosis are present in both conditions. It has therefore been suggested that, on the basis of the similarity of signs, symptoms and response to treatment, malignant catatonia and NMS should be considered to be the same disorder; NMS may also be understood as an antipsychotic-induced form of lethal catatonia.¹⁷ Interestingly, both NMS and catatonia might be seen in a patient at the same time, with one evolving into another in the course of illness.^{18,19}

Catatonia resistant to benzodiazepine and electroconvulsive therapy has been treated with NMDA-antagonists (amantadine and memantine).²⁰ Theoretically, however, these may exacerbate anti-NMDA-receptor encephalitis. Care should be therefore taken to avoid diagnostic overshadowing in people with autism and intellectual disability who have communication difficulties, as early treatment prevents mortality and long-term cognitive complications.²¹ A recent case report of catatonia in a deaf patient²² highlights this important issue in a vulnerable population with communication difficulties.

It is also important to be aware of other differential diagnoses such as viral encephalitis,²³ a catatonic state induced by a psychiatric disorder or catatonia seen in people with autism spectrum disorder,²⁴ substance misuse, serotonergic syndrome, heat stroke,²⁵ other autoimmune encephalitides such as antiphospholipid syndrome,²⁶ and catatonia induced by pernicious anaemia.²⁷

This report highlights the complex presentation of anti-NMDA-receptor encephalitis in two patients with intellectual disability and autism. Whether or not people who have underlying brain pathology are more prone to develop this type of encephalitis or have a worse prognosis in comparison with the rest of the population needs further exploration through future case studies and multicentre research projects.

We are grateful to our patients and their families who kindly gave permission for the publication of this case report. We also thank our colleagues from allied healthcare professions for their invaluable input in the management and rehabilitation of our patients.

1.8.41 Preventing Mental Ill-Health: Informing Public Health Planning and Mental Health Practice

- *Preventing Mental Ill-Health: Informing Public Health Planning and Mental Health Practice*

This book covers an ambitious breadth of material concerning the definition, determinants and interventions for prevention of mental ill health. The sheer scale of material covered means that the reader should not expect an in-depth critique of all the evidence presented and this can pose questions around the methodology and conclusions of studies. The author notes that she is an agnostic entering the houses of such new religions as biological psychiatry and positive psychology. Their differing perspectives occasionally lead to a conflict in argument, which is not always resolved. Psychiatric labels are defended for their contribution to research, while later it is reported that improved understanding of schizophrenia has derived from breaking the diagnosis down into constituent symptoms.

My favourite statistic from the book is the reported finding that 2.4% of women from a Basque-speaking rural area screened positive for depression compared with 11% of women in a Spanish-speaking village in the Basque region. The degree of integration in each community is cited as an explanation, echoing the famous theories of Emile Durkheim around suicides and social cohesion.

Despite a thought-provoking chapter on ‘society, status and participation’, the focus of the book is very much on the individual’s place within society. There is a good discussion of negative consequences of housing policy and a look at unemployment and inequality, but in terms of social determinants of mental health, I was left wondering how to build societies with the kind of integration that seems so protective. For the individual, the take-home message is that what matters is to feel loved, safe, valued and in control.

1.8.42 Heads in the sand may leave old age psychiatry looking foolish and vulnerable

: Commentary on ... A memory clinic v. traditional community mental health team service

David Jolley

Correspondence

David Jolley

(David.jolley@manchester.ac.uk)¹

date

2015-2

Abstract

Dementia has been recognised as a major challenge to health, social care and economies. Research by Rubinsztein and colleagues, in this issue, has compared the services provided by memory clinics with those of traditional community mental health team services. They conclude that memory clinics offer a more comprehensive and multidisciplinary service at no extra cost. Here I will question some of their findings and highlight the importance of better continuity of care between primary and secondary services.

 - * *Conclusions*

These are heady times for the dementia lobby. London's G8 Conference on dementia was the latest in a series of national and international 'think-ins' that has seen the condition emerge from the shadows of denial and neglect to be recognised as the single most significant challenge to health and social care, economies and personal philosophy now and for the predictable future.¹

The Guardian's letters page and a thoughtful article from Richard Ashcroft laid bare the realities of our situation.^{2,3} Awareness of dementia has been improved, but are services being made available to help people affected by it and are the research initiatives producing better lives and reducing stress associated with the condition? Richard Ashcroft's mother-in-law received a diagnosis and was discharged after two contacts by 'old age psychiatry', leaving her, her family and general practitioner to feel left adrift in a sea made no-less frightening by having acquired a label.

Rubinsztein *et al*'s research

Judy Rubinsztein and her colleagues⁴ provide an interesting and important description and analysis of what happens when someone with a memory problem is referred by primary care for specialist assessment and advice. They compare the experiences and costs associated with a memory clinic, the model that has become the Holy Grail of assessment through the National Dementia Strategy,⁵ and assessment with less formality by a community mental health team (CMHT). Referral rates were similar: 5 per 1000 of the over 64-year-old population per annum. The CMHT patients were older, they were less impaired and were seen more quickly after referral. The diagnostic spectra were similar. Neither service was bedevilled by a long waiting list such as is described by many floundering services.⁶ Stakeholders were happy with both systems but measures that equate quality with assessment by more than one profession, and make use of formalised paper protocols and checklists, prefer the memory clinic model: memory clinic patients were twice as likely to receive a copy of the letter summarising the findings and plans for their future care.

The increased 'quality' attributed to the memory clinic is said to be achieved at no greater, actually lesser, cost. Yet, we might wonder how useful all those paper scaled measures are and many will question the costings: digging deeper we find that half of patients referred to the CMHT service were seen only once, and by a consultant in their own homes. The paper judges this to be poor practice, yet this is not reflected in stakeholder views. It might alternatively be viewed as an elegant and efficient approach that reserves multidisciplinary assessments at the clinic, which are time-consuming, less convenient and more costly for patients and carers, for people with more complex presentations. The memory clinic model might be construed as: 'one-size-fits-all' with everyone attending the clinic, 22/33 having two to six contacts. This is the sort of consideration that makes people question the advantages of clinic-based services. The differential that deems the CMHT model more expensive relates exclusively to travel costs, where the high salary of consultants who are travelling and one outlier who was visited eleven times, load the CMHT pricing. This is a brave and important attempt to capture costs and relate these to activities and effectiveness. It leaves us to reflect how difficult a task this is.

The paper opens a fascinating window on what actually happens in this world of dementia care. A total of 35% per cent of people 'eligible' for cholinesterase inhibitors did not receive them. This is the reality and gives a degree of balance to criticism of the UK for its relatively low rate of prescribing these substances:⁷ even when assessed, not every patient will accept such treatment, others will encounter side-effects or become disabused. One wonders what is happening in those countries that report prescriptions to near 100% of the predicted prevalence of Alzheimer's disease.

Three CMHT patients (10%) were retained for further care, but only 1 of 33 in the memory clinic was directed to their CMHT. One patient (out of 66) received cognitive stimulation therapy and three saw a neuropsychologist. The memory clinic is applauded for 'signposting' more patients to other services: third sector, social services or benefits. Overall, Richard Ashcroft might be forgiven for feeling that not much of substance is evident after the initial flurry.

Identifying weakness in existing services

The arguments in favour of including specialist memory services within the spectrum offered by old age psychiatry and other disciplines are strong, cogent and widely accepted.⁸ With great respect, however, both models described here are failing. Their referral rates are such that they cannot close the gap that still exists between predicted prevalence and diagnosed prevalence.⁹ There is no increase in referrals associated with the memory clinic arrangement, nor are the patients seen by that clinic earlier in the course of their dementia (as measured using the Mini-Mental State Examination). Tellingly, neither makes a tangible contribution to the continuity of care that patients, families and colleagues in other agencies respect and expect.

Variations that simply replace doctors with cheaper nurses, rate per hour¹⁰ may not be more cost-effective. They are more likely to rely on standardised protocols with inclusion/exclusion criteria designed to be risk-avoidant and limit workload rather than respond to patient need.¹¹ Lessons from the 10/66 studies and initiatives encourage the use of low-tech, clinically competent approaches with training and support to local healthcare agents.^{12,13}

In countries with established large populations of older people, including the UK, the realisation is that we must bring specialist skills into primary care so that people with dementia can be assessed, treated and supported by a competent local team that knows them as whole people with multiple strengths and multiple weaknesses associated with a range of pathologies.¹⁴⁻¹⁶ Models that do this achieve referral rates more than twice those reported in East Anglia, sustain

patients, carers and primary care colleagues throughout the journey of dementia and other frailties before death, and reduce expenditure on secondary health care.¹⁷

Despite the rhetoric of ‘war on dementia’, and exposure of the myth of the dependency ratio,¹⁸ actual service support for older people, including those with dementia, has been reduced by 30% in this country.¹⁹ Populist politicians are given column space to stir up unjustifiable resentment against old people.²⁰

Psychiatrists and their colleagues need to remain clear-headed, open and honest as advocates and providers for people with dementia and their families. We are learning what works and is affordable and this is what matters.

Conclusions

Rubinsztein and her colleagues have done us good service in dissecting and comparing the innards of clinic-based and community-based memory services. They have answered some questions and opened others to be pursued, which is all to the good; but we must lift our heads from the sand of what we have been doing within the comfort and discomfort of secondary care to work across the false border that is assumed between primary care and secondary care. There is little to be gained from a well-made diagnosis unless it is part of a meaningful, continuing process of care for the patient and their caring family.

1.8.43 Cognitive-behavioural therapy by psychiatric trainees: can a little knowledge be a good thing?

Eric Kelleher Melissa Hayde Yvonne Tone Iulia Dud Colette Kearns Mary McGoldrick Michael McDonough

Correspondence

Eric Kelleher (eric.kelleher@tcd.ie)¹

Abstract

Aims and method To establish the competency of psychiatric trainees in delivering cognitive-behavioural therapy (CBT) to selected cases, following introductory lectures and supervision. Supervisor reports of trainees rotating through a national psychiatric hospital over 8.5 years were reviewed along with revised Cognitive Therapy Scale (CTS-R) ratings where available. Independent *t*-test was used to compare variables.

Results Structured supervision reports were available for 52 of 55 (95%) trainees. The mean result (4.6, s.d. = 0.9) was at or above the accepted level for competency (3) for participating trainees. Available CTS-R ratings (*n* = 22) supported the supervisor report findings for those particular trainees.

Clinical implications This study indicates that trainees under supervision can provide meaningful clinical interventions when delivering CBT to selected cases. The costs of supervision need to be judged against these clinical gains.

- *Cognitive-behavioural therapy by psychiatric trainees: can a little knowledge be a good thing?*
 - *Method*
 - *Results*
 - * *Characteristics of trainees*
 - * *Patient characteristics*
 - * *Supervisors' structured ratings of all trainees delivering CBT*
 - * *Trainees' ratings of supervisors*
 - *Discussion*

Developing competencies in psychotherapy is a requirement of basic psychiatry specialist training in both the UK and Ireland.^{1,2} Of the psychotherapies, cognitive-behavioural therapy (CBT) has gained increasing prominence both as a treatment alternative and adjunct to medication due to its proven efficacy in the treatment of mood,³ anxiety,⁴ psychotic⁵ and eating disorders.⁶ In England, the Improving Access to Psychological Therapies (IAPT; www.iapt.nhs.uk) outlines the government's commitment to use CBT in the future.⁷ This highlights a clear practical need for all psychiatric trainees to develop competencies in CBT.

In clinical practice, psychotherapy is often delivered by psychotherapy trainees under supervision, such as post-doctoral fellows or pre-doctoral interns in psychology or social work.⁸ Previous work by Brittlebank & Owens suggests that psychiatric trainees can deliver CBT effectively to patients.⁹ To date, much of the literature on psychiatric trainees delivering CBT has focused on comparing the recommendations of the Royal College of Psychiatrists with clinical practice^{9,10} and looking at strategies to improve its organisation.¹¹ Recommendations such as improving the availability of supervision,¹² protected time¹³ and suitable cases have been made.^{14,15} Although there has been literature published on the assessment of psychotherapy competencies for psychiatric trainees,^{16,17} to the best of our knowledge, there is little published on the competency of psychiatric trainees to actually deliver CBT based on structured feedback from supervisors and the use of structured tools such as those found on postgraduate psychotherapy courses.

Cognitive-behavioural therapy supervision sessions are based on an established format.¹² This incorporates agenda-setting, case discussion/review of session, didactic discussion of the CBT model for the presenting problem, questions for supervision, plan for next session with patient, homework task (e.g. recommended reading) and audio/videotape review if available. Trainees are expected to work with their patients for up to 12 sessions and are encouraged to record their sessions (audio or video) with the patient's consent. Trainees should attend regular supervision sessions with their allocated supervisor. Excerpts from the therapy session recordings are listened to and used as a tool to guide the trainee's supervision.

In addition to structured supervision reports, a further method of establishing trainee competence is the revised Cognitive Therapy Scale (CTS-R).^{18,19} The CTS-R is widely used in postgraduate CBT training courses as a way of grading course work and, although not without controversy, is considered the gold-standard measure of clinical competence.

We hypothesised that psychiatric trainees would perform effectively and competently as CBT therapists (based on structured supervision reports) if well supervised and if allocated suitable, uncomplicated cases.

Our aims were as follows:

to retrospectively review all available supervision reports for psychiatric trainees rotating through a national psychiatric hospital to investigate their competency at delivering CBT; to investigate whether CTS-R reports, where available, supported the findings of the supervisor's report; to investigate trainee satisfaction with receiving CBT supervision.

Method

The study was undertaken in St Patrick's University Hospital, a 300-bed facility in Dublin affiliated with the University of Dublin, Trinity College. It has a well-developed psychotherapy service. The hospital receives trainees from the Dublin University Psychiatric Regional Training Programme (DUPRTP) on 6-month rotations.

Since 2009, there has been a single, time-protected psychotherapy post on the DUPRTP located in this hospital, with supervision provided by a consultant psychiatrist with psychotherapy training. The time for this CBT delivery is protected by another trainee covering their work. Obtaining this post is a competitive process and trainees are expected to complete at least one case using CBT during their rotation.

All therapists working in the hospital have been accredited by the British Association of Behavioural and Cognitive Psychotherapies (BABCP) and are involved in training and examining on the cognitive psychotherapy course, University of Dublin, Trinity College, which uses the CTS-R extensively.

All trainees at the outset of their 6-month rotation in St Patrick's University Hospital were invited to provide psychotherapy with CBT under supervision. Initial consultant-led teaching is provided on basic psychotherapy and CBT skills. This comprises of three introductory 2-hour seminars for each 6-month intake of trainees at the hospital. The teaching sessions comprised: introduction to the CBT model; cognitive distortions; structuring a session; use of behavioural techniques; guided discovery and Socratic questioning; planning a course of therapy; and use of supervision.

The cases undertaken by the trainees were recruited from both out-patient and in-patient CBT waiting lists and assessed for suitability prior to allocation. Suitable training cases were individuals deemed to have a typical Axis 1 disorder²⁰ without active complications or comorbidities, who were easy to engage interpersonally. Trainees were encouraged to record their sessions using audiotape or videotape – with patient consent – for discussion at supervision. Supervision sessions occurred fortnightly.

Following the end of therapy, supervisors completed a structured report used by the hospital's psychotherapy service for rating trainees, using the common headings: Establishing a therapeutic relationship; Ability to apply CBT model; Understanding of model preparation; Use of supervision time; and Overall. They rated trainees using a simple Likert scale (0–6) that was incorporated from the CTS-R¹⁸ and work by Dreyfus.¹⁹ Ratings are: 0, negative impact; 1, no impact (neutral); 2, minimal impact; 3, some positive impact; 4, moderately successful impact; 5, successful impact; and 6, highly successful impact. A result of 3 or over for each item indicates competence.

All trainees under supervision were invited to submit an audio/videotape recording to be assessed using the CTS-R. The CTS-R¹⁸ is a revised version of the existing Cognitive Therapy Scale.²¹ The rater assesses trainee competence in 12 areas:

agenda setting and adherence
feedback
collaboration
pacing
efficient use of time
interpersonal effectiveness
eliciting appropriate emotional expression
eliciting key cognitions
eliciting behaviours
guided discovery
conceptual integration
application of cognitive change
homework setting.

Ratings are given using the same 7-point Likert scale as described above to establish the trainee's competency in each area. A result between 36 and 48 from a total of 72 establishes competency in that assessment.^{18,21} The CTS-R has demonstrated high internal consistency and interrater reliability.²²

Trainee satisfaction with the quality of supervision and free-text comments were also recorded using a specifically designed questionnaire (details available from the authors on request). Trainees were asked about: availability of supervision; atmosphere conducive to feedback; availability of suitable cases; supervisor's ability to communicate theory; and an overall rating.

Following approval by the hospital's ethics committee, we reviewed all available supervisor reports and CTS-R ratings made between July 2004 and December 2012.

Results

Over an 8.5-year period, 95 trainees expressed interest in participating in training to treat a patient using CBT (*Fig. 1*). Twenty-one trainees subsequently dropped out, citing lack of free time for psychotherapy and work pressures.

Seventy-four trainees attended introductory lectures and were allocated to a CBT supervisor. Of these, 37 attended supervision with nurse therapists and 37 attended supervision with the consultant. Nineteen trainees attended an initial supervision session but could not recruit a training case or a suitable training case was not available. Of the 95 trainees, 55 (58%) treated at least one patient using a CBT model.

Complete data were available for 52 of the 55 participants (95%). The remaining three supervisor reports were not completed or could not be located. Of the 55 participating trainees, 7 rotated through protected psychotherapy.

Characteristics of trainees

In total, 55 trainees treated a patient using CBT (55% male, mean age 31 years (range 25.1–42.8)). All were psychiatric trainees pre-membership (MRCPPsych) with no previous experience of delivering CBT. Trainees had spent a mean of 15 months (s.d. = 8.2) in psychiatric training.

Of the 55 trainees, 7 completed a protected training post. Characteristics of this subgroup were well matched to other trainees (43% male, mean age 31 (range 26.5–32.8)).

In total, 38 trainees took on 1 case, 14 trainees took on 2 cases, and 3 trainees took on 3 cases (total = 76 patients). Twenty-two trainees (40%) availed of the opportunity to have an assessment rated using the CTS-R. For those trainees who saw more than one case, we reviewed their CTS-R from their first case only.

Patient characteristics

Of the 76 patients seen, the initial working diagnoses included depression ($n = 21$), obsessive-compulsive disorder ($n = 12$), social anxiety ($n = 10$), panic disorder ($n = 7$), generalised anxiety ($n = 7$), health anxiety ($n = 3$), low self-esteem ($n = 2$) specific phobia ($n = 2$), eating disorder ($n = 2$), non-epileptic seizures ($n = 1$), behavioural activation ($n = 3$), anger management ($n = 3$), psychosis ($n = 2$) and borderline personality ($n = 1$).

Supervisors' structured ratings of all trainees delivering CBT

The average result for the complete data available for the 52 trainees was found to be at or above the accepted level for competency (3) across a range of areas. Results for each item were: Establishing a therapeutic relationship, mean = 4.6, s.d. = 0.7; Ability to apply model, mean = 4.4, s.d. = 0.9; Understanding of the model/reading preparation, mean = 4.5, s.d. = 0.9; Use of supervision time, mean = 4.7, s.d. = 0.9; and Overall, mean = 4.6, s.d. = 0.9. Trainees in the protected post ($n = 7$) scored higher in all areas of the supervisor's report compared with non-protected posts ($n = 45$). The greatest difference was seen in trainees' ability to apply the CBT model and the use of supervision time (*Table 1* and *Fig. 2*).

There was a significant difference ($P < 0.001$) in the supervisor scores obtained by those trainees ($n = 22$) who submitted an audio/videotape to be reviewed using the CTS-R (mean = 4.9, s.d. = 0.158) compared with the remaining ($n = 30$) trainees (mean = 4.28, s.d. = 0.13): $t(50) = 15$ (*Table 2*). Of the 22 trainees who submitted a tape, 7 were in the protected psychotherapy post. The remaining trainees ($n = 15$) were in a range of general adult psychiatry posts.

The average rating for all 22 trainees was 41.74 (s.d. = 5.16). Trainees were rated highest in interpersonal effectiveness (4.14) and eliciting key behaviours (3.89) and cognitions (3.63), and lowest at eliciting appropriate emotional expression (2.98). The results of the CTS-R findings are displayed in *Table 3*.

Trainees' ratings of supervisors

Of the 55 trainees, 49 (89%) rated their satisfaction with supervision over the training period. Six trainees did not return forms. The majority reported the supervision they received as either excellent, very good or good in separate areas: availability of supervision (48/49, 97%); atmosphere conducive to feedback (49/49, 100%); availability of cases (41/49, 84%); supervisor's ability to communicate theory (49/49, 100%); and overall satisfaction (49/49, 100%). Remaining trainees rated the availability of cases as adequate or unsatisfactory and 1 trainee rated the availability of supervision as unsatisfactory.

Free-text section feedback suggested that trainees wished for more opportunities to continue with psychotherapy training, more suitable training cases to apply the CBT model and more protected time. Those who agreed to have an audio/videotape reviewed using the CTS-R found it helpful for guidance as to what areas to focus on for future therapy sessions. Anecdotal feedback from supervisors suggested that the training experience was positive; however uncontracted 'goodwill' supervision of psychiatric trainees was felt to place an unsustainable extra demand on busy CBT practitioners. Arranging CBT supervision within the same multidisciplinary team was deemed ideal as the psychiatric trainee can take on cases that would have been allocated to the team's CBT practitioner.

Comparison of mean structured ratings for trainees in protected and non-protected and non-protected posts

Supervisor rating	Protected posts ($n = 7$) mean score	Non-protected posts ($n = 45$), mean score	Overall ($n = 52$) mean score
Establish therapeutic relationship	5.1	4.5	4.6
Ability to apply model	5.4	4.2	4.4
Understanding of model/reading preparation	5.4	4.3	4.5
Use of supervision time	5.7	4.5	4.7
Overall	5.5	4.4	4.6

Comparison of mean structured supervisor ratings for trainees who did (+) and did not (-) submit a recording to be rated using the revised Cognitive Therapy Scale (CTS-R)

Supervisor rating item	Mean supervisor rating CTS-R (+) ($n = 22$)	Mean supervisor rating CTS-R (-) ($n = 30$)	Overall mean ($n = 52$)
Establish therapeutic relationship	4.8	4.5	4.6
Ability to apply model	4.7	4.1	4.4
Understanding of model/reading preparation	4.8	4.2	4.5
Use of supervision time	5.1	4.3	4.7
Overall	5	4.3	4.6

Discussion

We conducted a retrospective review of supervisor assessments for psychiatric trainees who, under supervision, engaged in a programme of delivering CBT to patients. The completion rate in our study (58%) was broadly similar to that reported in other similar studies¹¹ evaluating a CBT training programme for psychiatric trainees. Our findings suggest that trainees can provide meaningful clinical interventions when delivering CBT under close supervision and with carefully selected cases. The mean rating for all trainees (i.e. 4.6, s.d. = 0.9) means that their CBT therapy had at least a moderately successful impact, which supports our primary hypothesis. Obstacles to participation cited by trainees included well-documented reasons of work pressures^{11,15} and lack of protected time.¹³ As the structured feedback shows, trainees who did participate found it a positive experience.

Trainees bring many strengths to the delivery of therapy as a result of their medical training, including knowledge of psychopathology and diagnostic systems and being used to working independently. Medicine as a profession has a strong academic base and doctors as professionals value characteristics such as ‘competence’.²³ A particular strength for the trainees in this study was their ability to establish a therapeutic relationship with clients. Indeed, this ability forms the foundation for delivering Table 3 Revised Cognitive Therapy Scale (CTS-R) ratings from 22 trainees who submitted a tape to be reviewed CTS-R item Mean rating

(*n* = 22) 1. Agenda setting and adherence 3.142. Feedback 3.203. Collaboration 3.324. Pacing efficient use of time 3.935. Interpersonal effectiveness 4.146. Eliciting appropriate emotional expression 2.987. Eliciting key cognitions 3.638. Eliciting behaviours 3.899. Guided discovery 3.3310. Conceptual integration 3.4011. Application of cognitive change 3.5812. Homework setting 3.20 Total (out of 72) 41.74 (s.d. = 5.16) therapy itself.^{24,25} It is likely to have contributed to trainee success.

Trainees who were in a dedicated psychotherapy post (*n* = 7) obtained higher supervision scores than those who were not (*n* = 45). They were time-protected during their delivery of therapy and were immersed in a team environment dedicated to delivering CBT. Furthermore, in obtaining their psychotherapy post, they were self-selected as having already an established interest in delivering psychotherapy. These factors are likely to have contributed to them obtaining higher scores than those who did not have protected time.

The competency ratings using the CTS-R are in line with the structured supervisor reports. For those who were assessed using the CTS-R, trainees were rated highest in interpersonal effectiveness and eliciting key behaviours and cognitions. They rated lowest at eliciting appropriate emotional expression. This is in keeping with our experience of supervising psychiatric trainees. Eliciting emotional expression is challenging because it requires the trainee to leave their established role as a doctor and enter the more experiential role of a therapist.

There was a significant difference in supervisor ratings in favour of those trainees who submitted an audio/videotape to be reviewed using the CTS-R (*n* = 22) compared with those who did not. We propose that these self-selected trainees were inherently more confident at delivering CBT to patients, as they agreed to an additional rating scale using the CTS-R. Trainees who did not submit a tape for CTS-R review were not surveyed as to reasons why, which retrospectively would have been helpful. Encouraging and engaging more apprehensive trainees in psychotherapy training and specifically video feedback may be a challenge. In many ways it is these trainees who might benefit most from structured/objective feedback. Meeting this challenge requires a judicious blend of mandatory training requirements and a supportive, non-judgemental training environment.

This study has several limitations. To reliably assess competencies on the higher diploma in cognitive psychotherapy offered by Trinity College, for example, one would need to examine one case report, one essay, three tapes and a class presentation. This study employed structured supervisor reports completed at the end of therapy and CTS-R assessments in some cases. The CTS-R was assessed at one time point during the course of therapy and ideally two time points should have been used.²² Furthermore, although all supervisors had been accredited by the BABCP, ideally an external supervisor should have also assessed the CBT delivered by trainees to remove any bias.¹¹ We do not have completed outcome measures from participating patients, which would have been useful.

With adequate planning, as in this study, trainees after a mean of 15 months’ training could treat selected cases with CBT, thus helping to address the demand for increased provision of ‘talking therapies’. Supervisors highlighted that

some supervision was delivered on a ‘goodwill’ basis and suggested that the cases chosen should come from the list of that particular team’s allotted therapist, thus helping to reduce their workload and enable them to provide supervision and protect their time. Trainees themselves can support their competencies by using structured outcome measures and session recordings when providing CBT. This can further help to demonstrate the therapeutic value of trainees’ CBT casework in resource-pressured clinical services.

Training in psychotherapy such as CBT affords the trainee the opportunity to enrich their role as a psychiatrist and gain valuable skills that can help them and the patients they treat throughout their career. In addition, it provides trainees with a valuable insight into a therapeutic intervention that they will be either delivering themselves or referring to another provider. As indicated in this study, trainees can provide meaningful clinical interventions when delivering CBT under close supervision and with carefully selected cases. The costs of training and supervision need to be judged against these clinical gains.

The authors would like to thank all the patients, trainees and supervisors who took part in this study.

1.8.44 Lorna Wing OBE, MD, FRCPsych Formerly psychiatrist and physician, Social Psychiatry Unit, Institute of Psychiatry, King’s College London, co-founder of the UK National Autistic Society

Fig. 16: Lorna Wing. © Rex Features.

The psychiatrist and autism researcher Lorna Wing, OBE, has died at the age of 85. Lorna Wing was the figurehead of autism knowledge and the one person in the field of autism research who always had it right, right from the start. She has been a pioneering figure both clinically and scientifically. A whole world including colleagues, patients and relatives mourn her death. She contributed to a better quality of life for millions of people with autism.

Lorna Wing studied medicine at University College Hospital Medical School, London and specialised in general psychiatry shortly after qualification. After obtaining her specialist diploma she was appointed in the mid-1960s to a position in the Social Psychiatry Unit at the Institute of Psychiatry, where she worked until she retired. In the 1960s Lorna, with other parents, was deeply involved in the formation of the UK National Autistic Society, aiming to develop better services for children and older people with autism. The organisation established the first specialist schools for children with autism and later also adult services.

After retirement from university employment, Lorna continued to be professionally active. In 1991, together with Judith Gould, under the auspices of the National Autistic Society, she co-founded the Centre for Social and Communication Disorders for diagnosis, assessment and guidance for people of all ages. In 2008 this was re-named the Lorna Wing Centre for Autism. Lorna Wing specialised in general psychiatry after medical school and worked in the 1960s, 70s and 80s at the Institute of Psychiatry in London, where her landmark studies on social communication disorders changed the concept of autism. Her early epidemiological work together with her husband John and Victor Lotter, and later with Judith Gould resulted in a new delineation of the syndrome, a so-called triad of impairments in the areas of social interaction, social communication and social imagination, which later – in a modified form – became the definition of autism. The three problem areas are still referred to as ‘Wing’s triad’.

In the 1980s Lorna Wing launched the concept of an autism spectrum, and – together with our group in Gothenburg – she was among the first to realise that autism could be considered dimensionally, have very many different aetiologies and affect all age groups and people at all levels of intellectual abilities. When, together, we published reports in the 1990s stating that the likely prevalence of autism was about 1%, other groups considered this to be overstated, but time has supported the claim, and Lorna had it right, right from the start.

In 1981, Lorna Wing launched the term Asperger's syndrome in a scientific paper in *Psychological Medicine*. She described Hans Asperger's 'autistic personality disorder' and speculated about outcome and aetiology. Thanks to this publication, Hans Asperger's findings from the 1940s were also introduced to the English-speaking part of the world. Since then, Asperger's syndrome has become one of the most talked about diagnoses and concepts in clinical medicine.

Based on her vast experience of individuals within the autism spectrum, she outlined different trajectories for development into adulthood: the active-but-odd, passive, aloof and rigid groups. Together with our group she was involved in friendly debates about whether or not all people might actually be reasonably characterised as falling into one of these subgroups and it is only the addition of autism that makes each subgroup stand out much more clearly as a 'specific type'.

Together with Judith Gould, Lorna Wing developed the most comprehensive autism diagnostic interview in the field, the DISCO (Diagnostic Interview for Social and COMMunication disorders). This instrument is widely used both in clinical settings and research to help in the diagnosis of autism spectrum disorders and related conditions. The DISCO has been translated into several languages and is used all over the world.

Lorna and John Wing had a daughter, Susie, who had severe autism. When Susie died unexpectedly at the age of 49, I remember Lorna's devastation. She described how Susie had never been able to clearly express her emotions, but how, when Lorna or John came home after work, her face would light up. Lorna said that the feeling that filled her then was absolutely wonderful, unlike anything else.

Lorna Wing published several influential books and about 60 major scientific papers, the last one in 2013, at the age 85. She was the recipient of many honours including the Order of the British Empire.

Lorna Wing also contributed to the development of the recent 'autism pride' movement. She believed, and would let people know that she did, that to be really successful in science and arts you need to have some clear autism traits. She also believed that most of us have some such traits. One of her favourite sayings was that 'nature never draws a line without smudging it; you cannot separate into those "with" and "without" traits as they are so scattered'.

Lorna Wing was one of those rare individuals without a false note in her. She was one of the gentlest people, always generous with her time if she believed she could be of help, humble, but never meek. She had a fierce intellect, but she used it in such a way that some of her contemporaries did not understand what hit them until it was too late. She would not suffer pomposity. She had the greatest sense of humour, and hearing her special laugh (and she did laugh a lot) was always a treat and it would put everyone around her in a good mood.

To paraphrase Winston Churchill: 'Rarely has one person had such an enormous impact on the lives of so many people with autism'. Lorna Wing will live on in many of us who had the great privilege to count her as a true friend.

Abstract

Aims and method To compare the cost and quality of a memory-clinic-based service (MCS) with a traditional community mental health team (CMHT) service. Using a retrospective case-note review, we studied two groups, each with 33 participants. Consecutive referrals for diagnostic ‘memory’ assessments over 4 months were evaluated. Participants were evaluated for up to 6 months.

Results The MCS was less costly than the CMHT service but the difference was not statistically significant (mean cost for MCS was £742, mean cost for CMHT service was £807). The MCS offered more multidisciplinary and comprehensive care, including: pre- and post-diagnostic counselling, more systematic screening of blood for reversible causes of dementia, more use of structured assessment instruments in patients/carers, signposting to the third sector as well as more consistent copying of letters to patients/carers.

Clinical implications An MCS service offered more comprehensive and multidisciplinary service at no extra cost to secondary care.

In the UK, the national dementia strategy¹ strongly supports the concept of timely diagnosis and intervention in dementia. The cost-effectiveness of such services has been demonstrated.^{2–6} Studies show that memory services may improve quality of life for patients and carers.^{7–9} The recognition of dementia enables the provision of safer care by considering, for example, accommodation and care needs and encouraging advanced decision-making. Reaching a diagnosis can help patients and carers to tolerate their symptoms better and suitable treatments can be considered.

Advocates of dedicated ‘memory clinic services’ (MCSs) point to the benefits of a less stigmatising setting, with a focus on psychosocial interventions, education and the promotion of research and clinical governance.^{5,7,10–14} Opponents are concerned with resources being diverted from community mental health teams (CMHTs) and point to higher costs of MCS services.^{15,16}

In this study, Trust A has a dedicated memory clinic service (henceforth called MCS group) as well as a CMHT. In Trust B there is a ‘traditional’ CMHT-based service (henceforth called CMHT group) where referrals of all types are seen. We compared the costs with those of secondary care and the quality of the service offered to similar types of patients referred for a non-urgent diagnostic memory assessment in these two service models in neighbouring trusts. Patients were evaluated retrospectively using case-note review in terms of the cost and quality of care they received in secondary care for up to 6 months in similar rural/suburban areas.

Method

Study design

This study was a health service evaluation and used retrospective data collected routinely as part of the usual services provided in both trusts, so local research ethics committee permission was not needed.

Demographic matching

Two rural and suburban eastern areas of England were matched using data from the Eastern Region Public Health Observatory (ERPHO). The number of people over the age of 65 years, based on general practice (GP) records in these areas, was recorded: 20 289 people in the MCS group and 21 112 people in the CMHT group. Data from the British primary care Quality and Outcomes Framework (QOF),¹⁷ which requires the recording of dementia and other chronic conditions, showed that the prevalence of dementia and strokes, and the recording of cholesterol and blood pressure, were similar in both groups. The Indices of Multiple Deprivation (IMD)¹⁸ show that the GP practices in the CMHT service (Trust B) experienced less deprivation. The range of the IMD was 11.5–17.7 for the MCS and 5.7–8.96 for the CMHT service.

Patient identification

We examined all referrals received over the time frame of the study (4 months) from specific, predetermined GP practices in these two rural/suburban areas. All patients included in the study had to fulfil Department of Health memory clinic referral criteria.¹⁹ These criteria state that memory services will see all patients with subjective memory problems or change in everyday function, or a carer’s report of change in a patient over a period of more than 6 months. Patients referred should have no previous or definitive diagnosis of dementia. The Department of Health stipulates that memory services will not see patients where urgent treatment is needed, for example those with more complex behavioural and psychological problems, patients with suicidal ideation, psychotic behaviour or a crisis situation from the carer’s perspective. Patients with early-onset dementia (age under 64 years) were also excluded because the two areas have different referral pathways for such patients. The MCS service received two referrals of early-onset dementia, which were excluded from this study; there were no such referrals in the CMHT service. All referrals had to have been received between August and November 2011 in both services.

For the MCS group, a computerised search of all memory clinic patients referred by GP practices in the designated area of the trust was performed for the specified time period. Thirty-four consecutive patients were identified and all fulfilled

the Department of Health memory clinic criteria.¹⁹ One patient refused the diagnostic interview after pre-diagnostic counselling and that patient was excluded. Occasionally, patients may be passed on to the crisis team or CMHT, but none on our list had been dealt with in this way.

For the CMHT group, a member of the research team (M.J.V.R.) manually searched all consecutive referrals to the service from particular GP practices from a central written database. Thirty-three referrals were included in the CMHT group (by coincidence, the same number of patients as the MCS group). These 33 patients all fulfilled Department of Health memory clinic criteria¹⁹ and were identified by consecutively recruiting from the original list. Patients were excluded only if they did not fulfil memory clinic criteria.¹⁹ A second member of the research team (J.S.R.) ensured that all referrals met these criteria for inclusion or exclusion. There was uncertainty as to whether to include one patient and a senior nurse's opinion from the MCS team was sought to arbitrate.

Questionnaires

Quality of service

A data extraction sheet to assess the quality of the service was developed for this study. It was used for case-note analysis and captured information routinely collected by clinicians for assessment purposes (*Box 1*). The quality criteria were chosen based on the National Institute for Health and Care Excellence (NICE) guidance for dementia services,²⁰ the Memory Services National Accreditation Programme (MSNAP) criteria where they could be applied to both services,²¹ and literature evidence.^{10,11,22} We pragmatically assessed whether the data could be extracted retrospectively from the services. This information was obtained from computerised and handwritten notes from the initial contact with the patient and for the following 6 months of contact with the mental health service. The psychiatrists involved in the data collection conferred about any uncertainties with recording of data. M.J.V.R. and Z.A.-S. each initially screened at least four sets of case records together with J.S.R. to ensure interrater reliability in recording of data. All entries were scrutinised by J.S.R. to ensure data entry was consistent. Any missing information was noted. It is the view of clinicians in both trusts that GPs are best suited to conduct physical examinations and these are stated in the requirements for referral to the service by the MCS trust. However, individual psychiatrists often choose to conduct some aspects of the physical examination themselves and the extent to which clinicians were doing this was noted.

Cost of service

The Client Service Receipt Inventory (CSRI)²³ was adapted for this study (available from the authors on request). This includes all the mental health service costs for each individual patient from the initial point of contact and then all subsequent contacts with the mental health service over the following 6 months. Costing stopped at the point the patient was discharged back to the GP. However, patients found to need more extensive follow-up for more severe or complex behavioural and psychological symptoms of dementia (BPSD) were referred to the CMHT service in Trust A (one patient) and Trust B (three patients). Costs were excluded from that point. Costing was calculated from the perspective of National Health Service care²⁴ (secondary care only evaluated in this study) rather than from a wider medical or societal perspective. Costs for hourly contact with professionals were mainly derived from the unit costs for health and Social Services compendium and included 'on costs', for example for a consultant psychiatrist this includes salary, national insurance and superannuation, qualifications, overheads, ongoing training and capital overheads.²⁵ From this document,²⁵ the cost per hour for consultant time is £162 (including on costs such as administrative support and buildings) and the cost per hour for a non-medical clinician (e.g. CMHT nurse) is £44. The costs of drugs prescribed by secondary care were derived from the *British National Formulary*.²⁶ The costs of scans were derived on the basis of the Department of Health's Dementia Commissioning Pack.²⁷ Costs incurred as a result of time spent on discussion and meetings were based on the size of individual teams, allowing for an average of 6 min discussion per patient (team sizes and calculations available from the author). The average time taken for domiciliary Table 1 Demographic data and results of assessment in memory clinic service (MCS) group and community mental health team (CMHT) group MCS group ($n = 33$) a CMHT group ($n = 33$) a P Comments Mean age, years 80.84 0.03 Significantly older in Trust B Mean age when leaving school, years 15.15 / >0.05 Not recorded in 4 patients in MCS and in

The mileage travelled by clinicians was calculated using the Automobile Association Website (www.theaa.com). Travel and transport costs are part of general overheads in the unit costs of health and social care,²⁵ but as this was anticipated to be an area of difference between the two models, this was calculated separately for each patient seen at the rate of 54p/mile up to 3500 miles as suggested in this unit cost document.

Box 1 Measures extracted regarding the quality of the memory service

Background characteristics (age, gender, marital status, employment, school-leaving age, accommodation) Waiting time to be seen Symptom time prior to referral Presence of a carer, relative, friend Pre-diagnostic counselling Dementia blood screen: ordered, examined Informal assessment of functioning, behaviour, depression, global assessment Structured questionnaires to assess functioning, behaviour, global assessment Brain imaging Physical examination (record from GP/psychiatrist) MMSE, ACE-R or other cognitive tools utilised Record of a diagnosis Record of risk assessment Record of post-diagnostic advice to patient/carer Record of discussion about driving Copying of letters to patients/carers

ACE-R, Addenbrooke's Cognitive Examination-Revised; GP, general practitioner; MMSE, mini-Mental State Examination.

Analysis

Data were analysed using Excel 2007 and Stata Version 12.1 for Windows (², Fisher's exact tests if less than 5 in a cell, Wilcoxon rank sum test). Parametric and non-parametric tests were applied, as appropriate, to evaluate costs and quality of care provided. To be conservative and because non-parametric distributions were predicted, the cost data were analysed using the Wilcoxon rank sum test.

² ACE-R, Addenbrooke's Cognitive Examination-Revised; GP, general practitioner; HoNOS, Health of the Nation Outcome Scales; MMSE, mini-Mental State Examination; n/s, non-significant.

³ Unless otherwise stated.

Results

Quality data

A similar range of diagnoses were seen in both areas (Alzheimer's or mixed dementia: 17 in MCS group, 15 in CMHT group; vascular dementia: 9 in MCS and 8 in CMHT; Lewy body dementia: 0 in MCS group, 2 in CMHT group; mild cognitive impairment: 6 in both groups; depression: 0 in MCS and 1 in CMHT; other diagnoses: 1 chronic subdural in MCS group and 1 multiple sclerosis-related cognitive impairment in CMHT group). Demographic data and the analysis of data collected during patient assessments are shown in *Table 1*.

Diagnostic assessments included a clinical assessment of behaviour, functioning and a global assessment of severity in nearly all patients, with no significant differences between groups on these variables. Some structured questionnaires (e.g. EQ-5D,³³ Cambridge Behavioural Inventory³¹) were sent to patients and carers before the actual appointment in the MCS group. Others were administered by clinicians during the clinic appointment. However, structured assessments in patients and carers using symptom rating scales in these domains were not routinely done in the CMHT group. A Mini-Mental State Examination (MMSE)²⁸ was performed in all patients except one in each group. In the MCS group, the Addenbrooke's Cognitive Examination-Revised (ACE-R) test²⁹ was performed routinely, with a median score of 67, but it was not performed routinely in the CMHT group. Computed tomography head scans were ordered as part of the assessment to a similar extent in both groups (19 in MCS and 17 in CMHT), whereas scans that had been done previously and considered by the clinician to be recent enough to be helpful amounted to a further 6 in the MCS and 5 in the CMHT group. So, only 8 MCS (24%) and 11 CMHT (33%) patients did not have scans available for diagnostic purposes. Scanning is widely available in both trusts and it was patient preference and some clinician guidance that determined whether a patient had a scan or not. Diagnoses were recorded by clinicians in 100% of letters sent to GPs. A psychologist saw two patients in the MCS group (one for neuropsychological testing and one for cognitive stimulation therapy) and two patients in the CMHT group had further neuropsychological testing.

The post-diagnostic advice given by clinicians to patients and/or carers from the MCS v. CMHT group in percentage terms was signposting: to the third sector (70% v. 24%; $P = 0.0002$); for welfare benefits (55% v. 36%; $P > 0.05$); to Social Services (67% v. 48%; $P > 0.05$); advanced Table 2 Mean costs in memory clinic service (MCS) group and community mental health team (CMHT) group

Costs	MCS group £ (mean per person ±s.d.)	CMHT group £ (mean per person ±s.d.)
Total Costs	742 (250)	807 (375)
Direct costs	271 (82)	252 (124)
Office costs	182 (81)	224 (130)
Travel time	76 (59)	186 (106)
Mileage costs	28 (21)	32 (31)
Multidisciplinary team costs	44 (15)	30 (41)
Scan costs	74 (67)	69 (72)
Drug costs	67 (103)	12 (31)

planning discussions (55% v. 45%; $P > 0.05$). Interviewers were better at documenting whether patients were drivers in the MCS group (information not recorded in three patients in the MCS group and nine patients in the CMHT group). Anti-dementia drugs were prescribed in 65% of patients eligible for prescriptions (if patients had Alzheimer's disease, mixed dementias or Lewy body dementia and MMSE scores greater than 10). Payment methods differed between groups, with the CMHT passing on prescribing to GPs after 1–2 months compared with the MCS group, where clinicians continued to prescribe for 3–4 months.

⁴ Bold denotes significance.

⁵ Small differences in the total means can be accounted for by rounding off.

⁶

The only significant difference between the groups was in the travel time costs $P < 0.0001$; $z = -5.14$ (Wilcoxon rank sum test). The drug, scan and multidisciplinary team costs were not formally analysed as their distributions were not suitable for parametric testing and there were too many ties for the Wilcoxon rank sum test.

Patient pathways

The major significant difference was that just under half of patients in the CMHT group ($n = 15$, 45%) were seen only by a doctor at their usual place of residence and then discharged, whereas in the MCS group 97% were seen by both a doctor and a non-medical clinician (once or twice). In the CMHT group, 55% of patients were seen by non-medical clinicians several times (range 2–11). Although some patients received no follow-up in the CMHT group, others received extensive follow-up within the 6-month period, incurring increased travel time, mileage and face-to-face costs. Most medical input was from the clinic base for the MCS group, but 85% of patients also received a domiciliary visit by a non-medical clinician either pre- or post-diagnosis (or both).

Costs of service

The total costs per person to secondary care between the MCS and the CMHT groups over 6 months were not significantly different in the non-adjusted analysis or the analysis adjusted for age and MMSE score. The mean total cost of care in the MCS group was £742 (median £722) and in the CMHT group it was £807 (median £833). Travel costs were significantly higher in the CMHT group where all patients were seen at their usual place of residence ($Z = -5.14$, $P < 0.0001$, effect size -0.63). Consultants travelling to see patients would often add a cost of £162/hour to each assessment in the CMHT group. This expense was not needed for clinic-based assessments by consultants in the MCS group. The costs for non-medical staff to travel to see patients more frequently than in the MCS group also added to this overall travel cost figure. Other costs between groups were not significantly different using non-parametric analysis (Table 2).

Discussion

This paper highlights the cost and quality differences between two service models for patients referred with concerns about their memory. The total costs to secondary care were less with the MCS-based service than the CMHT-based service (median cost of £722 v. £833 per patient), but this difference was not statistically significant. The MCS offered significantly more multidisciplinary care to a greater number of patients than the CMHT service. Both services offered a high-quality diagnostic service but we argue that the MCS service was able to offer more systematic and comprehensive care, including pre-diagnostic counselling, more systematic screening of blood tests for reversible causes of dementia/comorbidity, more extended cognitive examination and structured assessment tools, better evidence of signposting to the third sector as well as copying of letters to patients and carers. It has been demonstrated that there is greater satisfaction with multidisciplinary assessment^{35,36} where diagnostic and management options are explained to both patient and caregiver.

It is possible that patients in the CMHT group were not typical for an MCS or that a selection bias was introduced, with only 33 patients in the CMHT group. However, we feel this is unlikely as the Department of Health memory clinic criteria were applied to all referrals accepted into the study in a systematic way.

We acknowledge that the numbers included in the study were small and the findings can only be regarded as preliminary. However, we cannot exclude the possibility that a CMHT service may be more economical for all types of patients as it was beyond the scope of this study to examine the costs for all patients entering CMHT services in both areas. The study was also not a full economic evaluation where costs and outcome data (such as delays to institutional care) are combined to reach conclusions. The CSRI²³ as adapted for this study only examines costs to secondary mental healthcare and not primary care, social care or carer time costs. Using the CSRI, we detailed the patient's involvement with doctors and other clinicians as accurately and comprehensively as possible. In real life, clinicians do not return to base between patient visits so costs may have been inflated in both services for travel time. We were aware that there seemed to be differences between groups in the rate whereby prescribing was handed over to GPs.

This was a retrospective service evaluation and we encountered many of the pitfalls of examining data that were not specifically collected for research purposes. However, the pragmatic design of this study also means it is more reflective of actual practice and therefore less subject to a Hawthorne effect.

Stakeholder views had been sought in both trusts and satisfaction was high with both services in the year of the study, but this was not evaluated specifically in this research and satisfaction cannot be inferred from these data.

There will, of course, be differences among clinicians about what determines the quality of a memory service and we acknowledge our own subjectivity. However, we took a pragmatic view on which variables to include, based on the literature and the information we were likely to be able to obtain from retrospective data in these two services. Other quality indicators for a memory service may be helpful to consider in future studies, for example the rate of reversible causes found, the rate of 'no diagnosis' made, the range of diagnoses or the rate at which drugs were accepted by eligible patients. However, this sample was too small to find significant between-group differences on these indicators.

The IMD in the MCS group was lower than in the CMHT group. This could possibly influence referral patterns but we acknowledge that this is a complex issue, involving the attitudes of patients, families and their referring GPs. Ethnicity was not specifically matched for in this study and this is acknowledged as a study limitation. We acknowledge that both groups had higher than expected rates of patients not receiving anti-dementia drugs. Clinicians did not always offer the drug, because they were concerned patients would not comply with taking the medication. However, some patients refused the drugs because of possible side-effects or other factors.

Another emerging care model in the UK utilises the services of 'allied mental health professionals' in making diagnoses and offering interventions with medical input not provided face to face for most patients.^{5,37,38} It may be argued that some of the diagnostic quality provided by a 'medical' view on diagnosis may be compromised in such services and this needs further evaluation.

We thank all the clinicians who provided information for this project, and Christine Hill (CLAHRC administrator), Sam Norton (statistician for CLAHRC in Public Health Department), David Rubinsztein (statistical support) and Dr John Battersby (ERPHO) for providing help with demographic and QOF data. J.S.R. thanks her colleagues in psychiatry at the West Suffolk Hospital, who provided support for the project and backfill for sessions during the CLAHRC year of training. J.S.R. also thanks all those in the CLAHRC, Cambridge and Peterborough scheme for their generous support of her fellowship.

1.8.46 The planning, implementation and publication of a complex intervention trial for chronic fatigue syndrome: the PACE trial

Abstract

The PACE trial was a four-arm trial of specialist medical care, compared with specialist medical care with a supplementary therapy: adaptive pacing therapy, cognitive-behavioural therapy or graded exercise therapy, for patients with chronic fatigue syndrome. The trial found that both cognitive-behavioural and graded exercise therapies were more effective than either of the other two

 - *Conclusion*

Chronic fatigue syndrome (CFS) refers to a constellation of symptoms, characterised by persistent and disabling fatigue that is typically made worse by exertion. Some believe that myalgic encephalomyelitis (ME) is another name for the same condition; others regard it as different. Whatever it is called, CFS or ME is an ‘orphan’ condition owned and cared for by no particular discipline. ME is classified within the *International Classification of Diseases (ICD-10)* as a neurological condition (G93.3),¹ yet the majority of UK neurologists do not regard it as such.² CFS may also be classified as neurasthenia (F48), a diagnosis found in the ICD-10 chapter on mental and behavioural disorders, or as a non-specific somatoform disorder.¹ However, psychiatrists rarely see the illness as a condition that they should treat and many do not regard it as a mental illness. Therefore, while there is a consensus that CFS exists as a discrete syndrome, there is little agreement about how it should be classified, who should treat patients suffering from it, or how it should be treated.

The PACE trial

The PACE (Pacing, graded Activity and Cognitive behaviour therapy: a randomised Evaluation) trial aimed to determine which of the non-drug treatments advocated for CFS worked best and was safe. The first research grant application to do a trial was submitted in 1998. At that time, two trials of cognitive-behavioural therapy (CBT) and two trials of graded exercise therapy (GET) had been published; these suggested that both were promising treatments, but neither treatment had been accepted by patient organisations. Therapeutic nihilism abounded and rest was often advocated as the only useful treatment.³

This original grant application was unsuccessful and it took a further 5 years before we obtained funding for a trial. In those 5 years, the trial design went through two more iterations. The first added a specialist medical care (SMC) arm to allow comparison of the two new therapies with the encouragement, education and support of a knowledgeable doctor. The second iteration was developed in collaboration with the patient organisation Action for ME, and added a therapy called pacing, which surveys of their members had suggested was the most helpful approach. The involvement of this patient charity, which included the involvement of the charity’s CEO as an active member of the trial management committee, was sought to ensure that the trial addressed the right questions in the right way, and to maximise the confidence of the patient community in its findings.

The concept of pacing had evolved from a strategy used in chronic pain. It is essentially an approach to management of the illness in which the patient is helped to better adapt to the symptoms by living within the limits they impose. The patient is encouraged to ‘listen to their body’ and to adopt the right balance between doing too much or too little. Pacing for CFS had never previously been tested in a trial, and the precepts behind it allowed a comparison of two different models of the illness: one adaptive (pacing), the other rehabilitative (CBT and GET). A standardised pacing therapy was

produced in collaboration with Action for ME and Professor Diane Cox of Cumbria University, who agreed to be the therapy lead, having had extensive experience in delivering an occupational therapy approach to CFS that incorporated pacing. We called it ‘adaptive pacing therapy’ (APT) so as to convey the main aim of the therapy – to enable the patient to optimally adapt to the illness.

The PACE trial was finally funded in 2003.⁴

Design issues

The PACE trial was designed to compare the efficacy and safety of SMC alone against SMC with additional APT, CBT or GET for patients with CFS recruited from six clinics in England and Scotland. We also sought to determine cost-effectiveness, mediators and moderators of outcome, as well as the patients’ long-term outcome. The trial raised a number of design issues.

Delivery of the therapies

A key design issue was how best to deliver the three therapies; should the same individuals deliver all three or should each be given by different people? We decided to have the most appropriate discipline deliver each therapy: CBT-trained therapists (clinical psychologists or nurse therapists) delivered CBT, physiotherapists (there was one exercise physiologist) delivered GET and occupational therapists delivered APT. This decision ensured optimal delivery of each therapy by the therapists most likely to deliver these therapies in clinical practice, but increased the risk that the relative effectiveness of the therapies could be compounded by differences in the effectiveness of the therapists themselves. Consequently, quality assurance of therapy delivery was vital. We did this in a number of ways: manuals for both therapists and patients were written and iteratively piloted, and extensive training and regular supervision of the therapists was provided.

Therapy quality was ensured by only allowing therapists to treat trial patients once their competency had been established with non-trial patients. Each therapy had a lead who delivered supervision: these were Mary Burgess, an authority on CBT for CFS; Jessica Bavinton and Lucy Clark for GET, a clinical specialist physiotherapist and a research sports physiologist, respectively; and Diane Cox for APT. All therapy sessions were audio-recorded to aid supervision and to allow ratings of therapy quality and fidelity.⁵ The treatment manuals we used in the trial are available for free download at www.pacetrials.org/trialinfo.

Eligibility criteria and outcomes

We decided that only patients who met the Oxford definition of CFS would be eligible to participate in the trial.⁶ This definition was widely used, broad and, unlike others, required fatigue to be the patients’ main complaint. This helped to differentiate CFS from other syndromes, such as fibromyalgia, in which fatigue is a common symptom. We were also interested in knowing whether the trial findings applied to the subgroups of patients who met alternative definitions of CFS and ME, so we stratified treatment allocation by the international criteria for CFS and also by the London criteria for ME.^{7,8}

The primary outcome was hard to decide on: should it be fatigue or disability? After much debate, we chose both as co-primary outcomes because we considered them equally important aspects of the illness and potentially different in their response to the different treatments.

In order to measure treatment safety, we chose to follow the stringent European Union Clinical Trials Directive for pharmaceutical interventions, a standard rarely applied to trials of therapies.⁹ The measures of safety included adverse events, serious adverse events and reactions, withdrawal from treatments, a global self-measure of worsening, and an *a priori* threshold for deterioration in physical disability.

We also measured a number of secondary outcomes as well as potential mediators and moderators. Outcomes were assessed at baseline, mid-therapy, the end of the main treatment phase and 1-year follow-up, as well as long-term follow-up 2.5 years after randomisation.

The analysis

Having two primary outcomes complicated the analysis, although the size of the trial gave sufficient power. Having three follow-up assessments allowed us to use a linear regression model that minimised any effects of the small amount of missing data, and also allowed us to adjust the model by factors such as baseline measures. We originally planned to use a composite outcome measure of the proportions of participants who met either a 50% reduction in the outcome score or a set threshold score for improvement. However, as we prepared our detailed statistical analysis plan, we quickly realised that a composite measure would be hard to interpret, and would not allow us to answer properly our primary questions of efficacy (i.e. comparing treatment effectiveness at reducing fatigue and disability). Before any examination of outcome data was started, and after approval by our independent steering and data monitoring committees, we decided to modify our method of analysis to one that simply compared scores between treatments at follow-up, adjusting the analysis by baseline scores. We also addressed the potential clustering effects resulting from different numbers of patients being treated by the different therapists.

The main results

Overall, we recruited 640 patients.¹⁰ Almost all participants (98%) provided some outcome data, and 95% provided outcome data at 12 months, with no significant differences between arms in missing data. These very high rates of follow-up were achieved as a result of the commitment of the participants and the assiduous work by the research staff. The strategies used by the latter included offering convenient interview times (including early evenings), mailing most questionnaires to allow sufficient time to answer them before interviews, paying travel expenses, following up non-attenders expeditiously by mail and telephone, offering to see the participants at their homes and, as a last resort, recording the primary outcomes over the telephone. However, if we were doing the trial again, we would seek ethical permission to also offer follow-up by email, Skype and FaceTime.

Only 8% of participants dropped out of treatment, again with no significant difference in dropouts between treatment arms. Between 82 and 88% of participants who received a therapy alongside SMC said that they were satisfied with it, whereas only 50% reported being satisfied with SMC alone.

Analysis of the primary outcomes revealed that both CBT and GET led to significantly greater improvements in both fatigue and physical disability than did either SMC or APT. The adjusted effect sizes ranged from 0.5 to 0.8. To our surprise, there were no significant differences between APT and SMC in either primary outcome.

The differences between treatments for the secondary outcomes were broadly similar to the primary outcome comparisons. There were no significant differences in any safety measures between treatment arms. There was also a similar pattern of results in the two subgroups that met the alternative criteria for CFS and ME.

The cost of one quality-adjusted life-year (QALY) gained was found to be £18 374 for CBT and £23 615 for GET.¹¹ Both CBT and GET were three times more likely to lead to recovery from the present episode of illness than SMC alone.¹²

We concluded that both CBT and GET were moderately effective, cost-effective and safe treatments for CFS. These results were important in confirming to patients, healthcare professionals and commissioners that the promise of CBT and GET found in the earlier and small trials was justified, and that these treatments were safe to receive, if delivered as designed by the appropriate therapists.

Implementation

The results of the trial supported the current National Institute for Health and Care Excellence (NICE) guidelines' recommendation that 'cognitive behavioural therapy and/or graded exercise therapy should be offered to people with mild or moderate CFS/ME [...] because currently these are the interventions for which there is the clearest research evidence of benefit.'¹³ The trial results also suggested that management by pacing, which was notably less effective than the other therapies, should not be recommended.

Now the trial has been completed and the main findings published, there is the challenging business of implementation within the National Health Service (NHS) at a time of reducing budgets. Despite the NICE guidelines suggesting that patients with long-standing CFS should be seen by specialists,¹³ many are now being sent to either Improving Access to Psychological Therapies (IAPT) services or mental health teams; these services are often neither confident nor competent in delivering CFS-specific CBT and GET. The evidence suggests that outcomes are better with specialist CFS services.^{14,15} Alternative ways of delivering therapies, such as through the internet and by telephone, which are easier to access and potentially more cost-effective, may provide ways to help patients in the future.^{16,17}

Challenges and solutions

Delivering treatment in a trial like this required the time and resources to recruit, employ, train and supervise numerous staff working across a wide geographical area. We also had to address staff turnover and the consequent extra training and supervision needed for new staff. Occasionally, it was necessary to train an existing therapist in a second therapy, which proved popular with those who did it. The morale of therapists giving a specific therapy was maintained by encouraging them to take ownership of their manualised therapy, by close supervision, and by peer support between centres.⁵

PACE was affected by several external influences. First, some patient organisations expressed opposition to the trial from the time that funding was announced.¹⁸ Our understanding is that this opposition reflected the fact that the trial did not focus on a biomedical approach to CFS. Meetings with those who objected did not alter their concerns and divergent views about the illness and its management continue to this day.¹⁹ Strategies against the trial have included a public petition to the prime minister and formal complaints to our funders and publishers.²⁰ None of these complaints have been upheld, but they did take considerable time to address. A large number of Freedom of Information Act requests seeking information on all aspects of the trial have been received since the main results were published in 2011. Both declined requests that were appealed all the way up to the Information Tribunal were rejected, one being considered 'vexatious'.²¹ There was even a debate on the trial in the House of Lords in 2013.²² Our deliberate policy, to help allay concerns about the trial, was to be as transparent as possible regarding what we did, while protecting medical confidentiality and our staff; this included publishing the protocol and the statistical analysis plan,^{4,23} and paying for open access to all publications. On a more positive note, some patient organisations, such as the Association for Young people with ME (AYME), have accepted the findings, and are advising their members accordingly.²⁴

Second was the challenge of delivering a complex trial in the NHS. One particular threat was the 'Agenda for Change' which had implications for the salary grades of therapists. As a result, some of the trial centres interpreted the fact that the trial therapists had to use a manual to mean that they were unskilled, and therefore should have their pay reduced. We were successful in making the case that the trial therapists were more rather than less skilled by taking on a research role. We also supported therapists in their career progression, providing guaranteed employment beyond the trial, when possible.

The third challenge was longevity. The trial was funded in 2003; the first patient recruited in March 2005; the last patient followed up by January 2010; the main paper published in February 2011. Eight years is a long time to keep a team together and motivated. The co-principal investigators (PIs) and treatment leaders had an important role in setting the standards for trial conduct and ensuring therapy and research team cohesion and direction. In turn, the external monitoring and support of the Medical Research Council, trial steering committee and data monitoring committees were essential in maintaining the morale of the PIs. All staff met annually for a team meeting, which incorporated fun as well as training and education, supplemented by regular newsletters updating staff about progress (www.pacetrail.org/trialinfo). It may be that the external criticisms of the trial enhanced the internal cohesion and determination shown by the 100 or so staff involved.

Conclusion

Delivering the PACE trial was an all-consuming, challenging, but ultimately rewarding task that lasted many years. We hope that it has provided useful information for patients, clinicians and commissioners about the efficacy, adverse effects and cost-effectiveness of rehabilitative interventions for CFS. We hope that we have also been able to show that it is possible to deliver a large trial of complex interventions in a challenging and sometimes hostile environment and to obtain clear results from it.

We thank the following for their involvement in the trial: the PACE Trial Management Group consisted of the authors of this paper plus (in alphabetical order): Brian Angus, Hannah Baber, Jess Bavinton, Mary Burgess, Lucy Clark, Diane Cox, Julia DeCesare, Eleanor Feldman, Kimberley Goldsmith, Tony Johnson, Paul McCrone, Gabrielle Murphy, Maurice Murphy, Hazel O’Dowd, Tim Peto, Laura Potts, Rebecca Walwyn, David Wilks. The Trial Steering Committee independent members included Janet Darbyshire (Chair), Jenny Butler, Patrick Doherty, Stella Law, Meirion Llewellyn and Tom Sensky. The independent members of the Data Monitoring and Ethics committees were Paul Dieppe (initial Chair), Astrid Fletcher (final Chair) and Charlotte Feinmann. The funders of the PACE trial were: the Medical Research Council, the Department of Health (England), the Department for Work and Pensions, and the Chief Scientist Office (NHS Scotland).

1.8.47 Illness perceptions in adolescents with a psychiatric diagnosis in Pakistan

Nazish Imran Muhammad Waqar Azeem Mansoor R. Chaudhry Zeeshan Butt

Correspondence

Nazish Imran (nazishimrandr@gmail.com)¹

date

2015-8

Abstract

Aims and method To assess adolescents’ perceptions of their psychiatric illness and the role of various demographic factors in a Pakistani setting. Adolescents with various psychiatric diagnoses were interviewed using a structured questionnaire including the Illness Perceptions Questionnaire–Revised (IPQ-R).

Results Fifty-two adolescents with various psychiatric illnesses were interviewed; their mean age was 12.7 years and the majority (67%) were female. Males had significantly higher scores on timeline and emotional representation ($P<0.05$), suggesting strongly held beliefs about chronicity of their illness and anger and worry about their condition. Adolescents’ own emotional state, stress, family problems and bad luck were endorsed by participants as some of the causal factors in their mental illness.

Clinical implications Despite the importance of early intervention in psychiatric problems, engaging youth in the treatment process in Pakistan remains difficult. Better understanding of how adolescents perceive their psychiatric difficulties may play a significant role in developing culturally sensitive interventions and better utilisation of services.

- *Illness perceptions in adolescents with a psychiatric diagnosis in Pakistan*
 - *Method*
 - *Results*
 - *Discussion*
 - * *Limitations*

The prevalence of child psychiatric disorders is reported to be high in Pakistan,¹ but engaging children and families in treatment remains challenging. Illness perceptions which are unique to different cultural groups have been found to be associated with families' engagement and help-seeking behaviours. Previous research has focused mainly on parental beliefs and identified various barriers which hinder help-seeking,^{2,3} but much remains to be known about how adolescents themselves perceive their illness. With changes evident in Pakistani society in the past few decades, adolescents' own views along with their families' perceptions are likely to influence their healthcare decisions. The current knowledge about Pakistani adolescents' perceptions of their illness, stigma and help-seeking behaviour is limited, despite assertions about adolescents' capability of 'making decisions and choices on the basis of their own representations of health threats and illness'.⁴ To address this knowledge gap, the current study focuses on the beliefs of adolescents regarding their psychiatric illness and treatment in the context of Pakistan's unique cultural, religious and social context and attempts to determine whether various demographic factors have any role in these perceptions. Insight into these factors may help in addressing the underutilisation of services by young people in Pakistan and to identify ways of engaging them in effective treatments.

Method

The study was approved by the Institutional Review Board of King Edward Medical University (KEMU). Participants were 11- to 18-year-old adolescents recruited from Child and Family Psychiatry Department of the KEMU/Mayo Hospital out-patient services. The adolescents included in the study had axis I psychiatric diagnoses (conversion disorder, major depression, schizophrenia, bipolar affective disorder, obsessive-compulsive disorder, generalised anxiety disorder and conduct disorder) and were taking psychotropic medications. Adolescents who were acutely ill or had intellectual disability, attention-deficit hyperactivity disorder (ADHD) and pervasive developmental disorders were excluded from the study because of the developmental nature of these disorders. Following informed consent from parents and assent from adolescents, a questionnaire was used to collect the demographic and relevant clinical information. The ICD-10 diagnostic criteria were used to assess the psychiatric diagnosis.⁵ The Illness Perceptions Questionnaire-Revised (IPQ-R) was used to glean the young people's perceptions of their illness.⁶ IPQ-R has various subscales reflecting different dimensions of illness perceptions: timeline (chronicity of illness), consequences (impact of illness on adolescent life), personal control (perception of their own control of their illness), treatment control (controllability of illness by treatment), illness coherence (adolescents' own understanding of their illness), timeline cyclical (cyclical nature of illness), emotional representations (feeling of emotions such as sadness, anger about their illness) and causes. Each statement is rated on a 5-point Likert scale ranging from 1, strongly disagree to 5, strongly agree, and addition of scores of various items yields subscale scores, except for causes in which individual items are scored as such. IPQ-R has been used in previous studies of adolescents with mental illness.⁷ The Cronbach alpha ranged from 0.79 for the timeline cyclical dimension to 0.89 for the timeline acute/chronic dimension. The questionnaire was administered to adolescents in an interview format to eliminate literacy concerns. Data were analysed using SPSS version 20. Descriptive statistics were used for socio-demographic information, and means and standard deviations of different subscales of IPQ-R were calculated. Independent samples *t*-test was used to compare the means of IPQ-R subscales across categories of binary variables such as gender, address etc.; $P < 0.05$ was considered as significant.

Results

Fifty-two youths were interviewed, with a mean age of 12.7 (s.d. 2.13) and the majority (67%, $n = 35$) being female. More than two-thirds of participants (71%, $n = 37$) lived in urban areas and almost half of the families had a nuclear family set-up (only parents and siblings) (52%) with monthly income of less than 15 000 Pakistani rupees. Family history of psychiatric illness was present in 21% ($n = 11$) and 15.4% ($n = 8$) had a history of psychiatric admission. Mean duration of illness was 14.4 months, ranging from less than 1 month to more than 30 months. Almost half of the participants had education up until the seventh grade.

Conversion disorder with comorbid emotional difficulties (depression and anxiety severe enough to warrant the use of psychotropic medication in addition to psychological treatment) was the diagnosis in 56% ($n = 29$) of patients. Other diagnoses were major depression (17.3%, $n = 9$), schizophrenia (5.8%, $n = 3$), bipolar affective disorder (3.8%, $n = 2$), obsessive-compulsive disorder (5.8%, $n = 3$), generalised anxiety disorder (1.9%, $n = 1$) and conduct disorder (1.9%, $n = 1$).

The mean scores of illness perceptions subscales along with standard deviation are presented in *Table 1*. Overall, the study sample perceived their illness' nature to be chronic and cyclical. The perception of significant negative consequences as a result of their mental health difficulties and a negative emotional response were also observed. There was a general perception of having some personal control of their illness as well as a positive belief in treatment role. Adolescents generally felt that they had a coherent model/understanding of their illness.

Participants' mean scores, standard deviation, median and range of subscales of IPQ-R

Cognitive processes	Items, n (maximum possible score)	Mean (s.d.)	Median (range)
Illness perceptions			
Timeline	6 (30)	16.4 (2.2)	16 (10)
Consequences	6 (30)	17.5 (2.4)	18 (12)
Timeline cyclical	4 (20)	11.0 (2.2)	11.5 (12)
Personal control	6 (30)	18.8 (2.2)	19 (10)
Treatment control	5 (25)	12.6 (3.2)	13 (16)
Illness coherence	5 (25)	14.8 (2.2)	15 (10)
Emotional representation	6 (30)	16.2 (3.5)	16 (10)

Table 2 shows the comparison of mean scores of IPQ-R subcategories across binary variables. Males had significantly higher scores on timeline and emotional representation, which suggests strongly held beliefs about chronicity of their illness and emotional representation (anger, worry) about the condition. Patients living in a nuclear family set-up had better beliefs about controllability of illness by treatment than those living in a joint/extended family system. The rest of the comparisons were not statistically significant.

Comparison of mean scores of subcategories of IPQ-R for binary variables

IPQ-R, Illness Perceptions Questionnaire-Revised.

Discussion

The present study provides insight into how adolescents in Pakistan understand their psychiatric illnesses. We observed poor mental health literacy among the adolescents in our study with regard to the nature, treatment and prognosis of their psychiatric illness. In comparison to a study of illness perceptions among Western adolescents with mood disorder,⁷ adolescents in our study believe their illness to be more chronic with serious adverse consequences. They also showed more emotional reactions (anger, sadness and worry) and appear less optimistic about the role of treatment in controlling their symptoms. Multiple factors such as cross-cultural differences, limited knowledge of available services, myths about possible causative factors and treatment for psychiatric illnesses, negative expectations of services by families, in addition to stigma, shame and reluctance to seek treatment may play a role in these beliefs as well as in underutilisation of services.⁸⁻¹⁰ Furthermore, children and adolescents with behavioural and emotional disorders either do not receive

treatment or do not take advantage of available services in high-income countries.^{2,3} Despite various psychoeducational measures even in high-income countries, literature suggests poor understanding among adolescents about the causes, nature and treatment of psychiatric health issues.

Depression in adolescents has been associated with most stigmatising attitudes.¹¹ In a study of 8- to 18-year-olds, 28% of respondents would prefer to 'wait for depression to go away' and 40% 'would try to think and act like normal'. Adolescents from higher socioeconomic status, of younger age at the start of treatment and with worries about public perception are associated with self-labelling and self-stigma.¹² These results are of concern as adolescents' own perceptions regarding their illness, stigma of treatment and concerns regarding confidentiality are considered to play an important role in professional help-seeking attitudes and behaviours.¹³ A significant proportion of children and adolescents with behavioural and emotional disorders in high-income countries either do not receive treatment or do not take advantage of available services.¹⁴

Our respondents' belief of treatment being not too helpful is likely to lead to reluctance to seek help or adhere to treatment. Misconceptions about psychiatric medications being addictive, need for medications to be taken for longer periods of time and slowness in learning because of medications may all contribute towards pessimistic views regarding psychiatric treatment.¹³ The majority of families perhaps prefer to seek help from informal sources such as the family, friends, religious scholars and faith healers, rather than mental health professionals, because of stigma. As a result, treatment needs of young people with a psychiatric illness remain largely unmet. There is a great need for evolving strategies to improve adolescents' perceptions about the effectiveness of treatment and to seek professional help for their emotional problems.

Gender differences were also observed in the study sample, with males being more concerned about chronicity of their illness. They also scored high on emotional representation, suggesting that they felt more shame, anger and became upset while thinking about their emotional and behavioural problems. This may be because of society's overall expectations for males to be stronger and able to manage their illness by themselves. It is important to highlight that the study sample is mainly composed of adolescents already in contact with mental health services and thus their perceptions might be different from perceptions of adolescents in the general population. The males' perception of showing 'emotions' as weakness in some studies¹⁵ may also explain stronger feelings of shame and anger among our sample who had to seek help because of the severity of their symptoms. Gender differences have been highlighted in previous research, with boys experiencing more stigma regarding mental illness, service use and treatment.¹⁶ Similarly, the positive perceptions of the role of treatment in helping their symptoms we observed in females is consistent with the results of previous studies.^{13,17}

The majority of adolescents in the study endorsed psychological and personal factors playing a role in their illness causation (i.e. my mental attitude, my emotional state, my personality, my own behaviour, poor medical care in my past) rather than genetic and immunological causes. Cultural differences have been observed in previous research on beliefs about causation of mental illness.¹⁸ In a few studies, however, adolescents did endorse genetics and biological factors, stress and personal responsibility as causes of mental illness in general.¹⁹⁻²¹ More negative causal attributions as compared with the general public, i.e. regarding illness as being caused by their own bad behaviour, is seen in adults and children with mental illness.²² These beliefs about causes of mental illness in turn influence public attitudes towards the patients, with studies reporting stigmatising attitudes, beliefs of lack of willpower and personal failure to overcome the illness.²³⁻²⁶ Children were blamed for their depression and ADHD by one in four peers in a study of stigma of mental illness among children.¹¹ Factors which are beyond patient control such as genetics and other biological causes are associated with less negative perceptions.^{26,27} Patients who attribute their illness to psychological factors have been shown to express more emotional reactions to their illness, as appears to be the case in the present study sample.⁶ Another interesting finding was an endorsement of bad luck by the study sample.

Pakistani culture has specific emphasis on religion and God's will, which can affect how adolescents perceive their mental illness. This is also seen in studies of Asian and Hispanic youth.²⁸ Anti-stigmatising strategies for adolescents in Pakistan need to take into account these cultural variations in beliefs about causation of these illnesses in order to address stigma as well as to develop effective, culturally sensitive psychological therapies to improve adolescents' sense of well-being.

Limitations

There were several limitations to this study. The sample size was small and was composed of people already utilising mental health services, thus results may not be generalisable to non-service-users in the general population. Furthermore, in-depth interviews in addition to a structured questionnaire are considered more helpful in understanding illness perceptions. It would also have been helpful to look at the attitudes towards professional help-seeking and determine if illness perceptions in our sample were associated with help-seeking behaviours. There was also no control group.

Despite the limitations, the study is important mainly because of its focus on adolescents' own understanding of their illness, its causation and the role of treatment. This significant area was largely ignored until now. It is difficult to develop psychoeducational programmes for the youth in Pakistan without understanding their own conceptualisation of the difficulties they are experiencing. Because of significant cultural, social and religious differences, multiple strategies need to be applied in improving mental health literacy among the youth. The stigma of psychiatric illness and treatment needs to be addressed to improve take-up of services. Counselling provision in schools and an awareness programme prepared and delivered in collaboration with paediatricians and family physicians may be more acceptable and helpful in engaging young people and families in services. Further research with a large sample, including representation from multiple sites, and in particular qualitative studies, are needed to understand and improve adolescent illness perceptions as well as attitudes towards seeking professional mental health services.

This study was presented as a poster at the 60th Annual Conference of the American Academy of Child and Adolescent Psychiatry in Orlando, USA, in 2013.

1.8.48 Impact of involuntary out-patient commitment on reducing hospital services: 2-year follow-up

Abstract

Aims and method To evaluate whether involuntary out-patient commitment (OPC) in patients with severe mental disorder reduces their use of hospital services. This is a retrospective case-control study comparing a group of patients on OPC ($n = 75$) and a control group ($n = 75$) which was composed of patients whose sociodemographic variables and clinical characteristics were similar to those of

the OPC group. Each control case is paired with an OPC case, so the control case must have an involuntary admission in the month that the index OPC case admission occurred. Emergency room visits, admissions and average length of hospital stay over a 2-year follow-up after the initiation of OPC were compared.

Results No statistically significant evidence was found in the use of mental healthcare services between the two groups. Different reasons for admission found between the groups limit similarity when comparing the two.

Clinical implications The findings cast doubt over the effectiveness of this legal measure to reduce emergency visits, the number of admissions and the length of stay in the hospital.

 - * *Limitations of the study*

Involuntary out-patient treatment was introduced into North America and Australia in the early 1980s as a measure intended to benefit persons with severe mental disorder who need ongoing psychiatric care due to their poor adherence to treatment and lack of insight.¹ Several publications confirm that adherence to pharmacological treatment in disorders such as schizophrenia diminishes relapses and, consequently, hospitalisations (revolving-door syndrome) and the progressive deterioration that successive recurrences bring about.²⁻⁵ In recent decades, there has been a gradual introduction of various forms of out-patient commitment (OPC). Nowadays, it is a reality in many countries, among them Australia, Israel, England, New Zealand and the USA.⁶ In Spain, although there is currently no specific legislation on OPC, it is used in some cities (e.g. Valencia, Alicante, Barcelona and San Sebastian).

Application of OPC has caused a sharp debate at both the legal and medical levels. Its defenders believe that it is a less restrictive measure than hospitalisation,⁷⁻¹² ensures adherence to treatment facilitating clinical stability,¹³ and thus provides more freedom for patients. Opponents however believe that OPC does not respect human rights. It destroys the therapeutic relationship, discriminates against the psychiatric patient and increases their risk of stigmatisation.¹⁴ They base their argument on the lack of scientific evidence supporting the efficacy of OPC.

OPC effectiveness data

Non-randomised studies have reported conflicting results. Some have found a statistically significant association with a reduced rate of admission^{9,12,15-17} and a reduced length of hospital stay.^{9,12,15,16} Swartz *et al*⁹ evaluated the effectiveness of the OPC programme in New York and found that while under OPC there is a reduction in the number of admissions and length of hospital stay. They also evaluated the perceptions of stigma, coercion and satisfaction with treatment during the OPC and found no changes. Once the OPC was terminated, there was a sustained improvement (lower rates of hospitalisation and medication non-adherence) in those patients who received intensive treatment or whose treatment lasted for more than 6 months. Another noteworthy result is that patients who were subject to an OPC combined with assertive community treatment (ACT) had a lower risk of hospitalisation than did those who received ACT alone, but the first group had greater resources at their disposal.

Van Dorn *et al*¹⁰ showed that reduced admission rates were maintained for 6 months after the OPC had ended. Nakhost *et al*¹⁷ evaluated the effectiveness of OPC in Canada, discovering an association between patients under an OPC and

a reduction in the number of readmissions. In addition, they found evidence that this positive effect on the rate of hospitalisation remained after the OPC had ended. This was most notable in patients who had no admissions or who had only one admission prior to the implementation of the OPC. They found no association with the length of hospital stay. By contrast, other studies¹⁸⁻²⁰ have shown an association between an increase in the rate of admissions and length of hospital stay.

In a recent randomised controlled trial (RCT) in the UK with 12 months' follow-up, Burns *et al*²¹ found no significant difference in the rate of admission and length of hospital stay in individuals under OPC. These results are consistent with two RCTs from the USA in which no significant differences were found in the use of health services, social functioning or quality of life between the OPC and treatment as usual.^{22,23} These three RCTs are the only ones we found in the literature on community treatment orders. Despite being in different jurisdictions with different mental health systems and different laws, the consistency of performance is significant.

A recent systematic review by Maughan *et al*²⁴ which looked at effectiveness of OPC concluded that it has no significant effect on other outcomes of hospitalisation and use of community services. These results are consistent with previous reviews of international experience, for example by Churchill *et al*²⁵ and Kisely *et al*.⁶

Aims

Most previous studies have been performed in Anglo-Saxon countries so the aim of the present study is to provide information about the effectiveness of this legal measure to reduce the use of hospital services in other countries. Previous observational studies at Valencia (Spain) concluded that involuntary out-patient treatment might be useful for certain patients with severe mental disorder.²⁶ Because of the weakness of observational studies, our team previously conducted a retrospective study of cases and controls during 1 year follow-up, but the results indicated that OPC wasn't more effective than standard treatment.²⁷ We consider that the information offered by the present study can be of interest given the long period studied.

If one considers that OPC increases commitment to the achievement of clinical stability in patients with severe mental illness, then it is expected that the application of this legal measure will decrease both the number of emergency room visits and the number of hospital admissions, as well as shorten the length of hospital stay.

Method

This is a retrospective study of cases and controls where we compare a group of patients under an OPC with a control group.

The study population consisted of all patients in the city of Valencia who had been under an OPC for at least 2 years at the time of the study's initiation in August 2009. The admission which prompted the request for OPC was considered the index admission.

The control group consisted of a sample of patients admitted to the psychiatric unit of the Hospital Clínico de Valencia. Each control case was paired with an OPC case, so each had to have an involuntary admission in the same month as the index OPC case. Moreover, the control case must have had the same clinical diagnosis, the same sociodemographic variables (age, gender, place of residence) and the same clinical characteristics (the same number of admissions during the 2 years before the index admission) as the paired OPC case. Both groups received a standard treatment consisting of out-patient psychiatric follow-up medication monitoring, and community-based treatment, such as day centres. The only difference between the two groups was that the control group was not under OPCs.

The study compared the number of psychiatric emergency visits, the number of admissions and length of stay in the hospital for the OPC and control groups over a 2-year follow-up once the OPC had been initiated.

We recorded the following for each patient: age, gender, place of residence, psychiatric diagnosis according to the DSM-IV-TR,²⁶ number of psychiatric emergencies, number of hospital admissions, main reason for admission and average length of hospital stay for 2 years before and 2 years after the initiation of the OPC. Emergencies included psychiatric emergencies only. Admissions included all admissions, voluntary and involuntary, registered in the psychiatric services during the study period.

Results

The two groups comprised 75 patients - 50 males (66.7%) and 25 females (33.3%) - each. The average age was 41.4 years for the OPC group and 41.7 years for the control group.

Diagnoses on Axis 1 are shown in *Table 1*. In both groups schizophrenia was the most common diagnosis, affecting approximately 3 out of 4 patients with OPC (73%). Bipolar disorder was the second most frequent diagnosis (12%), followed by schizoaffective disorder and delusional disorder.

Diagnosis on Axis I (DSM-IV-TR)²³

	<i>n (%)</i>	
Schizophrenia	55 (73)	57 (75)
Bipolar disorder	9 (12)	8 (11)
Schizoaffective disorder	6 (8)	5 (7)
Delusional disorder	5 (7)	5 (7)
Total sample	75 (100)	75 (100)

OPC, out-patient commitment.

There are differences in the motives for index admission between the groups (*Table 2*). In the involuntary OPC group the main reasons were clinical decompensation because of non-adherence to treatment (78%) and aggressive behaviour (22%). In the control group, admission occurred mostly due to clinical decompensation without a clear non-adherence to treatment (47%), for example inconsistent use of medication, changes in the pharmacological pattern or substance misuse.

Main reason for index admission

	<i>n (%)</i>	
Aggressive behaviour	16 (22)	10 (16)
Abandonment of treatment	56 (78)	16 (26)
Suicide attempt	0	7 (11)
Clinical decompensation without clear treatment drop-out	0	29 (47)
Total	72 (100)	62 (100)

OPC, out-patient commitment.

The number of emergency visits, number of admissions and average length of hospital stay in the 2 years leading up to the start of the OPC index admission did not reach significant difference between the OPC group and the control group (*Table 3*). These results have led us to conclude that they were two 'similar' groups using healthcare services.

Use of hospital mental health services in the 2 years before and in the 2 years during out-patient commitment (OPC)

	2 years before OPC, mean		2 years of OPC, mean			
Admissions, <i>n</i>	2.16	2.4	0.6	1.69	1.34	0.4
Emergency visits, <i>n</i>	1.84	1.77	0.7	0.77	0.53	0.2
Hospital stay, days	21.94	21.33	0.7	16.41	19.55	0.3
Patients, <i>n</i> (%)	75 (100)	75 (100)		31 (41)	24 (32)	

Regarding the number of admissions in the 2 years before the index admission in both groups, more than half of the patients (52%) had one hospital admission ($n = 39$), 27% had two admissions ($n = 20$), and the rest (21%) had more than 2 admissions (between 3 and 6 in the previous 2 years).

At 2 years after the index admission, the same three variables were checked. A significant decrease in the number of emergency visits and admissions and a decrease in the average length of hospital stay were found in both the OPC and the control group when compared with the results for the previous 2 years. There were, however, no statistically significant differences found when comparing the OPC group with the control group (*Table 3*).

Overall, 41% of patients on an OPC and 32% of controls had a hospital admission during the 2 years after the index admission. Of the patients in the OPC group, 20% ($n = 5$) and of those in the control group 17% ($n = 13$) had only one admission, whereas the remainder (21% in the OPC group and 15% in the control group) had more than two admissions.

Discussion

In the present work, and in agreement with the medical literature, OPC is applied with greater frequency to persons with schizophrenia (73%). Like other authors,^{6,21,22,27-29} we found no significant differences between the control and OPC groups in the use of healthcare services: number of emergency visits, number of hospital admissions and average length of hospital stay.

The results of this work cast a shadow of doubt on the effectiveness of OPC as a measure of compulsory treatment in the community. No statistically significant differences were found between the number of emergency visits (mean 0.77), admissions (mean 1.69) and the length of hospital stay (mean 16.41 days) for the OPC group and for the control group (0.53, 1.34 and 19.55 respectively) (*Table 3*). If efficacy is defined by the reduced use of hospital services as examined in this study, our results indicate that this legislation is not more effective than standard treatment.

Limitations of the study

On the one hand, the differences found between the reasons for admission for the OPC group and for the control group undermine the similarity of the two study groups and, therefore, the suitability for comparison. On the other hand, there are the general limitations of retrospective case-control studies (such a study cannot rule out selection bias nor confounding bias given the impossibility of performing a random assignment of the participants).

It is striking that despite evidence in the literature that OPC has no significant effects on hospital service use outcomes, there is a remarkable consistency in the characteristics of patients who should undergo this intervention.^{22,26} The application of OPC should not be a generalised measure, but should be limited to those patients with severe mental disorders in whom a lack of therapeutic adherence will lead to a severe deterioration of the illness or the appearance of violent behaviour and, therefore, seriously compromise the patient's ability to live in the community.

One important question is whether OPC improves outcomes in services that are already offering a good quality of care. The answer at present appears to be no judging by the balance of evidence. Nevertheless, even if intensive follow-up programmes such as ACT are provided, it may be necessary in some cases to apply OPC.³⁰

The effectiveness of OPC can be estimated using other outcomes, for example patient satisfaction or adherence to treatment during or after the application of OPC. Further studies are required to provide more information about the effectiveness of this treatment strategy and to clarify the contradiction between negative scientific evidence and its use in clinical practice.

1.8.49 Stigma and self-esteem across societies: avoiding blanket psychological responses to gay men experiencing homophobia

Karyofyllis Zervoulis Evanthia Lyons Sokratis Dinos

Correspondence

date

2015-8

Abstract

Aims and method The relationship between homophobia (varying from actual and perceived to internalised) and measures of well-being is well documented. A study in Athens, Greece and London, UK attempted to examine this relationship in two cities with potentially different levels of homophobia. One-hundred and eighty-eight men who have sex with men (MSM) living in London and 173 MSM living in Athens completed a survey investigating their views on their sexuality, perceptions of local homophobia and their identity evaluation in terms of global self-esteem.

Results The results confirmed a negative association between homophobia and self-esteem within each city sample. However, Athens MSM, despite perceiving significantly higher levels of local homophobia than London MSM, did not differ on most indicators of internalised homophobia and

scored higher on global self-esteem than London MSM. The city context had a significant impact on the relationship.

Clinical implications The findings are discussed in relation to the implications they pose for mental health professionals dealing with MSM from communities experiencing variable societal stigmatisation and its effect on a positive sense of self.

Goffman¹ identified homosexuality as falling into a stigmatised category based on moral failing (i.e. being responsible and therefore being blamed for the condition) and rooted in patriarchal and heteronormative positions as well as the main, mostly monotheistic, religions. The most commonly used term to describe the stigmatisation of lesbian, gay and bisexual (LGB) people is ‘homophobia’ as the dislike or hatred towards homosexuals.² Homophobia is often experienced by gay people from their early years at school, within their families, within their immediate daily environment and in broader society including its institutions, such as the media, workplaces or legislative bodies. Homophobia takes many forms that have been described extensively in the literature in terms of discrimination, violence, prejudice and stereotypes and harassment.³⁻⁶ Importantly, homophobia appears to affect gay people’s own beliefs and attitudes towards themselves. This is known as ‘internalised homophobia’, the phenomenon where gay people are to a variable extent unhappy about their sexual orientation because of societal homophobia.⁷

In general, stigmatisation of an attribute may have a negative effect on a person’s positive sense of self. In the case of LGB people, there is evidence that homophobia, both perceived and internalised, affects them in terms of their overall well-being and often in terms of their self-esteem.⁸⁻¹¹ Self-esteem is an individual’s own evaluation of their personal worth and, according to Rosenberg,¹² it refers to the notion of a relatively stable sense of an overall or global, as it is often described, personal worth. There is a voluminous amount of work which has found a relationship between self-esteem and depression,¹³ anxiety,¹⁴ anger, hostility and aggressiveness¹⁵ and life satisfaction.¹⁶ Therefore, self-esteem is an important construct that mental health professionals need to take into account when dealing with mental health problems.

There are many recent surveys in the UK suggesting that homophobia is still widespread and experienced by gay men in their daily lives, affecting their psychological well-being. A number of studies have also shown the direct relationship between homophobia (or fear of being discriminated against) and mental health problems.^{4,6} Furthermore, recent epidemiological studies found that LGB groups have a significantly higher prevalence of mental health problems than the general population; in particular, conditions including common mental disorders and alcohol and substance misuse, and attempted suicide.^{17,18} In addition to a higher prevalence of mental health problems in gay men and LGB groups in general, further evidence suggests that there are disparities in access to mental healthcare. For example, LGB people report a mixed reception from mental health services.¹⁷ In particular, mental healthcare for LGB groups is very often associated with depreciation of their domestic circumstances, refusal to accept partners as next of kin,

professionals' excessive curiosity about LGB lives, concern about confidentiality, and fear that their sexuality will be regarded as the 'pathology' requiring attention.^{19,20} Along these lines, Kitzinger & Coyle²¹ argue that psychological research has always presented homosexuality as a form of pathology and, when dealing with gay or lesbian issues, it is concentrated in clinical and psychotherapeutic psychology.

Societal homophobia is not evident or perceived to be at the same level across all countries or societies. There are historical, cultural and institutional factors that affect its factual or perceived prevalence.^{8,21,22} For example, in institutional terms, there is a broad spectrum that includes countries where homosexual activity is punished to countries where same-sex marriage is recognised. Between these two ends, there are countries where homosexuality is neither illegal nor there are provisions for equal treatment of people irrespective of their sexuality. In relation to the context of this study, there is evidence that Greek society is more homophobic than the UK society^{23,24} and that Greek LGB people tend to face greater difficulties in disclosing their sexuality than Anglo-Americans.²⁵⁻²⁷ In Greece, sex between men was decriminalised in 1951 while there was never any mention of lesbians in Greek law. Today, the age of consent for gay men is set at 17, higher by 2 years than for heterosexuals. There is no official recognition of same-sex couples in any terms. In the UK, although 'homosexuality' was decriminalised later, in 1967, legislation today does not discriminate on the basis of sexuality. Currently, same-sex couples can marry and adopt children.

It needs to be noted that metropolitan and cosmopolitan cities such as London consist of people from a variety of countries and cultures. People who live in London or Athens are not exclusively of White English or Greek ethnic background, nor have they been born and lived in either city all their life. So, the term cross-cultural should be avoided in studies such as this one; instead, cross-city comparisons resemble more and should be referred to as cross-national comparisons. The term 'national' entails the space and the local rules of law, it does not necessarily refer to participants' nationalities in legal terms and in this case, it can include MSM from potentially any cultural communities that live within the national space, although the existence of a predominant cultural and ethnic majority should be acknowledged.

Aims

This study aimed to investigate the link between homophobia and self-esteem in Athens and London, two cities with potentially different levels of perceived homophobia. It investigated the following research questions: Is there a difference in perceived and internalised homophobia between MSM living in London and Athens? Does perceived homophobia relate positively to internalised homophobia and do they both relate negatively to self-esteem of London and Athens MSM? Is there a difference in self-esteem between London and Athens MSM? The study also attempted to investigate whether societal context is important in explaining the relationship between perceived and internalised homophobia and self-esteem.

Method

Participants

The sample included 188 MSM living in London and 173 MSM living in Athens, their mean age being 32 (range 16-64) and 27 (range 16-50) years respectively. The mean time of living in the city was longer for Athens than for London MSM. There was ethnic variation within both samples, but to a lesser degree in Athens than in London; the majority of both samples were White. In terms of sexuality, 89% of London MSM reported that they were sexually attracted to men only, with the remaining 11% being attracted to both men and women. The corresponding figures for Athens MSM were 71% and 29% respectively. In relation to educational level, about 7 in 10 London MSM and 8 in 10 Athens MSM reported to have at least a university degree. Finally, nearly half of the Athenians were recruited and completed the questionnaire online and the rest used a hard copy whereas a small majority of Londoners (56%) filled out the survey online. *Table 1* provides a summary of this demographic information.

Sample characteristics by city

	London (<i>n</i> = 188)	Athens (<i>n</i> = 173)
Age, years (mean)	32	27
Living in the city, mean	12 years 4 months	20 years 3 months
Ethnic group, %		
White	56.3	86.1
Other	43.7	13.9
Sexuality, ^a %		
Gay	89.1	71.4
Bisexual	10.9	28.6
Participation method, %		
Offline	44.1	52
Online	55.9	48

London *n* = 183, Athens *n* = 168

As there was some scepticism as to whether living in a city for only a few years would be considered sufficient for the participants to be 'typical' Londoners or Athenians and because such participants may not have had informed views about how their fellow citizens view gay men in their city, differences in the responses given on all variables of the questionnaire between participants living in London for less than 5 years or more than 5 years were investigated. No statistically significant differences were found. A similar analysis could not be conducted for the Athenian sample because only a handful of participants lived in the city for less than 5 years.

Procedure

A survey took place in the capital cities of Greece and the UK in Greek and English respectively. Participants were recruited using two methods: the distribution of questionnaires at gay venues (the questionnaires were then self-completed) and through an online questionnaire advertised in several popular gay-themed websites. The study was presented as one examining gay men's views about their social environment, being part of a broader research programme into how gay men see themselves and deal with everyday issues. Potential participants had to be residents of London or Athens for at least the past 12 months. They were assured that their responses and their participation in this research project would remain entirely anonymous and they were informed of their right of withdrawal. Data collection took place over a period of the same 3 months for both cities, although the majority of offline survey data were collected over 2-week periods in each city within those 3 months when the online survey link was live.

Materials

The study was conducted through a survey that, apart from questions on demographics, included four scales: ‘disclosure of one’s sexuality’, ‘perceived homophobia of the general public and of people close to the participants’, MSM’s ‘internalised homophobia’, and ‘global self-esteem’. The scales, based on existing English-language scales or developed first in English, were translated to Greek and back-translated until they matched each other so that similar items were asked to both English-speaking participants in London and Greek-speaking participants in Athens. Because of the cross-national element of the study, original scales were subjected to psychometric testing to standardise the scales between the two samples. In particular, all Likert-type scales were subjected to factor analyses for the English and Greek versions separately. Cross-language structurally identical scales were formed following the factor analyses solutions as well as conceptual interpretations, and the reliability of each emerging scale was measured in terms of Cronbach’s α in English and Greek separately. Details of the measurements used are given below.

Disclosure of one’s sexuality

Participants were asked to report the extent to which they were ‘out’ at work, to friends and family. For example, participants had to state whether they had discussed their sexuality with all, some or none of their friends.

Perceived homophobia of the general public and of people close to the participants

Participants’ perceptions of other people’s homophobic feelings and attitudes were assessed using 36 items based on the Modern Homophobia Scale developed by Raja & Stokes.²⁸ Eight items were preselected according to their original loadings in the factor analysis that Raja & Stokes ran. Preference was shown to items with higher loadings under each of the three factors of the authors’ factor analysis solution as well as items with relevance to this study and its cross-national context. For example, an item referring to gay men being allowed to join the military rather than the item that referred to openly gay celebrities advertising products was chosen despite the lower loading of the former; the reason was that both countries have armies but there are no openly gay celebrities in Greece. Furthermore, the selected items were modified to reflect representations of homophobia; instead of using the original statements written in the first person such as ‘I wouldn’t mind going to a party that included gay men’, the statements were modified to read ‘I think that most Londoners/Athenians wouldn’t mind going to a party that included gay men’. The same preselected eight items were repeated four times each to capture the perceptions of our participants on how homophobic they think that (a) the general public, (b) their family members, (c) their friends, and (d) their colleagues are. So, the expression ‘most Londoners’ or ‘most Athenians’ was replaced by ‘most members of my family’, ‘most of my friends’, and ‘most of my colleagues’ accordingly. Note that the wording of these representations assessed homophobia in terms of attitudes and behaviour towards gay men only rather than sexual minorities in general. All statements were scored on a 1 to 5 Likert-type scale with 1 meaning ‘strongly disagree’ and 5 meaning ‘strongly agree’. Reliability alphas for the scales made up of 8 items each and assessing perceived homophobia of the 4 different groups of people in both London and Athens were good and varied from 0.76 to 0.93.

Internalised homophobia

Mayfield’s²⁹ Internalized Homonegativity Inventory was used, including its three factors referring to ‘personal homonegativity’ (e.g. ‘I feel ashamed of my homosexuality’), ‘gay affirmation’ (e.g. ‘I believe being gay is an important part of me’) and ‘morality of homosexuality’ (e.g. ‘I believe it is morally wrong for men to be attracted to each other’). Factor analyses run for each sample confirmed the existence of these factors. One item was excluded from the ‘morality of homosexuality’ factor as it was reducing the α of the Greek scale below the 0.60 level; the same item had to be removed from the English version for equivalence. The alphas of the three factors were 0.69, 0.77, 0.90 and 0.63, 0.76, 0.88 for the English and Greek versions respectively.

Self-esteem scale

Finally, Rosenberg's¹² Global Self-Esteem Scale consisting of ten items was used in full to provide a measure of the participants' perception of self-worth. The items of the original scale were rated on a 4-point 'strongly disagree' to 'strongly agree' scale but we added a middle fifth option of 'neither disagree nor agree' to increase variance in the data. A single-factor solution was produced for both city samples with reliability 0.88 for London and 0.87 for Athens.

Results

In analysing the data, missing values met within any section of this survey were not treated in any way, and cases with missing values were excluded analysis by analysis. Because numbers of valid cases for each analysis conducted were adequate, treating of missing values with the potential to affect results was seen as erroneous.

Initially, in establishing potential differences in the views and attitudes of Athens and London participants themselves, an important observation was that there were statistically significant differences between the two city groups in relation to the disclosure of their sexuality to other people (*Fig. 1*). The scores obtained on this measure were subjected to a 3×2 chi-squared analysis. Differences between the samples were found to be highly significant when discussion with family members ($\chi^2 = 45.25$, d.f. = 2, $P < 0.001$) and friends ($\chi^2 = 39.15$, d.f. = 2, $P < 0.001$) was concerned and as far as hiding ($\chi^2 = 65.96$, d.f. = 2, $P < 0.001$) or revealing ($\chi^2 = 72.46$, d.f. = 2, $P < 0.001$) sexuality from colleagues at work or university was concerned.

A multivariate analysis of variance (MANOVA) was then conducted to investigate the differences seen in *Table 1* between London and Athens MSM in their views on how they think the general local public and people close to them see gay men (*Table 2*). Overall, Athens MSM perceived other people's homophobia, whether general public, friends, family members or colleagues, to be higher compared with London MSM perceptions. There was a significant overall difference between the two populations on the combined four dependent variables ($F_{(4, 298)} = 36.63$, $P < 0.001$; Wilks's $\lambda = 0.67$, partial $\eta^2 = 0.33$). In the separate analyses for each dependent variable, all differences between Londoners and Athenians were also found to be highly statistically significant (*Table 3*).

Descriptive statistics of the Likert-type variables of the study

5-point Likert-type variables (<i>n</i> items)	London <i>n</i> (mean) s.d.	Athens <i>n</i> (mean) s.d.
Perceived homophobia		
General public (8)	176 (2.38) 0.59	166 (3.14) 0.63
Friends (8)	176 (1.75) 0.63	156 (2.40) 0.68
Family (8)	175 (2.37) 0.96	156 (3.23) 0.83
Colleagues (8)	173 (1.98) 0.73	155 (2.67) 0.73
Gay men's personal homonegativity (11)	184 (1.87) 0.72	167 (1.95) 0.70
Gay men's negative views on morality of homosexuality (4)	185 (1.25) 0.46	167 (1.37) 0.51
Gay affirmation (7)	186 (3.72) 0.66	166 (3.60) 0.67
Self-esteem (10)	172 (3.92) 0.68	155 (4.10) 0.65

Between-subjects effects on the variables referring to perceived homophobia of others

Variables	<i>F</i> _a	<i>p</i> ²
Perceived homophobia of general public (8)	111.889	0.271
Perceived homophobia of friends (8)	85.349	0.221
Perceived homophobia of family (8)	75.872	0.201
Perceived homophobia of colleagues (8)	72.925	0.195

d.f. = 1, d.f. for error = 301, $P = 0.000$ for all variables.

In investigating the differences between the two samples in relation to 'internalised homophobia' as again seen in *Table 1*, a one-way between-groups MANOVA showed that there was a narrowly statistically significant difference between Londoners and Athenians on the combined dependent variables ($F_{(3, 340)} = 2.65, P < 0.05$; Wilks's $\lambda = 0.98$, partial $\eta^2 = 0.02$). When the results for the three dependent variables were considered separately, Athens MSM scored significantly higher only on the 'morality of homosexuality' variable ($F_{(1, 342)} = 6.545, P < 0.05$, partial $\eta^2 = 0.02$).

Third, an independent-samples *t*-test was conducted to compare the self-esteem scores (*Table 2*) for the London and Athens samples. There was a significant difference in scores between the two groups with Athenians reporting a higher self-esteem than Londoners ($t = 2.421$, d.f. = 325, $P < 0.05$, $r = 0.13$).

Correlational analysis showed, as expected, positive relationships between most perceived and internalised homophobia scales and negative relationships between homophobia and self-esteem scales. Online tables DS1 and DS2 show that these findings are relatively consistent across the two city samples. Further regression analyses were carried out to test the relationship of both internalised and perceived homophobia of others controlling for city. Correlations showed that factors for each scale were significantly associated with each other; this was expected given that they are subscales of the same construct. Therefore, and to avoid multi-collinearity, the composite scores of the scales were used. To test whether city explained the relationship between homophobia (internalised and perceived) and self-esteem, a stepwise hierarchical regression was conducted. The first step tested the relationship between homophobia and self-esteem and the second step tested whether the addition of city had a significant impact on the model. The inter-correlations between 'self-esteem' and 'perceived homophobia of others' as well as 'internalised homophobia' were significant ($r = 0.15, P < 0.05$ and $r = 0.27, P < 0.001$ respectively). The correlation between perceived and internalised homophobia was also significant ($r = 0.29, P < 0.001$). Model 1 is statistically significant (adjusted $R^2 = 0.070, P < 0.001$) but self-esteem is explained significantly only by internalised homophobia (*Table 4*). City, in model 2 has a significant impact on the relationship between internalised and perceived homophobia of others and self-esteem (adjusted $R^2 = 0.12, P < 0.001$). In particular, city explains an additional 5% of the model. Moreover, both homophobia scales in the model independently explain self-esteem significantly.

Explanation of self-esteem by homophobia scales (composite scores) and the role of city context

Independent variables	Standardised	<i>T</i>	<i>P</i>
<i>Step 1</i>			
Perception of homophobia in others	0.079	1.403	n.s.
Internalised homophobia	0.242	4.313	~0
$F_{(2, 321)} = 13.1, R = 0.275, R^2 = 0.076, \text{adjusted } R^2 = 0.070, P < 0.001$			
<i>Step 2</i>			
Perception of homophobia in others	0.228	3.479	0.001
Internalised homophobia	0.210	3.805	~0
City context	0.260	4.147	~0
$F_{(3, 320)} = 14.9, R = 0.351, R^2 = 0.123, \text{adjusted } R^2 = 0.12, P < 0.001.$			

Discussion

The first aim of this study was to explore potential differences between MSM living in Athens and London in relation to how they view their sexuality and on the ways in which others in their broader environment or those close to them see gay men. The findings suggested that there are indeed some significant differences between the samples of the two cities. Athens men were more 'closeted' than London men and reported higher levels of homophobia in terms of how the general public and people in their close environment see gay men. However, although Athenians again scored higher in the internalised homophobia scales, such a difference was found to be narrowly significant only when all factors measuring internalised homophobia were combined for the analysis. Finally, there was a difference between scores on the self-esteem scale with Londoners this time reporting lower levels of self-esteem than Athenians. Along these lines, society played a significant role in the relationship between homophobia and self-esteem; the relationship became stronger as a result of city of residence.

In general, Athenians appeared to perceive that they lived in a more homophobic city than Londoners and this could relate to the observation that they felt less comfortable to disclose their sexuality publicly. This finding comes into agreement with the difficulties reported by ethnically Greek gay people in Phellas's²⁶ and Fygetakis's²⁵ studies. One would expect, however, that Athenians' self-esteem might have been lower than Londoners' self-esteem, which in this study was not the case. This could be due to the likely possibility that sexuality was not considered to be the sole or even the most important and salient element of one's life. Our findings support Abrams & Hogg's³⁰ claim that global self-esteem evaluation may not reflect the particular group membership under investigation and also support other findings on the relationship between stigma and self-esteem not being inevitable.³¹ Similarly, Brady & Busse³² found no significant difference in terms of psychological well-being and adjustment among open or closeted respondents in the last three stages of Cass's coming out model. Such findings may relate to Alquijay's³³ argument that, in cultures where interdependence is valued, the meanings of self and self-esteem may be different; this point could be very relevant for our Athens participants. In general, progression through the stages proposed by Cass's model on 'sexual identity formation'³⁴⁻³⁶ may be influenced by expectations of the Greek society. Global self-esteem and its relationship to stigmatised identity may be negotiated in different ways by Greek sexually stigmatised groups compared with other nationalities or to other type of stigmatised groups, again because of specific societal norms that relate to sexuality.

It needs to be underlined that there was a clear negative correlation between self-esteem and personal homophobia in both samples; this supports findings such as Szymanski *et al's*,¹¹ among others, who linked internalised homophobia to the well-being of lesbians and gay men. There were also significant positive correlations between all measurements of perceived homophobia of family members and colleagues with internalised homophobia variables (the direction was negative for 'gay affirmation') and friends' homophobia was found to have the strongest relationship. Such findings demonstrate the potential consequences of societal homophobia on gay men and women. Therefore, it is society that needs to change; this can happen via the promotion of institutional social equity for gay people's self-acceptance and the building of a positive identity as Berg *et al's*⁸ argue.

Limitations

Although our results suggest some interesting relationships, there are limitations regarding the interpretation of findings. One of the main limitations is the correlational nature of the study that does not allow the data to show causal relationships regarding the extent of the contextual impact of homophobia on self-esteem. Additionally, the concepts' measures are related highly to each other and this may have an impact on the results and subsequent conclusions regarding the strength of associations. It would have been beneficial to have used additional outcomes variables that measure mental health and broader well-being. Although self-esteem is a good indicator of well-being, it does not capture its complexity. Therefore, the issue of homophobia and its relationship to well-being in conjunction with societal or cultural differences needs to be unpacked further.

It should also be acknowledged that one of the main limitations of this study is the inability to account for non-response due to the use of online data collection. This is a weakness of internet-based surveys because non-response can threaten the validity of data; participants may differ from non-participants on a number of characteristics. Still, as internet use and internet-based research are gradually becoming more and more common, at least within European contexts such as those in this study, issues of generalisability and validity are dealt with. As Hewson stated,³⁷ there is gradually less

sample bias as potential internet-based research participants are less and less the White, middle-class, technologically proficient people. Mathy *et al.*,³⁸ for example, compared the demographics of a small sample of lesbian and bisexual women with a larger sample collected by a large polling organisation and they found that their rigorous internet sampling designs were found to be more robust and equally representative of the US general population. The internet sample was more representative in terms of education and income and broader ethnic diversity and it was equally effective in representing the distribution of population in rural and urban areas. In addition, there is a point to be made on the online facilitation of self-disclosure and this is very relevant for this study as we recruited people who belong to a stigmatised group. The effectiveness of online or computer-based surveys or interviews for researching sensitive issues such as sexual behaviour is well established. There is ample evidence that computerised internet interface tends to facilitate self-disclosure and honesty among research participants and that participants report lower social anxiety and social desirability when they are using the internet than when they are using paper-based methods.³⁹⁻⁴⁵

In investigating cross-city differences, this study and the way it recruited participants could not have and does not claim to have done such investigations by employing homogeneous cultural groups within each city. Both cities, and especially London, include microcultures within any culture due to the diversity of their populations. This makes it impossible for this study to claim consistency of experiences among participants of each city. However, owing to the way data were collected, the study captures a relatively diverse sample of microcultures that constitute the populations of MSM within each city.

Relevance to mental health services

In conclusion, until societal changes in terms of homophobia happen, mental health professionals need to be aware of contextual differences in dealing with gay men and women who seek help. Although literature suggests that evidence-based interventions for the general population can also be beneficial for gay men,⁴⁶ studies (mainly qualitative in nature) have shown that LGB services are preferred over mainstream ones.²⁰ For example, research has shown that 'gay affirmative therapy' is preferred by LGB people as it views LGB lifestyles and sexual identities positively without pathologising them.⁴⁷ However, these findings come from qualitative studies with purposive samples. There needs to be a strong understanding of indigenous psychologies and the relationship between culture and psychology. Providing blanket responses to feelings of rejection, for example, which may encourage clients to disclose their sexuality as part of the process of self-acceptance and building a positive sense of self is not always the optimal strategy. Complete 'coming out' should not always be seen as the end goal because it may be that it has much graver consequences than incomplete 'coming out' within some societies. The existence of close societal ties between people may be more important for one's well-being. Jeopardising such ties as part of the 'coming out' process may be counterproductive for the gay individual. This may be particularly important in societies that do not have a developed gay community and gay movement that could provide alternative adequate support mechanisms.

1.8.50 Difficult to treat? A comparison of the effectiveness of treatment as usual in refugees and non-refugees

Abstract

Aims and method To examine treatment response in traumatised refugees, we compared routine outcome monitoring data (Harvard Trauma Questionnaire) of two refugee populations with those of individuals experiencing profession-related trauma who were treated at a specialised psychotrauma institute.

Results Asylum seekers/temporary refugees ($n = 21$) and resettled refugees ($n = 169$) showed significantly lower post-traumatic stress disorder (PTSD) symptom reduction between intake and 1 year after intake than did a comparison group of non-refugees ($n = 37$), but the interaction effect was clinically small (partial $\eta^2 = 0.03$). Refugees who had more severe symptoms at intake showed significantly greater symptom reduction after 1 year.

Clinical implications Therapists and refugee patients should have realistic expectations about response to treatment as usual. Additional treatment focusing on improving quality of life may be needed for refugees whose PTSD symptom severity remains high. At the same time, novel approaches may be developed to boost treatment response in refugee patients with low responsiveness.

Among many clinicians, traumatised asylum seekers and refugees have a reputation of being difficult to treat. Low treatment response in refugees is often attributed to patient-related factors,¹ such as trauma history, current stressors and complex psychopathology. Many asylum seekers and refugees have been exposed to multiple, prolonged, interpersonal traumatic events such as war and human trafficking.² In addition, they have to handle the stress of forced migration, including involvement in legal procedures³ and loss of their home country, cultural resources, family and social status.⁴ Apart from post-traumatic stress disorder (PTSD),⁵ they may experience comorbid symptoms including depression, anxiety and psychosis,⁶ as well as symptoms sometimes referred to as complex PTSD.⁷ By contrast, some clinicians argue that it is the treatment offered to refugees, rather than their potential to benefit from treatment, that leads to low treatment response,⁸ and that refugees, like other adults with chronic PTSD,⁹ should be treated with trauma-focused interventions. One way to examine treatment response in refugees is by comparing the effectiveness of different kinds of treatment in refugee samples. In recent years, randomised trials have shown promising effects for trauma-focused treatment in refugees.¹⁰ Another way to examine treatment response is to compare the effectiveness of treatment in refugee samples and non-refugee samples. This has been done little, if at all. This study's aim is to compare traumatised

The Authors own the copyrights to the individual articles.

asylum seekers' and refugees' response to treatment as usual with that of another multiply traumatised population: individuals affected by profession-related trauma (i.e. military veterans and police officers).

Method

Setting

Data were collected in Centrum '45, a Dutch mental health institute specialising in treatment of complex psychotrauma. Specific populations include asylum seekers and refugees, veterans of various peace missions, World War II resistance fighters as well as concentration camp survivors and their offspring, and police officers. Centrum '45 receives national referrals of patients who, owing to their psychosocial complexity, cannot be treated in general mental healthcare or who have shown insufficient response to treatment in general mental healthcare. Treatment for PTSD (individually or in groups) generally consists of a combination of supportive therapy, pharmacotherapy and trauma-focused therapy, particularly eye movement desensitisation and reprocessing (EMDR),¹¹ narrative exposure therapy (NET)¹² and brief eclectic psychotherapy for PTSD (BEPP).¹³ As these three trauma-focused treatments are evidence based, choice of treatment mainly depends on the therapist's training. Art therapy, psychomotor therapy and music therapy are also offered, especially to patients who follow a clinical or day-clinical programme.

Assessments

To evaluate the effectiveness of treatment as usual, Centrum '45 has routinely administered assessments at intake and at the end of treatment. Since 2007, a routine outcome monitoring (ROM) assessment 1 year after intake has been added for all patient populations. Since its introduction, ROM response has increased from around 40 to 55% in 2012. For several years, the Harvard Trauma Questionnaire (HTQ)¹⁴ was used as a ROM instrument with refugees and for a shorter period also with non-refugee populations. The HTQ has been specifically designed for use with refugee populations. It is a self-report instrument that consists of two parts: one focusing on traumatic events and one on symptoms of post-traumatic stress (specific to DSM-IV¹⁵ and additional symptoms reported by traumatised refugees). Symptoms are rated on a four-point scale ranging from 1 (not at all) to 4 (extremely). A mean score of 2.5 has been recommended as cut-off score for PTSD,¹⁶ although this recommendation has not been validated in a wide range of patient populations.

Sample

To answer our research question, we had at our disposal a ROM data-set that consisted of 577 patients who had completed assessments both at intake and 1 year after intake (with a range of 8 to 16 months). From this data-set, we excluded all partners and children of war-affected persons ($n = 218$; primarily children of parents traumatised in World War II) because their reasons for seeking help, generally speaking, do not include PTSD. We then excluded all patients who at intake had not been administered the HTQ ($n = 125$) but another instrument to assess PTSD (a Dutch self-rating inventory for PTSD).¹⁶ As the final dataset contained only a small number of patients traumatised during World War II ($n = 7$), we also excluded those patients. The final data-set consisted of 227 patients who had had their second assessment between March 2007 and April 2013. We divided the sample into three groups: asylum seekers/temporary refugees (i.e. those who are still awaiting the decision on their asylum application and those who have obtained temporary refugee status, which may not be extended after 5 years), resettled refugees (i.e. those who have obtained permanent refugee status or subsequent Dutch nationality), and patients with profession-related trauma (i.e. military veterans and police officers).

Statistical analysis

All analyses were performed using SPSS version 20.0 for Windows. Demographical and clinical characteristics were calculated, and chi-squared and *t*-tests were conducted to check for demographical and clinical differences between the groups. For the HTQ, mean PTSD severity at intake (T1) and one year after intake (T2) was computed as well as the difference between the two (PTSD symptom reduction). We checked HTQ variables for extreme outliers, but we found none. Missing data for the HTQ consisted of missing mean scores at T2 for 7 patients (2 asylum seekers/temporary refugees and 5 resettled refugees) and missing events scores at T1 for 42 patients (4 asylum seekers/temporary refugees, 34 resettled refugees and 4 professionals). We handled missing data by using pair-wise deletion.

We conducted pair-wise *t*-tests to determine treatment response within each group, and calculated by hand the effect sizes (η^2). Following Cohen, we interpreted $\eta^2 = 0.01$ to be a small effect, $\eta^2 = 0.06$ as moderate and $\eta^2 = 0.14$ as large.¹⁷ We set confidence intervals at 95%. To examine potential differences in treatment response between the three groups, we conducted repeated measures analysis of variance (ANOVA), using time as within-subjects factor and group as between-subjects factor. For the interaction effect, an effect-size (partial η^2) of 0.01 was interpreted to be small, 0.09 as medium and 0.25 as large.¹⁷ To examine variables associated with treatment response in asylum seekers and refugees, we performed a multiple regression analysis with PTSD symptom reduction (HTQ score at T1 minus HTQ score at T2) as the dependent variable and demographic variables (gender, age and refugee status (no/temporary/permanent)) and clinical variables (PTSD severity at T1, number of traumatic event types and time between assessments) as independent variables.

Results

Demographic characteristics

For demographic and clinical characteristics of the final sample, see *Table 1*.

Demographic and clinical characteristics of the groups

	Asylum seekers/ temporary refugees (<i>n</i> = 21)	Resettled refugees (<i>n</i> = 169)	Profession-related trauma (<i>n</i> = 37)	<i>F</i>	d.f.	<i>P</i>

HTQ, Harvard Trauma Questionnaire.

^a $\eta^2 = 9.47$.

Experienced or witnessed.

Because this study was observational, we found significant differences in demographic and clinical characteristics between the three groups for all variables. Asylum seekers/temporary refugees came predominantly from Afghanistan, Armenia, Iraq and Sierra Leone ($n = 3$, 14.3% for each country); resettled refugees came predominantly from the former Yugoslavia ($n = 59$, 34.9%), Iraq ($n = 28$, 16.6%) and Afghanistan ($n = 22$, 13.0%); and patients who had profession-related trauma came predominantly from The Netherlands ($n = 33$, 89.2%). The traumatic events that the asylum seekers/temporary refugees most frequently reported were physical torture ($n = 17$, 81.0%), threat of physical torture ($n = 17$, 81.0%) and other life-threatening situation ($n = 17$, 81.0%). Resettled refugees most frequently reported being close to death ($n = 135$, 79.9%), other life-threatening situation ($n = 125$, 74.0%) and forced isolation from family ($n = 123$, 72.8%). Professionals most frequently reported other life-threatening situation ($n = 34$, 91.9%), combat situation ($n = 34$, 91.9%), serious injury ($n = 31$, 83.8%) and being close to death ($n = 31$, 83.8%).

Treatment outcome

Figure 1 shows the results of the repeated measures ANOVA for the three groups.

Fig. 17: PTSD symptom severity at intake and after 1 year.

Mean PTSD symptom severity decreased from 3.13 (95% CI 2.91 to 3.35) to 2.92 (95% CI 2.65 to 3.20) for asylum seekers/temporary refugees; from 3.10 (95% CI 3.03 to 3.18) to 2.88 (95% CI 2.79 to 2.98) for resettled refugees; and from 2.80 (95% CI 2.64 to 2.96) to 2.31 (95% CI 2.11 to 2.51) for patients suffering from profession-related trauma. Paired-samples t -tests revealed a significant decrease in PTSD severity for resettled refugees (0.22, s.d. = 0.52, $t_{(163)} = 5.39$, $P < 0.001$) and for professionals (0.49, s.d. = 0.64, $t_{(36)} = 4.65$, $P < 0.001$), but not for the smallest group, asylum seekers/temporary refugees (0.21, s.d. = 0.59, $t_{(18)} = 1.53$, $P = 0.143$). Effect sizes for treatment response in asylum seekers/temporary refugees and resettled refugees were moderate ($\eta^2 = 0.12$ and $\eta^2 = 0.15$, respectively); effect size for patients with profession-related trauma was large ($\eta^2 = 0.38$).¹⁶ Repeated measures ANOVA showed a significant effect for time ($F = 32.27$, $P < 0.001$) with a medium effect size (partial $\eta^2 = 0.13$), and a significant group \times time interaction effect ($F = 3.65$, $P = 0.028$) with a small effect size (partial $\eta^2 = 0.03$).¹⁶

We then combined the two refugee groups and, using multiple regression analysis, we examined whether seven demographic and clinical variables were associated with PTSD symptom reduction (Table 2).

Factors associated with reduction in PTSD symptom severity in refugees after 1 year

	B	95% CI		P
Demographic variables				
Gender	0.11	0.07 to 0.29	0.09	0.238
Age	0.00	0.01 to 0.00	0.09	0.277
Refugee status				
None v. permanent	0.03	0.37 to 0.31	0.01	0.872
Temporary v. permanent	0.14	0.52 to 0.24	0.06	0.464
Clinical variables				
PTSD symptom severity at intake (HTQ)	0.48	0.32 to 0.64	0.45	<0.001
Traumatic event types (HTQ), n	0.01	0.03 to 0.00	0.11	0.157
Time between assessments, months	0.01	0.06 to 0.05	0.01	0.851

B, regression coefficient; , standardised regression coefficient; HTQ, Harvard Trauma Questionnaire; PTSD, post-traumatic stress disorder

As shown in Table 2, refugee patients with more severe PTSD symptoms at intake had significantly stronger reductions in PTSD symptom severity after 1 year. The other variables were not significantly associated with PTSD symptom reduction. The percentage of variance explained by the model (R^2) was 21.5%.

Discussion

This study shows that asylum seekers/temporary refugees and resettled refugees experienced significantly lower PTSD symptom reduction between intake and 1 year after intake than did a comparison group of multiply traumatised military veterans and police officers. However, greatest differences between groups were found in PTSD symptom severity at intake and 1 year after intake rather than in PTSD symptom reduction. Explorations of PTSD symptom reduction in refugees showed that those who had more severe symptoms at intake experienced significantly greater symptom reduction after 1 year; other variables (including variables related to refugee status and number of traumatic events) were not related to symptom reduction.

The results show that despite specialised treatment being offered to refugees, treatment response can be limited and PTSD severity frequently remains high. Possible explanations, and consequently clinical implications, might be three-fold: patient-related, therapist-related and treatment-related. As for patient-related factors, the multiple determinants of PTSD might influence refugees' ability to benefit from treatment. It is generally acknowledged that PTSD in refugees is influenced by both traumatic and current stressors, some (or many) of which may be beyond the patients' and therapists' control.¹⁸ Following this explanation, clinicians and patients should have realistic expectations about what treatment may achieve in such a heavily traumatised and burdened population. Interventions that focus on improving quality of life rather than on further symptom reduction, such as acceptance and commitment therapy,¹⁹ might be useful for those patients who despite prolonged treatment continue to suffer from clinically significant PTSD. Clinicians sometimes suspect asylum seekers to exaggerate symptoms to remain in medical care and thereby increase the chance of obtaining a refugee status. We found no substantiation for this hypothesis of 'secondary gain' - in our study, not having a permanent refugee status was not associated with a decreased treatment response.

As for therapist-related factors, therapeutic skills that might suffice in trauma-focused treatment of other multiply traumatised groups might fall short in the treatment of refugees. Therapists might need more extensive training and supervision regarding choosing and staying with a treatment focus, categorising and selecting of target memories, and understanding and restructuring of trauma-related cognitions in order not to lose their way in the multitude of symptoms, memories and transcultural challenges. At the same time, therapists need to maintain a sense of being 'good enough' to provide treatment to refugees with limited responsiveness.²⁰

Finally, regarding treatment-related factors, not all evidence-based treatments will work with all refugees. Therapists will need to explore non-response, and they may need to consult refugee patient populations themselves²¹ to examine which treatment aims and techniques speak to refugees who insufficiently benefit from treatment as usual. In addition, novel approaches may be developed to enhance treatment response. Centrum '45 is currently exploring the feasibility of refugee treatment that focuses primarily on prolonged grief rather than on PTSD, and of intranasal oxytocin as a novel strategy to boost treatment response in refugees.²²

Limitations

Although this study is valuable for comparing the effects of treatment as usual in refugee populations with those in a non-refugee population (which, to our knowledge, has not been done before), it also has several limitations. First, a division of the asylum seeker group into asylum seekers and temporary refugees, and of the profession-related trauma group into military veterans and police officers, would have been clinically meaningful but was not possible due to limited sample sizes for these groups. Second, some variables that might have shed light on differences in treatment response between the three groups (including comorbid disorders, the amount and content of treatment, change in refugee status and chronicity of PTSD) were not included in the data-set. Future studies should use a broader range of variables to more comprehensively assess predictors of refugees' treatment responses. Third, ROM assessments at our institute are completed by about 55% of patients, and findings might not generalise to our complete patient population, nor to traumatised refugees in general.

Nevertheless, our study contributes to the debate on refugees' treatment response by showing that it is indeed relatively lower than that of multiply traumatised non-refugees.

We thank Niels van der Aa for providing us with the data-set and methodological information.

1.8.51 Brain fog syndrome: a culture-bound syndrome that may be approaching extinction

Abstract

Aims and method To explore the current salience of ‘brain fog’ as a nosological, diagnostic and clinical construct in modern West African psychiatry. A semi-structured questionnaire and vignette based on classical symptoms of brain fog syndrome were used to explore current knowledge, explanatory models and practice among Nigerian psychiatrists.

Results Of 102 psychiatrists who responded, 98% recognised the term ‘brain fog syndrome’ and most recognised the scenario presented. However, only 22% made a diagnosis of brain fog syndrome in their practice preferring diagnoses of anxiety, affective and somatic disorders.

Clinical implications A decreasing number of Nigerian psychiatrists are making a diagnosis of ‘brain fog syndrome’. We found strong evidence of nosological and diagnostic decline in the syndrome in its place of birth. This may signal the early extinction of this disorder or nosological metamorphosis from a ‘culture-bound’ syndrome in West African psychiatric practice.

In 1960 Raymond Prince,¹ a founding figure in the field of transcultural psychiatry, published a seminal paper describing unique cultural observations in Nigeria, a newly independent country in British West Africa. At the time, Prince (a Canadian psychiatrist) had been working in Yoruba-speaking south-western Nigeria. In the paper he described a cluster of symptoms he observed in Nigerian students, which were associated with study and manifesting a range of emotional and somatic complaints. Given the recurrent reference to mental exhaustion ('brain fog') Prince named this symptom cluster 'brain fog syndrome'.

Distinctive symptoms of the syndrome were: intellectual impairmentsensory impairment (chiefly visual)somatic complaints, most commonly of pain or burning in the head and neckother complaints affecting the student's ability to studyan unhappy, tense facial expressiona characteristic gesture of passing the hand over the surface of the scalp or rubbing the vertex of the skull. Citing Prince: "Most often the symptoms commenced during periods of intensive reading and study prior to examinations or sometimes just following periods of intensive study ... The patients generally attribute their illness to fatigue of the brain due to excessive "brain work".' (p. 561)¹" As Price elaborated, it is for this reason that the term brain fog syndrome has been used. The expression seems to be used by Nigerians generally to describe any psychiatric disturbance occurring in 'brain workers'. Exploring the unfamiliar nature of the presentation, brain fog was at the time ascribed to 'a clash between Western and African cultural values'.¹

This unfamiliar clinical presentation and manifestation of distress was initially felt to be a culture-bound syndrome localised to southern Nigeria. Subsequently, further reports were published from other African regions.^{2,3} These case reports and student population surveys highlighted psychological distress associated with study in some African students.^{2,3} Over the decades, there has been some debate by predominantly African psychiatrists as to whether this actually constitutes a unique nosological entity, cultural manifestation or unique amalgamation of more established mental disorders.⁴⁻⁶ An interesting review of brain fog syndrome literature by Ola *et al*⁵ details the different arguments.

While reference is made to brain fog syndrome in both the tenth edition of ICD-10⁷ and the 'Glossary of Culture Bound Syndromes' in the fourth edition (revised) of DSM-IV-TR,⁸ the current relevance to clinical practice is uncertain. The DSM IV-TR described brain fog syndrome as a culture-bound syndrome attributed to overwork and affecting West African students. Characterised by a loss of ability to concentrate, learn, remember or think and usually accompanied by sensations of pain, pressure or tightness around the head or neck and blurred vision, a condition which 'can resemble certain Anxiety, Depressive and Somatoform Disorders'.⁸ The newer DSM-5, however, is less detailed regarding brain fog and cites it as an example of a cultural anxiety syndrome.⁹

Nigerian psychiatric services, although based on Western models, are also familiar with the assessment and treatment of West African cultural presentations of affective, psychotic and anxiety disorders. Competition with traditional and faith healers abounds as do belief systems about emotional distress. The ICD-10 is primarily used for diagnostic classification, although DSM classification is also recognised. Medical instruction and scholarship is in English and the majority of practitioners are at least bilingual and speak one or more indigenous languages.

The limited diagnostic clarity about the validity of this culture-bound syndrome⁵ justifies an exploration of the existence of brain fog in modern West African psychiatry. A factor analysis and differentiation of somatic symptoms in Africans with depression¹⁰ and the validation of burning and crawling sensations in the Brain Fog Syndrome Scale are important empirical steps towards this.¹¹ If a prevalent disorder, the exponential growth in secondary and tertiary educational institutions (online Fig. DS1) would potentially have an impact on the mental well-being of millions of adolescents and young adults with health and resource implications. Conversely, if the diagnostic status is unclear, the pathologisation of young people may lead to inappropriate help-seeking or impair education.

When brain fog syndrome was originally described in Nigeria in 1960, Western models of psychiatric care were in their infancy, with only four indigenous, linguistically and culturally embedded psychiatrists in the country. International

psychiatrists from the UK, the USA, Canada (including Raymond Prince) and Germany made significant contributions to service development and the training of mental health professionals in the country. While the number of mental health professionals has shown sustained growth over the years, the number of psychiatrists remains grossly inadequate, with an estimated 0.15 psychiatrists per 100 000 Nigerians.¹⁰ Unfortunately, 25% migrate within 5 years of completing training.¹² Such specialist workforce changes may influence skill stability.

There have been no known surveys to date of West African mental health professionals on their opinions and practice relating to brain fog syndrome.

Aim

This study aimed to explore awareness of brain fog, its aetiology, diagnosis, explanatory models and management by psychiatrists in Nigeria, where this disorder was originally described.

We sought to explore the nosological salience of brain fog syndrome among contemporary West African psychiatrists in Nigeria and to ascertain whether it is still regarded as a distinct disorder or an idiomatic expression. We were also interested in exploring the historical course of the syndrome over time. Opportunities to explore the modern and cultural history of disorders do not arise often in anthropological medicine.

Method

A semi-structured, self-administered questionnaire that incorporated both coded and written text responses was designed as a survey of 'psychological distress' among students. It was mailed to psychiatrists in tertiary, secondary and private psychiatric facilities across Nigeria. Electronic copies were also disseminated. Further uptake was facilitated at the conference of the Association of Psychiatrists in Nigeria, the key professional body for psychiatrists. Questions were clustered into the following categories: clinical experience in psychiatry (number of years of practice, seniority) setting of clinical practice (e.g. teaching hospital, specialist psychiatric hospital, general hospital and private practice) geographical region of country clinical case-load and number of patients seen per month. Respondents were presented with a vignette (*Box 1*) describing classic brain fog features in a student. Though based on core diagnostic features of brain fog syndrome, the term 'brain fog' was withheld from respondents until the end of the questionnaire. Respondents were asked a few short questions (e.g. 'Are you familiar with this type of presentation in your practice?'), the frequency and approximate number of patients with this unnamed symptom cluster they had seen in the past 12 months. It is worth stressing that these questions referred to symptoms in the vignette and not a specific diagnosis of brain fog syndrome.

Box 1 Vignette presented to psychiatrists in the study

A 20-year-old student presents complaining of 'burning heat or pain in the head and neck'. The student also experiences difficulty concentrating, assimilating and recalling things studied, as if 'the brain ... is dead or not working'. Vision is sometimes blurred. Sleep has also been poor. The student wishes to pursue further studies and is concerned about the implications of this experience.

From the vignette, the psychiatrists were then asked to consider a diagnosis and differential diagnosis as they would in routine clinical practice such as anxiety disorder, depressive disorder, somatisation disorder, psychotic disorder, or another category. In addition, they were asked to proffer aetiological explanations for the presentation as well as the therapeutic options that they would offer the individual in the scenario. This was a free-text section so as to allow folk, social and other non-medical explanatory models. A content analysis of these responses was carried out to identify themes.

The concept of brain fog syndrome was introduced in the final part of the questionnaire to minimise contamination or bias to the earlier responses. This section explored whether the respondent had ever heard of brain fog syndrome and whether they made this diagnosis in routine clinical practice. The psychiatrists were encouraged to provide additional comments or alternative explanations, views and opinions on any aspect of the study.

Questionnaires were returned by prepaid envelope, hand delivery and electronically.

In addition, five decades of historical context into psychiatric services in Africa and the genesis of brain fog syndrome were obtained through personal communication with current and retired psychiatrists, as well as an anthropological field worker and interpreter used in the original work. Full qualitative details are outside the scope of this paper, but are being prepared for publication in another paper.

Results

Overall, 102 responses were received from all regions of the country. The national response rate of 36%, while relatively low, overcame logistical challenges and showed a good geographical, ethnic and clinical spread across Nigerian mental health services. Interestingly, this rate mirrored a mail survey of psychiatrists by the World Health Organization and the World Psychiatric Association (Nigeria 36%, USA 21%, UK 22%, South Africa 24%) across 44 countries¹³ and was also similar to other non-incentivised physician surveys.¹⁴

So as not to restrict opinions, more than one diagnostic response was permitted to some questions, therefore some totals were over 100%.

Psychiatrist characteristics

Forty-four percent of respondents were registrars, 33% senior registrars, 21% consultants and 2% psychiatric medical officers. The mean number of years of experience in psychiatry was 6.3 with a median of 4 years and a range of 1-37 years (*Fig. 1*). The doctors saw an average of 152 patients per month.

Location of practice

Sixty-nine (68%) of the psychiatrists were from the south of Nigeria and 33 (32%) were from the northern regions. This distribution closely reflects the regional density of psychiatric services in the country.

Awareness of symptoms in the brain fog questionnaire vignette

The majority of psychiatrists (95%) were familiar with the presentation in the vignette in their routine practice and 84.3% ($n = 86$) had seen patients with similar symptoms within the past year (*Fig. 2*). On average, each psychiatrist saw 14.2 patients presenting with vignette symptoms annually, approximately 0.78% of their annual clinical case-load or 1:128 patients.

Fig. 18: Number of patients with brain fog symptoms seen in past year

Nosology of symptoms and signs

The vignette symptoms were classified as an anxiety disorder by 49% of psychiatrists, while 37% considered brain fog syndrome; 36% felt the presentation was consistent with a depressive disorder and 30% associated it with somatisation disorder.

Aetiological explanations and attributions

Nigerian psychiatrists suggested a number of possible aetiological factors for the brain fog syndrome core criteria vignette symptoms (*Table 1*). Content analysis observed explanatory themes attributed to the following causes: mental disorders (9.23%), psychogenic (24.10%), educational difficulties (32.31%), sociocultural (9.23%), interpersonal (3.59%), biological (9.74%), substance misuse (4.61%) and demographic factors (1.02%) while 6.15% of the psychiatrists gave no aetiological explanation.

Causes of vignette symptoms suggested by respondents ($n = 195$)

Category	Subcategory	<i>n</i>
Mental disorder ($n = 18, 9.23\%$)	Somatisation	14
	Anxiety	2
	Depression	1
	Psychiatric history	1
Psychogenic ($n = 47, 24.10\%$)	Stress	29
	Psychological	12
	Poor coping mechanisms	3
	Behavioural	2
	Loss	1
Study and education ($n = 63, 32.31\%$)	Educational concerns	31
	Influence of foreign language	10
	Intensive study	9
	Desire to succeed	7
	Fear of failure	2
	Goal failure	1
	Motivational factors	1
	Low productivity	1
	Modernisation through study	1

Interpersonal issues ($n = 7, 3.59\%$)	Personality	4
	Strained relationships	1
	Family disharmony	2
Organic/biological ($n = 19, 9.74\%$)	Genetic	13
	Biological	2
	Sympathetic activity	2
	Trauma	1
	Malaria	1
Demographic ($n = 2, 1.02\%$)	First born	1
	Male gender	1

Unknown ($n = 12$, 6.15%)

Management

Nearly half of the psychiatrists (46.47%) advocated the use of psychological therapies such as psychotherapy, counselling, cognitive-behavioural therapy and family therapy in the management of the symptoms. Psychotropic medications (e.g. antidepressant, anxiolytics) were suggested by 42.75%. Lifestyle changes such as changing study methods and sleep hygiene were recommended by 4.83% of the respondents (*Fig. 3*).

Fig. 19: Management of brain fog symptoms

Recognition of brain fog syndrome

Ninety-eight percent of the psychiatrists surveyed had heard of brain fog syndrome. However, only 22% of them actually made this diagnosis in their daily clinical practice.

There was a significant association between the duration of practice in mental health services and the diagnosis of brain fog syndrome ($P = 0.007$), with those practising for more than 5 years making the diagnosis more frequently than those practising for 5 years or less (59% *v.* 41%, $P = 0.003$), despite all but one being aware of the diagnostic features of brain fog. Similarly, seniority in clinical practice was associated with the diagnosis of brain fog ($P = 0.003$), with consultants diagnosing more than their junior colleagues. There was no difference in proportion of psychiatrists diagnosing brain fog when comparing respondents from different states and regions of Nigeria ($P > 0.05$). Also, the level of specialisation of institutions was not associated with a difference in likelihood of diagnosing (general hospital 23% *v.* teaching hospital 20%, $P > 0.05$). Using binary logistic regression analysis, the only independent predictor of diagnosing brain fog syndrome was the seniority of clinician ($P = 0.008$). Registrars were least likely to make a diagnosis compared with consultants (odds ratio 0.1, 95% CI 0.03-0.38, $P = 0.001$).

Discussion

These important findings suggest that the less experienced psychiatrists, who are more likely younger, made a diagnosis of brain fog syndrome least. It is unclear whether they found brain fog less attractive than their senior colleagues or if this may reflect differences in training (postcolonial *v.* contemporary) and diagnostic emphasis between the groups (A. Ayonrinde, personal communication, 2012) Should this trend persist, we foresee decline and possible extinction in the use of this diagnosis among Nigerian psychiatrists, critically within the society in which this culture-bound syndrome was originally described.

Symptom recognition and diagnostic instability

We observed diagnostic inconsistencies among Nigerian psychiatrists presented with the vignette with features of brain fog syndrome. Although familiar with the presentation (98%), and some consideration given to brain fog, the majority of psychiatrists preferred the more familiar ICD-10 diagnoses to a culture-bound syndrome. The phrase 'brain fog' was once a familiar idiom of distress during the earlier educational years of some senior clinicians, however, it is no longer common cultural parlance within Nigerian society. High rates of term recognition may also be a consequence of postgraduate psychiatric training where brain fog is taught as a disorder with a West African history. In fact, the authors (of Nigerian ancestry) with cultural and clinical experience of Nigerian mental health services have rarely heard use of the term brain fog outside academic circles.

The clinical and cultural consonance of the psychiatrists surveyed in this study enriches the findings as they span several decades of experience, clinical centres, ethnic and geographical regions. Their clinical and social awareness of emotional distress among students gives useful insight into the contemporary concept of brain fog.

Our finding of diagnostic fluidity and heterogeneity between anxiety, somatisation and depressive disorders is consistent with the DSM-IV-TR statement that brain fog syndrome can resemble anxiety, depressive and somatoform disorders.⁷

The diagnostic instability evident here calls into question whether brain fog syndrome is a homogenous or unique diagnostic entity, or actually a symptom co-variant of other somatisation, anxiety and affective disorders. The weight of cognitive and somatic complaints has been observed to differentiate from core features of depression in Nigeria and may well confirm unique culture-specific presentation¹⁰ as was proposed in the 1960s.¹⁵

Educational concerns, intensive or excessive study and the drive for success were the most common explanatory models for the vignette (32%). The emphasis on education and 'study' in the brain fog narrative may unwittingly bias clinicians towards cerebral and mental symptoms, thereby distracting from other somatic complaints. We hypothesise that brain fog was probably a historic idiomatic expression of impaired mental function with presentation of somatic complaints. Sleep impairment, poor attention and concentration and somatic complaints in an anxious or depressed individual would understandably impair educational activity – whereby symptoms worsen the potential to study rather than study triggering a mental disorder.

The brain fog explanatory models presented biological, psychological, social and stress models of illness. To date these aetiological links are lacking in robust empirical evidence. Further exploration of the somatic manifestations of common tropical diseases such as malaria would be insightful. Interestingly, one respondent cited 'witchcraft'. Beliefs in evil spirits, curses and malevolent forces are not uncommon in West African cultures. Psychoactive substance use and their effects such as impaired concentration and sleep difficulties and somatic effects may also easily mimic the brain fog symptoms.

Management

The preference for psychological therapies appears to reflect the aetiological attributions given to the symptoms such as stress, educational aspirations and interpersonal difficulties. To date there has been mainly anecdotal evidence or brief reports on treatments for brain fog.¹⁶ It is unclear from our findings what the response is to these therapeutic interventions and the degree of symptom relief. Given that the majority of psychiatrists were of the opinion that the symptom clusters were features of somatisation, anxiety and affective disorders, the additional choices of psychotropic medication are understandable.

Improving our understanding of the causes of brain fog symptoms has potential benefits in terms of identifying susceptible individuals and subsequently being able to manage them more appropriately. The fact that nearly a third of respondents pointed to educational concerns as a factor in the development of brain fog could have a significant influence on educational and public health interventions, policies as well as practice. Inaccurate information regarding causative factors and the care of mental distress in students carries a risk of prolonging mental distress. This confusion may result in individuals with depression or an anxiety disorder believing themselves to experience brain fog and abandoning education.

There is a need for improved understanding of mental disorders ascribed to study in this West African culture given the cultural salience of education as a key to success and social mobility. It remains unclear whether brain fog is a mental sequel of educational difficulties or the somatic, neurotic, cognitive and affective manifestation of distress in students. Significantly more research is required into cultural concepts of distress,⁹ an important consideration for the ICD-11.

Over half a century on from the original observations on brain fog it seems that our understanding of this culture-bound disorder has not advanced much. This study found that a large proportion of psychiatrists in Nigeria were familiar with and regularly manage students who present with anxiety, affective, cognitive and somatic symptoms. However, these African psychiatrists in the home of the brain fog syndrome infrequently consider this diagnosis in their routine clinical practice.

The semiotic salience of brain fog as a distinct, relevant and contemporary culture-bound syndrome is not supported by our findings in Nigeria. Idiomatic and syndromic use of the term brain fog became extinct in 19th- and 20th-century Britain, before its resurgence in Africa.^{17,18} Should the modern decline in brain fog persist, this culture-bound syndrome may well face diagnostic extinction.

1.8.52 What is culturally informed psychiatry? Cultural understanding and withdrawal in the clinical encounter

2015-8

Abstract

What is culturally informed psychiatry? What does it mean, and why is it important? These questions are discussed with a focus on the cultural aspects of the clinical encounter. The *DSM-5 Outline for Cultural Formulation* was developed as a method of assessing the cultural factors affecting the clinical encounter. It calls for the assessment of the cultural features of the relationship between the patient and the clinician; however, there is a lack of debate about what this means in practice. Clinicians run the risk of withdrawal rather than cultural understanding when facing patients with different cultural backgrounds. Using ethnographic material from anthropological fieldwork, I suggest that the encounter with cultural differences could be a useful point of departure for the clinician to develop cultural understanding. It is argued that recognising the experiences of differences is crucial in strengthening transcultural communication and preventing misdiagnosis in the clinician–patient encounter.

“‘Pathology’ is always a measure of difference.¹” Increased evidence points towards culture as one aspect influencing the prognosis, cause, manifestation and course of mental health problems. Mental health problems are more frequently misdiagnosed among patients from ethnic minority, immigrant and refugee groups than among native-born patients.² Misdiagnoses may involve failing to recognise the mental health condition or mistaking culturally normative behaviour for psychopathology.³ The cultural formulation in DSM-5 was developed as a standard method of applying cultural perspectives to the clinical evaluation.⁴ The *Outline for Cultural Formulation* (OCF) has been field-tested for diagnostic

usefulness among clinicians.⁵ The cultural formulation has been praised as the most outstanding anthropological contribution to psychiatry, yet it has also been met by critiques by some medical anthropologists and psychiatrists. With the cultural formulation in the DSM-5 and its critique as the point of departure, this article questions what culturally informed psychiatry means. The argument is that the encounter between the patient and the clinician is a crucial, yet underappreciated, position from where the clinician might develop a cultural understanding.

DSM and the problem with culture

The contemporary model of the cultural formulation in the DSM-5 and DSM-IV dates from the criticism of the insensitivity to cultural issues in the DSM-III.⁶ The institutional culture of medicine was characterised as a 'culture of no culture', with limited interest in cultural issues.⁷ The OCF was first published in the DSM-IV in 1984, with a glossary of culture-bound syndromes, culturally relevant diagnostic categories and cultural considerations in the narratives introducing each chapter.⁸ The National Institute of Mental Health in the USA supported the creation of a culture and diagnosis group in 1991, whose main goal was to advise the DSM-IV task force on how to make culture more central to the manual.⁹ However, although the culture and diagnosis group succeeded in emphasising the relevance of cultural issues in psychiatry, there has been criticism of the cultural formulation from leading medical anthropologists over the years. This criticism can be summed up in the following four points. There is a lack of evidence that culturally informed therapeutic practices work.^{10,11} Kleinman & Benson suggest that the major claims about the value of cultural competence for professional caregiving are not supported by evaluation research showing that systematic attention to culture really improves clinical services.¹¹ This lack of evidence is a failure of outcome research to take culture seriously enough to assess the cost-effectiveness of culturally informed therapeutic practices.¹¹ Moreover, evidence-based practice should include a broader view of evidence that takes into account how different cultures recognise different ways of knowing.¹⁰ In striking contrast to its current use in anthropology, the concept of culture tends to be defined in medicine as something possessed by the patient and not the doctor. Culture is conceived as a confounding variable that White practitioners must deal with when they interact with people from ethnic minority groups.¹ The locus of normality is white. Taking whiteness for granted represents a specific view of culture that is shared by many White practitioners.¹³ The Black and minority ethnic patient is construed as the object of specialised knowledge, while the professional and their cultural context are left unquestioned.¹³ Historically, this view is reflected in the ways of linking psychiatric knowledge production and implementation to a strictly Western agency, while non-Westerners are often posited as passive receivers of this knowledge.¹⁴ Clinicians are criticised for lacking a cultural self-reflexive attitude towards their own professional practice.¹⁵ The cultural formulation of the DSM-5 aims to address these criticisms. The OCF is converted into the Cultural Formulation Interview (CFI), including 16 questions focusing on the patient's presenting concerns and definition of their problem and idiom of distress.^{16(p.749-760)} Culture is defined as the systems of knowledge, concepts, rules and practices that are learned and transmitted across generations, yet are open, dynamic and undergo continuous changes over time.

The formulation emphasises that cultural information must not be overgeneralised or stereotype groups of fixed cultural traits.^{16(p.749)} The OCF calls for a systematic assessment of the following four categories when conducting the CFI: cultural identity of the individual, cultural conceptualisation of distress, psychosocial stressors and cultural features of vulnerability and resilience, cultural features of the relationship between the individual and the clinician.^{16(p.750)}

A persistent challenge faced by clinicians in implementing the cultural formulation in the DSM-5 is how to translate insights from the social sciences in intelligible, practical and sustainable ways.¹⁷

I aim to delve deeper into the fourth category: the clinical relationship. I aim to translate insights from anthropological fieldwork into practical methods for clinicians. Cultural difference can affect the clinical encounter, and part of the role of culturally informed psychiatry is to address this difference. Using ethnographic material from my anthropological fieldwork in Tanzania, I explore the cultural experience evoked in the encounter. This knowledge is transferred into the context of medical practice.

White person, where are you going?

Dressed in training tights, a t-shirt and running shoes, I stood in an outside gathering hall in a squatter area of Dar es Salaam, Tanzania, in January 1989. I was preparing to exercise young Tanzanian women in aerobic. As a new teacher in physical education from Norway, I was engaged for 1 month in the Norwegian sports development project, Sports for All, with the aim of giving working class women the opportunity to exercise. Twenty women arrived; none of them was wearing training gear or running shoes, but they had colourful dresses or blouses and skirts and were barefoot. I started to count one, two, three, and then pressed the play button on the music player. The Tanzanian women questioned every move I made. They wondered if they would get paid for exercising. They wanted to touch my white, pale skin and glanced at my freckles. They laughed in a friendly way at jumping up and down, commenting that the moves were a bit childish. Every day, when I left the daily training, people glanced at me and called out: ‘White person, where are you going?’ This question persecuted me in the years to come during several field visits to Tanzania and filled me with uneasiness, curiosity and amazement.¹⁸

The amazement was first and foremost a ‘culture shock’ that caused me to question my whiteness, my way of practice and instruction. The Danish anthropologist Kirsten Hastrup used the term ‘amazement’ as a cultural pivotal point and a way of understanding that brings a person through emotional and embodied states.¹⁹ When our habitual practices are questioned we become amazed. When the Tanzanian women questioned the way I moved my arms up and down, they questioned body practices that were part of my professional education and that I had taken for granted. When they commented on my moves or skin colour, I was amazed, as I never thought about these in terms other than ‘normal ways’. The amazement is embodied and cultured.²⁰

It was in the encounter with the Tanzanian women that I became aware of my habitual practices and cultural ways. It was by being amazed that I became conscious that, like the Tanzanians, I too possessed systems of knowledge, concepts, rules and practices that are learned and transmitted across generations, yet are open, dynamic and undergo continuous changes over time.

Next, I will discuss how this experience can be relevant to a Western clinician by elaborating on some characteristics of the encounter between the doctor and patient, as discussed by Roland Littlewood, among others.²¹

The clinical encounter

The encounter between the psychiatrist and the patient involves two people who have their own expectations. If the doctor–patient situation is familiar to both, they will each probably make an effort to live up to the other’s expectations. For example, the expectation that the patient is seeking advice to solve a specific problem and that the doctor is an expert who will provide this advice. However, the psychiatrist and the patient face challenges if their cultural backgrounds differ considerably. The psychiatrist might have a less clear expectation of how the patient is likely to behave and what the limits of normality and abnormality are. In this sense, the encounter between the psychiatrist and the patient shares several similarities with the encounter between the researcher and informants from different cultural contexts. The psychiatrist’s attitude towards a patient from a minority ethnic background will be informed by the clinician’s own experiences, stereotypes and conscious and unconscious racial assumptions. For example, the clinician might have certain race-related assumptions and the patient might be assumed to have a core set of beliefs.²² Stereotypes of how other groups of people (such as Danish-Somalis, Native Americans and British Pakistanis) tend to behave influence the treatment options. Patients have their own expectations and the extent to which they see themselves as mentally ill varies with cultural background. What might be tolerated in Tanzania, such as spirit possession, witchcraft and healing ritual, are regarded as forms of abnormality (if not mental illness), in Britain.²³ Patients with a migrant background seeking help in psychiatric out-patient clinics in European countries might have experiences of mental illness that differ from the doctor’s experiences. For example, they might experience their illness as a physical disability or have felt lost in a fragmented health system.⁵ How the psychiatrist copes with their own amazement is therefore of importance.²⁴ I present two cases based on my own experience to demonstrate two ways clinicians might respond to amazement.

Amazement: cultural understanding or withdrawal?

Culturally informed psychiatry is required in domestic contexts familiar to the clinician. Clinicians' experiences of differences, such as language barriers, patients' expressions of distress and orientations of belief can trigger fear, anxiety and amazement. To be aware of one's own amazement might uncover issues taken for granted that the clinician assumes to be inevitable and universal. These often unnoticed assumptions may refer to all sorts of beliefs, habits, practices and values, from body comportment to being accustomed to urban infrastructure. I suggest two responses to this amazement: cultural understanding and withdrawal.

Example 1

At a Swedish conference on psychiatry and the cultural formulation in the DSM-5, the participants discussed diagnostic practices for asylum seekers. A psychiatrist said: 'It is very hard when you receive a refugee. The first thing you are supposed to do is to consider the person's mental health. I was really amazed when I discovered that my patient's strong sense of confusion was not necessarily due to his mental condition. Rather, it could be ascribed to his overwhelmed experience of seeing a Swedish city ... We should not be too quick to diagnose refugees with post-traumatic stress disorder [PTSD], before they have time to get used to the new cultural context.' The discussion that followed concerned various clinical experiences with 'cultural differences', such as the difficulty in understanding patients' expressions of distress and in making meaningful diagnostic evaluations.⁵ The psychiatrist was amazed at his own cultural attention to the patient. He took for granted, as a prerequisite for professional practice, that the patient was familiar with the material surroundings of the therapy practice: the buildings, roads, transport and so on. In the encounter with the patient, he had quickly diagnosed the patient's confusedness as PTSD. Although the refugee suffered in some ways because of his experience in a war-ridden country, the psychiatrist's amazement and reflection on it gave him alternative ways of interpreting the patient's suffering.

The psychiatrist was able to reflect critically upon his own cultural background and his taken-for-granted perspectives, which places him in a better position to understand and reconsider the mental state of the asylum seeker.

Example 2

A Norwegian family therapist was observing an 8-year-old Afghan boy to assess his mental health. The boy was not very talkative and was by himself. He had arrived in Norway with his family some years ago. His parents were reluctant towards family therapy as it appeared quite unfamiliar to them. The therapist, on the other hand, aimed at making a decision on the diagnosis of the boy. The parents came with the boy the day that the therapist informed them about the boy's problems. She explained to them that their son was diagnosed with autism spectrum disorder.^{16(p.50-55)} The therapist informed the parents about their welfare rights that followed their son's acknowledged diagnosis, information that was quite new to them. The therapist made a new appointment with the parents and their son. However, only the father attended the next appointment. He informed the therapist that they had received a letter from the director of the hospital claiming the director regretted that their son received the diagnosis and confirmed its withdrawal. Their son did not have autism. The father said there was no more to do, and politely left. Leaving behind the astonished therapist, the director of the hospital confirmed that the letter was never written. When the therapist called the father of the boy to tell him that there was never such a letter, the father replied that it must have been lost. The therapist was never in contact with the family again.

When giving this account, the therapist expressed great frustration that the family did not see the value of this diagnosis. She saw it as her duty to assess and diagnose the patient. She was amazed that the family did not accept the diagnosis and she thought of this as a cultural problem. Therefore, she did not try to explore how her own amazement could be interpreted as a cultural response to an unfamiliar situation (that the parents did not accept the diagnosis). In the encounter, the family therapist took it for granted that the patient and their relatives would accept the diagnosis given to them.

The amazed clinicians might not be able to develop an understanding in the encounter with the patient, but might withdraw instead. Clinicians may respond to their own experience of difference by using cultural categories on the

patients, setting themselves as the normative standard. Imposing identities on patients, such as ‘boy with autism’, ‘woman with bipolar disorder’, ‘man with suicidal tendencies’, helps clinicians feel more secure with their own identity and withdraw from an alternative identity experienced by the patient.²⁵

To be able to learn from one’s own amazement to develop understanding as a researcher requires a culturally reflexive research position. In anthropological fieldwork the researcher must take into account that they are always part of the situation being studied. Part of the criticism of the cultural formulation, as discussed earlier, is a lack of self-reflexivity among clinicians when it comes to their professional background. A clinician who understands something of their own cultural background and how it contributes to their values, perceptions and personal style is in a better position to learn from the clinical encounter with others.²⁶ Amazement that stems from the encounter with difference is, in this regard, a trigger point.

The two examples above demonstrate that it is not a straightforward matter for the clinician to use amazement as a tool to gain cultural understanding of the clinical situation.²⁷ Emotions can be as deceptive as statistics. That the clinician registers their own amazement does not mean the interpretation is accurate.

Conclusions

Multicultural societies with increasingly complex health problems make the practice of culturally informed psychiatry urgent. This article has demonstrated that the encounter between the patient and the clinician is a crucial, yet underappreciated, position from which the clinician might develop a cultural understanding. The cultural dimension of the clinician–patient relationship must be explored in actual situations through the clinician’s self-reflexive focus on amazement and questions such as, ‘How do I respond to situations where I become amazed?’, ‘Is it possible for me to develop understanding rather than withdrawal?’

The clinician is always formed by social and cultural contexts and is never culturally neutral. Moreover, the clinician has a clinical responsibility to make explicit his or her own assumptions, premises and categories in relation to patients to prevent misunderstandings and misdiagnoses. Culturally informed psychiatry cannot be defined once and for all; it is not a quick-fix technique or manual. It is rather the continuous development of a professional attitude, perceiving all human beings, including the clinician, as cultural bearers and cultural learners.²⁸ The clinician should take seriously their own amazement as a point of entry to this attitude. However, to develop amazement as a clinician to strengthen culturally informed psychiatry does not lead to an easy resolution of a client’s problem. A whole new series of questions arises, and we need culturally reflexive psychiatrists to deal with these questions.

1.8.53 ‘Spirituality’ and ‘cultural adaptation’ in a Latino mutual aid group for substance misuse and mental health

Abstract

A previously unknown Spanish-language mutual aid resource for substance use and mental health concerns is available in Latino communities across the USA and much of Latin America. This kind of '4th and 5th step' group is a 'culturally adapted' version of the 12-step programme and provides empirical grounds on which to re-theorise the importance of spirituality and culture in mutual aid recovery groups. This article presents ethnographic data on this organisation.

Group Higher Power (a pseudonym, to protect confidentiality) is a mutual aid group in Northern California for Latinos with substance use problems and other mental health concerns. (By 'Latinos' we are referring to a very diverse population of persons from Latin America or their descendants. We do not mean in any way to present Latinos as a homogenous group.) It is a '4th and 5th step' group (grupo de Cuarto y Quinto Paso, henceforth 'CQ'), a variation of the 12-step recovery programme that was founded in Mexico in 1991.¹ New members join Group Higher Power by completing seven preparation meetings followed by a 2-day *experiencia espiritual* (spiritual experience) in a secluded mountain forest preserve a couple hours from where the group holds its nightly meetings. During the experience, the new members complete the 4th and 5th steps of the 12-step programme: step 4, 'We made a searching and fearless moral inventory of ourselves'; step 5, 'We admitted to God, to ourselves, and to another human being the exact nature of our wrongs'.² Afterwards, they are encouraged to attend the nightly meetings, which usually open with the meeting coordinator reading the bye laws of the group, including: 'Here is a 4th and 5th step group. We are a group of men and women that maintains itself by our own contributions'. In a traditional Alcoholics Anonymous (AA) group, the coordinator would next say: 'The only requirement for being here is that you wish to stop drinking'. But at Group Higher Power, the coordinator says: 'The only requirement for being here is that you wish to transcend the pain in your life, and to stop suffering'.

Unlike in AA, CQ members may identify as an *alcohólico* (alcoholic), a *drogadicto* (drug addict), an *enfermo emocional* (emotionally ill, used interchangeably with *neurótico* (neurotic)) or any combination of these. 'To be an *enfermo emocional*' is an idiom of distress³ that signifies a 'spiritual' ailment thought to be at the root of addiction, depression and other 'neuroses'. The idiom also indicates a correct form of treatment which members learn to engage in and provide to others in the spiritual experience – a dramatic, cathartic style of testimony.

This form of 'spiritual healing' can be found in CQ groups like Higher Power located throughout Mexico, the USA, Central America and in some parts of South America and Europe. Because there is no central organisation that unites all CQ groups, it is impossible to know exactly how many there are (see directory of US groups affiliated with the Amor y Servicio branch of CQ: www.amoryserviciosusa.org/directorio). That said, our preliminary ethnographic findings suggest that CQ is growing rapidly in Mexico and the USA, making it a community-based mental health resource for potentially thousands of Latinos across North America.

The apparently rapid growth of CQ is important from a public health perspective and interesting for theorising what makes psychotherapy 'culturally adapted'. Mutual aid groups for addiction are known to be cost-effective interventions.⁴

Latinos in the USA have a disproportionate burden of substance use,^{5,6} and yet they are underserved in the areas of substance use and mental health treatment.^{7,8} There is therefore a pronounced need for accessible, community-based and culturally adapted care for Latinos in the USA.^{9,10} Alcoholics Anonymous may meet this need for some, but whereas Latinos in the USA are thought to recommend AA equally as often as other ethnicities,¹¹ Project MATCH¹² suggests that AA has trouble attracting and retaining Latinos in the USA. Interestingly, Project MATCH also found that, relative to White Americans, Latinos who do attend AA display higher levels of involvement, including ‘God consciousness’,¹³ after out-patient alcohol treatment and several authors have suggested that the incorporation of spiritual and religious elements into culturally appropriate substance use treatment for Latinos merits further examination.^{7,12–14} However, the majority of Latinos in the Project MATCH study sample were south-western Hispanos and it is likely that their responses are not representative of other Latino groups in the USA, such as Puerto Ricans, Mexican–Americans and Mexicans.

Highly spiritual and religious behaviour can already be found in Spanish-speaking AA groups in the USA¹⁵ and especially in Mexico,² where AA has become over the past several decades the most prevalent source of substance use treatment in the country.^{16,17} But even members of these groups sometimes criticise CQ as being overly religious and refer to CQ derogatorily as a ‘religious sect’. So, if CQ is as popular among USA-based Latinos as our qualitative data suggest, we propose this may be due to how CQ incorporates a culturally appropriate form of spirituality into their recovery programme. In this article, we present ethnographic data on the therapeutic practices of Group Higher Power, which largely resemble those of other CQ groups we have observed in the USA and Mexico. In doing so we attempt to offer a qualitative understanding of ‘spirituality’ in CQ and more specifically, how the ‘spiritual experience’ is configured as a treatment for being *enfermo emocional*. Through this we enquire into how this form of mutual aid spirituality may mediate a successful cultural adaptation of the 12-step programme for underserved Latinos in the USA.

Data collection and study aims

The ethnographic data presented here come from an ongoing anthropological study of drug addiction, violence and treatment modalities for substance-using Latinos in Mexico and the USA. CQ has been a central focus of our ethnographic fieldwork since January 2013. We have observed and documented the therapeutic practices and living conditions of members of ten CQ groups (4 in Mexico) as well as several other 12-step groups that are specifically for Latinos.^{15,16} We have also conducted dozens of formal and informal interviews with 12-step group members, their family members and health professionals in both countries. Many of the 12-step members had participated in more than one kind of 12-step group over their lifetime (e.g. CQ and AA) and so we were able to gather information on CQ from interviewees who were not currently active CQ members. We have observed one spiritual experience hosted by Group Higher Power. In accordance with exploratory qualitative research methods,¹⁸ research sites and participants were selected by convenience, as dictated by the opportunities and challenges inherent in maintaining relationships with a dynamic and mobile population over several months. Iterative interpretive analysis of research materials (field notes, interview transcripts, photographs and videos) was conducted to better understand the emic categories of illness, health and healing. This study has been approved by the Institutional Review Board of Stanford University. A draft of this article in Spanish was presented to Group Higher Power, and it is being published with the group’s blessing.

Group Higher Power – characteristics

On its surface, Group Higher Power looks like other Spanish-language 12-step groups in the USA.^{15,19,20} Nightly meetings are held from 19.00 to 21.00 in a suburban storefront in a predominantly Latino neighbourhood. The membership consists of men and women ranging in age from their 20s to their 60s. They mostly hail from Mexico, but some are from Central America and many were born in the USA. Several members are undocumented immigrants. Many speak English, but meetings and informal conversations are conducted in Spanish.

The setting

The main room of the group has large posters with the 12 steps and 12 traditions of AA, which are in Spanish and hang on the far wall above the desk of the meeting *coordinador* (coordinator) and the podium where members stand and share their testimonials. Between the posters of the 12 steps and the 12 traditions hang framed portraits of Bill W and Dr Bob, the co-founders of AA. The other three walls of the room are adorned with one or two images of Jesus Christ and many more colourful framed certificates and plaques that Group Higher Power has received for giving *compartimientos* ('sharings' or testimonies) at the anniversary celebrations of other CQ groups in California, Nevada and Utah. By the dates on the certificates, most groups in this part of the country have only been in existence for 3 to 4 years; a few have been around for up to a decade.

There is a small room in the back where *ahijados* and *ahijadas* ('sponsees') can receive *apadrinamiento* (counsel) from their *padrinos* and *madrinas* (sponsors, also known as godfathers and godmothers) in private. And like in so many other Latino 12-step groups, on the wall near the main entrance hangs a black-and-white print of a man, shirtless, dishevelled and shackled, with the words *Reconozco mi derrota ante el alcohol* (I recognise my ruin from alcohol) (Fig. 1).

Group members

Unlike in Latino AA groups, members of Group Higher Power are explicitly seeking help for more than just their alcoholism; they say they want to cure their 'emotions'. To be an *enfermo emocional* is to have suffered traumatic and painful events in one's past, often as a child, and then to go through life with the memories of these events smouldering in the unconscious, causing the person to repeatedly hurt others and themselves. This pain is what CQ members say they used to try to avoid when they drank alcohol and used other drugs. The same pain led other members not to use substances, but instead to be 'neurotic' or unhappy and self-destructive. Like the 'dry drunk' in AA, the *enfermo emocional* displays the same harmful behaviours of an alcoholic who is abstinent but not in recovery, namely lying, being violent and generally suffering from 'ego'. The prescribed treatment is lifelong dedication to CQ's spiritual path, which starts with completing a spiritual experience.

This is why in the back of the Group Higher Power main meeting room there is another, medium-sized room where the seven preparation meetings are held for newcomers, called *escribientes* ('writers'), who will soon undergo their first *escritura* ('writing', meaning spiritual experience). There is no podium in this room, but there is a wooden desk behind which a coordinator sits, with two other members to his right and left, usually a man and a woman. Some days up to a dozen *escribientes* at a time are being prepared in this room, sitting in their brown, metal folding chairs facing the desk, above which also hang portraits of Bill W and Dr Bob. A couple of *escribientes* typically trickle in late, apologising for not being able to get off of work in time at the factory or cleaning houses. The usual attire is jeans, old tracksuit bottoms, well-worn tennis shoes, but there is also the occasional nice fleece or stylish watch. After everyone is offered coffee or water, the first prayer of the night, the Serenity Prayer, is recited and then the meeting begins.

The meeting

The members share their testimonies with the *escribientes*, weaving in the benefits they have received from being in the group, like gaining insight into their emotional problems. One man shared: 'When I came to the group, I had just smoked \$100 of crystal meth. I wanted to die ... It wasn't until the experience when I realised things were wrong; I had erased those memories. In the experience, I remembered these dark things. I remembered my dad dying, and when I was molested as a child.'

Testimonies also often include mention of a transformation or rebirth in the experience that has helped the person stay sober. It is common for CQ members to admit that they were actually drunk or high when they went for their first experience, but then after that day they no longer needed to drink, smoke or use.

Over the seven preparation meetings, the *escribientes* are gradually introduced to the cathartic style of testimony that is at the very core of CQ's 'emotional' therapy. When 'sharing' their testimony, members frequently cry, swear and shout, even to the point of sometimes becoming totally distraught. The *escribientes* do not practise giving testimony in the preparation meetings; they do not even speak for the duration of the 2-hour meetings. Instead, they are instructed to sit

and reflect on what is being shared with them. Once, after a meeting, an *escribiente* asked the meeting coordinator: ‘Do they always use so many bad words?’ She continued: ‘Because I was thinking about bringing my daughter here, but now I don’t know; I don’t want her to hear those things’. The coordinator smiled from behind the desk and counselled her with a phrase that is often said at the beginning of the preparatory meetings: ‘If you hear strong language, don’t focus on the words, focus on the feelings’. This is the heart of what the *escribientes* are being trained to do – to engage in a reflective, contemplative practice in which they identify with the testimonies of the group members to learn to identify these same emotions in themselves and then release them during the spiritual experience.

The spiritual experience

At Group Higher Power’s spiritual experience each *escribiente* underwent their 4th step by writing a ‘moral inventory’ for about 24-hours straight, with no sleep, little food and lots of coffee. They were instructed to be ‘100% honest’ while answering questions about their lives; these questions are standard across CQ groups and come from the 12-step literature. The 4th step culminated in a celebratory moment in which the *escribientes* and the members held hands in a circle formed around a large wooden cross, crying, reciting prayers and singing Christian hymns in Spanish backed up by a CD playing over a pickup truck’s stereo. The *escribientes* were encouraged to have visions of God while they looked up into the starry night sky.

A *padrino* in Mexico City with significant experience in CQ said that the point of the experience is to get the *escribiente* to go through a *colapso a fondo del ego* (‘when the ego hits bottom’) because that is when ‘your spirituality starts to flow’. Group Higher Power members joke that they ‘enter the fourth dimension’ during the experience, meaning that they go into a trance-like state. It is this state that lets them do the emotional healing that they say they cannot achieve with a psychologist, a doctor, not even a traditional AA group. Many cite the spiritual experience as their reason for why they stay in CQ, and why CQ has helped them make behavioural changes that they could not achieve otherwise.

After the experience, the members will attend nightly meetings and continue to rehearse and refine the dramatic testimonial style they learned in the experience. They will stand at the podium, look out of the corners of their eyes, and try to re-enter their painful or shameful memories, recounting them for the group, complete with details of the sights, sounds and smells of what it was like to be there. The meetings are brought to a close with the lights off and everyone standing in a *cadena de amor y servicio* (chain of love and service), holding hands in a large circle. As Christian worship songs are softly played in the background, members are instructed figuratively to leave in the room what they heard and felt that night by whispering it to God. They recite the Serenity Prayer, the AA Responsibility Declaration and the Our Father, and then the meeting is over.

Discussion

What exactly is it about CQ spirituality that makes this mutual aid organisation especially culturally adapted for Latinos? One observation that seems clear is that the kinds of dramatic public testimony, group prayer and healing and rebirth practices in CQ resemble those of the Pentecostal and Charismatic Catholic movements, which are currently quite popular in Mexico.^{21,22} While true, this does not explain with any real specificity why this would make CQ spirituality congruent with Latinos’ cultural frames and therefore a popular choice for those seeking psychological help.

Based on their meta-analysis of psychotherapy studies, Benish *et al*²³ propose that the key factor for enhancing the cultural adaptability of psychotherapy is the incorporation of an ethnic minority’s ‘illness myth’. This suggests that we should consider more closely the CQ idiom of distress, *enfermo emocional*, as a key to what makes CQ culturally adapted for Latinos. CQ emic understandings of being an *enfermo emocional* are sculpted out of a psychodynamic language of neurosis, the unconscious and childhood trauma. The fact that this aetiological discourse is flourishing within a spiritual healing movement might at first seem paradoxical, yet it arguably makes good sense given psychoanalysis’ historical ties with religion in Mexico. One of Mexico’s better known early champions of Freudian thought, the Catholic monk Gregorio Lemerrier, actually attempted in the 1960s to use psychoanalysis to revitalise monastic life,²⁴ whose traditions of intensive contemplative practices and spiritual retreats have strong parallels with much of what we see in CQ’s modifications and interpretations of the 12-step programme.

The highly 'spiritual' nature of being *enfermo emocional* has further implications for CQ's acceptance by Latinos that become even clearer when we consider how 12-step programmes are often criticised for disempowering their members by encouraging them to submit to a higher power and to identify as sick addicts who will forever be in recovery. In CQ, the *enfermo emocional* takes this a step further and is not only eternally in recovery, but they are also intermittently 'mad'. CQ members sometimes describe their spiritual experience as a form of *locura* (madness); and Mexican AA members and clinicians alike not only allege that CQ's cathartic practices are crude and ineffective, but some have even warned the public against participating in the CQ spiritual experience because of case reports of individuals who have developed psychosis or died by suicide shortly after their experience.

Nevertheless, perhaps it is by making its recovery programme even more 'spiritual' than AA that CQ is able to invert these concerns of clinical ineffectiveness and harm, turning the submission to a higher power into a much more positive experience. In Asad's critique of the secular notions of agency and pain,²⁵ he delineates how the modern narrative of agency makes clear that agency must be used to avoid suffering (p. 71). Moreover, one who gives into religious 'emotions' (glossed 'passions') is said to lack the prized agency of a rational subject. To counter these assumptions, Asad pushes us to consider a notion of sanity which, instead of turning on the ideal of self-control, 'presupposes knowing the world practically and being known practically by it' (p. 73). He asserts that this 'allows us to think of moral agency in terms of people's habitual engagement with the world in which they live, so that one kind of moral insanity occurs precisely when the pain they know in this world is suddenly no longer an object of practical knowledge' (p. 73). According to this alternative understanding of agency, sanity and pain, CQ members could submit to a higher power, enter a state of *locura* in the spiritual experience and dive into the passions of their 'sick emotions', and actually thereby maintain, or even regain, their *sano juicio* ('sanity'), as the 2nd step says can happen ('[We] Came to believe that a Power greater than ourselves could restore us to sanity'²). But for this to be a healthy process requires CQ groups to provide a practical purpose for members to relive their suffering night after night through the testimonies. And hence the prayer circle that ends every nightly meeting and spiritual experience, the *cadena de amor y servicio* (chain of love and service), points up the symbolic importance of service in CQ's practice of spiritual healing. Service, including sharing one's testimony and counselling one's sponsee, is the suture that stitches together CQ sociality and repairs the psychic wounds of the *enfermo emocional*. Given how important sponsorship is in AA in Mexico relative to the USA,²⁶ we propose that CQ capitalises on this Mexican proclivity for service to create a mutual aid environment where sectarian notions of agency and suffering can be more fully embodied, thereby allowing CQ members to more adequately respond to the spiritual 'illness myth' of the *enfermo emocional*.

Finally, we must stress that reports on the rapid uptake of CQ throughout North America are to this point based on qualitative data alone and they require triangulation with quantitative measures (our research team is currently preparing a survey of CQ groups in Northern California). Moreover, other elements beyond spirituality need to be considered to understand why CQ might be a highly 'culturally adapted' form of AA for Latinos. The role of family involvement in CQ should not be underestimated, especially since membership is not restricted to 'alcoholics', but can also include 'drug addicts' and 'neurotics' who do not use substances. Also, larger issues of political economy, state insecurity and violence should not be overshadowed by a narrow interest in 'cultural adaptability' when trying to understand why a grassroots treatment modality such as CQ is reported to be growing rapidly in underserved, displaced and marginalised communities. In the neighbourhoods where CQ seems to be growing the quickest, families must deal with poverty, a lack of access to healthcare and the general social fragmentation that Mexico's drug war-related violence has wrought on the country for the past decade. Detailed consideration of these factors is, however, beyond the scope of this article.

We thank all the *compañeros* and *compañeras* who participated in this research. We also thank Dr Guilherme Borges and Dr Martha Romero of the Instituto Nacional de Psiquiatría Ramón de la Fuente Muñiz for their generous consultation and Mónica Martínez, Michael Nedelman and Keith Humphries for their collaboration.

1.8.54 Dementia in a Black and minority ethnic population: characteristics of presentation to an inner London memory service

Rosalyn Tuerk Justin Sauer

Correspondence

Rosalyn Tuerk (rosalyn.tuerk@slam.nhs.uk)¹

date

2015-8

Abstract

Aims and method To examine data on referrals to an inner-city London memory service to explore any differences in referral rates, cognitive assessments and stages of dementia at presentation between ethnic groups.

Results African–Caribbean patients were well represented in the memory service. They were diagnosed with dementia on average 4.5 years younger than their White British counterparts and were more likely to be diagnosed with a vascular or mixed type dementia. However, scores on initial cognitive testing were significantly lower in the African–Caribbean group, possibly representing more advanced disease at presentation.

Clinical implications Initiatives to access Black and minority ethnic populations earlier in the course of their illness should be considered. Professionals need to consider the potential for cultural bias in memory testing and diagnosing dementia in these populations, and the importance of cultural competency in assessments.

The number and proportion of Black and minority ethnic (BME) people with dementia is set to increase sharply over the coming years.¹ As the ‘most ethnically diverse area’ across England and Wales,² memory assessment services in London must be able to meet this challenge and address the needs of people from BME backgrounds. Established in 2010, the Southwark and Lambeth Memory Service (SLMS) provides memory assessment services in two inner London

boroughs, to people over the age of 18 with mild to moderate memory problems and without an existing diagnosis of dementia. Patients are offered a comprehensive assessment, with initial cognitive testing using the Standardised Mini-Mental State Examination (SMMSE) and Addenbrooke's Cognitive Examination III (ACE-III). Patients are also offered brain neuroimaging and, where indicated, additional neuropsychological testing. Diagnoses are considered within a multidisciplinary team and appropriate treatment and follow-up are agreed with patients and carers.

The National Dementia Strategy³ prioritises early diagnosis and intervention in people with dementia. Current research, however, suggests that people from BME backgrounds present to memory assessment services later in the course of their disease.⁴ This prevents them from benefiting from intervention and treatment as early as their White British counterparts.⁵ This study examines the stage at which the BME population presents to SLMS and their rates of dementia diagnosis, and considers subsequent areas for service development to better meet the needs of different ethnic groups.

Method

The study received approval from the shared research and development office of the Institute of Psychiatry and Maudsley Hospital. The analysis used anonymised data from a referrals database, maintained for the purposes of service monitoring, and includes patients referred during the first 2 years of the SLMS's operation. Information on patients' ethnicity, age at the time of referral, scores on initial cognitive testing and the diagnosis given by the service was collated. Data are drawn from the SLMS's use of earlier versions of the cognitive tests cited above (the Mini-Mental State Examination (MMSE)⁶ and Addenbrooke's Cognitive Examination Revised (ACE-R)⁷). In cases where patients' diagnostic classification changed during the course of their involvement with the service (e.g. from mild cognitive impairment to dementia), the initial diagnosis is used. To avoid bias, people unable to fully complete the two cognitive tests were excluded from the analysis.

We used the harmonised ethnic group categorisations from the 2001 UK census⁸ to allow for comparisons between the SLMS sample and data on the ethnic composition of the local population. For the purpose of data analysis, patients were divided into two groups: White British (WB) and Black and minority ethnic (BME). Definitions of BME are wide-reaching and may include anyone with a 'cultural heritage which is differentiated from that of the White majority of the UK'.⁹ Owing to the very small number of patients from some ethnic groups in the SLMS sample, only patients from Caribbean and African backgrounds were included in the BME group. Comment is made in the discussion section on the relevance of the findings to people from other BME backgrounds.

Differences in the stage of presentation to the memory service were analysed by comparing patients' ages at the time of referral and MMSE and ACE-R scores on initial cognitive assessment. The prevalence of dementia diagnoses within each of the two groups was compared using Pearson's chi-squared test. Scores on cognitive testing for patients receiving a diagnosis of dementia were also compared. Unless otherwise stated, all means were compared using Student's *t*-test, having first satisfied the criteria for Levene's test of equality of variances; $P=0.05$ were deemed to be significant.

Results

Overall, 460 patients referred between January 2011 and December 2012 completed the assessment process and received a diagnosis from the service. Of these, 384 were from White British, Black Caribbean and Black African ethnic groups (WB: $n = 239$, 68.7%; BME: $n = 109$, 31.3%). Then, 290 patients completed cognitive testing in full; proportions of patients from each group able and/or willing to complete full cognitive testing were similar (WB: $n = 199$, 83.3%; BME: $n = 91$, 83.5%).

The majority of SLMS patients were over 60 years of age. *Table 1* compares the most common ethnic groups within the SLMS sample and the local population of people over the statutory retirement age. These are notably different in distribution, with the SLMS sample comprising a smaller percentage of White British patients and larger proportions of the other featured ethnic groups.

Comparison of most common ethnic groups in the SLMS sample and local population

Ethnicity	Patients in SLMS sample (<i>n</i>)	Percentage of total SLMS sample ^a	Local population over 60 years of age (<i>n</i>) ¹⁰	Percentage of local population ^a
White: British	239	52.0%	36 100	63.4%
Black or Black British: Caribbean	86	18.7%	6300	11.1%
White: any other white background	47	10.2%	3500	6.2%
White: Irish	38	8.3%	3800	6.7%
Black or Black British: African	23	5.0%	2400	4.2%
Asian or Asian British: Indian	12	2.6%	1300	2.3%
All other BME groups	15	3.3%	3500	6.2%

SLMS, Southwark and Lambeth Memory Service.

Percentages may not add up to 100 owing to rounding.

At referral to the service, BME patients (mean age 77.19 years, $s = 7.094$) were significantly younger than WB patients (mean age 80.23 years, $s = 8.777$; $t(212.729) = 3.132$, $P = 0.002$). In this case, Levene's test could not conclude equality of variances ($P = 0.026$), therefore a t -test appropriate to samples with potential unequal variances was used. The age gap increases in patients subsequently diagnosed with dementia (mean age: BME patients 78.69 years, $s = 6.208$, WB patients 83.25 years, $s = 6.599$; $t_{(187)} = 4.685$, $P < 0.001$).

Patients in the BME group scored significantly lower on both the ACE-R and the MMSE: ACE-R total possible score 100; mean score: WB patients 66.2, $s = 16.652$, BME patients 54.5, $s = 14.482$; $t_{(288)} = 5.768$, $P < 0.001$, MMSE total possible score 30; mean score: WB patients 23.4, $s = 4.917$, BME patients 21.7, $s = 4.573$, $t_{(288)} = 2.759$, $P = 0.006$.

In patients subsequently diagnosed with dementia, there was a significant difference in scores on the ACE-R (WB mean score 57.4, $s = 13.464$; BME mean score 48.7, $s = 11.226$; $t_{(187)} = 4.431$, $P < 0.001$). BME patients with a new diagnosis of dementia also scored lower on the MMSE, but this difference was not found to be significant (WB mean score 21.0, $s = 4.613$; BME mean score 20.1, $s = 4.166$, $t_{(187)} = 1.294$, $P = 0.197$).

Three-quarters of the BME group (75.2%, $n = 82$) were diagnosed with dementia, compared with 65.7% of the WB group ($n = 157$). There was no significant relationship between ethnic group and the likelihood of receiving a diagnosis of dementia ($\chi^2_{(1, N = 348)} = 2.739$, $P = 0.098$). When dementia subtypes were considered, significantly more patients from the BME group were diagnosed with a dementia with a vascular component (either vascular dementia or mixed Alzheimer's disease and vascular dementia) ($\chi^2_{(1, N = 348)} = 4.531$, $P = 0.033$).

Discussion

Ethnic identity is multifaceted, subjective, can change over time¹¹ and may be based on collective identity, common ancestry, heritage, religion, culture, nationality, language and territory.⁸ Individual beliefs may be influenced by culture, and thus culture can shape the meaning which individuals ascribe to dementia.¹² Beliefs about dementia, such as it being part of normal ageing,¹³ may create barriers to help-seeking and influence when individuals present to memory services.¹⁴ Current research suggests that BME older people access services at a more severe stage of cognitive impairment than White British people,¹⁵ which may account for their lower cognitive scores in this study. In BME populations, the decision to seek formal help tends to be precipitated by a health or behavioural crisis¹³ or the emergence of neuropsychiatric symptoms and problems with basic activities of daily living.⁴ It may also be influenced by varying knowledge of Alzheimer's disease and dementia across ethnic groups (although all groups hold significant misperceptions).⁵ All ethnic groups attach stigma to dementia, although the extent and nature of this varies;^{5,16} family concerns about previous negative experiences of psychiatric services may, however, be particularly significant to BME groups.⁴

Cultural bias in cognitive testing may also explain the difference in scores. African–Caribbean patients have consistently been found to score lower than White British patients on the MMSE^{17–19} and the standard cut-off of 24 may have a high rate of false positive screening for dementia in BME groups.^{20,21} Adjusting for factors such as educational attainment did not always explain these differences;^{17,22} scores may also have been affected by unfamiliarity with the language and culture of the test setting, and higher levels of anxiety during testing.²³ The idea of cultural bias is particularly supported by one study which found that White British participants scored equally well on both the traditional version of the MMSE and a version validated for use with older African–Caribbean people,²⁴ while African–Caribbean participants scored significantly better on the culturally modified version.¹⁹

The ACE-R differs from the MMSE in its greater sensitivity to detect early dementia.²⁵ Modifying and validating it for other cultural contexts has required more than straightforward translation, including adaptations to cater for study participants with lower levels of education,²⁶ cut-off scores stratified by educational background²⁷ and modified cut-offs to account for variations in structure and difficulty between languages.²⁸ This demonstrates the difficulty of administering the test to a sample as culturally diverse as that found at the SLMS. Studies validating the ACE-R's diagnostic accuracy fail to mention ethnic diversity within their samples^{7,25,29,30} and tested a clinic-based population with a notably younger mean age than the SLMS sample, therefore their findings may not be transferable. A study carried out in another area of the UK required lower cut-offs to preserve diagnostic accuracy,³¹ although again the ethnic breakdown of participants is unknown.

Most studies carried out in the UK to date have also found a higher prevalence of dementia among African–Caribbean older people,^{17,19,32} although one found differences only between English and non-English-speaking members of BME groups.³³ The current study found no overall difference in dementia diagnosis rates, but revealed an increased prevalence of dementia with a vascular component in the African–Caribbean group. Although most of the studies cited did not explore dementia subtypes, one linked an increased incidence of conditions such as hypertension and diabetes to a higher prevalence of vascular dementia in their African–Caribbean sample.¹⁷ Another found an equal prevalence of hypertension in the African–Caribbean and British-born groups, but that awareness of it was reduced among African–Caribbean people, who were significantly more likely to have dementia if hypertension was not correctly treated.³⁴ Health education about risk factors for vascular dementia could therefore potentially benefit BME groups, especially given the earlier age of presentation to the SLMS.

Patients access the SLMS through their general practitioner (GP), therefore GPs influence the stage at which patients access specialist help. A suspicion of emerging dementia is often followed by 'watchful waiting' in primary care rather than immediate referral to a specialist.³⁵ People from BME backgrounds access primary care at a similar rate to White British people,^{4,36} however, there appears to be little research into factors which may influence this wait for specialist referral. Difficulties in cognitive screening in primary care may be further compounded when assessing older BME people, where culture and the language used to describe problems may influence presentation.²²

International evidence

This is a UK-based study at a local level, however, its findings are consistent with research carried out abroad. A survey of clinical dementia centres across Europe found varying levels of access by BME patients and that where these patients did access services, diagnostic evaluation was more challenging owing to language barriers and the availability only of cognitive assessment tools validated in Western cultures.³⁷ Older Chinese and Vietnamese patients in Australia were believed to present to memory services at a more advanced stage of cognitive impairment³⁸ and linguistic and cultural complexities may have contributed to longer waits for diagnosis in primary care.³⁹ BME populations were diagnosed with dementia at an earlier age in one Danish study,⁴⁰ and similar barriers to help-seeking for carers of BME patients with dementia were evident in research from both Australia^{38,39} and the USA.⁵ Given the international recognition of the growing need for culturally sensitive memory services (including throughout Europe,^{37,40} the USA¹² and Australia^{38,39}), the findings of this study are likely to be relevant to those working in such settings.

Limitations

This study is limited in its use of data collected in the course of routine clinical practice. Assessments were carried out by a variety of clinicians and although all were trained in the cognitive tools used, the question of interrater reliability remains. Standardised data on the educational background of participants are also unavailable. In addition, only patients who consented to and completed the assessment and diagnosis process were included in this study. There is no data on the ethnicity of the patients who refused assessment or who were unable to complete the process for other reasons, thus we cannot speculate on whether ethnicity may influence this. Some ethnic groups, such as South Asian people, were not represented in our analysis. The issues influencing presentation to memory services may be similar for these groups; for example, a study on Gujarati populations also found lower MMSE scores and a lower median age in the Gujarati group of a community screening programme.⁴¹ The small numbers of patients from other BME populations indicates the need for further research into the extent to which they are accessing the SLMS, and limits the ability of this study to draw wider conclusions about the experiences of BME people.

Clinical implications

Compared with local population figures, the SLMS sample includes a higher proportional representation of African–Caribbean-born people than might be expected. While this finding may seem positive, our results show a more marked degree of cognitive impairment in the BME group, despite the younger age at presentation. This indicates a need to work with local stakeholders to ensure a lower threshold for referring African–Caribbean patients to the service, and to investigate ease of access for patients from other BME groups.

Culturally sensitive assessment is also required. This includes reflection on the way cognitive impairment is assessed in a population with varied cultural and educational backgrounds⁴² and an avoidance of stereotypical beliefs.⁴³ Culturally sensitive cognitive tools should be used where they exist, and cognitive testing should not be the only means of determining diagnoses.²⁹ The SLMS should continue the approach of considering cognitive test scores in the context of patient and carer accounts, brain neuroimaging, screening for affective disorders and additional neuropsychological testing to ensure accurate diagnosis. GPs also need to be aware of potential differences in age at onset of dementia and vascular risk differentials, to ensure effective cardiovascular preventative measures and arrange appropriate and early onward referral to secondary care.

Further analysis of similar data from a range of local memory services would be useful in detecting whether the trends evident in this study are reflected in the local population and other BME groups. It would be useful to include non-mental health services diagnosing dementia (e.g. geriatricians' clinics and neurology) in this analysis. The analysis into severity of impairment at presentation could be expanded by combining cognitive scores with other rating scales assessing neuropsychiatric symptoms and activities of daily living. Differences in other aspects of service provision and quality of life, such as assessment refusal rates, treatment with cognitive enhancer medications and the role of support networks in encouraging or discouraging help-seeking could also be explored.

Caution must be applied to the interpretation of these results. Although the term BME may imply homogeneity, it encompasses a wide variety of unique individual and collective experiences⁹ and the diversity both within and between ethnic groups must not be overlooked. Ethnicity may play an important role in influencing presentation to memory services, but this is only one part of the picture, and consideration for individual difference must always remain paramount.

We thank Martin Scott for his assistance with statistical analysis.

1.8.55 Culturally adapted mental healthcare: evidence, problems and recommendations

Sokratis Dinos

Correspondence

Dr Sokratis Dinos

(sokratisdinos@bpp.com)¹

date

2015-8

Abstract

Evidence suggests disparities in the prevalence of mental health problems and access to mental healthcare for a number of minority groups. The main response from mental health services falls into two related categories: (a) cultural adaptations of existing evidence-based interventions (EBIs) and/or (b) cultural competence of mental health professionals. This editorial looks at the evidence on culturally adapted EBIs and argues that although such interventions can be effective, they also carry the risk of alienating members of the groups they are aimed at. Recommendations focus on identifying issues that pertain to being from a racial minority and/or possessing other stigmatised identities that can have an impact on mental health problems, which may be overlooked by mental health services by assuming an overarching predominant cultural identity.

Contents

 - *Cultural adaptations: do they work?*
 - *Culture v. subculture: does one size fit all?*
 - *Where next?*

Evidence suggests that disparities exist in the prevalence of mental health problems and access to mental healthcare for a number of high-risk groups.¹ Many of these groups share similar characteristics in terms of minority status (e.g. Black and minority ethnic (BME) groups) or belong in subgroups that exist within a larger racial/ethnic population (e.g. lesbian, gay, bisexual and transgender (LGBT) people, older people, refugees, asylum seekers). Findings from earlier and more recent reviews suggest that mental health services are unattractive to these diverse cultural and subcultural

minority groups, who complain of stigmatisation, prejudice, unsuitable treatments and adverse experiences and as a consequence, seek care less frequently and drop out of contact more often than others.^{2,3} Anxiety about potential discrimination or inability of the services to understand the diversity of needs can cause reluctance to access healthcare, resulting in delayed treatment.

The main response from mental health services to deal with mental health problems in minority populations falls into two related categories: (a) cultural adaptations of existing evidence-based interventions (EBIs) to clients' cultures and backgrounds and/or (b) cultural competence of health professionals in terms of specialist knowledge relating to particular lifestyles and needs. It can be argued that cultural adaptations do not automatically translate into mental health professionals' cultural competence and similarly, cultural competence of health professionals does not translate to provision of suitable, culturally adapted EBIs. Although culturally adapted EBIs seem to be the right way forward, they can also be conceptually simplistic and narrow. On the other hand, cultural competence can solve many of the conceptual problems that cultural adaptations may pose but any subsequent interventions need to be evidence based.

Cultural adaptations: do they work?

Culture is a complex concept encompassing a number of elements, including shared knowledge, language, behaviours, cognitive constructs (e.g. thoughts, schemas, beliefs, norms). Health practices such as those around food and exercise, health beliefs about aetiology, course and outcome of illness as well as health behaviours are also heavily influenced by culture.⁴ Cultural adaptations of mental health EBIs incorporate some or all of these elements with the aim of narrowing inequalities in care and reducing the higher prevalence of mental health problems in disadvantaged groups.

Meta-analyses of such interventions have produced mixed, inconclusive or positive results.⁵⁻⁸ In particular and when compared with traditional EBIs, control groups and/or other care, effect sizes have ranged from small to moderate (0.21-0.46). Interventions analysed have included individual therapy or group therapy or a mixture of both. Clinical characteristics included at-risk groups, clinical populations already diagnosed with a mental illness, and community members without a psychiatric diagnosis. There was no reference to whether services were in-patient or out-patient. Results from the meta-analyses did not differ by type of intervention, clinical characteristics, gender and ethnicity. One of the meta-analyses has also produced effect sizes for a number of different elements of culturally adapted EBIs.⁷ For example, cultural, ethnic and racial matching of individuals from BME groups with service providers was more effective than when clients were not matched with the provider or therapist ($d = 0.58$ v. $d = 0.31$). Furthermore, non-English and/or ethnic-specific services were more effective than non-ethnic-specific services ($d = 0.49$ v. $d = 0.21$).

Culture v. subculture: does one size fit all?

It can be argued that overall the evidence for culturally adapted EBIs is encouraging. However, cultural adaptations may also carry the risk of alienating members of those groups they are aimed at. One of the risks is that mental health professionals and researchers often make the assumption that individuals from specific subgroups possess certain cultural characteristics^{9,10} and fail to take into account that within a larger group there are a number of subgroups with different characteristics, which may be overlooked by attaching an overarching cultural identity to them. These subgroups may also be those with the highest risk of developing mental health problems. We can refer to them as subcultural groups which exist within a larger racial population and share similar life experiences and a mutual sense of belonging.

For subcultural groups racial identity may be secondary and the primary identity may be either more in tandem with the mainstream culture where they reside or related to a different group membership. Such group membership may be related to another stigmatised identity such as ethnic minority, LGBT groups, refugees, asylum seekers, older people. Therefore, some minority groups may find themselves in membership of multiple stigmatised identities in addition to ethnicity and mental illness (e.g. sexuality, single motherhood, asylum seeker, offending, poverty). In these situations mental health professionals would need to question whether an existing culturally adapted intervention would be beneficial. Therefore, subcultural differentiation is important when both adapting EBIs and delivering a culturally competent mental healthcare, as it provides specific information that goes beyond the ethnic identity and can capture other characteristics and/or needs that are not ethnic specific.

A further risk of cultural adaptations is the cultural contexts where the original interventions were developed. In particular, the majority of EBIs have been developed with participants from majority groups (e.g. Western, White) and then have been culturally adapted and applied to minority groups residing in the context where these were developed originally. Since many cultural adaptations are developed from existing EBIs, they very often overlook the factors related to being a minority, such as racism, stigma, poverty, internalised oppression, and mainly focus on culture and mental health. For example, coping with a stigmatised identity has been found to be a crucial factor in recovering from mental illness in a number of studies. In particular, in a systematic review of published descriptions and models of personal recovery, Leamy *et al*¹¹ found that recovery for ethnic minority groups involved racial discrimination, stigma of mental illness and stigma of ethnic minority identity. Therefore, recovery was not as narrowly defined as recovering from mental illness.

A good example of incorporating these issues can be found in a culturally adapted mindfulness-based stress reduction (MBSR) intervention developed by Dutton *et al*.¹² The intervention was adapted for African American women from low socioeconomic background who were in abusive relationships and experienced post-traumatic stress disorder. Interviews and focus groups revealed that the main concerns were related to problems posed by living on a low income, lack of space to practise MBSR exercises (e.g. breathing, yoga, meditation), exposure to trauma, and also the structure of the intervention (e.g. time frames and length of sessions) in relation to childcare demands. Therefore, the adaptation involved, among other elements, shorter sessions and availability of childcare as well as a special focus on dealing with the everyday stressors of low-income existence and coping with trauma. The specificity of race did not appear to be a theme that needed to be included in the development of the intervention. However, the stigma of mental illness and the stigma of using mental health services, which has been found to be prevalent among African American populations,¹³ was also evident in the interviews and led to adaptations that involved elements to cope with the stigma of mental illness.

Where next?

Overall, it can be argued that mental health services are going in the right direction in terms of culturally adapting EBIs to reach at-risk groups and narrow the gap of mental health inequalities. However, cultural adaptations can be beneficial if applied by health professionals who are culturally competent and have the ability to explore differing values and needs with their clients instead of assuming cultural characteristics that may be either non-existent or not predominant. Therefore, training of staff which focuses on removing prejudice and promotes cultural competence and specialist knowledge pertaining to particular lifestyles needs to go hand in hand with cultural adaptations of EBIs. Cultural competence will help mental health professionals to make an assessment focusing on each client's experience before applying cultural adaptations. Such assessments need to happen on a case by case basis and mental health professionals need to identify a number of issues before making a decision. Such issues pertain to: (a) exploring the predominant identity of the client (e.g. cultural or other), (b) identifying issues that may be related to being a racial minority (e.g. internalised racism and discrimination) and/or having a mental illness (e.g. mental illness stigma in a particular culture) and (c) exploring the client's membership in other groups that may be stigmatised or have an impact on mental health (e.g. LGBT, low socioeconomic status).

In relation to exploring a client's predominant identity, Rucker Sobczak & West¹⁴ suggest that the initial assessment needs to involve an understanding of whether the client subscribes to a collectivistic (e.g. seeing the self as part of a cultural group or others with collective goals) or individualistic (e.g. seeing the self as a separate entity to others with individual goals) self-identity as this can have significant outcome implications. Such assessment can also add clarity about whether there is a dominant identity and whether this is the cultural one. Similarly, assessment measures that deal with issues related to being in a minority group such as stigma and perceived racism may reveal what type of interventions may be more beneficial for, or applicable to, which individuals.¹⁰

Finally, it is important to stress that cultural adaptations and cultural competence have to operate along other initiatives that aim to reduce discrimination and tackle social exclusion, which have an impact on further socioeconomic disadvantage and place someone at increased risk of mental illness, and to promote outreach effort to recruit underserved clients from high-risk groups and actively target communities with higher concentration of socially excluded groups (e.g. BME communities). Needless to say, culturally adapted EBIs and cultural competence training as well as initiatives to reduce discrimination and social exclusion must be evidence based and be subject to evaluations on

what works and for whom. Currently, most of the evaluation data on culturally adapted EBIs come from US studies, so future interventions and subsequent evaluations need to happen in a UK context.

1.8.56 Trauma exposure and refugee status as predictors of mental health outcomes in treatment-seeking refugees

Abstract

Aims and method This study aimed to identify predictors of symptom severity for post-traumatic stress disorder (PTSD) and depression in asylum seekers and refugees referred to a specialised mental health centre. Trauma exposure (number and domain of event), refugee status and severity of PTSD and depression were assessed in 688 refugees.

Results Symptom severity of PTSD and depression was significantly associated with lack of refugee status and accumulation of traumatic events. Four domains of traumatic events (human rights abuse, lack of necessities, traumatic loss, and separation from others) were not uniquely associated with symptom severity. All factors taken together explained 11% of variance in PTSD and depression.

Clinical implications To account for multiple predictors of symptom severity including multiple traumatic events, treatment for traumatised refugees may need to be multimodal and enable the processing of multiple traumatic memories within a reasonable time-frame.

Refugees and asylum seekers have been shown to be at substantially higher risk of developing post-traumatic stress disorder (PTSD)¹ and comorbid mental health problems than the general population,² compatriots who have stayed in the refugees' home country,³ and economic migrants.⁴ Exposure to a high number of potentially traumatic events, involvement in asylum-seeking procedures and forced migration are stressors that set refugees apart from other populations and increase their psychological vulnerability. In Western psychiatric practice, insight in the determinants of PTSD and comorbid disorders in refugees may be helpful in guiding treatment interventions. Meta-analyses have shown that torture and cumulative traumatic events are the main predictors for development of PTSD in refugees.⁵ Additionally, researchers have begun to investigate whether different symptom profiles in refugees are related to different traumatic experiences. In a sample of Bosnian refugees, Momartin *et al*⁶ found that life threat and traumatic loss were related to PTSD and depression. In a sample of Mandeian refugees, Nickerson *et al*⁷ found that PTSD and prolonged grief disorder were predicted by traumatic loss, whereas PTSD only was predicted by difficulties related to loss of culture and support.

While these findings are highly relevant to treatment-seeking refugees, similar analyses have not yet been carried out in large, treatment-seeking refugee samples. In this study we examine whether symptom severity of PTSD and depression is predicted by refugee status as well as accumulation and specific domains of traumatic events in a sample of refugees seeking specialised mental healthcare.

Method

Participants

Participants were asylum seekers and refugees referred for treatment at Foundation Centrum '45, a specialised Dutch centre for diagnosis and treatment of complex psychological trauma. Refugees are individuals who have been granted temporary or permanent refugee status in The Netherlands whereas asylum seekers are those still awaiting a final decision. In 2001, Foundation Centrum '45 started to routinely monitor treatment outcomes by administering questionnaires to patients at intake and annually during treatment. For the present study, data collected at intake were used. Complete data with regard to refugee status, traumatic experiences and symptom severity of PTSD and depression were available for 688 asylum seekers and refugees. Characteristics for the total sample are presented in *Table 1*. Participants came from three main regions: 58% from the Middle East (e.g. Afghanistan, Iraq, Egypt, Libya), 17% from Sub-Saharan Africa (e.g. Burkina Faso, Eritrea, Congo) and 16% from Balkan Europe (Bosnia, former Yugoslavia, Croatia).

Demographic characteristics of the total sample and the main regions of origin

	Total sample (<i>n</i> = 688)	Middle East (<i>n</i> = 397)	Sub-Saharan Africa (<i>n</i> = 114)	Balkan Europe (<i>n</i> = 111)	Other regions (<i>n</i> = 66)
Male, <i>n</i> (%)	488 (71)	306 (77)	66 (58)	70 (63)	45 (68)
Age, mean (s.d.)	40.4 (10.4)	41.3 (9.9)	32.2 (8.5)	45.2 (9.1)	41.4 (11.2)
Permanent refugee status, <i>n</i> (%)	585 (85)	361 (91)	73 (64)	107 (96)	44 (67)

Measures

Traumatic experiences and PTSD symptom severity were assessed using the Harvard Trauma Questionnaire (HTQ).⁸ The HTQ consists of three parts, the first two of which were used in this study. In the first part participants were asked to indicate which of the 19 traumatic events they experienced, witnessed or heard of, and only self-experienced traumatic events were used in the study. For each participant a total number of different self-experienced traumatic events was calculated (range 0-19). In the second part of the HTQ the severity of DSM-IV PTSD symptoms was assessed by asking participants how much they were bothered by 16 PTSD symptoms during the past week, rated on a 4-point scale ranging from 1, not at all to 4, extremely. PTSD symptom severity was computed by averaging responses (range 1-4). The HTQ recommends a cut-off score of 2.5 to identify clinically significant PTSD. Internal consistency of the scale was high (Cronbach's 0.86).

Symptom severity for depression was assessed with the Hopkins Symptom Checklist (HSCL-25).⁹ Participants were asked to indicate how distressed they were by rating 10 symptoms of anxiety and 15 symptoms of depression during the past week on a 4-point scale ranging from 1, not at all to 4, extremely. Symptom severity of depression (range 1-4) was computed by averaging responses on the 15 depression items. The HSCL-25 recommends a cut-off score of 1.75 to indicate clinically significant depression. Internal consistency was high (Cronbach's 0.89).

The HTQ and HSCL-25 are self-report questionnaires that are widely used with refugees and are available in many different languages. Questionnaires were administered in the patient's native language if possible and interpreters were used when necessary. Both instruments have good psychometric properties.¹⁰

Statistical analyses

Statistical analyses were performed using SPSS version 20. To investigate whether specific domains of traumatic events could be identified, a principal component analysis with oblique rotation (direct oblmin) was conducted on the total set of self-experienced traumatic events. An initial analysis was run to obtain eigenvalues for each factor in the data and to evaluate the substantive contribution of each item to the extracted factors. Stevens¹¹ recommends interpreting factor loadings greater than 0.4 as substantive. The analysis was rerun without the items that did not contribute substantively to the extracted factors. For each participant a total score was computed on each of the extracted domains of traumatic events by counting the total number of self-experienced traumatic events within the domain.

Hierarchical regression analyses were used to test whether refugee status, total number of self-experienced traumatic events and the domains of traumatic events predicted symptom severity of PTSD and depression. These variables were independently added to the regression models, together with the gender and age covariates, as these have been found to predict PTSD in refugee samples.¹² Scores on the extracted domains of traumatic events were recoded into dummy variables before being added to the hierarchical regression models. To allow for multiple tests the alpha level of significance was set to 0.01.

Results

First, it was investigated whether specific domains of traumatic events could be identified by conducting a principal component analysis. In the initial analysis, four factors had eigenvalues greater than 1. Four traumatic events (combat situation, brainwashing, rape or sexual abuse, and being close to death) did not contribute substantively to any of the four extracted factors and the analysis was rerun without these items. Four factors were retained with eigenvalues greater than 1.0, which together accounted for 56.7% of the total variance. *Table 2* presents the factor loadings after rotation. The traumatic events that cluster on the same factor suggest that the first factor represents human rights abuses (31.1% of the total variation), the second factor traumatic loss (10.0% of the total variation), the third factor a lack of necessities (8.7% of the total variation), and the fourth factor separation from others (6.9% of the total variation).

Summary of principal component analysis for traumatic experiences^a

	Rotated factor loadings			
Threatened to be executed	0.78	0.13	0.13	0.09
Physical torture	0.77	0.10	0.03	0.12
Threatened to be physically tortured	0.77	0.03	0.10	0.08
Threatened to watch torturing	0.66	0.04	0.07	0.04
Serious injury	0.50	0.01	0.21	0.11
Lost or kidnapped	0.46	0.15	0.13	0.04
Imprisonment	0.46	0.04	0.16	0.28
Murder of family or friend	0.02	0.85	0.04	0.01
Unnatural death of family or friend	0.12	0.79	0.04	0.11
Murder of stranger or strangers	0.15	0.63	0.03	0.02
Lack of shelter	0.03	0.05	0.79	0.12
Lack of food or water	0.07	0.03	0.78	0.15
Ill health without access to medical care	0.13	0.03	0.68	0.07
Forced separation from family members	0.04	0.09	0.02	0.85
Forced isolation from others	0.14	0.03	0.06	0.75

Factor loadings over 0.40 appear in bold.

Mean symptom severity was 3.1 (s.d. 0.5) for PTSD and 2.9 (s.d. 0.6) for depression both within the clinical range. A clinical level of symptom severity for PTSD and depression was reported by, respectively, 84% and 95% of participants. Participants reported a mean of 11.2 different self-experienced traumatic events (s.d. 4.7). The most commonly reported events were being close to death (80%), forced separation from family members (74%), murder of family or friend (72%), threatened to be physically tortured (72%), and unnatural death of family or friend (66%). With regard to the trauma domains, human rights abuses were reported by 90% of participants, traumatic losses by 83%, lack of necessities by 77%, and separation from others by 81%.

Hierarchical regression analyses were used to test whether possession of refugee status, the total number of different self-experienced traumatic events, and different domains of self-experienced traumatic events predicted symptom severity of PTSD and depression. Results of the hierarchical regression models are shown in *Table 3*. First, symptom severity of PTSD and depression was adjusted for gender and age by adding them to the model in step 1. Refugee status was added to the model in step 2. Lack of refugee status was significantly associated with increased symptom severity for PTSD and depression. Refugee status accounted for 2% of the variation in symptom severity of those disorders. Total number of different self-experienced traumatic events was added to the model in step 3. Increased number of different self-experienced traumatic events was significantly associated with increased symptom severity for PTSD and depression. Total number of different self-experienced traumatic events accounted for 8% of the variation in PTSD symptom severity and for 7% of the variation in symptom severity for depression. To test the unique effect of different domains of self-experienced traumatic events to symptom severity of PTSD and depression, human rights abuses, traumatic loss, lack of necessities and separation from others were added to the model in step 4. None of

these domains were significantly associated with symptom severity. Adding the different domains of self-experienced traumatic events to the model accounted for an additional 1% of the variation in symptom severity.

B, Unstandardised regression coefficient; Beta, standardised regression coefficient; PTSD, post-traumatic stress disorder.

Dependent variables: symptom severity with regard to PTSD and depression.

$P < 0.01$

R^2 , change in R^2 compared with previous step.

Clinical implications

In a large sample of asylum-seeking and refugee patients seeking treatment within a specialised Western mental health setting, PTSD symptom severity and depression was predicted by lack of refugee status and cumulative traumatic events, but not by specific domains of traumatic experience. Refugee status, total number of self-experienced traumatic events, domains of traumatic experiences, and gender and age together accounted for only 11% of variation in symptom severity of PTSD and depression. These results are in stark contrast with earlier findings among non-treatment-seeking refugee populations, which showed that torture and cumulative traumatic events accounted for 34.4% of variance in PTSD prevalence rates and for 33.4% of variance in depression prevalence rates.⁵

Clearly, PTSD symptom and depression severity among asylum seekers and refugees seeking specialised treatment is influenced by multiple factors, including some that were not measured in this study. To map predictors for PTSD and depression in refugee patients, assessment may need to focus on a broader range of both stressors and resources, including stressors and resources related to forced migration, such as safety of family in the home country and social support. Rather than traumatic stress, it may be the burden of current stress and lack of resources that leads to PTSD and depression, prompting refugees to seek mental healthcare. This finding implies that clinically, in this severely traumatised population, an exclusive focus on processing of traumatic experiences as prescribed in PTSD treatment guidelines may result in only limited symptom reduction. Consequently, for refugee patients with severe psychopathology treatment may need to be multimodal rather than trauma-focused only.

In addition, in contrast to other studies, which showed an association between life threat and traumatic loss on the one hand and PTSD and comorbid disorders on the other, in our treatment-seeking sample no such associations were found. In our sample, the number rather than domain of traumatic events was associated with symptom severity. This implies that trauma-focused treatments for refugees should be designed to enable the processing of a large number of traumatic events within a reasonable time-frame. Treatments such as narrative exposure therapy and trauma-focused cognitive therapy may enable that to a greater extent than *in vitro* exposure therapy or eye movement desensitisation and reprocessing therapy, which in refugees may require several sessions for the processing of a single memory.

Although our findings can be generalised to mental healthcare-seeking refugees and asylum seekers only and the range of questionnaires was limited, merits of this study lie in the satisfactory cultural validity of the questionnaires and the large sample size. Future studies using a broader range of instruments are needed to identify predictors for PTSD and depression in treatment-seeking refugees.

1.8.57 A guide to a new short course to promote interest and engagement in psychiatry in medical students

Abstract

This article describes a new course for preclinical medical undergraduates designed to promote interest and engagement in psychiatry. The course employed a range of innovative teaching techniques alongside ward visits to provide students with early clinical experience. Unusually, assessment for the course involved the production of creative works as well as reflective writing about students' experiences. We collected a variety of feedback from participants showing that they found the course enjoyable and educational. We conclude that, overall, the course had a positive effect on student perceptions of psychiatry.

Psychiatry is one of several medical specialties undergoing a crisis in recruitment, with a 15% shortfall in core trainee (CT1) allocations year by year.¹ The Royal College of Psychiatrists is seeking to address this deficit by engaging with students before, during and after medical school,² with recommendations for interventions at each level. One such intervention is the provision of student selected components (SSCs) in psychiatry. In this paper, we discuss our experience of developing and delivering an innovative optional module for second-year medical students studying for the Bachelor of Medical Sciences (BMedSci) degree at the University of Nottingham and the impact this had on their attitudes towards psychiatry.

Aims and objectives

The aims of the module were: to stimulate students to learn more about psychiatry before entering traditional 6-week clinical placements in year 4 to demystify and destigmatise the specialty and consider how psychiatric practice differs relative to the traditional medical models of medicine and surgery to improve students' critical reflection skills and to allow them to improve their medical practice by reflecting on personal experience.

When designing this course, we were guided by our aims and objectives and by literature available about other psychiatry SSCs (see below). We were, however, constrained by some practical considerations. The module had to fit into an existing undergraduate timetable that was already very busy. This meant that the SSC had to be completed in one semester and we managed to negotiate eight sessions of varying length for our teaching. The total duration of the course, including time for submitting the assessments, was approximately 3 months. We were also keen to avoid duplicating the teaching and experiences that students would receive during their clinical attachments to psychiatry in their fourth year.

A literature search was conducted to see whether other medical schools had undertaken similar SSCs and, if so, what their experiences were. A range of databases (AMED, Embase, HMIC, MEDLINE, PsycINFO, BNI, CINAHL, Health Business Elite) were searched using all combinations of the terms 'psychiatry', 'student selected component', 'special study module', 'SSC' and 'SSM'. This search yielded 21 results and, after removal of duplicates, review of the abstracts identified 4 articles of particular interest. Brown *et al's*³ survey of Scottish psychiatrists supported our view that engaging medical students early in their training was important for promoting positive attitudes towards psychiatry. We also found three published examples of SSCs/SSMs in psychiatry. One of these was a 3-week SSC at Hull York Medical School on mental health and the arts.⁴ The other two were both SSMs looking at the representation of mental illness in films.^{5,6}

Some parts of our design were influenced by these reports. For example, we included short examples from films and other popular media in our seminars (e.g. *Winnie the Pooh* cartoons). We also acknowledged the natural link between mental health and the arts in our innovative assessment scheme where students were asked to prepare and present creative pieces influenced by their experiences during the module. However, we felt that a design using only one approach (e.g. film or arts in general) would not allow us to meet all of our objectives. Hence, our course included a variety of teaching modalities and, very importantly, used early clinical experience in the form of structured ward visits.

The module structure comprises lectures, small-group teaching, student-led presentations, group work, self-directed learning and two field trips to psychiatric hospitals. The intention was not necessarily to recruit every member of this group to the specialty, but to sow the seeds of positive regard for psychiatry and its patients and to destigmatise mental illness.

The course consists of five 2-h seminars on the following topics: the history of psychiatry, psychosis, neurosis, the subspecialties and ethical dilemmas in psychiatry. Interspersed with these seminars are two clinical visits supervised by senior clinicians, each 3 h long. Twelve students are accommodated on the course. This early exposure to mental health in-patient care is to our knowledge rare in the UK. In the final 3-h seminar students present part of the course assessment in the form of a creative piece about psychiatry to an audience of their peers, consultants and an assessment panel.

Interesting and interactive sessions were devised which minimised didactic teaching, as far as possible, while still introducing the serious and sensitive nature of mental illness. It was also important not to duplicate any of the curriculum material the students would receive in their later fourth-year clinical psychiatry placements.

Course structure and materials

Seminar 1: History of psychiatry

An assumption was made that students' prior knowledge was comparable to a member of the public's and therefore likely to be influenced by popular media portrayals of mental illness⁷ or personal experience involving themselves, friends or relatives.

The session begins with students having to define the job descriptions of psychologists and psychiatrists in an interactive session with the facilitators for 20 min.

'Getting away with murder' is then played. This is an exercise designed to draw out student preconceptions and prejudices, which could then be challenged and revisited throughout the course. Students are divided into two groups and asked about the role mental illness plays in violence. A scenario is presented whereby students are asked to imagine they have committed a murder and have decided to feign symptoms of a mental illness to be found not culpable. Working in their groups facilitated by course tutors, the students then brief a patient simulator (who is experienced in portraying the symptoms of mental illness in medical assessment and training) on how to behave and what to say. Next, a specialist forensic psychiatry trainee interviews the simulators in front of both groups. Students are positively rewarded with chocolate for the simulator portrayal of a convincing symptom or syndrome of mental disorder.

This exercise successfully sparks the students' interest and leads to an open discussion, guided by feedback from the interviewing psychiatrist, about the symptoms the students describe and why they believe them to represent mental illness. The symptoms generated by the students were contrasted with symptoms that are typically seen in forensic psychiatry settings. The remainder of the session is spent presenting students with a broad history of psychiatry through the ages with a focus on attitudes towards mental illness in different societies and contrasting these with the students' own attitudes.

Seminar 2: Psychoses

The second seminar focuses on the nature of psychosis and the challenges it poses to patients, mental health services and society. The students are shown a video interview with a patient who experiences features of psychosis. To facilitate empathy, the patient selected for interview was also a student of a similar age. He talks through his experiences – the first time the students hear a description of a psychotic episode – and the impact the illness has had on his life. This challenges the students' previously expressed views as to the experience of mental illness and the information generated by students during the 'getting away with murder' game is revisited. A discussion is facilitated to establish the nature of the symptoms of psychosis.

To enable students to develop an experiential insight into schizophrenia, we attempted to simulate a psychotic symptom. There is an existing body of literature to support this approach.⁸ The experience of an auditory hallucination is simulated for the students by listening to an audio file played on their own mobile phones or other devices via headphones. The scripts were based on patients' descriptions of their auditory hallucinations and then anonymised. The hallucinations were voiced by members of the teaching team, recorded and mixed together. The audio file was distributed to students via the Moodle virtual learning environment (<https://moodle.org>) with instructions to bring it to the relevant session on a device with headphones attached, having not yet listened to it.

The pressure to perform well academically in medical students is well known, as is their competitive nature. A quick-to-administer intelligence test was identified and students take the test under normal conditions. Next, they complete a comparable test while listening to the simulated auditory hallucinations on their headphones. The tests are scored and students compare their two sets of individual results; group means are calculated and a paired *t*-test performed to demonstrate the effects of hallucinations on intelligence testing.

Seminar 3: Neuroses

This seminar aims to introduce depression and anxiety disorders by highlighting issues related to defining the boundaries between normal and pathological experiences. A small degree of anxiety is generated in students at the beginning of the session. On arrival they are told they are to sit an *ad hoc* examination under strict conditions. The teaching team act in an anxious manner themselves, talking about the need to standardise the course for external examiners, while students wait silently for everyone to arrive. When instructed to turn the exam paper over students discover a questionnaire asking about the acute symptoms of anxiety derived from the ICD-10 criteria for generalised anxiety disorder. Students then reflect on their feelings on being told they had an examination and how these match to those probed in the questionnaire. A number of anxiety symptoms are elicited. Having induced symptoms of anxiety, prior learning is then activated by a group discussion reminding the students of the biological basis of the physiological changes that occur in anxiety.

To further illustrate the concepts included in the broad area of neurosis, video clips of characters from *Winnie the Pooh*⁹ are then shown and discussed in the group. This illustrates how disorders can be identified (e.g. depressive disorder in Eeyore, anxiety disorder in Piglet) and the importance of having a structured means of drawing the line between the normal and the pathological.

It was considered important that issues of suicide and risk assessment are discussed. To facilitate this, examples of famous people who have died by suicide are called upon, allowing this emotive topic to be discussed in a sensitive way within the now-bonded group.

Seminar 4: Subspecialties

As psychiatry is a medical specialty with many subspecialties that most medical students do not get experience in, the students were introduced to the main subspecialties with brief talks from consultant psychiatrists in various fields (old age, child and adolescent, intellectual disability, forensic and psychotherapy). Exposure to the enthusiasm and expertise of specialist consultants is a valuable part of the module and speakers are briefed to talk to the topic 'I like my job, because ...' for 20 min and allow 5 min for questions. Following this seminar, students are asked to express individual preferences for their visit to a subspecialty unit.

Seminar 5: Ethical dilemmas in psychiatry

Psychiatrists face numerous clinical ethical dilemmas. It is important to introduce the students to these issues; they are taught ethical principles at an early stage in the medical curriculum and have a basic understanding of the area. Consultants from subspecialist areas within general adult psychiatry present to the students real clinical cases featuring ethical considerations. The consultants specialise in liaison psychiatry, perinatal psychiatry, eating disorders and gender identity issues. Feedback from students indicated that, before the presentations, they were unaware of some of these specialist areas of psychiatry.

Clinical visits

Within the module are two visits to in-patient psychiatric units. Students attend in pairs: visiting one of the six local acute general adult wards on the first visit and one of the available subspecialty in-patient units on the second visit (drug and alcohol, perinatal, forensic, intellectual disability, child and adolescent, old age). To prepare the students for the visit, information is given about ward etiquette (dress, ID, behaviour, safety), suitable questions are suggested for the meeting with a patient and opportunities are given to ask questions about the visits. Senior doctors, either consultants or higher specialist trainees, lead the visits. The visit format is prescribed as follows. First, students observe the psychiatrist interviewing a consenting patient (30 min) and then discuss the case. After a coffee break, students are introduced to a consenting patient to speak with them in a communal ward area for 30 min. Following this, students have the chance to reflect verbally on their experiences with the psychiatrist and ask questions about the patient they

have seen. By encouraging the students to focus on the impact of the mental illness and the care received, rather than take a formal psychiatric history, the importance of and need for high-quality psychiatric care is reinforced.

Assessment

As an optional module contributing towards an intercalated BMedSci degree, a summative assessment is mandated. As the aim of the module is to demystify and destigmatise psychiatry as well as developing empathy the assessment places emphasis on reflective processes. Students are required to produce two reflective essays, one entitled 'My impressions of psychiatry' (1500 words) and the other 'Meeting a psychiatric patient' (1000 words). They are also required to produce a piece of creative work that communicates their understanding of any aspect of psychiatry with an accompanying written explanation of the work. This was presented to the student group, the facilitators, consultants and psychiatric staff who facilitate the ward visits. A psychiatric occupational therapist helped to develop the marking criteria and was a member of the assessment panel. The creative work presented was emotionally poignant and exceeded expectations; students produced paintings, photography, poetry, interpretative contemporary dance, short films and sculptures. Their work has been exhibited at the medical school and is available for future groups to see online.

The student experience

The Attitudes to Psychiatry (ATP) questionnaire¹⁰ and a bespoke questionnaire to obtain qualitative and quantitative feedback on the creative assessment and the role of reflection in medical training were completed by students both before and after the course. There were no statistically significant differences in attitudes to psychiatry question items before and after the course. There were 11 students who completed the ATP before the module and 10 who completed it at the end of the module. When individual statements were examined using chi-squared results for the responses before and after the module compared with the mean response before the module for each question on the ATP, three questions initially seemed statistically significant (Question 3: 'Psychiatric hospitals are little more than prisons', Question 9: 'Psychiatric teaching increases our understanding of medical and surgical patients', Question 29: 'Psychiatric patients are often more interesting to work with than other patients'). However, once adjusted for multiple testing using a Bonferroni correction, the results were no longer statistically significant. The lack of statistically significant results in the ATP is probably due to the small sample size and the fact that students self-selected the course, which might have resulted in the group being biased positively towards those attracted to psychiatry at the outset.

The most positive effect of the course was apparent in the essays the students produced. Most chose to reflect on their personal journey through the course, with a common theme being the realisation that previously held stereotypic views of the psychiatrist and their patients were inaccurate. Our aim to give students a positive experience of psychiatry was achieved – one student wrote 'Considering that I chose this module having no intention of taking a career route in psychiatry, I must say that the module has certainly left positive impressions upon me, and right now, I definitely would not rule out such a possibility'.

An example of the impact of the module is voiced by a student who wrote: 'My impression of psychiatry has been very positive. [Psychiatry] is an exciting and ever-evolving profession'. Admittedly, students were aware of the 'hidden agenda' created by the recruitment crisis in psychiatry and perhaps they knew we would be delighted to read quotes such as, 'I have ended this course wanting to pursue a career in old age psychiatry'.

Another common essay theme was the belief that medical students should be taught about psychiatry earlier in their training. One student stated: 'My impressions of psychiatry have changed dramatically over the [past] year and I am of the opinion that all medical students would benefit from early exposure to this [specialty]'. Another student, having highlighted the stigma among medical students towards people with mental illness, said: 'I believe there should be a lot more emphasis on mental health in ... the preclinical phase of medical training, perhaps this can reduce the stigma associated with the subject'.

Clinical visits received excellent feedback from the students. One wrote: 'Probably the most important factor in sculpting my impressions, were my own experiences on the wards ... It felt like no other hospital ward that I'd been on before'. Another student wrote: 'Experiences such as meeting this patient, and the ward round, changed my views

and attitudes towards psychiatry entirely'. The effect of the contact with patients was clear, with one student writing: 'Thinking about psychiatry now, the patients are what I will take from this module'.

The aim to reduce stigma both towards psychiatric patients and their psychiatrists appears to have been achieved. One student stated 'I was greeted, not with a room of [Freuds], but kind, friendly, relaxed psychiatrists. People who seemed like the most passionate doctors of any [specialty] I'd encountered'. Another said: '[The course] has stripped away levels of stigma I barely knew I had, yet which society had conditioned me into having'. Several of the students commented on their desire to see stigma towards those experiencing mental illnesses to be reduced, typified by one student who wrote 'Mental illness is just as real as physical illness and deserves the same amount of respect'.

Discussion

It should be noted that the sample size of the first cohort was small, only 12, so it is difficult to draw anything more than impressions from the data collected. The course has been repeated but again with only 12 participants. Because funding streams are different for preclinical and clinical medical students at present there are practical limitations on the number of students who can undertake the module. However, with minor alterations, the module could be taught with larger numbers of students and in medical schools throughout the UK. A useful follow-up would be to conduct the ATP on second-year students who do not undertake this module and compare the results. In addition, following up this group of students to see whether the changes in attitude are sustained or short-lived might be of value. Comments made by the students during the module indicated that negative attitudes regarding mental health services are being propagated even in preclinical teaching sessions. As it has not been possible to do a long-term follow-up of these students yet, the effect of studying other areas of clinical medicine on their long-term career choice has not been established. This positive change in attitudes to psychiatry may or may not be sustained in the long term, but at least we have a tool that has demonstrated a positive impact on medical students that could be repeated in larger numbers.

Summary

In conclusion, by using innovative, interactive teaching techniques combined with early clinical visits to psychiatric units, the course achieved its aims of demystifying and destigmatising psychiatry. At the start of the course, none of the students had considered psychiatry as a career; by the end 25% stated they intended to become psychiatrists and a further 17% said they would consider a career in psychiatry. More than half of the students requested to do their BMedSci projects in areas related to psychiatry through the Institute of Mental Health, Nottingham. The remainder acknowledged a positive change in their attitudes towards psychiatry, viewing it as an interesting and important medical specialty. We are currently exploring the possibility of offering a similar bespoke course for local sixth-form pupils to encourage those interested in psychiatry to apply to medical school.

The assessment work demonstrated that all the students had increased their knowledge of psychiatry, with most having undertaken further personal study that was referenced in their submissions. The assessment process included a reflective piece enabling the students to develop reflective skills, with some being more able to demonstrate this in written form than others. As students are motivated by assessment, using an assessed reflective piece encouraged their focus on this skill that will benefit them in their future medical careers. Psychiatry in particular is an area where reflective practice is vital, so this assessment tool has face validity. We would encourage all psychiatrists in medical education to reflect on how we can make changes to improve recruitment of appropriately skilled doctors to psychiatry and present this module as one suggestion.

1.8.58 Nick Kitson MB, BS, FRCPsych

: Formerly consultant psychiatrist, Cornwall Partnership NHS Foundation Trust and Springfield University Hospital, honorary senior lecturer, St George's Hospital Medical School

- *Nick Kitson MB, BS, FRCPsych*

– : *Formerly consultant psychiatrist, Cornwall Partnership NHS Foundation Trust and Springfield University Hospital, honorary senior lecturer, St George's Hospital Medical School*

Nick Kitson, who died suddenly at the age of 64 while on holiday on 24 February 2014, was a pioneer and national expert in the psychiatric disorders of deaf people. He was the Founding Chair of the British Society for Mental Health and Deafness and the longest serving president of the European Society for Mental Health and Deafness (1990-1997), remaining honorary member and honorary vice president of each, respectively. He was clinical advisor to the Towards Equity and Access Implementation Panel (the Department of Health and National Institute for Mental Health England commissioning panel) in 2006/2007 and 'responsible owner' of a National Deaf Mental Health Commissioning Project. He remained a trustee of and medical advisor to the Sign health charity and awarded the title of Pioneer. He was joint editor of the standard introductory textbook *Mental Health and Deafness*. At the World Congress of Mental Health and Deafness held in 2014, a prize for the best poster was established in his name.

Nick completed his medical training at St Bartholomew's Hospital in 1975. He was appointed consultant psychiatrist at Springfield University Hospital and honorary senior lecturer at St George's Medical School in 1984. He was clinical director for the Specialist Mental Health Services for the Deaf Community at Springfield and medical director of Pathfinder NHS Trust from 1994 to 1998. When he became responsible for the psychiatric care of people with deafness, his health authority gave him 9 months to learn sign language. He visited psychiatric units for deaf people in America and realised the importance of employing deaf people fluent in sign language. At the time he wrote about sign language: 'It is a very sophisticated language capable of expressing everything you can say in English.' The service for deaf people that he led and developed for 18 years, with his wife Karen, covered the southern half and then a third of England. He became a Member of the Royal College of Psychiatrists in 1980 and was elected a Fellow in 1996.

While working as a consultant, he trained in short-term dynamic therapy in 1984 and group analytic psychotherapy in 1989. He became an associate member of the London Centre for Psychotherapy (British Psychotherapy Foundation) in 1989 and a Full Member in 1996, supervising short-term dynamic psychotherapy at the Tavistock and latterly at the London Centre for Psychotherapy. Psychotherapy was always an integral part of his clinical practice. He provided strong support for Jane Douglas, the first profoundly deaf person to train as a psychoanalytic psychotherapist.

Knowing the West Country well, Nick left London and moved to Cornwall in 2002. He initially worked as a community and in-patient psychiatrist covering the St Austell area but, wishing to reduce his workload owing to ill health, he became part-time consultant to the psychiatric intensive care unit (PICU). The service was awarded the National PICU of the Year in 2005. Formally retiring in 2009, he continued as his own locum for the PICU, regularly sailing and taking trips abroad with Karen and his family.

Nick was a hugely respected consultant psychiatrist. His colleagues frequently sought his advice in difficult circumstances, and the advice he gave was wise and supportive. He was down-to-earth and sensible; he never pretended he knew the answer when he did not, but his advice was even sounder in these circumstances. He continued to use his therapeutic skills after retirement and remained enthusiastic and determined to help the most challenging and difficult patients.

He will be sorely missed by his colleagues but his wise leadership will continue to be influential. He is survived by Karen, his two daughters and his grandchildren.

Abstract

Aims and method To identify the patient characteristics and rates of retention in a residential rehabilitation drug and alcohol service (Springhill) based on an eclectic model of care. Patients were assessed using the Alcohol and Drug Outcome Measure (ADOM), a brief tool designed for the New Zealand setting. We looked at correlations between demographic, social and drug use parameters. Logistic regression assessed the relative impact of each variable on completion.

Results The 183 patients who completed the data collection did not differ from 47 non-completers by demographic data; 62.2% of patients completed the programme, with equal number of men and women. One in five participants was Maori, the indigenous minority. Alcohol (51.9%) was the commonest drug of misuse, with methamphetamine (16.4%) and cannabis (14.2%) also significant. Completers were more likely to be Maori, have conflict with family and housing problems, although the last became non-significant in logistic regression.

Clinical implications Retention rates are higher in Springhill than in comparable programmes. Ethnicity and family conflict predict completion, although the reasons for this are unclear. ADOM is an effective tool that can be used in a clinical setting to enable analysis of service provision.

Substance use disorders (SUDs) are relapsing and remitting disorders that affect a significant proportion of the community. One-year prevalence rates of alcohol use disorders range from 3.5%¹ to 8.7%,² with lifetime rates for SUDs reaching 12.3%.³ The commonest age of onset for alcohol and drug problems is early adulthood,^{4,5} although the diagnosis may not be stable at this point.⁶ Not only are SUDs common, they cause significant social morbidity,¹ physical morbidity⁷ and mortality.⁸ The reasons for ongoing use in the face of such difficulties is unclear, however, this may be due to the compulsive nature of substance use.⁹ Despite this, recovery from alcohol use is an achievable goal,¹⁰ hastened by effective management strategies.

A wide range of treatment options are used clinically, adopting both harm reduction¹¹ and abstinence¹² models. The latter is often the preferred choice, yet the success of these treatments is well known to be poor.¹³ The most intensive intervention for addiction is residential rehabilitation,¹⁴ used in most countries and considered integral by almost half addictions clinicians.¹⁵ Drop-out remains a major difficulty for residential programmes^{16,17} and improved retention is related to improved outcomes.¹⁸ Patient factors such as family involvement and employment improve retention,¹⁹ as do interpersonal factors such as the therapeutic alliance.²⁰ A number of programme factors may also be important, including the ratio of counsellors to patients and a structured programme of therapy, as well as a balance between contributing to the community, specific addictions work and free time.²¹ Psychopathology has not been found to be correlated with outcome^{22,23} and this is interpreted as support for residential treatment for patients with drug use disorders and co-existing mental disorder.^{24,25}

Developing routine assessment of residential interventions enables both description of patients presenting to these services and analysis of outcome. Although previous research is a useful guide, it may not be generalisable. Country and culture are two factors that may have an impact on alcohol and drug use and its management.^{26,27} Similarly, the attitudes and beliefs of addictions clinicians are of significance in deciding who is referred for residential treatment.²⁸ Differences in culture,²⁹ policy,³⁰ funding and politics³¹ shape service provision and necessitate country-specific research. They also point to the need for country-specific, ideally easy to implement, research tools that have the capacity to translate into routine clinical practice. Only one New Zealand study has examined residential interventions,²³ despite the importance of understanding this costly intervention and for whom it is most appropriate. This study supported a 'non-discriminating approach' to referral but did not use New-Zealand-specific measures and assessed a long-term treatment setting. Replication and assessment in short-duration residential treatment settings is important to both compare outcomes and examine possible differences.

For these reasons, we investigated the outcomes in a short-duration (8-week), eclectic residential programme using a locally designed and validated tool and report on factors that were associated with programme completion.

Method

In total, 230 clients consecutively admitted to the Springhill residential rehabilitation programme were included in this study. These clients were admitted during 2011/2012. All completed standard clinical documentation on admission to Springhill and in addition were asked to complete an Alcohol and drug Outcome Measure (ADOM) on admission and discharge. The research was approved by the Southern Health and Disability Ethics Committee and the local district health board.

The programme

Springhill runs an 8-week residential rehabilitation programme for all substance use disorders. Up to 15 patients can be admitted at any one time. Patients undergo managed withdrawal with their referring teams before admission if this is considered necessary, particularly from high-dose alcohol. It is unique in New Zealand insofar as the clinical programme is delivered by clinicians from a district health board (a public health provider) but the facility is governed by a private trust. All clinicians are registered health practitioners with clinical expertise in addiction treatment. The programme has input from a substance misuse psychiatrist and general practitioner with a special interest in addictions providing medical oversight. The programme is abstinence based, including abstinence from tobacco, and draws on principles from the 12-step programme, cognitive-behavioural therapy, family systems theory and some elements of a therapeutic community. In this way it is similar to residential programmes elsewhere³² and would best be considered as eclectic. Each week is structured around facilitated large group sessions with all clients, supplemented by individual and family work. Exercise and involvement in the running of the facility are part of the programme. Each client has an individual therapist to work with alongside the group and all clients are reviewed medically and have access to psychiatric review if necessary. At the conclusion of the programme clients are referred back to their community addictions providers.

Client characteristics

Patients are accepted primarily from secondary addictions services in the community when this intervention has been ineffective as judged by their community clinician. There are few specific exclusion criteria and referrals are assessed on a case by case basis. Referrals are received from the lower North Island of New Zealand and include both rural and urban settings. Programme entry requires that there is a service to refer the client back to on completion. In the case of abrupt discharge each client has a person whom they have agreed to be contacted, with the referring service contacted the following day. If there are clinical concerns, a psychiatric crisis team is available to undertake assessment as deemed necessary. A clinical diagnosis of alcohol or drug dependence is a requisite for consideration for admission. Judicial direction is a specific exclusion criterion (i.e. clients cannot be legally directed into treatment at Springhill).

The ADOM tool

The ADOM is a brief tool to collect outcome data and measure improvements after intervention in substance dependence, specifically in a New Zealand setting. Part A of the tool is validated²⁴ and part B is similar to other tools used to collect information on social support and context, in line with other addictions rating instruments.³³ Part A focuses on drug use, particularly number of days' use in the past 4 weeks and total use of alcohol in units, this being the most prevalent drug of misuse in New Zealand. Tobacco use is measured as average number of cigarettes a day. Part B asks clients to rate the frequency of problems in multiple social domains as a result of drug dependence, again in the past 4 weeks. These include problems related to physical health, mental health, conflict in interpersonal relationships, difficulties with work or other structured activity, housing and criminal activity. These are self-reported on a 1–5 Likert scale. A score of 1 represents no difficulty in the social variable measured, whereas a score of 5 represents daily or almost daily problems. These variables were measured for the 4 weeks preceding admission during engagement with community alcohol and drug services. This allowed for a measure of current social problems and can allow for examination of changes on these scales over time. The advantage of a self-report measure is its acceptability to patients and the reporting of perceived difficulty as assessed by the client.

Data collection and analysis

At admission basic demographic information was collected from the patient and the ADOM tool was completed by the patient with their admitting therapist. At discharge, all patients completed discharge paperwork with their discharge therapist and the ADOM tool was again administered at this point. If clients were discharged outside of working hours they were contacted the following day to complete the ADOM if this was possible. All analysis was carried out in SPSS 19 for Windows and undertaken by one of the authors (J.S.).

The primary goal of this analysis was to identify what, if any, factors were associated with retention in the programme to 8 weeks or attrition over the 8 weeks. The purpose of this analysis is to provide services with information about clients who are at greater likelihood of succeeding to completion. All demographic and ADOM data used in this analysis are based on the measures collected at admission.

Descriptive statistics on sociodemographic and basic clinical characteristics (as collected at admission) are reported as means, standard deviations and proportions as appropriate. Logistic regression analysis was used to examine unadjusted relationships between each of the potential predictor variables and the outcome of completing the programme (defined as 8 weeks' participation in the residential programme). The predictor list set was developed *a priori*.

To consider the potential impact of confounding on the modelled estimates, subsequent logistic regression analysis looked at adjusted estimates for programme completion. Adjusted results are presented in four blocks. First, sociodemographic variables (age, gender and ethnicity) were entered into the model. Block two consisted of adding the primary drug of dependence as identified by the patients themselves (simplified to alcohol, cannabis, amphetamine and other drugs (e.g. opioids) and no drug specified). The third block included adding physical and psychological health variables and finally, social variables including work, paid employment, housing and crime. The model was developed to identify for whom completion was most likely as a proxy marker for positive long-term outcomes.

Results

Patient demographic data

During the study period 230 patients were admitted to Springhill, of whom 183 (80%) completed ADOM data on admission and discharge. The 47 patients for whom complete data were not available did not differ from the included patient data-set on basic demographic data. Overall, 143 patients (62% of all admitted patients) completed the 8-week programme (including 2 patients who stayed 9 weeks and 1 patient who stayed 10 weeks). For those included in the analysis the average age was 37 years with equal numbers of men and women. The majority of clients (74%) were White, 21% were Maori and the remainder identified with other ethnic backgrounds. At the time of admission 33% of clients had a partner, although 1 in 5 declined to answer this question. These variables are similar to those of clients not included in further analysis and similar to the demographic of the region (*Table 1*).

Demographic and drug use of the client group

Client status (at admission)	Analysed data (n = 183)	Missing data (n = 47)	Total (n = 230)	N valid by question
Age, years: mean (s.d.)	37.4 (11)	36.2 (11.5)	37.1 (11.1)	230 (100%)
Gender				
Male	96 (52.5%)	20 (58.8%)	116 (53.5%)	217 (94.3%)
Female	87 (47.5%)	14 (41.2%)	101 (46.5%)	
Ethnicity				
Maori	39 (21.3%)	3 (23.1%)	42 (21.4%)	196 (85.2%)
White	136 (74.3%)	9 (69.2%)	145 (74%)	
Other specified	8 (4.4%)	1 (7.7%)	9 (4.6%)	
Relationship status				
Partner	51 (32%)	8 (36%)	59 (33%)	181 (79%)
No partner	108 (68%)	14 (64%)	122 (67%)	
Main drug at admission				
Alcohol	95 (51.9%)	9 (33.3%)	104 (49.5%)	210 (91.3%)
Cannabis	26 (14.2%)	7 (25.9%)	33 (15.7%)	
Amphetamine, other	30 (16.4%)	5 (18.5%)	35 (16.7%)	
None selected	32 (17.5%)	6 (22.2%)	38 (18.1%)	
Substance use in past 4 weeks by main drug of dependence, days: mean (s.d.)				
Alcohol (n = 104)	13.2 (9.5)	11.1 (4.9)	13.1 (9.2)	95 (91.3%)
Cannabis (n = 33)	16.4 (11.8)	12.7 (12.8)	15.6 (11.9)	26 (78.8%)
Amphetamines (n = 27)	4.2 (7.6)	9.3 (12.7)	4.9 (8.4)	23 (85.2%)
Cigarettes (n = 230)	12.4 (12.8)	13.5 (11.7)	12.5 (12.6)	183 (79.6%)

A total of 8 clients reported using other substances outside the main categories.

Days' use represents the number of days' use of the substance identified as the primary drug of dependence by the client. The exception is mean number of days nicotine used; this is for the whole sample.

Amphetamine usage among those with amphetamine as main drug at admission.

Drug use variables

The commonest drug of dependence in the sample was alcohol with 51.9% of clients identifying this as their most problematic drug. Amphetamine, primarily methamphetamine (16.4%), and cannabis (14.2%) were the other significant primary drugs of misuse. Thirty-two patients could not identify a primary drug of misuse, having problems associated with multiple drug use. Eight patients identified sedatives, opioids or other drugs as their primary drug of dependence with no more than three in each group. Twelve patients used the intravenous route for drug administration in the 4 weeks before admission, with 3 patients sharing needles.

Patients with primary alcohol dependence drank on average 14 units a day in the month before admission, with alcohol consumed for 13 of the past 28 days. Those with cannabis dependence smoked on 16 of the past 28 days on average. The 27 patients with amphetamine dependence used on 4 of the 28 days before admission. All groups were engaged in community alcohol and drug out-patient programmes prior to their admission. Tobacco smoking was common in this group despite the admission criteria to Springhill identifying it as a smoke-free rehabilitation facility, with the expectation of discharge if smoking occurred during the admission.

Social variables

A quarter of clients stated their drug use led to daily physical health problems, with almost two-thirds identifying physical health problems occurring at least weekly and directly related to their drug use. Mental health problems occurred on a daily basis for one in seven patients, with three-quarters identifying mental health difficulties related to the use of drugs of dependence. Social difficulties were also common: 20% of patients recorded daily conflict with family or friends and almost two-thirds recognised conflict at least weekly. Recreational and work were similarly compromised, with 83% and 67% of clients respectively identifying problems at some point. Housing was a daily problem for three-quarters of clients. Despite the specific exclusion of referrals from the judicial systems, more than 90% of clients identified crime (other than the use of illicit substances) as related to their drug use, with more than half stating this was an almost daily problem.

Univariate predictors of programme completion

Sociodemographic, clinical and social variables were examined as univariate predictors of programme completion using logistic regression (*Table 2*). Identifying as Maori, conflict with family and problems with housing were associated with increased rate of retention. Only ethnicity had an odds ratio greater than 2. Drug of dependence was not associated with programme completion and no association was found between coexisting mental health problems and programme completion.

Unadjusted odds ratios for completion of the 8-week residential rehabilitation programme among respondents with complete data ($n = 183$)

Factor	Odds ratio (95% CI)	<i>P</i>
Age (analysed in 5-year blocks)	1.13 (0.98, 1.29)	0.10
Gender		
Male	0.97 (0.53, 1.77)	0.92
Female	1 (reference)	
Ethnicity		
Maori	2.31 (1.02, 5.23)	0.04
White/other	1 (reference)	
Primary drug of dependence		
Alcohol	1 (reference)	0.74
Cannabis	0.69 (0.29, 1.68)	
Amphetamine/other	0.66 (0.29, 1.54)	
None selected	0.85 (0.37, 1.95)	
Physical health problems _a	1.05 (0.87, 1.27)	0.64
Mental health difficulties _a	1.02 (0.83, 1.24)	0.97
Conflict with family _a	1.30 (1.04, 1.62)	0.01
Social role difficulties _a	1.17 (0.96, 1.42)	0.08
Employment problems _a	1.10 (0.92, 1.32)	0.24
Housing problems _a	1.47 (1.10, 1.96)	0.03
Crime _a	1.11 (0.87, 1.41)	0.40

Odds ratios are increase in odds of completion per one unit in change in the scale.

Regression modelling of programme completion

Logistic regression was carried out using a four-block, sequential adjustment method. Regression estimates (presented as odds ratios and 95% confidence intervals) are presented in *Table 3*. Model A included age, gender and ethnicity as predictors of treatment, model B added in the primary drug of dependence, while model C added scores measuring physical health, mental health and levels of conflict with family. The fully adjusted model (model D) added variables on social role, employment, housing and crime.

Logistic regression of factors associated with completion of residential treatment programme among clients with complete data (n = 183)

	Model A	Model B	Model C	Model D				
Age (per 5 years)	1.14 (0.99, 1.32)	0.07	1.12 (0.96, 1.31)	0.14	1.1 (0.94, 1.29)	0.231	1.08 (0.91, 1.27)	0.38
Gender								
Male	1.01 (0.55, 1.87)	0.97	1.03 (0.56, 1.92)	0.92	0.81 (0.41, 1.61)	0.55	0.80 (0.39, 1.63)	0.54
Female	reference)		reference)		reference)		reference)	
Ethnicity								
Maori	2.48 (1.08, 5.66)	0.03	2.57 (1.10, 5.98)	0.030	2.83 (1.18, 6.75)	0.02	2.82 (1.15, 6.92)	0.02
White/ other	reference)		reference)		reference)		reference)	
Primary drug of dependence								
Alcohol			reference)	0.93	reference)	0.92	reference)	0.95
Cannabis			0.72 (0.27, 1.89)	0.70 (0.26, 1.93)	0.74 (0.26, 2.08)			
Amphetamine/ other			0.88 (0.35, 2.17)		0.91 (0.36, 2.28)		0.94 (0.36, 2.47)	
None selected			0.93 (0.40, 2.19)		0.88 (0.36, 2.13)		0.88 (0.36, 2.15)	
Physical health problems <i>a</i>					1.09 (0.86, 1.39)	0.46	1.11 (0.86, 1.42)	0.434
Mental health difficulties <i>a</i>					0.86 (0.66, 1.12)	0.26	0.85 (0.64, 1.12)	0.248
Conflict with family <i>a</i>					1.47 (1.12, 1.93)	0.01	1.44 (1.03, 2.00)	0.031
Social role difficulties <i>a</i>							1.01 (0.74, 1.38)	0.96
Employment problems <i>a</i>							1.13 (0.92, 1.39)	0.25
Housing problems <i>a</i>							1.35 (0.97, 1.89)	0.078
Crime <i>a</i>							1.00 (0.73, 1.36)	1

Odds ratios are increase in odds of completion per one unit in change in the scale.

In the fully adjusted regression model (model D), only increasing conflict with family and ethnicity (being Maori) significantly predicted completion of the residential rehabilitation programme. Of all variables, being Maori more than doubled the odds of programme completion. Drug use was not predictive of completion. Notably, there was significant use in the 28 days prior to admission and no medical detoxification offered. This suggests clients did not leave rehabilitation because of withdrawal phenomena. Housing problems were not significantly associated with programme

completion in the full model, but the magnitude of the observed odds ratio and confidence interval (OR = 1.35, 95% CI 0.97, 1.89) suggest that such problems might also be associated with increased rates of programme completion. The modelling was reviewed using ordinal regression with weeks completed from 1 to 8 as the step-wise variable. This statistical model was largely the same as the linear regression, with the only alteration being the somewhat increased association between criminal activity and completion. Using ordinal modelling criminal activity significantly predicted greater length of stay (regression model available on request).

Discussion

The current research uses a specific tool, ADOM, to assess patient characteristics and potential indicators of programme completion within a residential rehabilitation setting in New Zealand. The ADOM tool was acceptable to patients with high completion rates, despite more than a third of patients leaving the service early. It was easily intercalated into routine clinical care and specific researchers were not used to collect this information, indicating its capacity for translation for routine use (see www.matuaraki.org.nz/supporting-workforce/adom). The potential for use throughout New Zealand would allow for in-depth understanding of addiction service use and potentially prediction of service matching.

Patients entering rehabilitation report high ongoing use of alcohol and other drugs, despite being engaged in community treatment programmes prior to entry. This implies difficulties for some patients with SUDs despite community intervention and the need to develop and deliver alternative interventions. Alcohol remains the most significant drug of dependence in those referred for residential support, although methamphetamine use is common. Low opioid use and low injecting rates may reflect the effectiveness of opioid substitution regimes.³⁴ The need for a drug-free environment is well recognised as a component in recovery for some patients and this is likely to remain the case. Completion rates of greater than 60% are high, with other programmes reporting rates as low as 16%,³⁵ and likely reflect a physical, social and therapeutic environment that is acceptable to patients. The lack of association between specific alcohol or drug use and completion demonstrates the ability to remain in a residential setting despite the varying biological impact of different drug classes and argues for a generic approach to treatment rather than one that is drug specific.

Significant morbidity is reported in physical, psychological and social domains by the patients in this study. These problems are directly related to drug use and small changes in use are likely to be associated with significant benefits to health, relationships and well-being. Previous economic analysis indicates major benefits associated with effective addictions intervention also.³⁶ The relative failure of community intervention for this cohort argues in favour of residential intervention, particularly if retention is high, and implies improved prognosis. This is the case for Springhill and may relate to positive longer-term outcomes.^{37,38} Follow-up studies will enable further examination of longer-term benefits and overcome the limitation of using completion as a proxy marker for improved prognosis.

Identifying who is likely to benefit most from residential treatment allows for a more targeted approach to management. Prior research has recommended a 'non-discriminatory approach to referral' and no clear indicators are apparent in the current literature base. Using regression analyses to consider the impact of several factors likely to alter treatment completion, we are able to show that Maori, the indigenous minority in New Zealand, and those with conflict in the home are more likely to complete the programme. The programme includes the capacity for patients to engage with a cultural assessment but does not include individual or group activities that are specifically culturally oriented. Previous research identifies greater social morbidity in Maori in an out-patient addictions setting³⁹ and greater satisfaction with a culturally specific service. Cultural factors have been a point of focus in policy debate about the provision of services,²⁹ with some advocating for a culturally appropriate approach research methodology frame, although support (and the application) of this is very limited. The current findings suggest Maori manage well in a generic eclectic setting. This does not indicate a generic service is likely to outperform a culturally specific service; rather, Maori are more likely than clients of other ethnicities to complete this programme. Ethnicity is not a proxy marker for social disadvantage as measured by social role difficulties, employment, housing problems and crime in this study as the linear regression of model D elucidates. Understanding the impact of homelessness in dependence is complex,⁴⁰ although the parsimonious explanation of having basic needs met does not preclude the potential for recovery and may be an important component of successful recovery.

The findings of this research are circumscribed by the limitations related to a naturalistic cohort design. Not all questions were completed by all patients and this leads to a weakening in the analysis, however, the advantage of developing the

data collection as part of routine care confirms its utility and capacity for translation from research to routine use. The benefits of using a country-specific tool may counterbalance the restrictions of its limited use. The outcome measure of programme completion is useful,^{37,41} however, long-term abstinence is a more powerful outcome. Follow-up studies are necessary to assess this.

This study highlights the acceptability for some of a residential setting to address their substance dependence. Significant pre-entry drug use, despite community care, does not prevent engagement and abstinence-based programme completion. Maori and homeless patients engage well and these factors predict retention. ADOM is a potentially valuable tool for monitoring outcome from a residential setting and has wider potential use in New Zealand.

1.8.60 The methamphetamine problem

: Commentary on ... Psychiatric morbidity and socio-occupational dysfunction in residents of a drug rehabilitation centre†

Niall Galbraith

Correspondence

Niall Galbraith (n.galbraith@wlv.ac.uk)¹

date

2015-10

Abstract

This paper introduces the reader to the characteristics of methamphetamine. Explored within are the drug's effects on those who consume it as well as the history and prevalence of its use. The highly addictive nature of methamphetamine is compounded by its affordability and the ease with which it is produced, with North America and East Asia having become established as heartlands for both consumption and manufacture. The paper discusses recent cultural depictions of the drug and also the role that mental health professionals may take in designing and delivering interventions to treat methamphetamine addiction.

The nature of methamphetamine

Methamphetamine ('meth') is a stimulant which increases levels of monoamines (particularly dopamine, but also norepinephrine and serotonin) in the central nervous system. Its pharmacological effects occur via a number of neurochemical processes, including disruption of vesicular¹ and transporter² functioning, through the inhibition of monoamine oxidase³ and the facilitation of tyrosine hydroxylase.⁴ Like other stimulants, such as cocaine and amphetamine, it produces feelings of euphoria, alertness and increased energy. Unlike cocaine though, a single dose of methamphetamine sustains these effects for many hours. Methamphetamine can be smoked, snorted, injected or swallowed. The psychological effects of long-term use include hallucinations and delusions, depression, suicidality and aggression.⁵ Withdrawal may exacerbate these symptoms, while also leading to fatigue and intense craving.⁶ Long-term health effects are considerable, and include neural damage and associated cognitive impairment,⁷ cardiovascular damage,⁸ dental disease⁹ and stroke.¹⁰ The drug is also associated with risky sexual behaviour, resulting in a high prevalence of sexually transmitted disease.¹¹ Methamphetamine is also noted for its addictiveness. Evidence shows that addiction occurs more rapidly than with cocaine¹² and that unlike with amphetamine, methamphetamine-seeking behaviour may persist even when tolerance is reached.¹³ The trajectory of methamphetamine use over a 10-year period has been found to resemble that of heroin more so than that of cocaine.¹⁴ Methamphetamine is also associated with criminality¹⁵ and social decline.¹⁶ It therefore represents a major public health, social and political dilemma.

Who uses methamphetamine and where?

Across the world, methamphetamine use as a recreational drug has increased significantly since the 1990s, and it is reported as the second most widely misused substance, exceeded only by cannabis.¹⁷ In the USA during the 1960s and 1970s, methamphetamine was produced and trafficked mainly by motorcycle gangs, mostly in California.¹⁸ Patrons were typically White, male, blue-collar workers, but the drug has since become popular among white-collar workers, students, ethnic minorities and women,¹⁹ and manufacturing has spread to Midwestern states.²⁰ One of the principal factors in its rise is the ease with which it can be manufactured. The chemicals necessary for its production (e.g. methylamine, ephedrine or pseudoephedrine) are relatively easy to obtain, as is the equipment required for the 'cooking' process. This has led to a cottage industry in methamphetamine production, with home-based laboratories being commonly uncovered by law enforcement agencies in the USA²¹ and in other parts of the world, particularly in Asia.²² In addition to the home lab phenomenon, there exist industrial producers of methamphetamine, who manufacture and transport large quantities of the drug.²³ In North America, large-scale production occurs in both Mexico and Canada and the product is then brought across the border for sale within the USA. In the USA itself, 4.7% of respondents to a national survey admit to lifetime use of methamphetamine.²⁴

Data from Asia also indicate high levels of use. Japan has a long history of misuse, dating back to the 1940s,²³ when military stocks of methamphetamine flooded the market, giving rise to high incidence of misuse among young people. A second epidemic occurred in the 1970s, when use soared among blue-collar workers. This crisis has now stabilised and Japan's methamphetamine users now represent an aging population. Since the 1990s, the popularity of methamphetamine has spread to other East Asian countries. By 2007, 63% of worldwide methamphetamine seizures occurred within the Southeast Asian region, and it is estimated that half of the world's methamphetamine users are found there.²⁵ The Mekong region of Myanmar, close to the border of Thailand and China, is identified as Asia's most prolific production centre for methamphetamine. From there the drug is transported across the borders for sale in neighbouring countries.²⁵ In Myanmar, it is usually pressed into pill form, known colloquially as yaba ('crazy medicine'). Thailand has suffered its own epidemic, with methamphetamine treatment admissions rising dramatically in the late 1990s,²⁶ but evidence of increasing methamphetamine use is also found in Brunei, Laos, the Philippines²² and Cambodia.²⁷

In Europe, the meth epidemic has not yet arrived, perhaps because there is already a congested market for stimulant drugs, although the Czech Republic and to a lesser extent Slovakia have a history of high methamphetamine use.²⁸ In Australia, use has increased in recent years but not dramatically.²⁹ In South Africa, the past decade has seen a significant increase in treatment admissions for methamphetamine.³⁰ This increase in methamphetamine use is positively associated with risk-taking sexual behaviour,³¹ which if unchecked may in turn exacerbate an already urgent HIV epidemic.

Cultural depictions of methamphetamine

The emergence of methamphetamine as one of the most widely used recreational drugs is associated with its rise in the media. Methamphetamine has become a cultural phenomenon, in much the same way that heroin, MDMA (contracted from 3,4-methylenedioxy-methamphetamine; ecstasy) and cannabis had become popularised already. The most obvious cultural reference to methamphetamine is in the hugely successful American drama series *Breaking Bad*. This drama describes the exploits of a terminally ill chemistry teacher who chooses to become a manufacturer and then seller of methamphetamine, initially to guarantee financial security for his family after his death. The series focuses on the corruption of the main character and the erosion of his relationships with those close to him. What is notable about the series though is that the problem of devastating effects of methamphetamine on individuals and communities occupies only a minor part in the story. The series has done much to publicise the existence of methamphetamine to households across the world, but in not fully exploring its sinister effects (other than the moral degeneration of those who manufacture it), the series runs the risk of sanitising or normalising this destructive drug to the wider society.

At the other extreme, also in the USA, there has been a widely publicised campaign to highlight the unpleasant physical effects of methamphetamine addiction. The 'Faces of Meth' project³² exposes police custody photographs of users, showing images of the same individual at different points in time, so as to longitudinally chronicle the ravages of the drug on physical appearance. These before and after photos – which reveal apparently common features of long-term methamphetamine use: skin damage (caused by obsessive picking) and dental ill health (or 'meth mouth' as it is colloquially known)³³ – are designed to shock and appal observers. The effectiveness of the scheme is difficult to assess due to the absence of trials, however, the use of fear and shock is not always an effective deterrent in health campaigns and is generally regarded as inferior to positive reinforcement approaches.³⁴

The Faces of Meth-type approach has come under criticism from Naomi Murakawa,³⁵ who argues that its focus on the visual effects of methamphetamine, mostly in White methamphetamine users, represents a type of social panic. Murakawa argues that historically, drug panics in the USA have been constructed in line with racial prejudices (e.g. Chinese-focused opium scares, Mexican-focused cannabis scares and Black-focused crack scares). Methamphetamine addiction is often described along racial lines as a 'White trash' phenomenon. Murakawa claims that decayed or missing teeth mark prevailing fears over the decline in White social status, as traditional representations of American so-called 'White trash' typically depict poor dental health as a visual indicator of lower class.

Given the prevalence of methamphetamine use across the globe, considerable effort has been put into designing effective treatment programmes for its users. Broadly speaking, these interventions are pharmacological, psychosocial or community-based prevention approaches. The evidence in favour of pharmacological treatments is mixed, although some promising findings with modafinil, bupropion and naltrexone have been reported.³⁶ Psychosocial interventions have proved effective in the short term, but more evidence is needed to demonstrate long-term benefits.³⁷ Community-based prevention schemes have also shown evidence of benefit.³⁸ The promise shown by such interventions is encouraging, given the addictiveness of methamphetamine, the intensity and duration of cravings experienced by those who go through withdrawal⁶ and also the psychological comorbidity. Interestingly for mental health professionals, there is evidence that the cost-effectiveness of treatment³⁹ and prevention³⁸ approaches may compare favourably with alternatives, such as, for example, interventions by law enforcement to disrupt the supply of the precursor chemicals needed for methamphetamine production.⁴⁰ Furthermore, given the advance of this drug across Asia and North America and its potential for expansion across thus far untapped markets (e.g. Europe and Africa), the further development of robust treatment programmes for the future is urgently needed.

1.8.61 Exit examination: a survey of UK psychiatrists' views

Nicholas S. Hughes Angela Haselgrove Matthew S. Tovey Waqqas A. Khokhar Muj Husain Victoria C. Osman-Hicks

Correspondence

Nicholas Hughes

(nickhughes1@nhs.net)¹

date

2015-10

Abstract

Aims and method The Royal College of Psychiatrists is considering how best to introduce a post-MRCPsych-examination assessment ('exit examination') in anticipation of external pressures to ensure patient safety through the use of such assessments. The Psychiatric Trainees' Committee conducted an online survey to gather the views of psychiatrists regarding the possible format and content of this examination in the hope that this information can be used to design a satisfactory assessment.

Results Of the 2082 individuals who started the survey, 1735 completed all sections (83.3%). Participants included consultants and trainees from a range of subspecialties. There was general agreement that the content and structure of the exit examination should include assessment of clinical and communication skills.

Clinical implications UK psychiatrists believe that an exit assessment should focus on clinical and communication skills. It should assess both generic and subspecialty-specific competencies and incorporate a mixture of assessment techniques.

- * *A question of awarding a diploma or certificate*
- *Discussion*
- * *Limitations*

The General Medical Council (GMC) is currently undertaking a review of the training and assessment of doctors in the UK, with a view to making a number of recommendations to improve the quality of training.¹ One of the main aims of the GMC in the area of training and education, as defined in their education strategy for 2011–2013, is that: “‘To ensure consistency and clarity, we will define clear outcomes which must be met by students and trainees on the completion of different stages of training.’”¹ Although higher specialist training examinations are not explicitly mentioned, the introduction of a clear means of ensuring that all doctors have been assessed as competent to practise independently before they are granted a Certificate of Completion of Training (CCT) is an important aspect of the GMC document. There is also inference that a final annual review of competence progression alone is not sufficiently rigorous and that some form of final, standardised assessment (an exit examination) is necessary. It has been acknowledged that an exit examination must be relevant and knowledge based, but its form and content has been left for individual medical Royal Colleges to decide.

Since 2008, psychiatric trainees have been required to sit three written papers and undertake one clinical examination (Clinical Assessment of Skills and Competencies, CASC) before gaining Membership of the Royal College of Psychiatrists (MRCPsych).² Before 2008, trainees would sit two written papers, an Objective Structured Clinical Examination (OSCE) and a long case examination. This increase in written papers was also accompanied by raising examination fees. These changes were viewed negatively by many trainees as it placed them under greater time and financial pressures.³ Further disquiet was caused among trainees in 2011, when it was revealed that the College had made a financial surplus from examination fees.⁴ In response to trainee concerns, the College has reduced the number of written papers to two and also cut exam fees.

In this historical context, there are fears that the introduction of an exit examination might be perceived unfavourably. With this in mind, the Psychiatric Trainees’ Committee (PTC), an elected group of psychiatric trainees from across the UK supported by the Royal College of Psychiatrists, established an Examinations Working Group in 2012, which set the following priorities: to ensure that the exit examination assesses what is really important for new consultants to ensure safe and effective care of patients to ensure the views of trainees have a major role in informing what the examination will look like and what it will assess.

Gaining the views of current trainees and consultants was seen as the necessary first step in working towards these priorities.

Method

Questionnaire development

A questionnaire was created by members of the PTC Examinations Working Group (see online supplement DS1). The first draft was piloted by an opportunistic sample of PTC members to determine where modifications were needed. Advice was obtained from senior officers within the Royal College of Psychiatrists and further modifications were made. In May 2013, the survey was uploaded to www.surveymonkey.com, an online survey hosting website.

A range of free-text responses were available. Owing to the unexpectedly large volume of such comments received, it was retrospectively agreed that they would be reported separately.

Recruitment of participants

An email was sent to all Members and Pre-Membership Psychiatric Trainees included in a mailing list held by the College (see online supplement DS2). In addition, PTC members were encouraged to pass on details of the survey to trainees and consultants locally. The survey commenced on 22 May 2013; responses were accepted up until 29 July 2013 (the initial deadline of 21 June was extended because the rate of responses remained high). All those who opted in to completing the survey were included in the final analysis.

Analysis

Data were separated with respect to participant seniority and by subspecialty. Subspecialty groups comprised both higher trainees and consultants. Given the categorical nature of the data collected, chi-squared tests were applied to identify differences between groups; calculations were performed on GraphPad, an online data analysis tool (<http://graphpad.com/quickcalcs>). It was anticipated that not all those who commenced the survey would complete all sections due to time constraints or distractions. It was agreed beforehand that all who had responded to any given question would be included in the analysis of that part of the survey.

For sample data to be accurate, they need to be representative of the population under consideration. Unfortunately, we were not able to ensure this because of governance difficulties. The mathematical theorems which justify standard statistical procedures apply only to random samples and so our statistical findings cannot be accepted as exact.

Results

Grade and specialty of survey respondents

Overall, 10 298 consultants and trainees were sent an email inviting them to take part in the survey. No email address was available for an additional 371 (3.6%) consultants and trainees in the College database. About a fifth of those contacted ($n = 2082$) started the survey and 1735 completed all sections (83.3%). These respondents included 487 core trainees (23.4%), 509 higher trainees (24.5%), 297 consultants with less than 5 years' experience (14.3%) and 788 consultants with more than 5 years' experience (37.9%).

Among higher trainees and consultants, there was a range of responses across the psychiatric specialties: 222 child and adolescent (10.7%), 146 forensic (7.0%), 810 general adult (38.9%), 117 intellectual disability (5.6%), 275 old age (13.2%) and 53 psychotherapy (2.5%) specialists.

Preferred content of assessment

In general, respondents considered clinical and communication skills to be the most important items to be assessed in an exit examination ($n = 1896$; *Fig. 1*); research methods, medico-legal issues, teaching and education and management were considered of lesser importance.

Examination content preferences by grade

There was little variability in the overall ranking of examination content when the data were separated with respect to seniority of survey participant. Clinical and communication skills were ranked first and second across all groups. Professionalism, team-working skills and leadership skills accounted for the next three components across all grades, although there were minor variations in their order, with senior consultants uniquely rating team-working skills above professionalism. In all groups, management skills, teaching skills and medico-legal issues were the next three components. Senior consultants considered teaching skills to be more important than the other two components, but consultants with less than 5 years' experience considered teaching skills less important, with a greater emphasis on management and

medico-legal skills. In all groups, research skills were considered to be the least important component of any proposed exit examination.

Consultants and trainees differed in their views regarding whether the exit examination should be specialty specific, general or a mixture of the two ($P < 0.001$; *Fig. 2*). The majority of trainees ($n = 472$; 52.3%), including 58.4% of higher trainees, thought that an exit examination should be unique to each psychiatric subspecialty, whereas consultants were predominantly of the opinion that it should comprise both subspecialty and general components (57.3% of all consultant participants).

Fig. 20: Preferences about subspecialty specificity by grade (%)

Examination content preferences by subspecialty

Despite the fact that the general pattern of rankings of examination content was similar to the overall ratings across subspecialties, there were some notable differences between specialty groups.

Clinical and communication skills were again ranked first and second in terms of importance for inclusion in an exit examination across all specialties. As was the case when the item rankings were separated by grade, professionalism, team-working and leadership were ranked in positions 3–5 across all specialties, although team-working skills were considered particularly important by those from the general adult, old age and medical psychotherapy Faculties.

Management and teaching skills were the items considered next by all groups except forensic psychiatrists. Forensic psychiatrists rated medico-legal skills higher than all other subspecialties at 6th v. 8th by all others. There was again a consistent view that research skills were the least important item to assess as part of an exit examination.

All subspecialties were consistent in favouring a mixture of subspecialty and general components to any proposed exit examination, with the exception of child and adolescent psychiatry, where 63.6% of respondents favoured a subspecialty-specific exit examination ($P < 0.001$).

Structure preferences

Across the whole sample ($n = 1818$) the majority of respondents ($n = 922$, 50.7%) were in favour of a mixture of practical, written and oral components; 361 (19.9%) favoured an oral examination alone, 285 (15.7%) opted for a practical examination and for 250 (13.8%) a written examination was the preferred option.

There were no significant differences between core and higher trainees in the overall distribution of responses given ($P = 0.65$). A mixture of practical, written and oral examination components was the preferred option across all groups regardless of grade, but significantly more popular with consultants (with a clear majority in favour) than trainees ($P < 0.0001$). On the other hand, a purely written examination was significantly more popular with trainees than with consultants ($P < 0.001$; *Fig. 3*).

A mixture of all three examination components was favoured by participants from all subspecialties. More than half of all participants preferred this option in all subspecialties except for intellectual disability psychiatry and there was a significant difference in the exam structure preferred by intellectual disability psychiatrists compared with the other subspecialties ($P = 0.003$). No significant differences were noted between the preferred exit examination structure of the other disciplines ($P = 0.25$).

Preferences for a written examination

We received 1818 responses about preferences regarding the format of the written component of any proposed exit examination. The most popular option overall was a reflective report about a clinical scenario and associated *viva* (37.2%). Short-answer questions and multiple choice questions (MCQs) were less popular, representing 23.3% and 23.2% of responses respectively. The least popular options were extended matching questions (EMQs; 10.1%) and essay writing (6.2%).

There was evidence of a clear difference in the preferred format of a written examination between trainees and consultants ($P < 0.0001$). Overall, trainees preferred MCQs (36.2%); however, core trainees were significantly more likely to favour MCQs than higher trainees ($P = 0.001$). The opposite was true with EMQs, with higher trainees being significantly more in favour of their use than core trainees ($P = 0.009$). Among consultants, only 11.5% favoured the use of MCQs; reflective report accompanied by a *viva* was the most popular option for the written component of the exit examination (44%). Essays were the least popular form of assessment by those of all grades, although consultants were nevertheless significantly more in favour of their use than trainees ($P = 0.007$).

There was a significant difference in views about how written examination components should be structured across the subspecialties ($P = 0.001$). Significantly more psychotherapists ($n = 31$, 70.5%) preferred the use of reflective writing and an associated *viva* than the other subspecialties ($P < 0.0001$). Excluding psychotherapy, there were no significant differences between subspecialties regarding their views about the use of MCQs ($P = 0.98$), EMQs ($P = 0.1$), brief assessment questions ($P = 0.12$) and essay writing ($P = 0.21$). There was evidence of a significant difference with regard to views about reflective practice ($P = 0.03$): this was popular among intellectual disability psychiatrists (48.1%) yet less favoured by forensic psychiatrists (30.1%).

Preferences for a practical examination

For two-thirds of respondents ($n = 1197$, 65.8%) assessments in the workplace (workplace-based assessments, WPBAs) were the preferred option for a practical examination; 621 (34.2%) were more in favour of the OSCE format. Higher and core trainees expressed a strong preference for the use of WPBAs over OSCEs, with a strong preference in both groups (80% of higher trainees ($n = 353$) and 80.4% of core trainees ($n = 336$)). Consultant psychiatrists favoured WPBAs over OSCEs and no significant difference between less experienced and more experienced consultants was found ($n = 147$, 58.1% v. $n = 361$, 51.1%; $P = 0.067$). On the other hand, there was greater support among trainee psychiatrists for WPBAs than among consultants ($n = 689$, 80.2% v. $n = 508$, 53.0%); this was a highly significant difference ($P < 0.0001$).

Preferences for an oral examination

Across all participants in the survey ($n = 1818$), 677 (37.2%) considered a structured *viva* to be the best option for an oral examination; 434 (23.9%) chose patient management problems (PMPs) and 707 (38.9%) opted for a combination of the two. There was no significant difference between the views of core and higher trainees ($P = 0.38$), who overall favoured the use of a structured *viva* alone (334 of 859 responses, 38.9%). Among consultants, the most popular type of oral examination was a combination of both structured *viva* and PMPs (427 of 959 responses, 44.5%), with no difference between consultants with more than 5 or less than 5 years' experience ($P = 0.79$). There was, however, a significant difference in the consultants' and trainees' preferences regarding any proposed oral examination components ($P < 0.0001$).

A mixture of PMPs and structured *viva* was the most popular oral examination structure for specialists in child and adolescent psychiatry (43.1%, $n = 197$), forensic psychiatry (45.9%, $n = 133$), general adult psychiatry (40.8%, $n = 701$) and intellectual disability psychiatry (42.6%, $n = 108$). Specialists in old age psychiatry and psychotherapy both preferred a structured *viva* alone (43.6%, $n = 243$ and 36.4%, $n = 44$). The differences between specialty groups did not reach statistical significance ($P = 0.39$).

A question of awarding a diploma or certificate

Across the whole sample, there was a small majority in favour of awarding a certificate or diploma for any proposed exit examination (50.2%, $n = 1818$); 10.3% were against and 39.5% were unsure or considered this matter unimportant. The numbers decreased with seniority, with 61% ($n = 418$) of core trainees, 56.5% ($n = 418$) of higher trainees, 45.5% ($n = 253$) of junior consultants and 41.5% ($n = 706$) of senior consultants considering a diploma to be necessary following successful completion of the proposed exit examination. The views of trainees and consultants were significantly different ($P < 0.0001$).

Discussion

The prospect of an exit examination to be taken by all psychiatric trainees before they are deemed eligible for a CCT is not new. Even before most current psychiatric trainees were born, Kendell⁵ wrote of his disapproval regarding the possible introduction of an exit examination at a time of major changes in the structure of postgraduate medical education in the UK. Kendell identified potential problems, including likely trainee dissatisfaction and the implications for recruitment into psychiatry. He expressed particular concern about the possible outcomes for those trainees who were unsuccessful in such exit examinations.

In the early 1990s, after the publication of the Calman report,⁶ both the then president of the Royal College of Psychiatrists⁷ and the Collegiate Trainees Committee⁸ (the predecessor to the PTC) spoke out strongly against the possibility of introduction of an exit examination.

Ten years ago, Tyrer & Oyebode⁹ discussed the need for changes to the College membership examinations. They acknowledged that political and other external factors would continue to have an influence on how doctors training to be psychiatrists would be assessed, predicting the likelihood of an exit examination being introduced at some point in the future. Around that time, major changes to the role and function of the GMC were proposed following the publication of the 5th report of the Shipman Inquiry¹⁰ and an associated growing public interest in the training and monitoring of doctors in the UK. In the intervening decade, there have been a number of reports highlighting concerns about patient safety and quality of care provided under the auspices of the National Health Service.^{11,12}

This paper presents one of the first psychiatry trainee- and consultant-wide surveys into exit examination of UK psychiatrists. The survey had a very large number of responses, giving insight into the views of about 2000 consultants and trainees from across the country. This no doubt reflects the understandable anxiety raised by the prospect of an exit examination. Owing to the number of responses we received, free-text comments were not included within this paper, nevertheless they are likely to provide an invaluable range of views that will further assist the College in ensuring that any future exit examination reflects the views of the College members and pre-membership trainees.

It is perhaps surprising that clinical and communication skills were considered the most important factors to be assessed, given that previous studies have demonstrated that these are the areas in which most new consultants feel relatively confident; resource management and supervision have been shown as areas in which new consultants feel underprepared by their training and might therefore be considered more important to assess towards the end of training.¹³ This may reflect the fact that trainees consider an 'examination' to be a concrete test of clinical or communication skill or knowledge and may not have considered other assessments, such as reflective writing, to be an 'examination'. An example of such an alternative assessment is the piloted Wessex advanced training professionalism programme.¹⁴

The degree to which an exit assessment should be generic for all trainees or should concentrate on testing subspecialty-specific knowledge varied significantly depending on the participant's status. Trainees were significantly more in favour of subspecialty-specific examinations, whereas consultants, particularly those with more experience, favoured a greater mixture of general and specialty-specific assessments. This may reflect the fact that on completion of the MRCPsych examinations, trainees feel confident with general psychiatry and that they consider a detailed knowledge of their subspecialty to be the primary goal of higher training. Those with more experience may value maintaining a broader skills base across the psychiatric disciplines. However, the recent publication of the *Shape of Training* review¹⁵ and its suggestion of broad-based training and post-Certificate of Specialty Training credentialing may complicate the issue of both when this assessment should take place in training and whether or not there is value in it being general across all psychiatric subspecialties.

Overall, the participants leaned towards a mixture of several different assessment styles for an exit examination. This finding could be explained by a perception that multi-modal assessment techniques increase the fairness, reliability and validity of an examination. Concerns have been expressed in the past by both trainees and consultants that changes made to psychiatric examinations (such as the introduction of CASC in 2008) did little to improve the validity and reliability of clinical examination.¹⁶

Exploration of views about the awarding of a diploma or similar certificate following successful completion of the exit examination revealed differences between trainees and consultants. A significant majority of trainees thought that such a reward should be provided, yet consultants differed markedly in their view. Given the potential difficulties in marketing the introduction of an exit examination to trainees, this difference in opinion might be something that the College should consider carefully.

Limitations

Despite the many strengths of this study, it is important to note that in pursuit of a wide range of responses, we were obliged to accept a number of methodological weaknesses that should be considered when interpreting the results. A study of this type is difficult to undertake in such a way as to encourage responses from a broad and representative audience; one of our principal goals was to gain the views from as many relevant individuals as possible. Given the subject investigated, it was essential to allow anonymous responses to the survey and this further limited our ability to control the recruitment of participants. Any sampling technique that would ensure a more demonstrably representative selection of views would have been associated with markedly fewer participants and might have led to the study being unfeasible, because of the difficulties in negotiating the relevant information governance arrangements of the Royal College of Psychiatrists. On balance, we agreed that the best way to obtain as representative a sample as possible in an acceptably efficient fashion would be to accept all responses from an open survey sent to all consultant psychiatrists and trainees known to the College. Consultants comprised 70% of those who were invited to participate, but only 52% of those who participated in the survey. It is perhaps unsurprising that this study would be of greater interest to those more likely to be directly affected by the introduction of an exit examination, but the possibility of bias should be borne in mind when considering results relating to the sample as a whole. We anticipated that the concerns about randomisation were likely to be magnified with regard to the data provided regarding the subspecialties. However, after comparing the survey data with a breakdown of the workforce as detailed in the most recently published census of the College membership,¹⁷ the distribution of survey respondents and the census data were broadly similar with respect to subspecialty, although the relatively small number of responses from psychotherapy and intellectual disability consultants might make their comments less representative.

In summary, this survey provides an interesting insight into the views of a wide range of trainee and consultant psychiatrists on the nature of any future exit examination. It suggests that overall trainee and consultant psychiatrists consider that if introduced, an exit examination should primarily focus on clinical and communication skills, should assess both generic and subspecialty-specific skills, and should be undertaken using a mixture of different assessment techniques.

1.8.62 New patient assessment in old age psychiatry: the importance of risk assessment

2015-10

Abstract

Aims and method In recent years, the role of non-medical community mental health team (CMHT) clinicians has widened to include new patient assessments. It is unclear whether all professionals have the skills and confidence to undertake these to a high quality. This project investigated which professionals are doing new assessments, evaluated their quality and explored the assessors' unmet training needs. The study was based on the data extracted from electronic notes and a complete audit cycle in South Oxfordshire Older Adults CMHT; this was a cross-sectional study across Oxfordshire older adults services.

Results Most new assessments (72.4%) were done by non-medical clinicians; the majority were missing important information, especially relating to medications and risk assessment. Only 75% of assessors felt at least 'partially confident' to do assessments and found them stressful, with 86% keen to undertake further training.

Clinical implications Simple measures such as an assessment form, a programme of training seminars and adequate supervision, delivered to all CMHT clinicians, can ensure high-quality assessment in diverse clinical environments.

The discipline of psychiatry has seen many changes in practice over recent years. One major change has been the shifting roles of the multidisciplinary team to include some clinical duties traditionally undertaken by psychiatrists.

New patient assessments are one task now frequently delegated to the wider multidisciplinary team.¹ Non-medical clinicians often have capacity to see the increasing number of referrals arising from an aging population and are a more affordable option than psychiatrists.

Psychiatrists are taught assessment skills gradually throughout their training. Formal teaching in assessment occurs throughout medical school and the foundation programme; skills are then enhanced and specialised within psychiatry through weekly supervision, workplace-based assessments and postgraduate examinations. The same structure (focusing on assessment) is not necessarily in place for non-medical professionals. The revised General Medical Council (GMC) *Good Medical Practice* document provides guidance to doctors needing to delegate tasks to colleagues: ‘When delegating care you must be satisfied that the person to whom you delegate has the knowledge, skills and experience to provide the relevant care or treatment; or that the person will be adequately supervised’.² Typically, non-medical clinicians are provided with a weekly team meeting in which to discuss patients with psychiatrists as well as regular individual supervision. It has been assumed that this is providing appropriate support and supervision. However, there is limited evidence pertaining to the skills and confidence that non-medical staff have in assessing newly referred patients. A report by the Royal College of Nursing has highlighted a need for continuing postgraduate education to ensure high standards of community psychiatric nursing, including updating skills as an individual’s role within a team changes.³ Similarly, the recent Francis inquiry emphasised the importance of ensuring individuals’ skills are appropriately matched to their duties to ensure global high-quality care within the National Health Service (NHS).⁴ Being asked to perform skills beyond a clinician’s training can be stressful and reduce performance as well as leading to burn-out.⁵

We hypothesised that as non-medical clinicians have been asked to undertake new patient assessments, a skills gap has emerged. We designed a service evaluation to test this hypothesis. The aims were to identify which professionals are undertaking new assessments, investigate the quality of these assessments and explore the level of confidence individuals have in carrying out this work. The primary method of investigation was a complete audit cycle, complemented by a cross-sectional survey.

Method

This was a service evaluation undertaken in the three community mental health teams (CMHTs) of the South Locality Older Adults Service (Oxford Health NHS Foundation Trust). South Oxfordshire has a population of approximately 134 300, including 33 200 people over 60 years of age.⁶ The service evaluation was made up of three components occurring between June 2012 and July 2013 (*Fig. 1*). All of the components of the service evaluation were carried out in the same group of clinicians.

Fig. 21: Timeline of events

Audit cycle

The aim was to determine if existing practice meets agreed standards as to what information should be recorded during a routine new patient assessment. The initial audit covered the period 1 June to 31 July 2012, re-audited for 1 June to 31 July 2013. All consecutive new referrals were included. No international or nationally agreed guidelines as to how a new patient should be assessed could be located in either 2012 or 2013, so the proxy standard used within Oxford Health NHS Foundation Trust was chosen. This includes the completion of each section of the ‘core assessment’ and ‘risk assessment’ of our RiO electronic notes system (www.servelec-group.com/Healthcare/RiO.html). Medical records were reviewed (by R.M.) first in November 2012 and then in August/September 2013: an audit tool form was completed for each individual. For each part of the assessment, if any comment was present pertaining to that area it was marked ‘yes’. This included explanations as to why information was not available at that time. During October 2012–January 2013, a pilot set of 2-h training seminars and interactive workshops covering common psychiatric presentations were delivered weekly to multidisciplinary team clinicians. A new patient assessment form was introduced at the same time (available as online supplement DS1).

Cross-sectional survey of non-medical clinicians' training needs

We devised a 21-item questionnaire (online supplement DS2) covering confidence surrounding current assessment and education, plus unmet training need. This was distributed by email to 50 non-medical staff in 3 older-adult CMHTs. These included nursing staff, occupational therapists, social workers, mental health practitioners and psychologists. Healthcare assistants and support workers were excluded as they do not undertake new patient assessments. Participants returned an anonymous hard copy to their team manager.

Retrospective evaluation of professionals undertaking new patient assessments

All patient contacts (new and follow-ups) covering the period 1 March 2012 to 30 April 2013 were downloaded from the RiO electronic notes system. The profession of the assessing clinician was recorded as 'medical' (consultants and junior doctors) or 'non-medical' and proportions in each category calculated.

Upon the completion of the audit cycle and survey, and using feedback from the pilot training sessions, a programme of training in assessment skills was devised. This will be delivered by psychiatrists over 7 weeks on a yearly basis to all CMHT clinicians. Staff turnover and sickness will be closely monitored.

Statistical analysis

All results were entered into a Microsoft Excel spreadsheet for basic analysis. Audit data were analysed with SPSS v. 21 for Windows using unpaired chi-squared tests with $\alpha = 0.05$.

Results

Audit cycle

In the initial audit, 40 consecutive referrals were received; this increased to 62 in 2013. The demographic profile of the sample remained unchanged for both audit cycles (*Table 1*). The professionals conducting assessments were community psychiatric nurses (CPNs; 64%), psychiatrists (20%) and occupational therapists (16%). Of the psychiatrists, there were three consultants and three psychiatric trainees.

Results from audit cycle: sample characteristics

	2012	2013
Gender, male (%)	44.0	42.5
Age, mean (years)	79.5	80.0
Referral from primary care (%)	93.0	95.0
Time from assessment to documentation complete (days)	4.4	3.8

In 2012, the proportion of assessments clearly marked 'new assessment' and properly structured with subheadings was 45%; this increased to 75% in 2013 after the introduction of an assessment form ($P = 0.003$). In 2012, the information most frequently omitted from assessment was medication history, family history, use of substances and risk assessment

(Table 2). With non-psychiatrist clinicians, there was a tendency to list all living family members under family history rather than record the presence or absence of mental disorder. However, this was not the case in assessments done by psychiatrists (e.g. 2013: 83% v. 0%). By 2013 there had been a significant improvement in recording of psychiatric history, medications, substance use, mental state examination and risks (Fig. 2). However, out of 17 RiO subsections, only 7 had been completed in at least 75% of assessments. Psychiatrists were significantly more likely to record at least 90% of RiO sections than non-medical staff (81% v. 10% respectively; $P < 0.001$).

Results from audit cycle: assessments

Chi-squared test. Non-significant P values not given.

Evaluation of cognition is an important part of assessment in older adults. In 2012, 70% of assessments included information on cognition and bedside cognitive tests; this fell to 58% in 2013 ($P = 0.04$). However, for patients referred with cognitive impairment, more than 95% had evidence of cognitive testing in both years.

Cross-sectional survey of assessment confidence and unmet training needs

This survey took place between the two audits but before the pilot intervention (*Table 3*). Overall, 36 questionnaires were returned (72%), representing CPNs (50%), social workers (17%) and occupational therapists (17%). Three-quarters (75%) of respondents felt at least 'partially confident' to assess a new patient, with 22% reporting 'no confidence'. Similarly, 75% reported feeling 'stressed or unsupported' while doing the assessment. Less than half of staff (44%) reported familiarity with the ICD-10 criteria for mental health disorders,⁸ and only 25% felt confident to use them to aid diagnosis. The majority of staff (80%) felt confident to 'cluster' patients according to type and severity of illness.

CPN, community psychiatric nurse.

Only 'Yes' responses given.

In all, 86% were keen for training in assessment, diagnosis and management of mental disorder. The conditions for which training was most frequently requested were (in order) bipolar disorder, depression, anxiety disorders, schizophrenia, personality disorders and dementia. The most popular methods of delivering training were seminars (83%) and 1-day short courses (78%). Most staff (85%) felt it was essential to have accreditation recognised by employers for attending training.

Retrospective evaluation of professionals undertaking new patient assessments

Between March 2012 and April 2013, 485 new patient assessments were carried out within South Locality CMHT. In total, 41 individual clinicians were involved in the assessments, with 84% of assessments being conducted by one person. The breakdown of professionals involved was as follows: 60% CPNs, 20% psychiatrists, 16% occupational therapists, 4% social workers. The majority of new patient assessments were carried out by non-medical clinicians: 72.4% v. 27.6%. Similarly, 86.2% of follow-up contacts were carried out by non-medical staff. Of the new assessments by medical staff, 58% were done by consultants.

Staff turnover and sickness

During the period from June 2012 to June 2013 the turnover of non-medical clinicians within the CMHT was 50% (compared with 12% trust wide).⁸ The average within the trust at that time was 8%. At the time of the initial audit, 12% of staff were on long-term sick leave, including two band 7 nurses (1.8% trust wide).

Discussion

This service evaluation investigated which professionals are undertaking new patient assessments and investigated unmet training needs of the clinicians involved. We hypothesised that a skills gap has emerged as more non-medical clinicians have started to participate in assessments and that they find these new duties very stressful; our results corresponded with this hypothesis.

The Royal College of Psychiatrists recommends that CMHTs should ‘ensure the appropriate numbers of professionals with appropriate skills and competencies are in place to respond to local needs ... for assessment’.⁹ Our surveys and audit clearly show that the majority of new patient assessments are now being done by non-medical clinicians and that they frequently do not feel confident to undertake this role. Not only does this pose clinical risks, but also contributes to rising financial costs due to high rates of stress-related sickness and rapid staff turnover. Our local experience is that many staff on long-term sick leave are experiencing ‘stress, anxiety or depression’; this tallies with national data.^{5,8} The way that mental health services commissioning is now linked to diagnostic clustering means that poor knowledge of diagnostic categories and grading of severity of mental health disorders could have financial implications. These implications could be reduced by providing appropriate training. Adequate knowledge of the local area and its resources is also important and this is hard to achieve with high staff turnover.

Our initial audit highlighted the poor quality of risk assessments undertaken during new patient assessments. Recent publications have alerted us to the need for high-quality risk assessment in older adults, especially for suicide and self-harm.¹⁰ This was an area of great concern in the 2012 audit, but the 2013 re-audit demonstrated that very simple measures – an assessment form and some pilot teaching sessions – made a significant improvement in our teams’ skills and documentation. Similarly, Huh *et al*¹¹ report that a 1-day course in suicide risk assessment for healthcare professionals working with older adults was highly effective at increasing staff confidence and the quality of risk assessment. The Department of Health has previously emphasised the need to provide a range of flexible approaches to education and training,¹² and this is especially important as we increasingly recognise different styles of learning and diversify our working patterns. Key to this will be standardising access to training, for example making sure that all professionals have similar amounts of study leave provision.

We demonstrated that the majority of staff would like to undertake further training in the form of seminars or short courses, and would like accreditation for this. We have been unable to find any similar audit or research data with which to compare our results, but the Royal College of Nursing reports similar findings.³ Their survey of over 800 UK mental health nurses found that 89% would like further training in ‘acute mental health conditions’ and the favoured delivery methods were also teaching sessions or short courses. This work only included nurses, whereas our study includes all non-medical clinicians, but the demographics are otherwise similar. It could be argued that the ‘team’ nature of CMHTs (e.g. having staff supervision and a multidisciplinary team meeting at which new cases are presented to the consultant) allows for appropriate clinical guidance, but we have found it can be difficult to provide such guidance when faced with a lack of information gathered at an initial assessment.

Limitations

The main limitation of this service evaluation is the sample size and the fact that it covers only one geographic area. It might also be hard to generalise to outside older adult psychiatry. The response rate for the questionnaire was low, which may be partially explained by the work having occurred during the holiday season, but other ways of reaching staff need to be investigated. It should also be remembered that staff have highly variable experience in terms of the years of practice; we cannot expect newly qualified colleagues to be comparable to those with more years of service and we did not collect this information.

Assessment training

We propose to improve standards in new patient assessment and increase clinicians' skills and confidence in our area by providing a comprehensive training programme within normal working hours for all non-medical clinicians and junior doctors in the CMHT. This will be delivered as seven 2–3-h interactive seminars and will cover general assessment, risk assessment and management of common disorders presenting to old age psychiatry (see online supplement DS3). It will be provided at least yearly to include all incoming staff and, while led by consultants, will provide a platform for psychiatric trainees to enhance their teaching skills. Re-audits of new patient assessment structure and content will occur yearly.

Assessment is the foundation of high-quality management in psychiatry: we should work hard to ensure that all clinicians are appropriately skilled and supported to manage the vulnerable patients presenting to our services.¹³ Psychiatrists should take a leading role in delivering appropriate knowledge whereas mental health trusts should facilitate training and seek ways to encourage and reward aspiration.

We thank all staff of the South Locality team for assisting with data collection and providing support with the project. Special thanks go to Marion Evans who downloaded the RiO data to establish who had undertaken assessments between 2012 and 2013.

1.8.63 Lurasidone: a novel antipsychotic agent for the treatment of schizophrenia and bipolar depression

Antony Loebel Leslie Citrome Correspondence to: Leslie Citrome (citrome@cnsconsultant.com)¹

date

2015-10

Abstract

Lurasidone is a novel antipsychotic agent approved for the treatment of schizophrenia in a number of countries including the UK, and is also approved in the USA and Canada for the treatment of major depressive episodes associated with bipolar I disorder as either a monotherapy or adjunctive therapy with lithium or valproate. In addition to full antagonist activity at dopamine D₂ ($K_{i(D2)} = 1$ nM) and serotonin 5-HT_{2A} ($K_{i(5-HT2A)} = 0.5$ nM) receptors, the pharmacodynamic profile of lurasidone is notable for its high affinity for serotonin 5-HT₇ receptors ($K_{i(5-HT7)} = 0.5$ nM) and its partial

agonist activity at 5-HT_{1A} receptors ($K_{i(5-HT_{1A})} = 6.4$ nM). Long-term treatment of schizophrenia with lurasidone has been shown to reduce the risk of relapse. Lurasidone appears associated with minimal effects on body weight and low risk for clinically meaningful alterations in glucose, lipids or electrocardiogram parameters.

 - *Summary*

Lurasidone is a second-generation antipsychotic agent that initially received regulatory approval for the treatment of adults with schizophrenia in the USA in 2010.^{1,2} In March 2014, it received marketing authorisation for this indication by the European Medicines Agency and has also been approved for the treatment of schizophrenia in Switzerland, Canada and Australia. Additionally, lurasidone recently received US and Canadian regulatory approval for the treatment of adults with major depressive episodes associated with bipolar I disorder (bipolar depression), as either a monotherapy or adjunctive therapy with lithium or valproate. Detailed systematic reviews of the overall efficacy, tolerability, safety and place in therapy of lurasidone can be found elsewhere,^{3,4} including analyses of number needed to treat (NNT) and number needed to harm (NNH).^{5,6}

The published literature has used the US convention of describing the dose of lurasidone as the combined weight of the active drug moiety (lurasidone) plus the hydrochloride (HCl) salt, with tablet strength expressed in multiples of 20 mg. In the European Medicines Agency *Summary of Product Characteristics*,² tablet strength refers to the weight of active drug only, excluding the contribution from the HCl salt (*Table 1* shows the dose equivalence), and this dose convention will be used in the current review.

Lurasidone dose equivalents in the European Union (EU) and the USA

EU doses (mg, active moiety)	US doses (mg, HCl salt)
18.5	20
37	40
56a	60
74	80
111a	120
148a	160b

Tablet strength not available in the EU.

Tablet strength not available in the USA.

The purpose of this overview is to describe the pharmacodynamics and pharmacokinetics of lurasidone, and to summarise its efficacy and safety for the treatment of schizophrenia and bipolar depression based on results from both short-term and longer-term controlled clinical trials. Relevant information regarding switching and extension studies is reported, including functional and cognitive outcomes.

Pharmacodynamics and pharmacokinetics

Similar to most other second-generation antipsychotic agents, lurasidone is a full antagonist at dopamine D₂ and serotonin 5-HT_{2A} receptors, with binding affinities $K_i = 1$ nM and $K_i = 0.5$ nM, respectively.⁷ In addition, lurasidone is distinguished by its high affinity for serotonin 5-HT₇ receptors ($K_i = 0.5$ nM; comparable with dopamine D₂ and 5-HT_{2A} receptors) and by its partial agonist activity at 5-HT_{1A} receptors ($K_i = 6.4$ nM).⁷ The serotonin 5-HT₇ receptor is a target of interest that may be associated with the potential for both pro-cognitive and antidepressant effects,^{8,9} whereas the 5-HT_{1A} receptor may have a role in the treatment of major depressive disorder¹⁰ and schizophrenia.¹¹ Lurasidone lacks affinity for histamine H₁ and muscarinic M₁ receptors.

The pharmacokinetic profile of lurasidone is consistent with once-daily administration, with an elimination half-life of 20–40 h.² Mean C_{max} and area under the curve (AUC) for lurasidone were approximately threefold and twofold greater, respectively, in a comparison of administration with food *v.* fasting.¹² Based on these data, and results from clinical trials, it is recommended that lurasidone be taken once daily in the evening, with a meal or within 30 min after eating.^{1,2} Lurasidone absorption is independent of food fat content.¹²

Metabolisation

Lurasidone is metabolised primarily via CYP3A4 and, consequently, its use is contraindicated in the presence of strong inducers and inhibitors of CYP3A4. In the presence of moderate inhibitors of CYP3A4, the recommended starting dose of lurasidone is 18.5 mg/day instead of the usual recommended 37 mg/day, and the highest recommended dose is 74 mg/day instead of the regular maximum recommended dose of 148 mg/day. Lurasidone does not affect the pharmacokinetics of other drugs including lithium, valproate or agents that are metabolised by the CYP3A4 pathway.¹³

Examination of population subgroups based on gender, age and ethnic background did not reveal any clear evidence of differential response to lurasidone,^{1,2} however, Asian subjects had one-and-a-half-fold increased exposure to lurasidone compared with White subjects.² Clinical studies with lurasidone did not include sufficient numbers of patients aged 65 and older to establish whether dose adjustment is necessary on the basis of age alone. In patients with moderate or severe renal or hepatic impairment, the recommended starting dose is 18.5 mg/day; the maximum dose should not exceed 74 mg/day in moderate to severe renal impairment or moderate hepatic impairment and 37 mg/day in severe hepatic impairment.

Efficacy in schizophrenia

Acute treatment

Based on a robust registration programme that included five informative and similarly designed 6-week, fixed-dose, placebo-controlled studies,¹⁴⁻¹⁸ lurasidone is approved for the treatment of schizophrenia within a dose range of 37–148 mg/day. Reductions in the Brief Psychiatric Rating Scale¹⁹ or Positive and Negative Syndrome Scale (PANSS)²⁰ total scores were consistently greater for lurasidone compared with placebo across the approved dose range. A starting dose of 37 mg/day has demonstrated significant efficacy, thus no initial dose titration is necessary. Subsequent dose increases can be made based on clinician judgement, typically in increments of 37 mg at approximately weekly intervals. Patients with suboptimal symptom control at lower doses of lurasidone may benefit from higher doses. The NNT of lurasidone (v. placebo) for a 30% reduction in PANSS total score was 4 (95% CI 3–5) for lurasidone 148 mg/day compared with 6 (95% CI 5–10) at 37 mg/day.⁵

The short-term effectiveness of lurasidone has also been evaluated in a study in which clinically stable but symptomatic out-patients with schizophrenia or schizoaffective disorder were switched from their current antipsychotic medication to lurasidone in a 6-week study that examined the efficacy and tolerability of three different dosing strategies (starting at 37 mg/day for 2 weeks, v. starting at 74 mg/day for 2 weeks, v. starting at 37 mg/day for 1 week followed by 74 mg/day the second week).²¹ The primary outcome was time to treatment failure, defined as any occurrence of insufficient clinical response, exacerbation of underlying disease or discontinuation due to an adverse event. No clinically relevant differences were observed among the three groups in efficacy or tolerability outcomes; treatment failure rates were low for all three switch groups (~8%).

Long-term treatment

Longer-term data for lurasidone in patients with schizophrenia are available based on randomised, double-blind, 12-month trials that include comparisons with risperidone in a safety study,²² and quetiapine extended-release (XR) in a double-blind extension to one of the short-term pivotal trials.²³ In the risperidone comparator study, treatment with lurasidone was associated with comparable improvement in efficacy, with similar relapse rates at 12 months. In the quetiapine XR comparator study, lurasidone was non-inferior to quetiapine XR in risk for relapse. At 12 months, treatment with lurasidone (modal daily dose 111 mg) was associated with a significantly greater improvement in PANSS total score compared with quetiapine XR (modal daily dose 600 mg), numerically lower risk of relapse (23.7% v. 33.6%; $P = 0.280$; *Fig. 1a*), significantly lower risk of re-hospitalisation at 12 months (9.8% v. 23.1%; log-rank $P = 0.049$; *Fig. 1b*) and significantly higher rates of remission (61.9% v. 46.3%; $P = 0.043$; *Fig. 1c*). In the same study, a computerised cognitive battery (Cogstate; <http://cogstate.com>) was administered at the end of 6 weeks of acute double-blind treatment and after 6 months of double-blind extension treatment. At both time points, treatment with lurasidone was associated with significantly greater improvement in cognition compared with quetiapine XR, with a moderate effect size.²⁴

The long-term effectiveness of lurasidone in the treatment of schizophrenia has also been evaluated in two open-label extension studies. In the first, a 6-month extension of the switch study summarised above,²⁵ the mean PANSS total score continued to show improvement. Moreover, low rates were observed for both psychiatric emergency services utilisation (mean: 0.8% per month) and contact with the criminal justice system (mean: 1.8% per month).²⁵ In a second open-label extension study in which patients received 6 months of treatment with lurasidone, antipsychotic efficacy was maintained, with further reduction observed in mean PANSS total scores, in patients who had initially received lurasidone, olanzapine or placebo during the acute treatment phase.²⁶

Preliminary results of a double-blind, randomised withdrawal study examining the maintenance of efficacy of lurasidone treatment in patients with chronic schizophrenia have been presented.²⁷ Patients experiencing an acute exacerbation of schizophrenia received flexible doses of lurasidone (37 or 74 mg/day) during a 12- to 24-week open-label stabilisation phase. Those who maintained clinical stability for 12 weeks entered a 28-week, double-blind withdrawal phase and were randomised to receive either lurasidone (at the same dose they were receiving at completion of the stabilisation phase) or placebo. Lurasidone significantly delayed time to relapse compared with placebo (log-rank test $P = 0.039$) and was associated with a 34% reduction in risk of relapse (Cox proportional hazard model ratio 0.66 (95% CI 0.45–0.98); $P = 0.041$).

Tolerability and safety

Commonly observed adverse reactions in short-term trials in schizophrenia (incidence on lurasidone 5% and twofold greater than placebo) were somnolence (17% v. 7%; NNH = 10), akathisia (13% v. 3%; NNH = 10), nausea (10% v. 5%; NNH = 20) and extrapyramidal symptoms (excluding akathisia and restlessness) 14% v. 6% (NNH = 13).^{1,2} Akathisia and extrapyramidal symptoms appear dose related within the dose range of 18.5 to 111 mg/day.¹ The frequency of akathisia in patients with schizophrenia was 5.6% for 18.5 mg, 10.7% for 37 mg, 12.3% for 74 mg and 22.0% for 111 mg. In a study where lurasidone was administered in the evening,¹⁸ akathisia was reported by 7.4% of patients receiving lurasidone 148 mg/day. It is possible that evening dose administration is associated with more favourable tolerability overall relative to morning dosing. Adverse event frequencies (including movement disorders) reported in the bipolar depression programme, where lurasidone was dosed at night in all studies, were generally lower than observed in patients with schizophrenia.¹ The mean change in weight observed across 6-week trials in schizophrenia was +0.43 kg for lurasidone v. 0.02 kg for placebo.¹ In contrast, mean change in weight was +4.15 kg for olanzapine and +2.09 kg for quetiapine XR in 6-week trials where these agents served as active controls.^{1,17,18} In 6-week trials, the proportion of patients with a clinically meaningful (7%) endpoint increase in body weight was 4.8% for lurasidone v. 3.3% for placebo (NNH = 67; not significant).¹ In contrast, the proportion of patients with clinically significant weight gain during short-term treatment in one comparator study with olanzapine v. placebo was 34% v. 7% (NNH = 4);¹⁷ and the proportion of patients with clinically significant weight gain in a second comparator study with quetiapine XR v. placebo was 15% v. 3% (NNH = 8).¹⁸ The proportion of patients with clinically significant weight gain on lurasidone was similar to the rate for placebo in both comparator studies (NNH > 55).^{17,18}

Longer-term studies for lurasidone are consistent with short-term findings regarding changes in body weight; in a long-term study lurasidone was associated with a mean change in weight of +0.73 kg at month 12, compared with +1.23 kg on quetiapine XR.²

The short-term effect of lurasidone on metabolic variables appears minimal.¹ In pooled short-term (6-week) clinical trials, the mean last observation carried forward (LOCF)-endpoint change in total fasting cholesterol was 0.15 mmol/L for lurasidone and 0.16 mmol/L for placebo;²⁸ for fasting triglycerides it was 0.15 mmol/L for lurasidone and 0.17 mmol/L for placebo;²⁸ and for fasting glucose it was +0.07 mmol/L for lurasidone and +0.03 mmol/L for placebo.²⁸ Long-term data regarding metabolic outcomes extending out to 12 months are consistent with the short-term data.^{1,28} In long-term studies,²⁸ mean LOCF-endpoint change on lurasidone was 0.08 mmol/L for total fasting cholesterol, 0.08 mmol/L for fasting triglycerides and +0.11 mmol/L for fasting glucose.

A moderate dose-dependent increase in prolactin was observed in patients treated with lurasidone, with more pronounced effects in female than in male patients; however, the increase was lower than what is observed with risperidone and haloperidol. In a randomised, 12-month, double-blind safety study comparing lurasidone with risperidone, mean change from baseline to endpoint in serum prolactin levels in men was +2.51 ng/ml for lurasidone and +9.45 ng/ml for risperidone, and in women it was +5.16 ng/ml for lurasidone and +33.90 ng/ml for risperidone.²²

Serial electrocardiograms during short-term and long-term trials indicate that lurasidone, at doses as high as 558 mg/day, does not have a clinically meaningful impact on the QT interval.¹

Bipolar depression

There is an unmet need for efficacious and tolerable treatments for bipolar depression. Patients with bipolar disorder spend most of their symptomatic time in the depressed phase of their illness.²⁹ While multiple agents are approved for the treatment of bipolar mania, there is a paucity of approved medications for the treatment of bipolar depression.³⁰ The older interventions (quetiapine and olanzapine–fluoxetine combination) are as likely to provide therapeutic benefit as adverse effects.³⁰ Cross-study comparisons in populations with bipolar depression suggest that treatment with lurasidone is associated with less sedation than quetiapine and less weight gain than the olanzapine–fluoxetine combination.³⁰

Lurasidone, in the dose range of 18.5–111 mg/day, demonstrated superiority *v.* placebo in two 6-week, randomised, double-blind, placebo-controlled, flexibly-dosed acute studies in patients with major depressive episodes associated with bipolar I disorder, one using lurasidone monotherapy and the other using lurasidone adjunctive with lithium or valproate.^{31,32} As reported by Citrome and colleagues,⁶ monotherapy treatment with lurasidone (*v.* placebo) was associated with an NNT of 5 (95% CI 4–8) for treatment response, defined as 50% reduction from baseline on Montgomery-Åsberg Depression Rating Scale³³ (MADRS) total score; adjunctive therapy with lurasidone was associated with an NNT of 7 (95% CI 4–24). NNT for remission, defined as a final MADRS total score ≤ 12 , was 7 (95% CI 4–14) for lurasidone monotherapy and 7 (95% CI 4–23) for adjunctive lurasidone. These results are comparable with NNT values reported for quetiapine (6 for response, 6 for remission) and olanzapine-fluoxetine combination (4 for response, 5 for remission).

Lurasidone was not associated with clinically meaningful mean weight or metabolic changes compared with placebo in these bipolar depression studies. This is in contrast to olanzapine–fluoxetine combination where the NNH (*v.* placebo) was 6 for clinically meaningful weight gain (7% from baseline).⁶ The three most frequently occurring adverse events with the largest difference in incidence for lurasidone *v.* placebo were nausea (NNH = 17 for monotherapy, NNH = 16 for adjunctive therapy), akathisia (NNH = 15 for monotherapy, NNH = 30 for adjunctive therapy) and somnolence (NNH = 25 for monotherapy, NNH = 19 for adjunctive therapy).⁶ The high NNH of lurasidone for somnolence compares favourably with the NNH of 3 (95% CI 2.2–2.7) reported for quetiapine in studies of bipolar depression, regardless of formulation or dose.⁶

Overall, the results of double-blind trials indicate that lurasidone has a highly favourable benefit/risk ratio for the treatment of bipolar I depression, with ‘single-digit’ NNT (indicating significant efficacy) and ‘double-digit’ or higher NNH (indicating high tolerability).

Summary

Lurasidone represents a new addition to the pharmacological armamentarium available for the treatment of serious mental disorders. It has demonstrated efficacy in the treatment of schizophrenia, within the dose range of 37–148 mg/day, and bipolar depression, within the dose range of 18.5–111 mg/day. Across both indications, treatment with lurasidone appears associated with minimal effects on body weight and low risk for clinically meaningful alterations in glucose, lipids or ECG parameters. Lurasidone’s combination of efficacy in schizophrenia and bipolar depression with minimal metabolic disturbance and little effect on movement disorders and prolactin represents a potentially important clinical advance.³⁴

1.8.64 Experiences of ward rounds among in-patients on an acute mental health ward: a qualitative exploration†

Reed Cappleman Zandra Bamford Clare Dixon Hayley Thomas

Abstract

Aims and method To address the gap in qualitative research examining patients' experiences of ward rounds. In-depth interviews were conducted with five in-patients on an acute mental health ward. Data were analysed using thematic analysis.

Results Data were organised into three first-order themes, positioned within an overarching theme relating to patients' perceptions of the use of power and control within ward rounds.

Clinical implications Systemic factors may make it difficult to facilitate ward rounds in a manner which leaves patients feeling fully empowered or in control, but there are practical measures to address these issues, drawn from participants' accounts.

* *Improving the patient experience*

Ward rounds are seen as a key component of care provision in in-patient psychiatric settings.¹ However, literature in this area has found that they evoke anxiety in a large proportion of patients,^{2,3} particularly when more people are present.⁴ Patients report not feeling listened to and feeling that information is withheld from them.³ Many patients also feel inadequately prepared for ward rounds by staff.⁵ Labib & Brownell³ highlight the scarcity of qualitative investigations in this area and suggest that addressing this may highlight additional unexplored factors affecting patient satisfaction with ward rounds. This study aims to address this need. It was carried out in an acute in-patient unit located in a district general hospital in the north west of England. The need for this project to take place was identified by the unit's psychiatry team, who wished to investigate how ward rounds could be adapted to facilitate patient satisfaction. It was also hoped the project might identify avenues of investigation for future researchers, as per Labib & Brownell's suggestions.³

Method

Participants

Participants were recruited from across three mixed-gender adult acute mental health in-patient wards attached to a general hospital. Each ward has a different consultant attached. Ward rounds within this unit are chaired by psychiatrists and bring together information from members of the multidisciplinary team (nursing, psychology, occupational therapy and psychiatry), followed by a direct review of the patient's progress and mental state, formulating risk and developing treatment plan changes accordingly.

Patients from the wards were eligible to participate if they had experienced two or more ward rounds. Although nine responded favourably and completed informed consent forms, four did not participate: two were unavailable on the days they were due to be interviewed, one declined to take part when approached by the interviewer, and one chose to terminate her interview citing her mental state as non-conducive to participation. Detailed characteristics of the five participants are presented in *Table 1*.

Participant characteristics

Patient	Gender	Age, years	Length of stay on ward, weeks	Ward rounds attended, <i>n</i>	Patient status
Patient A	Female	20	11	Too many to recall	Detained
Patient B	Male	41	4	4	Detained
Patient C	Male	36	5	4	Detained
Patient D	Male	49	2	2	Informal
Patient E	Male	27	1.5	Too many to recall	Detained

Data collection

Ethical approval was granted from a local research ethics committee and research and development department. Participants were recruited following an initial approach being made by an assistant psychologist. All participants were interviewed in the ward's 'quiet room' by R.C., using an interview topic guide (questions included 'Tell me how you've found the ward rounds here so far' and 'How do you feel when you're in the ward round?'). Interviews lasted between 30 and 45 min, were audio-recorded and were transcribed verbatim.

Data analysis

Data were analysed using thematic analysis, a flexible approach for organising large amounts of qualitative data.⁶ Data analysis followed the four conventions for thematic analysis suggested by Braun & Clarke.⁶

1. Familiarisation with the data, re-reading transcripts looking for patterns and meanings.
2. Generating initial codes: organising the data into groups according to content and meaning. Transcripts were then re-coded and initial codes were grouped into 'second-cycle' codes.⁷ For example, initial codes from patient C's transcript, such as 'feeling intimidated' and 'not being co-operative backfires' were subsumed under the second-cycle code 'serious consequences to not behaving in the right way'.
3. Searching for themes: second-cycle codes were grouped together into broader themes and subthemes. For example, codes such as 'staff as a supportive network' and 'approval means more within a good relationship' were grouped together in the development of a theme about the importance of relationships.
4. Reviewing themes: ensuring each theme was coherent and that themes capture the essence of the data. At this point the theme 'power and control' was identified as an overarching theme and remaining themes designated as first-order themes.

Coded transcripts and themes were reviewed by the research team to ensure analysis possessed sufficient quality and rigour.

Results

As the analysis of participants' accounts progressed, data were organised into an overarching theme running throughout the data, representing the data at the highest level of abstraction, and first-level themes representing participants' accounts in less abstract, more concrete ways. The terminology of 'overarching themes' and 'levels of themes' is derived from Braun & Clarke.⁶

First-level theme: not considering the patient's emotional state ('They could possibly take into account a little bit more how you are at that moment in time')

This theme concerns how the majority of participants felt that the ward round process does not take the patient's emotional state into account and actually increased their anxiety at times when it was already high. The theme's title is a quote from patient C, who reported unease at 'probing' questions in the ward round when he was also experiencing feelings of paranoia. Participants frequently admitted to anxiety about discussing personal issues with a group of people, some of whom were unknown to the participant: "'Well ... they can be scary at first ... 'cos there's all different people there, you've got support workers, staff nurse there, there's your consultant, there's a SHO [senior house officer,] there, you can have students there, I could be there, my parents could be there. So it's like a lot of people in the ward review and, er, it's like they're all talking about you' (patient E)."

Another point raised in relation to this theme was the timing of information-giving about the ward round. For example, patient B stated that when the ward round process was initially described to him: "'... they use all this, all this jargon, and you know, when your head's up your arse so to speak, you don't take much of it in, you're just looking at a load of professionals and you don't know what they do.'"

For patient B, information about the ward round which would have helped ameliorate anxiety was given at a time (and by a means) that did not take account of his mental state at that point.

First-level theme: 'behind closed doors' (wanting more involvement in the process)

Participants felt that staff held control over ward round processes and wished for more involvement. Participants described a lack of collaboration in the area of decision-making, where they felt their views were often not taken into account and that decisions were made away from them, without their involvement.

‘... it’s like most of the things they’re behind closed doors, and, and then they let you know, in your review they let you know “right we’re going to follow this, we’re gonna review this”.’ (patient E)

For patient A, the way in which events during ward rounds are documented was an area where control lay with staff and where she wished for more input and collaboration: “‘I think as well you should get like a copy of what they’ve wrote [sic] (...) ‘Cos you don’t know what they write down and stuff, I reckon they should tell you what they’ve wrote down so you could like read it for a bit and then next week feed back on what they’ve said and maybe like, like add things to it or develop what they’ve wrote.’” However, some participants devised ways of being able to have more input into the process, within the parameters they were confronted with. Patient C articulated this using a ‘game playing’ metaphor: ‘it’s gotten better now because I’ve just got some leave you see but I wasn’t entirely aware of how to play the game’. This was linked to the idea of having to adhere to unwritten rules of behaviour in the ward round: ‘there was a charge nurse in the last ward who was getting very frustrated with me because she was trying very clearly to show me the right way to behave and I was digging my heels in’. This resulted in what patient C described as a ‘meet you halfway situation, where if I cooperate with their goals they’ll offer me incentives’.

First-level theme: the importance of relationships ('He's the only one who has listened')

Participants stressed the importance of good relationships with staff and that such relationships had a positive impact on their ward round experiences. The theme is named after a quote from patient D, who said: “‘Like I say, he listened. That’s the main thing. And when you’re in. . . when you’re in the kind of situation I’m in at the moment, if people listen to you it’s half the battle, when you’ve got someone you can talk to, and I felt I could talk to that doctor and he listened.’”

Patient A described finding the ward rounds themselves daunting, but expressed a wish to use positive relationships she’d formed with staff to help her cope with them: “‘If you’re close to that member of staff and they’re sat at the side of you and if you were both speaking together . . . Like that would be good. ‘Cos you’d feel like somebody’s there for you, like, rather than being on your own.’” However, patient A also added that the parameters of these helpful relationships were controlled by staff, who may not always recognise the positive effects of staff relationships on ward round experiences. This could result in the ward round being set up in a way which does not take account of the importance of relationships for patients, for example when there are short-notice changes to which staff attend: ‘it’s nerve-wracking enough going into your ward review and then at last minute, “oh yeah by the way, such and such a person isn’t coming, this person’s coming in”.’

Overarching theme: power and control ('they can keep renewing my section')

The themes so far can be understood as part of an overarching theme relating to power and control. Issues of power and control were implicit within many issues that participants raised. The quote in this theme’s name originates from patient E’s interview, and relates to how some participants described their awareness during ward rounds that staff have the power to decide if they stay in hospital or leave.

Participants often talked about issues of power and control by describing staff in terms of police or other agents of the law. For example, while describing being assessed in ward rounds, patient C stated: ‘yeah, it’s kind of the feeling where, I don’t know if you’ve ever been stopped by the police but they do that kind of thing, you can feel them looking up and down at you . . .’. Such comparisons seemed to arise from participants’ awareness of the assessment function

of ward rounds and professionals' power to determine the outcomes of these assessments. Patient B described how this awareness led to anxiety about the outcome of ward rounds: '... at first, it's like having to tell these people here, if I tell them I'm having these mad thoughts, they're gonna lock me up forever'. As described in the first-level themes, participants felt that professionals hold power and control over how the ward round, and therefore the assessment process within it, is conducted. However, as indicated by the first-level theme 'the power of relationships', participants suggested these issues could be ameliorated by positive, collaborative relationships with staff.

Patient B also described how interpretations of the actions and intentions of those in the ward round may be influenced by previous encounters with those in authority: "'Cos my personal experience of walking into a room with loads of people is walking into a courtroom ... 'Cos they sent me to jail. So, I didn't have a very good experience of loads of people if you like.'" This account suggests that some ward round procedures may evoke patients' negative memories of encounters with powerful figures.

Suggestions for improvements

Participants seemed eager to share their ideas about practical improvements that could be made to ward rounds (*Box 1*). Indeed, in discussion with R.C. during recruitment, participants often cited the desire to share such ideas as their primary motivation for taking part.

Box 1 Participants' suggestions for improvements to ward rounds

- Allow patients access to ward round records and the power to negotiate additions to them
- Invite a smaller number of staff into patients' initial ward rounds and increase the number gradually
- Be open about when patients are being assessed on particular areas of their mental state and why
- Utilise patients' one-to-one time with named nurses so ward rounds can be prepared for
- Issue patients with a booklet about hospital procedures on admission, including information about ward rounds. This would serve as an aide memoire for patients to return to so they can remind themselves of ward round procedures

Discussion

Our participants' accounts lend support to past research indicating that patients may find ward rounds anxiety provoking.^{3,5} In support of previous findings linking ward round size to patient anxiety,^{4,8} participants in this study also spoke of the difficulties in talking to a room containing a large number of people unknown to them. Participants also reported that ward rounds are more distressing if they are already in an anxious or distressed state, an association which has not yet been studied in the quantitative literature. Findings from this study suggest that a lack of well-timed information about ward rounds could also contribute to anxiety.

As hoped, using qualitative methods led to a deeper understanding of participants' ward round experiences than has previously been possible using quantitative methods. It was hoped that more participants would be recruited but this proved difficult within the time available, owing to potential participants' apparent fluctuating mental state and their availability and motivation to take part. Although this is an exploratory study with a small sample, the findings highlight previously unexplored issues that may deserve further investigation. One such area is that of the potential importance to patients of their relationships with professionals and how sensitive use of positive relationships may positively affect the ward round experience. For example, future research might investigate whether anxiety in ward rounds is mitigated by the presence of patients' favoured members of staff, such as named nurses or key-workers.

Improving the patient experience

Study results and participants' suggestions for improvements to ward rounds were fed back to the research site's consultant psychiatrists. This generated discussion around how the practical measures suggested by participants (*Box 1*) may provide safeguards to minimise the issues of power and control that inevitably influence in-patient settings, and how members of other disciplines (e.g. nursing) can play a key role in ensuring that patients feel prepared for ward rounds, supporting them to manage their anxiety in the process. The study's findings contributed to a subsequent reorganisation of ward round procedures at the research site. During the feedback process, the psychiatry team emphasised that continuing cuts to National Health Service in-patient care may lead clinicians to change how they facilitate ward rounds and that keeping the patient experience in mind will be a challenging but essential task.

Using qualitative methods to investigate acute mental health in-patients' experiences of ward rounds led to a richer understanding than has previously been possible using quantitative methods. The findings suggest possible directions for future research into ward rounds and prompted clinical discussions that have informed changes to ward round practice at the research site.

We thank participants who gave their time; Charlene Rouski, James Dudley, Katie Usher and Dr Sarah Jones for their help with recruitment; and the psychiatry team on units K1, K2 and K3 at Royal Bolton Hospital for their support.

1.8.65 Update on the Improving Access to Psychological Therapies programme in England: author's reply†

Sami Timimi

Correspondence

Sami Timimi (stimimi@talk21.com)¹

date

2015-10

Abstract

Fonagy & Clark confirm in their rebuttal that they have an ideological commitment to the failed technical model of understanding and intervening in mental health problems that dominates current service provision. They fail to acknowledge the limitations and problems associated with Improving Access to Psychological Therapies (IAPT) and Children's and Young People's IAPT (CYP-IAPT) and offer an unconvincing explanation for why they did not allow some of the vast tax payers' money that they had at their disposal to be used to implement evidence supported relational models.

Contents

- *Update on the Improving Access to Psychological Therapies programme in England: author's reply†*

I will mainly comment on professors Fonagy and Clark's article¹ as they have attempted an evidence-supported rebuttal. Dr Law's letter² calls for more dialogue, which by itself will not change the implementation fundamentals, whereas Ms Swaile's letter³ points out the obvious – that if you spend more on psychological therapies, more of them will be available – whereas my editorial⁴ was critiquing how this extra available money was spent.

¹

Sami Timimi FRCPsych, is a consultant child and adolescent psychiatrist for Child and Family Services at the Horizon Centre, Lincoln.

Fonagy & Clark's article reminded me why I initially got excited about Children and Young People's Improving Access to Psychological Therapies (CYP-IAPT), with its desire to engage with the evidence and talk of improving access, collaborative working, focusing on outcomes, local learning and so on. My original enthusiasm was misplaced as there is a fatal flaw, which they seem unable to get past – their belief that the poor outcomes and inefficiencies of mainstream services happen because we are not rigorous enough in the way we enforce technical aspects of care. Their ideological intransigence on this matter has created a cartel-like monopoly where existing and successful alternative models have no opportunity to be tried.

Their critique of relational/contextual models (they refer to as 'common factors') is unconvincing. The most rigorous meta-analyses of evidence from randomised controlled trials (RCTs) note that of course papers can be found showing some model differences, but the overall evidence base finds that across presentations by far the biggest factors influencing outcomes have little to do with what we do – so called extra-therapeutic factors (the real-life contexts, beliefs and histories), whereas within therapy it is the therapeutic alliance.⁵ Therapeutic alliance is not a one-dimensional construct and includes, for example, the degree of 'engagement' – a two-way process including understanding what is meaningful to the patient. Thus, if a computer program provides a meaningful methodology for a patient, then that is where their 'alliance' may form.

The authors predictably avoid bigger issues with National Institute for Health and Care Excellence (NICE)-guideline-derived evidence-based-therapies (EBTs). In mental health (unlike the rest of medicine), NICE guidelines are eminence not evidence based, in other words they rely more on who was on the guideline group than what the evidence says.^{6,7} NICE guidelines focus on process adherence, but have little to say about outcomes. They derive from diagnostic constructs that have done little to advance scientific knowledge or clinical practice, and have no capacity to match treatments to aetiology, thus failing the basics required of a technical model.⁸ Mental health treatment RCTs use exclusion criteria, which often means the sort of multi-problem, diagnostic overlap patients typical of those who attend our clinics are not adequately represented. Like me, Fonagy & Clark want to do something about the dreadful record for outcomes that real-world mental health services have. Their solution is to 'beef up' existing diagnosis-based NICE-guideline EBTs that we have been using for years, but using more manualised process adherence. But the fantasy that expertise in technique is king is what got us into this mess in the first place. This ideological commitment seems to have by-passed simple logic. If the outcomes with a patient show improvement, does it matter what model you use to help achieve this? If an outcome is not improving, then it surely does matter and irrespective of what your manual says you may need a rethink what you are doing altogether.

As far as their concept of 'relational' is concerned, they describe a collaborative 'light' model. In the primacy of the technical model, 'collaborative' essentially amounts to convincing the patient that the expert knows what is wrong with them and what the right treatment is. Prioritising the relational means that therapy is potentially 'co-constructed' at every step. In a proper relational model we are constantly encountering 'experts by experience' whose insights, skills, choices, autonomy and resources should be harnessed to help shape therapy session by session.

Fonagy & Clark's article does little to dent the critique that CYP-IAPT has not, thus far, managed to develop patient-empowering, outcomes-focused, collaborative practice. Tellingly, after 4 years of implementation they were unable to reference any patient outcome data for CYP-IAPT. In the 3 years of our local Outcomes Orientated Child and Adolescent Mental Health Services (OO-CAMHS) project, we have amassed a database with over 4000 discharged cases with outcome ratings where a reliable clinical improvement and/or 'recovered' rate of 75% is being recorded. It is time for CYP-IAPT to stop being frightened of relational models and give them a seat at their table. If Fonagy & Clark wish to maximise the chances of having services that can improve the lives of many more people, then they should embrace the opportunity to include alternative models such as the Partners for Change Outcome Management System/OO-CAMHS that have a proven track record in real-world services, to keep open possibilities for discovering ways of designing services that are most effective and efficient. If they remain ideologically belligerent (as they have thus far), every word of my critique stands.

1.8.66 Update on the Improving Access to Psychological Therapies programme in England†

: Commentary on ... Children and Young People's Improving Access to Psychological Therapies

Abstract

Professor Sami Timimi recently expressed concerns about the Improving Access to Psychological Therapies (IAPT) programme. We argue that the concerns are largely unfounded and provide readers with an update on the programme.

We are pleased to have the opportunity to respond to Professor Timimi's editorial in the April 2015 issue of *BJPsych Bulletin* and his comments on the Improving Access to Psychological Therapies (IAPT) programme in general and the Children and Young People's Improving Access to Psychological Therapies (CYP-IAPT) programme in particular. We hope to point out that many of his concerns about both programmes are unfounded, either because evidence we have collected should allay his concerns or because the issues he identifies represent misunderstandings of the literature and the initiatives.

Adult IAPT

The IAPT programme for adults aims to make National Institute for Health and Care Excellence (NICE)-recommended psychological treatments for depression and anxiety disorders more widely available by training 6000 new psychological therapists and deploying them in specialised stepped-care services, along with experienced staff. The initiative has several distinctive features, which an editorial in the journal *Nature* described as ‘world-beating’.¹ For the first time, therapist training follows nationally agreed curricula that focus on the competencies required to deliver those treatments that have been shown by randomised controlled trials (RCTs) to be effective for particular conditions. An innovative session-by-session outcome monitoring system captures clinical outcomes on almost everyone (97%) who has finished a course of treatment (liberally defined as at least two sessions, although many people have more),² and clinical commissioning group (CCG)-level outcome data are published on a public website.³ This contrasts sharply with the picture before IAPT, when psychological therapy services obtained outcome data on less than 40% of patients and are likely to have overestimated their value, as people whose data are missing tend to have done less well.⁴

What does the more complete IAPT data tell us? Nationally, of patients who have finished a course of treatment in IAPT, 45% recover (based on a strict double criterion – dropping below the clinical threshold for both anxiety and depression) and a further 16% show reliable improvement that falls short of full recovery.^{2,5} However, there is considerable regional variability. About a third (70 of 211) of CCGs now report recovery over 50% and some are consistently over 60% (www.hscic.gov.uk). This shows what the IAPT model can achieve in services with a sufficiently large and appropriately trained workforce that benefits from excellent clinical leadership. The challenge for the next phase is to raise other CCGs to the same level.

Professor Timimi’s editorial⁶ asserts that there is little evidence for the premises on which adult IAPT is based, and that IAPT services are less effective and more expensive than pre-existing counselling services. Both assertions can be refuted.

IAPT outcomes

IAPT delivers therapies that have been shown to be effective for particular conditions in RCTs, on the assumption that this is the best way of ensuring good clinical outcomes. Timimi argues this is mistaken because ‘within treatment, the factor that has the biggest impact on outcomes is the therapeutic alliance (as rated by the patient) with matching treatment model to diagnosis having a small to insignificant impact’.⁶ Contrary to this statement, there is evidence in all anxiety disorders that some psychological treatments are more effective than others.⁵ In depression, the picture is less clear. Several psychological therapies have been shown to be better than placebo or no treatment, but there is little evidence of differential effectiveness between these therapies.⁵ However, there is no such thing as a therapeutic alliance therapy. Even if therapeutic alliance were the most important factor, one would still need to train therapists in procedures that allow the therapeutic alliance to emerge. Clearly, it makes sense to choose procedures from treatments that are known to work. It is also important to note that the use of weak research designs means that many studies of therapeutic alliance are likely to overestimate the importance of this factor. Alliance is often measured late in therapy when some patients have already improved. The correlation between alliance and outcome may therefore be a consequence, rather than a cause, of clinical improvement. Feeley’s studies⁷ showing that late alliance is related to outcome but early alliance is not are consistent with this point of view. Alliance studies rarely measure the competence with which a treatment is delivered, so we cannot rule out the possibility that positive alliance ratings reflect competent and sensitive delivery of a treatment, not just the establishment of a good therapist–patient relationship. The remarkable success of internet-delivered therapies strongly challenges the claim that a strong therapeutic alliance is essential.

The report⁸ that Professor Timimi cites as evidence that IAPT services are less effective and more costly than pre-IAPT counselling services is flawed. It was produced by a charity that funded some pre-IAPT counselling services and does not appear to have gone through a normal peer-review process. It fails to describe its methods and measures in the level of detail required for a journal article. However, from the details that are available, it is clear that the report is comparing chalk with cheese. IAPT recovery rates were based on all patients who had at least two sessions. Pre-IAPT services had high post-treatment missing data rates⁴ and recovery rates were based on those who contributed post-treatment data, which will inevitably inflate estimates.⁹ The IAPT recovery criterion was a strict double-measure criterion, whereas pre-IAPT recovery was based on a more lenient, single-measure criterion. Costs for IAPT and non-IAPT services were

also estimated differently, with the former including set-up, staff training and premises costs, while it seems unlikely these figured in the comparator costs.⁸

The characterisation of IAPT as a ‘fetishisation’ of cognitive-behavioural therapy (CBT) is also misplaced. As NICE only recommends CBT for anxiety disorders and depression, the initial focus of IAPT was on this modality. However, the programme now supports the training and employment of therapists who can deliver the four other therapies that NICE recommends for depression (counselling, couples therapy, interpersonal psychotherapy and brief psychodynamic therapy). Counselling is already strongly represented, by over a quarter of all IAPT high-intensity therapists. There is a need to build further capacity in the other three therapies and this is already underway. In the past 2 years IAPT has trained more therapists in non-CBT modalities than in CBT.

Children and Young People’s IAPT

Children and Young People’s IAPT (CYP-IAPT) is training many more systemic family practitioners, interpersonal psychotherapists and parenting therapists than CBT therapists, and our core curriculum has made use of client feedback to inform practice across modalities. Professor Timimi’s emphasis on therapeutic alliance is consistent with CYP-IAPT’s fundamental concern with collaborative practice and shared decision-making.

Professor Timimi’s first concern about CYP-IAPT is the risk of a top-down *v.* bottom-up approach to service transformation. He suggests that rather than using research evidence to guide selection and implementation of interventions, it would be cheaper and better for child and adolescent mental health services (CAMHS) simply to roll out usual care based on his own Partners for Change Outcome Management Systems (PCOMS) model for service transformation. He cites a selection of meta-analyses to suggest that interventions targeted at specific disorders have no effect, even when we know RCTs indicate large effect sizes. Comparisons of psychological therapies with usual care indeed tend to have small effects but this depends entirely on the services offered in usual care. For example, multisystemic therapy has very large effects because the usual care comparator is often part of youth justice provision.¹⁰ Comparisons with community-based active treatments yield far smaller effects. Many advocates of evidence-based therapies (EBTs) have pointed this out,¹¹ and there are indications that modular-based approaches integrating a range of EBT elements may well be the way forward.¹² On the whole, comparisons with usual care show the difficulty of designing new interventions that systematically outperform the old.¹³ But does this warrant complacency about usual care in CAMHS? Existing evidence for the effectiveness of ordinary CAMHS in the UK and elsewhere should worry both clinicians and policy makers. The observed effect sizes are small and sometimes even statistically insignificant. The majority of children receiving community-based usual care do not show clinical improvement.^{14,15}

Unfortunately, bringing about improvements appears quite challenging. In his editorial Professor Timimi cites the historical Stark County and Fort Bragg studies, which are relevant to this debate for two reasons. First, they highlighted the importance of the method of implementation in service improvements. When major service improvement initiatives are launched, evidence now has to be presented that implementation science principles are followed. For example, organising observation of clinical work as part of supervision is essential for rigorous training of therapists,¹⁶ as is the structuring of services to accommodate EBTs.¹² Second, the two studies led implementers and others to stress the likely importance of continuous, clinically meaningful feedback and progress monitoring. Implementation science considerations and meaningful use of session-by-session outcome measurement have informed CYP-IAPT’s work from the beginning.¹⁷ Rather than seeking to impose a single solution on all services, we have tried to disseminate a set of clinical principles (outcome focus, increased patient and parent participation, use of EBTs) and to implement these through local collaborations engaging a range of services, which jointly tried to find the best way forward.

CYP-IAPT: a model for child mental health services

There is no template for a CYP-IAPT service; there are services that use CYP-IAPT principles. PCOMS, or any other service model, could only be universally implemented as part of a top-down initiative. As Professor Timimi highlights, this was precisely what went wrong at Fort Bragg and Stark County, and we did not wish to repeat the error. As a national programme, CYP-IAPT required a modest governance structure, including focused work streams to develop curricula, outcomes measurement and service organisation, but it was delivered within CAMHS partnerships made up of commissioners and both statutory and non-statutory providers who wanted to deliver local change. Through a well-recognised (evidence-based) phasing of the change process (exploration, installation, initial implementation, innovation and sustainability), we engaged services covering 68% of the population in the 1–19 years age bracket within 4 years. Although we may not have succeeded everywhere, our explicit strategy was to mobilise the local leadership and workforce to engage children/young people and their parents in the process of service transformation, including – but reaching out beyond – the National Health Service (NHS), to achieve sustainable results.

A recent benchmarking survey found that 70% of CAMHS questioned said they were working to CYP-IAPT principles.¹⁸ According to the annual update of data submitted for CYP-IAPT, data completeness of matched cases at time 1 and time 2 cases was 63.2%.¹⁹ The Rapid Internal Audit²⁰ of 12 representative partnerships, over 350 clinicians and several focus groups of children and parents/carers found that: The percentage of cases closed by mutual agreement out of all closed cases has increased by 75% since the initiation of CYP-IAPT. The number of weeks between referral and first appointment has decreased from 16.6 in year 1 of CYP-IAPT to 6.6 in year 5. The proportion of self-referrals, although still relatively small, increased by 51%. 54% of clinicians agreed that the service was working towards the principle of increased self-referral; 61% agreed that access had improved for their local population over the past year. Well over half of clinicians questioned reported often or always using outcome data to review treatment progress or to inform therapy; a similar percentage reported often or always discussing outcomes data with children/young people and families. More than three-quarters of clinicians reported usually or always engaging in shared decision-making activities with parents/carers and children. Children in focus groups spoke spontaneously about how their involvement in service delivery gave them a personal sense of worth and empowerment. Children and young people also agreed that monitoring outcomes helped to keep things focused. Professor Timimi identified delivering EBTs as the sole objective of CYP-IAPT. In fact, we set ourselves six evidence-based objectives to improve services for children and young people (www.cypiapt.org/children-and-young-peoples-project.php). In addition to (1) delivering EBTs, we aimed to (2) improve access through self-referral, (3) work in partnership with the young person and their parent or carer throughout treatment, (4) deliver outcomes-focused treatments, (5) provide supervision to support delivery of evidence-based, user- and outcomes-informed practice, and (6) support whole-service transformation through leadership training. As we understand PCOMS' priorities, these have much in common with the CYP-IAPT curricula: the emphasis on consultation, involving optimal collaboration with other agencies; outcomes focus, using session-by-session patient-rated outcome data and changing treatment if outcomes are not improving; developing effective treatment alliances aided by the outcomes focus; developing team cultures that are recovery focused; and understanding how to use outcome data for clinical reflection, supervision and whole-team development.

CYP-IAPT insists on the use of treatment protocols based on manuals validated by one or more RCTs. Delivery of these protocols requires a clear set of competencies, which therapists must show they possess. Professor Timimi is committed to the common factors model of therapeutic change, and believes that generic therapeutic competencies are sufficient to deliver effective help regardless of the nature of the child's disorder. Although many therapies share important elements, such as a strong therapeutic relationship, researchers have found that not all therapies work equally well for all childhood disorders.²¹ Some therapies have actually been shown to be harmful.²² In the case of conduct problems, anxiety-related diagnoses (e.g. generalised anxiety disorder and obsessive-compulsive disorder), attention-deficit hyperactivity disorder and a number of other disorders, there is clear evidence supporting skilled manualised interventions, which could not be accounted for by common factors such as the therapeutic alliance.²¹ We also know from implementation science that attending training workshops is not sufficient to acquire competence in an intervention.¹⁶ The CYP-IAPT training includes intensive workshops and ongoing supervision/consultation, including practice sample review (e.g. audiotape review).

During the earliest exploration phase of the implementation process, the Department of Health and then NHS England sought to learn from local providers to build on existing best practice rather than implementing from above. We established collaboratives based around higher education institutions to lead the implementation locally, as individuals,

organisations and system units gained competence and confidence in the new ways of delivering therapy. In the current ‘innovation’ phase of CYP-IAPT, a national group, the Collaborative of Collaboratives, is presenting opportunities for CAMHS partnerships to refine and expand both the treatments and the implementation of the programme, and the group tasked with service transformation has drawn up a template for improved services (*Delivering With and Delivering Well*),²³ co-authored by the Child Outcomes Research Consortium (CORC), the Quality Network for Community CAMHS (QNCC), the Choice and Partnership Approach (CAPA) and Youth Access, young people and other voluntary organisations, against which the quality of services can be judged.

Our current focus is the sustainability phase, which requires a national system of quality assurance of training, performance and service characteristics so that CAMHS partnerships can be held to account for maintaining the system they have established. An Accreditation Council – working in partnership with the Royal College of Psychiatrists, the British Psychological Society, NHS England, Health Education England, the QNCC, and the professional groups representing family therapists, interpersonal psychotherapists and CBT therapists – has developed an individual accreditation system for CYP-IAPT. These measures help commissioners and providers ensure that children, young people and parents receive the appropriate, evidence-based, outcomes-focused care they deserve.

That these improvements have been possible against the background of the most significant challenges across child mental health since the establishment of child guidance clinics 60 years ago is a testament to the incredible commitment to innovation of the CAMHS partnerships, their clinicians, leaders, the children, young people and parents, as well as the higher education institutions supporting their development. The high profile of children and young people’s mental health has been boosted by the demonstration of effectiveness. We look forward to a brighter future for CAMHS, characterised by improved accessibility, more participation, an increased outcomes focus, greater transparency, and continued respect of NICE guidance and evidence-based practice.

1.8.67 Payment by results in forensic mental health

Luke Gibbons Lucy McCarthy

2015-10

Abstract

Forensic mental health services are low-volume, high-cost services. Payment by results (PbR) is the UK’s latest attempt to improve efficiency and controls pending behaviours within the secure services. This article discusses the utility of the PbR mechanic in forensic mental health. It explores PbR implementation in non-forensic mental health settings, similar funding processes internationally, and early PbR implementation work in the UK’s secure services. Finally, the article discusses the challenges faced when implementing PbR in forensic mental health services and puts forward possible next steps in determining the utility of PbR in forensic mental health.

The majority of mental health services in England, including forensic mental health services, have previously been funded via block contracts, with annual budgets set and agreed between commissioners and service providers. Providers then distribute the finances, balancing governmental directives and strategies against local priorities. However, it has been reported that block contracting offers very little incentive to improve efficiency and control spending behaviours.¹ Payment by results (PbR), soon to be called pricing and currency, is 'the payment system in England under which commissioners pay healthcare providers for each patient seen or treated, taking into account the complexity of the patient's healthcare needs'² that attempts to address such issues. It is England's answer to a case-mix approach, in which funding involves the use of a predefined average care package, which is applied with a fixed price when certain diagnoses or factors are present. In 2003, this method of commissioning started to be rolled out in areas of physical healthcare and now the PbR mechanism is utilised in the bulk of elective in-patient/out-patient and emergency procedures. The government believes that it will provide more clarity on what to expect from services and achieve better, more efficient outcomes.³

PbR: key concepts

Within the scheme, when operating for physical health purposes, a currency represents a unit of healthcare for which a payment is made and a tariff represents the price paid for each currency. Consequently, varying patients are grouped into healthcare resource groups (HRGs), in accordance with similar consumption of National Health Service (NHS) resources. In mental health services, 'clusters' are used as the so-called currencies, which in turn define a relevant care pathway and ultimately the contract between commissioners and service providers.⁴ Similar to HRGs, clusters represent individuals with similar needs, requiring similar resources. Whether the PbR mechanism can be applied to a mental health domain is questionable. Owing to the complex nature of human condition and the often long-term nature of mental disorders, it would be naive to think that categorising mental health patients into discrete groups would be as simple as categorising patients with similar physical health problems.⁵ Consequently, any success of the PbR mechanism in the physical health domain does not necessarily mean that it is transferable to a mental health domain.

Are the positive effects of PbR smoke and mirrors? Evidence from non-psychiatric settings

Several countries operate mechanisms that attempt to match resources more directly to measured needs. This particular approach seems sensible for both commissioners and healthcare providers, as theoretically hospitals are prospectively reimbursed in accordance with diagnosis. Thus, any additional funding needed for a mismatch between diagnosis and service will result in financial loss for the hospital. Alternatively, any funds left unspent will result in profit for the service provider, offering incentive for careful management of funds.⁶ In addition, it has been reported that PbR may result in reductions in length of stay and shorter waiting lists for elective procedures.⁷ On the surface, PbR looks beneficial to commissioners, patients and possibly the service providers.

The seeming efficiency in terms of the management of finances, reduction in patient waiting times and shortened length of in-patient stay may not be all it seems. Reservations over taking such consequences at face value are held by the International Council of Nurses,⁸ who fear that such 'positive' effects may actually result in patients being discharged too soon ('quicker and sicker'), placing an extra burden on other support networks. It is possible that the PbR process in acute care does not offer monetary rewards for results as such, but rather it remunerates activity,¹ and activity that may not be necessary or in the patient's best interest.

'Gaming' in mental health services

Consistent and significant mismatches between clustering and ICD-10 diagnosis may be down to service providers 'cherry picking' cheaper cases and manipulating patient coding into higher tariffs.⁹ These fraudulent processes can be broken down further, illustrating how the system may be manipulated: 'cream skimming' or adverse election of lower-cost patients; 'skimping' or a reduction in quality of care; 'up-coding', which refers to the categorisation of patients into higher-income clusters than what is clinically necessary; and 'dumping', which is the selective, inappropriate referring of patients to other care settings.¹⁰ Such openness to fraudulent processes or 'gaming' is of interest to not only commissioners and service providers, but also auditors and researchers.

Informing funding through diagnosis: problems and international perspectives

The use of diagnosis to inform funding has been questioned in countries that have already rolled out similar schemes.¹¹ Mason & Goddard¹¹ reviewed the international literature on PbR in mental health along with an economic assessment of the approach in England. It is acknowledged that mental health treatment often extends far beyond the hospital sector and thus, by putting a limit on funding a care package, mental health patients' treatment may be cut short. There is evidence that individuals with mental health problems are more likely to experience physical ill health and are more likely to have greater non-clinical needs, such as educational, social and/or employment support.¹² The interface between in-patient and community care poses problems in predefining care pathways and currencies, as prognosis and course of treatment is highly variable, regardless of similar mental health diagnoses.

'Length of stay' has been found to be a major explanatory variable for cost variation between 'similar' patients, which would be particularly relevant for the NHS as a whole, if not for individual service providers, and a fair payment system must be able to compensate by being flexible enough to make appropriate adjustments for patients.¹¹ US health providers recognise such variation between mental health patients in both in-patient and outpatient settings and consequently operate a per diem system: there is recognition of the complexities of psychiatric problems coexisting in mental health patients and so funds are distributed on a day-to-day basis, taking into account average costs that are adjusted to account for diagnosis and comorbidity.

Alternatively, the Canadian methodology separates length of stay into three separate parts that are defined through resource intensity, allowing for an adjustment to payments for interrupted stays.¹ This is a vital consideration as, by comparison, the within-class homogeneity of the Australian and New Zealand mechanisms (the two systems that have the most resonance with the UK's) resulted in the systems never being rolled out to direct funding. However, they were never rolled out to direct funding, in the main because of within-class resource homogeneity. It is extremely difficult to classify resource consumption of different patients even though they may have similar diagnoses.

Both the American and Canadian methodologies account for outliers and facilitate flexibility around length of stay. The conversion of costs to price is not a simple exchange. The English methodology does acknowledge the need for review dates and results in some flexibility. Nevertheless, the date defines cluster episodes and costs, and so the malleability of care clusters may be somewhat limited when compared with its American and Canadian counterparts.

PbR in forensic mental health

The complexities of care for individuals who have mental health problems make PbR a difficult mechanism to employ with this population. It is noted that even though the rollout of PbR in mental health services has begun, it is still in its infancy. The acute hospital setting had a decade of development and refining. PbR in mental health services has yet to result in subsequent national tariffs and therefore block contracting still informs funding. Such complexities may be further extenuated when a forensic mental health population is considered.

Development of forensic clusters

The Mental Health Clustering Tool (MHCT)¹³ describes 21 clusters of mental health symptoms and treatment needs observed in general psychiatry. The tool is designed to assess and group individuals according to their clinical needs and resource consumption. It is a pivotal tool in PbR. It has been modified by a group of forensic practitioners to account for risk profiles and personality disorders, in an attempt to make it suitable for a forensic population.¹⁴ This modified version is called the forensic MHCT.

The modification of the MHCT leaves serious doubts about the suitability of the subsequent forensic MHCT. A multi-disciplinary team working in forensic services was convened and split into small groups. They then applied the MHCT to both fictitious and real patients in order to identify actual or possible issues when applying the MHCT to their forensic patients. To the best of our knowledge, there are no statistical underpinnings of the forensic clusters. Only the original clusters, devised through non-forensic samples, have any statistical underpinnings,¹⁵ and these do not allay concerns over the statistical foundations of the tool.

Forensic clusters and pathways: research so far

McCann & Green¹⁴ carried out pilot work to test the utility of the forensic MHCT and another ‘grouping’ instrument developed by forensic practitioners, the Five Forensic Pathways (5FP),¹⁴ which uses data from the HCR-20,¹⁶ HoNOS-Secure¹⁷ and patient’s offending history. Small sample size precluded sufficient statistical analysis, making it difficult to draw conclusions from the study.

Other considerations

Adaptability of PbR

It is not yet possible to see whether clustering routes lack specificity with regard to individual needs and resource consumption or whether such routes actually avoid creating complexities that could hinder the applicability of PbR to forensic mental health services. PbR guidelines recognise that patients’ needs change over time and that frequent re-assessment and clustering is needed to continually provide individuals with the appropriate care.¹⁸ The booklet states that ‘lessons are still being learnt’ about how well the PbR system reflects, and how well it accommodates, the dynamic needs of forensic mental health patients, highlighting the need for further research. If it is not known how the system adapts with changing patient needs then it cannot be used to define an individual’s care funding.

Patient outcomes and effects on funding requirements

Outcome measures are a further consideration in investigating the utility of PbR within forensic mental health. In England, the Department of Health is looking at outcome measures far more now than they did previously.¹⁹ In non-forensic settings, there is scope for outcome measurements in a set of quality indicators: clinician-related outcome measures (CROMs), patient-reported outcome measures and patient-reported experience measures.²⁰ How such outcome measurements transfer to a forensic setting has to be explored. Quality indicators in a forensic setting could include the percentage of patients with a forensic MHCT and 5FP score at admission and subsequent care pathway approach meetings. Similarly, CROMs could include HoNOS-Secure measurements.

However, such proxy measures undertaken when patients are contained cannot reliably inform on how a patient will behave or feel on release into society. Patients discharged from secure care are vulnerable to re-admission, re-offending and mortality,^{21,22} and therefore insight into how clusters and treatment pathways relate to patients' routes after discharge is imperative. A shorter length of stay, for instance, does not portray a positive outcome if the individual in question is subsequently re-admitted or re-convicted as a result of being discharged too soon. A patient's course after discharge should be considered as part of the clustering process, having a role in informing funding and not merely being used as an evaluative tool. Therefore, even though outcome measurements may be transferrable from non-forensic mental health to forensic settings, there are further considerations that should be undertaken due to the nature of the patient population.

Next steps

The utility of PbR within forensic mental health needs thorough examination. Currently, the only insight has been gained through small preliminary investigations conducted by proponents of PbR. The system has already been rolled out within acute hospital settings and the application of the process to non-forensic mental health is well underway. Even so, the Royal College of Psychiatrists released a statement at the beginning of 2014, expressing concerns over PbR.²³ More specifically, they highlight reservations over the statistical analyses underpinning the 21 clusters, the range (or lack) of complexity involved in the clustering process, whether the clusters allow for best evidence-based practice, the lack of outcome measures and consequent effect on costs of patient care and ultimately, concerns that the current system would risk severe destabilisation financially and organisationally.

The reservations over the implementation of the mechanism in general mental health generates concern as PbR in forensic mental health is in its comparative infancy. Indeed, the forensic MHCT clusters and the pathways in the 5FP have no statistical underpinnings.

To determine the utility of PbR in forensic mental health, the relationships between diagnoses, care needs assessments and outcomes post-discharge need to be explored. Economic assessments of the treatment costs throughout in-patient and post-discharge accommodation need to be undertaken. There needs to be a profile of economic outcomes for each care cluster if the PbR mechanism is to be rolled out within forensic mental health and ultimately define patient funding. There is a clear and urgent need for research focusing on how the forensic MHCT can be used (if at all) to best cluster patients and what complexities and difficulties exist in the clustering process.

1.8.68 Epidemiology on demand: population-based approaches to mental health service commissioning

Abstract

One in three people will experience a mental health problem in their lifetime, but the causes and consequences of psychiatric morbidity are socially patterned. Epidemiological studies can provide aetiological clues about the causes of disorder, and when they can provide robust estimates about risk in different strata of the population these can also be used translationally, to provide commissioners and service planners with detailed information about local service need. This approach is illustrated using a newly developed population-level prediction tool for first-episode psychosis, PsyMaptic. Such public mental health prediction tools could be used to improve allocation of finite resources, by integrating evidence-based healthcare, public health and epidemiology together.

 - *Population-level psychosis prediction*
 - *Conclusions*

One in three people will experience a psychiatric health disorder in their lifetime, according to recent estimates from a whole-population epidemiological study in Denmark.¹ Such burden is not shared ubiquitously across populations, but is highly patterned, be it by largely unknown, rare or non-specific genetic variants and abnormalities, observable phenotypes (age, gender, ethnicity) or environmental exposures (including, but not limited to, socioeconomic position, education, substance use, prenatal insults, childhood adversity, traumatic life events and neighbourhood social disadvantage). For example, the incidence of psychotic disorders is several times higher in some sociodemographic groups, such as certain migrant and ethnic minority groups,² most notably among Black Caribbean and African groups in England³ and Moroccan and Surinamese groups in The Netherlands,⁴ where excess rates are around 3–5 times greater than in the background population. Rates also vary in highly replicable ways by age and gender, with young men particularly at risk of psychotic disorder.⁵

While some of this patterning may be stochastic⁶ (genetic risk under non-assortative mating) or under biological control (risk by age or gender), the risk sets for, and consequences of, psychiatric disorders will also be shaped by socially patterned forces, which are disproportionately likely to affect poorer, more marginalised and vulnerable members of society, who are likely to shoulder the burden of our psychiatric morbidity. In terms of risk, this patterning may arise as a function of exposure to adverse environmental factors (independent or arising from gene-environment correlation),⁶ genetic risk due to assortative mating,⁷ epigenetic modifications⁸ or the role of cognitive impairment on risk of psychiatric disorder (which probably lies on the causal pathway between genes, environment and disorder).^{9,10} The consequences of psychiatric morbidity are also subject to strong social patterning, meaning some sections of society might be doubly disadvantaged.¹¹ For example, with respect to psychotic disorders, people may experience social decline or drift,¹² probably beginning premorbidly and usually sustained after the onset of first-episode psychosis (FEP), as a consequence of the onset of psychotic symptoms, especially negative symptoms,¹³ and cognitive impairment.¹⁴ This de-

cline may continue or become exacerbated after onset of disorder as a result of additional issues, including side-effects from medication and stigma and discrimination experienced by people following psychosis onset. Social isolation,¹⁵ unemployment¹⁶ and drift into more disadvantaged communities¹⁷ are likely to be commonplace, in addition to the deleterious, and possibly synergistic,¹⁸ risk associated with these exposures.

Early intervention for psychosis

While we have yet to elucidate clear, specific aetiologies through which genetic and environmental factors operate to cause psychosis, epidemiological studies can provide reliable, accurate estimates about the risk of disorder in different communities, based on both incidence (risk) and prevalence (risk and consequences) of psychotic disorder.^{5,19} Such data should be a valuable resource for mental healthcare service commissioners, who must make difficult choices about the efficient and effective allocation of finite resources for mental and physical health disorders throughout the population. The visionary commissioning of early intervention in psychosis (EIP) services,²⁰ for example, was highly concomitant with a public mental-health-based approach for psychotic illness, based on available evidence. Thus, arising from evidence that a longer duration of untreated psychosis was associated with worsening functional, clinical and social outcomes,²¹⁻²³ EIP services sought to intervene early in the initial presentation of psychotic symptoms.^{24,25} This approach partly targeted improving the consequences of illness onset and was a universal public health measure, broadly aimed at the group for whom a first episode of psychosis was most common – people under 35 years old.⁵ Some EIP services also provided early detection of psychosis provision at the stage which precedes psychosis, termed clinical high risk state,²⁶ which focuses on preventing transition to a first episode of psychosis.^{27,28} This approach used both selective (young people with a family history of psychosis) and indicated (young people with early signs and symptoms of psychosis including a decline in functioning) prevention criteria to manage risk of disorder.

Accumulating evidence suggests that EIP services provide benefits across a plethora of individual, healthcare and societal outcomes.²⁹⁻³¹ They are seen favourably by young people experiencing psychotic symptoms,³² given the holistic service model that targets a range of domains, including mental and physical health, identity and well-being, family involvement and vocational support. They reduce the risk of compulsory treatment and suicide in young people with psychosis,^{33,34} and fewer people with psychosis in EIP services are unemployed than in standard mental health services,¹⁶ although this figure remains stubbornly high when compared with their population-based peers.³⁵ There is also a strong economic argument for EIP services. It is estimated that the NHS would save up to £44 million per year from fewer in-patient admissions if EIP were fully deployed,³⁶ and there is consistent evidence that EIP provides long-run, sustained economic incentives over standard care;³⁷⁻⁴⁰ there is evidence that every pound invested in EIP services results in £18 of downstream savings.³⁶ Psychotic disorders, more generally, also have pernicious effects on society. This can be measured acutely via lost economic productivity, with disorder onset typically coinciding with the age at which people have just completed their educational or vocational training and are about to enter the labour market.⁴¹ In the most severe cases, lost or reduced economic productivity may persist across the entire working age. The total societal cost of psychotic disorders in England has been estimated at £11.8 billion per year.³⁵ By keeping more people in employment and improving other social outcomes,²⁹ EIP services will provide long-term benefits to individuals, the economy and society over time.

Despite the strong rationale for such services, EIP have not been universally accepted or implemented.⁴² Services have faced a number of criticisms (see McGorry et al⁴³ for an introduction), some better supported than others, including a lack of sufficient evidence for individual benefit when care is not sustained,⁴⁴ cherry-picking of ‘easier’ cases,⁴⁵ inadequate flexibility of EIP service delivery in rural communities,⁴⁶ diversion of resources from standard mental healthcare services,⁴² case-loads being either below⁴⁷ or in excess of government targets,⁴⁸ and delays in treatment within mental health services in some regions threatening to jeopardise the very purpose of early intervention.^{34,49,50} This background of criticism has coincided with an increasingly difficult commissioning landscape⁵¹ where, despite ring-fenced NHS expenditure, real-term cuts to mental health services of 2% have been particularly keenly felt in EIP services, which have come to be viewed in some trusts as an unaffordable luxury.³⁴ A recent audit by the mental health charity Rethink found that 50% of EIP services have experienced healthcare cuts in the past year alone, with a parallel perception by staff that the quality of service has also been reduced.³⁴ Continued removal, reduction or restructuring of EIP services now threatens to undermine one of the National Health Service’s (NHS’s) exemplar models of integrated healthcare,⁵² at a time when other areas of healthcare delivery are moving towards such models.⁵³ Indeed, this perverse logic runs counter to National Institute for Health and Care Excellence (NICE) recommendations that EIP should be

provided for everyone in their first episode of psychosis, irrespective of age.⁵²

Towards integrated healthcare

Since the long-term clinical, social and economic benefits of EIP are most likely to be achieved when a full EIP package is implemented,⁵⁴ which includes providing physical health checks and supported employment opportunities, clinical commissioning groups (CCGs) should favour full-fidelity EIP models.^{52,55} This is undoubtedly challenging in stringent economic times, when commissioners must make difficult decisions about the allocation of a finite set of resources across the spectrum of healthcare services. While piecemeal implementation of EIP services may provide the illusion of integrated healthcare for young people with severe mental health problems, piecemeal solutions are only likely to deliver piecemeal results, leaving services as precariously positioned to deliver expected results as they currently find themselves.

The integrated healthcare model envisaged by the Department of Health has the potential to offer an alternative approach to difficult decisions about resource allocation across health and social services,⁵³ intractably founded on the fundamental principle of evidence-based decision-making. I suggest there are three aspects of the evidence base that need appraisal and integration to maximise the efficiency and effectiveness of resource allocation in an integrated healthcare model (*Fig. 1*). First, reliable and robust evidence about the epidemiological characteristics of any given disorder are required to understand whether and how risk varies between different members of the population, with a view to identifying those groups who are at greatest risk (empirical epidemiology). Second, services and treatments that have been shown to provide patient benefit in terms of prevention, reduced relapse or re-admission or improved quality of life and clinical and social prognosis must exist (evidence-based healthcare). Such care packages should also ideally have demonstrable cost-effectiveness over the medium- to long-term. Finally, a precise understanding of local population characteristics is required to understand how epidemiological risk translates into the public health impact of different disorders in different populations (evidence-based public health). An understanding of local needs is seen as central to the government's move towards integrated health,^{53,56} particularly as, with the exception of psychosis, less than a quarter of people experiencing mental health disorders are likely to be receiving any kind of treatment.⁵⁶⁻⁵⁸ This will only be achieved if the Department of Health, working alongside CCGs, can integrate these three strands of the evidence base to develop a detailed understanding of the multifaceted needs of local populations, and thereby allocate finite resources as efficiently as possible in response to dynamic local health issues.

Evidence-based EIP services

With respect to EIP services, an integrated evidence base has allowed us to develop, validate and refine an online planning tool for the prediction of FEP at the population level, based on local need. The prediction tool combines empirical estimates about the risk of developing psychotic illness by major sociodemographic and environmental factors,^{5,59} such as age, gender, ethnicity and population density, with information about the population structure of different local authorities in England and Wales. This gives rise to the expected number of new FEP cases that would occur in a given population each year, providing commissioners with guidance on likely resource needs for psychotic disorders. We have made predictions freely available for every local authority in England and Wales, broken down by age and gender, in an online repository known as PsyMaptic (Psychiatric Mapping Translated into Innovations for Care, www.psymaptic.org). The predictions from the tool have been validated in East Anglia⁶⁰ by comparing the predicted number of FEP cases with those empirically observed in a population at risk of nearly 1.4 million people over 2.5 years. We have recently published a revised version of this tool (version 1.1), which makes several important updates to improve its predictive accuracy (*Table 1*). Importantly, the new version simultaneously accounts for the effects of population density and socioeconomic deprivation,⁶¹ both of which are associated with the incidence of psychotic disorders, is validated over a longer period (3.5 years), and uses the latest population statistics for England and Wales, estimated from the 2011 census.

Model comparisons between PsyMaptic versions 0.5 and 1.1

	Version 0.5	Version 1.1
Models tested	7	36
Denominator source	2009 mid-year census estimates	2011 census
Observation period, years	2.5	3.5
Person-years at risk (16–35 years)	1397 305	2 021 663
Minimum level of geography	Local authority	Local authority
Best-fitting model covariates	Age group, gender, age* sex interaction, ethnicity, population density	Age group, gender, age* sex interaction, ethnicity, population density, extent of deprivation, quadratic for extent of deprivation
Observed FEP cases (ICD-10), <i>n</i>	522	676
Predicted FEP cases (ICD-10), <i>n</i> (95% CI)	508 (459, 559)	667 (610, 722)
Equivalentised RMSE (EIP level) ^a	19.0	16.3
Equivalentised RMSE (LAD level) ^a	7.8	6.4
EIP correct (<i>n</i> = 6) ^{b, n}	5	5
LAD correct (<i>n</i> = 21) ^{b, n}	19	19

FEP, first-episode psychosis; EIP, early intervention psychiatry; LAD, local authority district; RMSE, root mean squared error.

RMSE gives a measure of how closely each predicted value was to the observed value, either at LAD or EIP level. Lower scores indicate better model fit. Versions 0.5 and 1.1 used different denominators and direct comparisons between the original RMSE values for version 0.5 (published in Kirkbride *et al*⁶⁰) and version 1.1 were not possible, so equivalentised RMSE values for model 0.5 are presented based on the denominator used in model 1.1.

The number of times the observed value fell within the 95% CIs of the prediction at EIP level (out of 6) or LAD level (out of 21). Both models perform equivocally at LAD and EIP levels in terms of number correctly predicted. However, the lower overall RMSE scores for model 1.1 provide clear evidence of improved fit, favouring model 1.1.

Population-level psychosis prediction

Some of the aforementioned criticisms of EIP implementation (such as shortfalls or overestimates of expected case-loads) may have arisen as a direct result of the lack of tools to inform healthcare planners and commissioners about variation in need for services at the population level. Our tool overcomes part of this challenge by providing epidemiology ‘on demand’, centred on local population need and underpinned by a robust evidence base for FEP. It is important to recognise that PsyMaptic is only one of a suite of health informatics that commissioners will require to make effective decisions about the provision of local mental healthcare. For example, PsyMaptic predicts the expected incidence of ICD-10 clinically relevant FEP (F10–33), as confirmed by detailed OPCRIT review of case notes (<http://sgdp.iop.kcl.ac.uk/opcrit/>). It does not currently predict the additional resources required by EIP services to manage referrals who may present with underlying psychopathology, but require signposting to other, more appropriate services. Other data, such as the National Mental Health Minimum Dataset, which more accurately reveal all service use (not limited to those meeting clinical threshold for disorder), should be used in conjunction with such tools to inform commissioners about the probable additional burden of non-psychotic clinical psychopathology that EIP services may see, but were not originally provided for in the Policy Implementation Guide.²⁰ It should be apparent that this problem becomes greater the earlier one tries to intervene, since early prodromal symptoms may be transitory or have relatively low specificity to later psychotic disorder.⁶² The recent trend in some CCGs to re-organise services around a clinical staging approach, with EIP services superseded by generalised youth mental health services,⁶³ might be a service-side response to this phenomenon, but the non-specific (and perhaps non-clinical) nature of some early mental health symptoms will be a challenge for delivering effective, evidence-based youth mental healthcare, particularly where, for justifiable clinical and social reasons, services may delay formal diagnosis. We recommend that service commissioners use PsyMaptic as one part of a suite of evidence-based information available to them.

PsyMaptic provides proof-of-concept that empirical psychiatric epidemiology can be used to inform mental health service provision and public mental health. Predictions are prone to error, and we welcome observations from services where the tool performs well and where it does not, to enhance future versions. If similar forecasting could be applied to other mental or physical health disorders which have a robust empirical epidemiology, CCGs would have more complete information on which to make funding decisions across all health services in their locality, helping to drive the important demand for parity of esteem between physical and mental health.⁶⁴ Fortunately, a growing range of tools is becoming available for services, CCGs and the Department of Health to make evidence-based decisions. PsyMaptic is one of a number of health indicators being used by Public Health England. For example, community mental health profiles,⁶⁵ which detail the prevalence of various mental health disorders as well as risk factors and the wider determinants of health, are available for all local authorities in England. A further tool, by UCL Partners, is providing comprehensive mental health needs assessments,⁶⁶ drawing on a range of data sources and providing estimates of local economic savings from intervention, including those for FEP and clinical high-risk states.

Conclusions

Translational epidemiological tools have the potential to arm commissioners with evidence to allocate increasingly finite resources more efficiently across populations, centred on local need. The Health and Social Care Information Centre already publishes public mental health statistics which provide relatively comprehensive data for secondary mental healthcare. However, this information is not routinely combined with local estimates of variation in the incidence of different mental health disorders, using tools such as PsyMaptic (currently restricted to psychotic disorders). This synthesis would then allow for the potential size of the local unmet mental health need to be estimated, which can then be used to effectively inform local joint strategic needs assessments (JSNAs). This in turn informs commissioning and health and well-being board strategies. Therefore, routine inclusion of such information in JSNAs could have a very large role in reducing the size of mental health unmet need.

1.8.69 Psychiatric morbidity and socio-occupational dysfunction in residents of a drug rehabilitation centre: challenges of substance misuse management in a Bruneian context†

Abstract

Aims and method In 2011, a psychiatric clinic was started in Pusat Al-Islah, a drug rehabilitation centre. Our aim was to record self-reported socio-occupational dysfunction and patterns of drug misuse and to evaluate the usefulness of a psychiatric screening tool. A two-phased approach using the Self-Reporting Questionnaire (SRQ) and the Mini International Neuropsychiatric Interview (MINI) was used to examine the rates of psychiatric diagnoses.

Results Methamphetamine was the most commonly misused substance in 94.5% of residents. High levels of socio-occupational dysfunction were reported. In total, 5.5% met criteria for major depressive disorder, 4.8% for lifetime psychotic disorder and 11.5% for suicidal ideation. In addition, 13.3% reported previous untreated mental health problems.

Clinical implications A screening tool such as the SRQ can be used to identify those needing further psychiatric assessment. Interventions to address amphetamine misuse and associated socio-occupational dysfunction are required. Societal views and legislation influence the management of substance misuse problems in Brunei.

Pusat Al-Islah is a residential drug rehabilitation centre run by the Narcotics Control Bureau (NCB) in Brunei, a small country in Southeast Asia. Residents are sent here after being convicted of drug use offences and testing positively for illegal substances. This is a prison diversion scheme that aims to rehabilitate drug misusers and reduce the rates of reoffending by offering a residential rehabilitation programme and post-release supervision. A small number are voluntary admissions. Treatment is based on a therapeutic community model and residents stay for up to 30 months. There is occupational training, Islamic religious lessons and counselling. A general practitioner and primary care nurse provide primary healthcare. In 2011, a psychiatric clinic was started. This was an opportunity to examine psychiatric morbidity among residents. The high prevalence of psychiatric morbidity in correctional and drug-misusing populations has been highlighted elsewhere, but there is no existing data for Brunei. This is a group who can be difficult to engage in treatment. Admission into the centre is an opportunity to screen for and treat any significant illness. Psychiatric morbidity is likely to have an impact on rehabilitation. Those individuals with mental disorders are more vulnerable to the adverse effects of imprisonment and are at higher risk of suicide.¹ They may have difficulty adhering to rehabilitation programmes.² We hypothesised that there would be a high level of psychiatric morbidity and socio-occupational dysfunction in this population. We also evaluated the usefulness of a psychiatric screening tool. Finally, we consider the challenges facing substance misuse management in the Bruneian context.

Method

This was a cross-sectional study. Ethical approval was obtained from the Research & Ethics Committee, Ministry of Health, Brunei Darussalam. Those who were residing in Pusat Al-Islah on 1 January 2012 or admitted by 31 March 2012 were approached to take part in phase 1 of the project after giving written informed consent. The interviews were conducted by three researchers, a consultant forensic psychiatrist (H.H.), a doctor training in psychiatry (A.M.A.), and a senior psychiatric nurse (R.O.).

Phase 1

All residents were interviewed using the Self-Reporting Questionnaire-24 (SRQ-24)³ between January and June 2012. This is a tool that has been shown to have good sensitivity and specificity for identifying psychiatric morbidity in primary healthcare settings.³ As Malay is the main language spoken in Brunei, we used a Malay language version that has been used to examine psychiatric morbidity in a Malay-speaking population.⁴ Questions 1–20 relate to neurotic symptoms and questions 21–24 to psychotic symptoms. Those who scored above a cut-off score of 6 and above for the first 20 questions and/or 1 and above for the last 4 questions, were entered into phase 2 of this study. This cut-off has been suggested to have the best ‘trade-off’ between sensitivity and specificity. Demographic details, educational and employment history, drug misuse history, psychiatric history, self-reported violence and offending history were also obtained. Data regarding socio-occupational function were obtained using an open questioning style. Any participant thought to require clinical assessment was referred to the psychiatric clinic.

Phase 2

Residents proceeding to phase 2 were interviewed using the Malay version of the Mini International Neuropsychiatric Interview (MINI, version 6.0).⁵ The MINI is a short semi-structured diagnostic interview for DSM-IV⁶ and ICD-10⁷ psychiatric disorders. It has been shown to have good validity and interrater reliability.⁵ The Malay version has been shown to have good reliability in diagnosing major depressive disorder and generalised anxiety disorder in a Malaysian community setting.⁸ The sections coding for the following groups of disorders were used: major depressive episode, suicidality, manic and hypomanic episodes, psychotic disorders and mood disorder with psychotic features, generalised anxiety disorder. The prevalence of these disorders was the main focus of the study as they are common treatable causes of psychiatric morbidity. All interview records were checked by the consultant forensic psychiatrist (H.H.) for accuracy.

Statistical analyses

Data were analysed using the Statistical Package for the Social Sciences, SPSS, version 16 for Windows.

Results

Demographics

In total, 195 residents were approached to take part and 165 residents (140 (84.8%) men and 25 (15.2%) women) consented and were interviewed for phase 1. Their mean age was 33.1 years (range 18–55, s.d. = 7.6). The mean length of stay before the interview was 14.8 months (range 1–33, s.d. = 9.7). A total of 155 (93.9%) were admitted under an order of the Courts or the Minister of Home Affairs; 10 (6.1%) were voluntary admissions. Of participants, 161 (97.6%) had been born in Brunei; 91 (55.2%) were married, 95 (57.6%) had children under the age of 18 years and 57 (34.5%) were unemployed at the time of admission. Well over half, 101 (61.2%) had not completed secondary school. All residents who declined consent were men.

Index offence

In total, 148 (89.7%) were admitted for a drug use offence alone, 16 (9.7%) were admitted for drug dealing in addition to a drug use offence. Data were missing for 1 (0.6%) resident.

Drug misuse history

The mean age of starting drug misuse was 19.8 years (range 9–46, s.d. = 7.1). The mean time period from starting drug use to the interview was 13.7 years (range 1–35, s.d. = 7.1). Methamphetamines were the most commonly misused substance. The drugs misused are described in *Table 1*. The majority of residents reported using drugs at least once a week and experienced some physical or psychological discomfort after a period of abstinence (*Table 2*).

Type of substance misuse ($n = 165$)

Substance misused	n (%)
Crystal methamphetamine	159 (96.4)
Main drug misused	152 (92.1)
Other amphetamine/stimulants	23 (13.9)
Cannabis	61 (37.0)
Cough medicine	52 (31.5)
Solvents	16 (9.7)
Opiates	8 (4.8)
'Pills'	64 (38.8)
Steroids	2 (1.2)
Intravenous drug misuse ^a	7 (4.2)
Alcohol problem ^b	102 (61.8)

All methamphetamines.

Residents who reported that they drank heavily or had an alcohol misuse problem.

Frequency of drug misuse, and symptoms after abstinence ($n = 165$)

	<i>n</i> (%)
Frequency of drug use	
Daily	72 (43.6)
At least twice a week	49 (29.7)
Once a week	16 (9.7)
1–3 times a month	24(14.5)
Less than once a month	3 (1.8)
Symptoms after abstinence	
Experienced physical (shaking, sweating, sleep disturbance) or psychological (irritability, craving, anxiety) discomfort	115 (69.7)

Psychiatric history

Of participants, 29 (17.6%) reported previous contact with psychiatric services, 9 (5.5%) residents were taking psychiatric medication (antidepressant, antipsychotic or mood stabiliser). In total, 13 (7.9%) had previous admissions for psychiatric treatment, 5 (3.0%) had received involuntary treatment under the Lunacy Act.⁹ Twenty-two participants (13.3%) reported experiencing mental health problems in the past, for which they had not sought treatment. There were 16 (9.7%) who reported experiencing previous suicidal ideation. In addition, 19 (11.5%) reported having a first- or second-degree relative with mental health problems. Psychiatric case-notes were found for 26 (15.8%) residents. When these were examined for recorded diagnoses, 13 (7.9%) had a psychotic illness (schizophrenia or acute psychotic episode), 9 (5.5%) had a depression, 1 (0.6%) had bipolar disorder, 2 (1.2%) had personality disorder and 1 (0.6%) had a child and adolescent mental disorder, unspecified. A total of 13 (7.9%) were recorded to have been non-adherent with treatment. Also, 9 (5.5%) participants had previous self-harm documented.

Forensic history

In total, 28 (17.0%) had previous admissions to Pusat Al-Islah; 61 (37.0%) had served at least one prison sentence; 20 (12.1%) had been convicted of an previous offence without a prison sentence, 39 (23.6%) had been remanded by the police but released without charge or conviction. Also, 41 (24.8%) reported performing previous physical violence such as assault.

Socio-occupational function

Of all the participants, 75 (45.5%) reported problems with their educational or work performance attributed to drug misuse. A total of 68 (41.2%) reported financial problems, 98 (59.4%) reported family relationship problems and 22 (23.2% of those with children <18 years old) reported having difficulty caring for their children adequately. Sixty participants (36.4%) reported offending behaviour related to their drug misuse. Also, 77 (46.7%) had a first-degree relative (parent, child or sibling) who misused drugs and 14 (8.5%) had a spouse or partner who misused drugs.

SRQ scores

The mean score for questions 1–20 was 3.6 (range 0–18, s.d. = 3.9) and for questions 21–24 was 0.25 (range 0–3, s.d. = 0.7). A total of 40 (24.2%) residents, 31 men and 9 women, met criteria for entry into phase 2. When means were compared using the independent *t*-test, no significant differences were found between the phase 1 and phase 2 groups for age (32.2 v. 33.4 years, $P = 0.386$), duration of drug misuse problem (13.75 v. 13.5 years, $P = 0.458$) and age of starting drug misuse (20.1 v. 18.9 years, $P = 0.357$).

Phase 2

Interviews occurred after phase 1 was completed, between August and October 2012. Of the 40 residents who were eligible for entry into phase 2, 10 residents had been discharged and were invited for interview, however, 7 discharged residents did not respond to the invitation for a second interview, 1 resident was not cooperative. Therefore, 32 participants (23 men (71.9%) and 9 women (28.1%)) were interviewed.

In total nine (5.5%) met criteria for major depressive disorder (two ‘current’, six ‘previous’ and one ‘current and previous’) of whom three (1.8%) met criteria for major depressive disorder with psychotic features (‘current’, ‘previous’ or ‘current and previous’). Three (1.8%) participants met criteria for previous manic episode, three (1.8%) met criteria for hypomanic episode (‘current’ or ‘previous’) and six (3.6%) met criteria for previous hypomanic symptoms. There were three (1.8%) participants who met criteria for bipolar I disorder (‘current’ or ‘previous’), three (1.8%) met criteria for bipolar II disorder (‘previous or current and previous’) and five (3.0%) met criteria for ‘uncategorised bipolar disorder’. Eight (4.8%) met criteria for lifetime psychotic disorder, of whom five (3.0%) met criteria for current psychotic disorder. There was one individual (0.6%) who met criteria for current generalised anxiety disorder. A total of 19 (11.5%) met criteria for suicidal ideation (15 at ‘low level’, 1 ‘medium level’ and 3 ‘high level’) (*Table 3*). Eight (4.8%) had more than one diagnosis.

Mini International Neuropsychiatric Interview (MINI) diagnosis	<i>n</i> (%)
Major depressive disorder	9 (5.5)
Major depressive disorder with psychotic features	3 (1.8)
Manic episode	3 (1.8)
Hypomanic episode	3 (1.8)
Hypomanic symptoms	6 (3.6)
Bipolar I disorder	3 (1.8)
Bipolar II disorder	3 (1.8)
Uncategorised bipolar disorder	5 (3.0)
Lifetime psychotic disorder	8 (4.8)
Current psychotic disorder	5 (3.0)
Current generalised anxiety disorder	1 (0.6)
Suicidal ideation	19 (11.5)
>1 diagnosis	8 (4.8)

Discussion

Screening and diagnostic tools

The SRQ is easy and quick to use. The interviewers found that questions 1–20, which asked about depressive and neurotic symptoms, were more easily understood than questions 21–24, which asked about psychotic symptoms. In particular, question 22 referring to grandiosity was often misunderstood. It was concluded that the first 20 questions would be a useful screening tool for depressive and neurotic disorders, whereas the psychosis questions should be amended. Of the 40 residents who entered phase 2, 24 (60%) were found to have a diagnosis and/or suicidal ideation when interviewed with the MINI. Thus, this method of identifying patients with psychiatric disturbance appeared to have produced a high 'yield'. The MINI, although straightforward to use as a diagnostic tool was time-consuming to

administer. We concluded that the SRQ could be used to screen residents on admission, and those scoring above the cut-off referred for further assessment.

Rates of mental disorders

Although the high prevalence of psychiatric morbidity in correctional populations has often been highlighted in Western countries,¹⁰⁻¹³ there is less data available in non-Western countries.¹⁴ High prevalence of mental disorders have been found in an Iranian prison population.¹⁵ Similarly, high rates of psychiatric morbidity were found in individuals who misused methamphetamine detained in Taiwan.¹⁶ This is the first investigation of psychiatric morbidity in a drug-misusing population in Brunei. Major depressive disorder was the most common diagnosis and was observed in 5.5% of the sample, similar to the Taiwanese finding. Lifetime psychotic disorder was found in 4.8% of residents, 3.0% of whom had a current psychotic disorder. Although we attempted to exclude psychotic symptoms directly associated with substance misuse, it is possible that some findings may have been methamphetamine psychosis rather than a primary psychotic disorder. Bipolar I disorder was observed in 1.8% of residents and bipolar II disorder was similarly observed in 1.8% of residents. The rates of psychotic¹⁷ and bipolar disorders¹⁸ appeared to be higher than in the general population, although no epidemiological data exist for the prevalence of mental disorders in Brunei.

Previous psychiatric disturbance and socio-occupational dysfunction

We found substantial rates of psychiatric morbidity. Our results also indicate substantial socio-occupational dysfunction, violence and offending behaviour. Given that these were self-reported, it is likely that they were underestimated. These findings emphasise the need for psychiatric, psychological, behavioural and socio-occupational interventions.

Pattern of drug misuse

Crystal methamphetamine is commonly available in Southeast Asia. It is locally known as 'syabu' and was the most common drug of misuse found in this sample. The first case of crystal methamphetamine misuse was reported to the NCB in 1993. Since then its use has spread across the country, affecting many lives and families. Drug supplies are manufactured abroad and transported across the border from neighbouring countries, often by land or water routes. Southeast Asia has a higher consumption of amphetamine-type substances compared with the global average. The neighbouring countries of Thailand, Malaysia, Cambodia and Indonesia have seized record high amounts of crystalline methamphetamine in the past few years. Annually, hundreds of illicit synthetic drug manufacturing facilities have been seized in the region over the same period.¹⁹ The availability of crystal methamphetamine is likely to contribute significantly to its popularity in Brunei. In contrast, the country has not had a widespread heroin misuse problem, avoiding the hazards associated with intravenous drug misuse. This pattern of drug misuse should inform national drug treatment and rehabilitation strategies. Substitute prescription such as methadone programmes used to treat heroin addiction more common elsewhere, cannot be usefully applied here.

We found that the rate of self-reported alcohol problems in this population was very high (61.8%). This may reflect the conservative Islamic view regarding alcohol use in Brunei, which may lower the threshold for viewing alcohol consumption as problematic and increase the likelihood of problems associated with its use.

Societal views of drug and alcohol use

Societal views regarding drug and alcohol use are generally very conservative. This is reflected in the heavy penalties imposed on those convicted of drug misuse, dealing and trafficking offences.²⁰ More than two-thirds of the population is Muslim and it is the official religion of the state. It is expected that alcohol should not be consumed at all by Muslims. The sale of alcohol is banned, and only non-Muslim adults are allowed to take controlled quantities into the country for personal use. Public drinking is not allowed. The phased introduction of the Syariah Penal Code,²¹ which began in April 2014, further increases the prospects of heavy punishment for those who contravene the strict laws relating to alcohol use. Under this new law, drinking alcohol is an offence for Muslims. Public drinking both in the country and abroad, providing alcohol to a Muslim and abetment of a Muslim to consume alcohol are listed as punishable offences for non-Muslims. Those convicted of alcohol offences may be fined, imprisoned and punished with whipping.

Treatment for alcohol and drug misuse

Many people are reluctant to admit their problems or seek help, although individuals can present themselves to psychiatric services. Pharmaceutical preparations such as disulfiram and naltrexone are available for the treatment of alcohol misuse. Structured community alcohol or drug misuse treatment programmes run either by medical services or the voluntary sector, are not available. There is limited open discussion about drug and alcohol misuse problems. The cause and impact of these problems locally and treatment and rehabilitation are areas that have received little research attention. Rehabilitation in Pusat Al-Islah, similar to other rehabilitation and training schemes in the country, places a strong emphasis on Islamic religious counselling. Psychological and behavioural treatment programmes require much development.

Our clinical experience working in psychiatric treatment facilities suggest that many individuals with substance misuse problems also have mental health problems requiring multidisciplinary care. The government provides largely hospital-based psychiatric services. Community, subspecialist and multidisciplinary services are limited although there have been some recent developments. New mental health legislation, in the form of the Mental Health Order 2014, has been approved. This legislation is designed to ensure the appropriate care of people with mental disorders and is scheduled to be implemented on 1 November 2014. The development of multisector partnerships is crucial to fully addressing the complex needs of this population.

Limitations

The two-phase design of this study may have reduced the accuracy of the results. Residents with a current diagnosis in phase 1 may have recovered before the phase 2 interview. However, the MINI allows for previous and lifetime diagnoses to be coded. The Malay translations of both tools may have limited validity in this population as the Malay dialect spoken in Brunei is slightly different to standard written Malay. The MINI interviewers were not masked to the diagnoses or treatment received by participants. This study depended on self-reporting of socio-occupational dysfunction as we were unable to obtain official reports. It is likely that the true prevalence of psychiatric disorders and socio-occupational dysfunction were higher given the limitations. The sample size in this study was small, with only 32 patients being finally assessed in phase 2. This may have affected the accuracy of our findings. We suggest that any future study should screen a larger sample of new residents on admission, with the diagnostic interview conducted as soon as individuals with mental disorders are identified. This would measure the incidence rates of mental disorders more accurately.

In conclusion, this is the first study to examine psychiatric morbidity, pattern of drug misuse and socio-occupational dysfunction in a Bruneian population of drug misusers. It highlights the treatment and intervention needs of this high-risk group and the challenges faced locally.

We thank the staff of Pusat Al-Islah and the NCB for their assistance. We thank David V. Sheehan and Christopher Gray of Medical Outcome Systems for their permission to use the MINI.

- *Bulletin comment: In praise of the psychiatric ward round†*

Facing a room full of strangers when hallucinating, delusional or suicidal could clearly be seen as an ordeal. However, such a situation continues regularly during ward rounds in psychiatric hospitals the world over. Campaigners advocating for the rights of patients or service users have repeatedly called for the trial of the weekly review to be abolished. It causes anxiety and stress, with most attendees complaining of feeling as though they had not been listened to and that vital information had been withheld from them.

Considerations of the power and more subtle dynamics between patients and staff – specifically the more senior clinicians – during the ward round provide helpful insights as to how damaging such regular interactions might be. The only conclusion surely must be the immediate cessation of such an anachronistic institutionalised process. However, the psychiatric ward must have some positive or beneficial aspects not only for a multitude of multidisciplinary members who attend it but also for the distressed, sick patient who has to endure it. Ward rounds have been taking place for decades; had they been purely detrimental they surely would have been junked years ago.

The chance for medical students and trainee doctors to see a senior clinician interview a patient in a difficult and challenging environment is invaluable. Observing such an interaction may offer junior staff insights into both beneficial methods that work and harmful approaches that should never be repeated. The opportunity to see signs and symptoms of psychiatric disease is educational for all.

Eliciting such phenomena may be harmful to the patient and the degree to which the assessment results in a negative experience is as much to do with the skill of the interviewer as it is with the patient's pathology.

Seeing how an individual deals with and reacts to a challenging situation often provides valuable insights as to any underlying psychopathology. The ward round might lead the patient with more personality-based difficulties to exhibit a pathognomonic response that might not have been otherwise observed. The previously elated patient with bipolar disorder who is able to sit in the ward round without breaking into song or rhyme is obviously improving.

And finally, following in the footsteps of Foulkes it might be argued that the social interactions of the patient in the group setting are providing some therapeutic benefit, however small.

1.8.71 Are psychiatrists only fools and horses to be open all hours?

Gary Wannan M. E. Jan Wise

Correspondence

Gary Wannan (gary.wannan@nhs.net)¹

date

2015-12

Abstract

The UK government's proposal for 24-hour healthcare means effectively asking doctors to work more unsociable hours for relatively little financial gain. In our opinion, psychiatry is particularly vulnerable to deterioration owing to negotiations of the terms of the current Consultant Contract that ensures fewer antisocial hours, whereas without parallel appropriate internal team and intra-agency working, provisions for which are not included in the government's proposals to extend care, patient care is vulnerable. Clarification and a narrower redefinition of what constitutes a psychiatric emergency is called for.

Contents

- *Are psychiatrists only fools and horses to be open all hours?*

Psychiatry is no stranger to major shifts in the way it thinks or is delivered. The pre-pharmacological treatments of the 1950s shifted into the Brave New World of Largactil, and reacted with the therapy-rich and anti-establishment fad made famous by Laing and the railing against biological facets exemplified by Szasz. With its diversity of self-reflection, psychiatrists have a legacy to assist in changing practice.

Methods or modes of delivery of care have also been criticised. Deinstitutionalisation was followed by the crisis of care in the community, amid a spate of high-profile homicides. Risk management, best represented by the Confidential Enquiry into Suicides and Homicides¹ and at worst an ill-thought-out bureaucratic bungle, added to the administrative burden without clear evidence that the public and patients are now safer.

Recent assaults on the financial health of medical staff working in the National Health Service (NHS) have included 6 years of pay cuts and raids on future pensions. More general cuts in the organisation they work in have led to low morale and allegations that rather than this being viewed as a new paternalism, that somehow 'nanny [the State] knows best', it is a neglecting and neglectful state.² After several years of the 'Nicholson challenge',³ with further cuts in funding to mental health services, resources are at a dangerously low level⁴ and the Cinderella of the NHS faces unprecedented challenges, singled out for selective cuts with resources not following morbidity.

In this environment, the government is proposing a '24/7 service'. On the face of it, running a psychiatric service is a 24-h activity anyway. In-patients require constant access to appropriate medical and nursing help; relapses and remissions of community patients do not always coincide with their care coordinator's availability. So it seems self-evident that psychiatric services run 24 hours a day, 365 days a year. To many it seems that a disingenuous impression is being created that consultants do not provide a 24-h service when in fact they do so across specialties in the NHS.⁵

The government appears to have used this sleight to demand that there be contractual changes to remove any obligation to pay consultants an appropriate premium for out-of-hours work.

However, if the government's drive is for the same level of service all the time, that is a separate matter. Examples of this would include routine out-patient clinics on a Sunday afternoon and late evening consultant-led ward rounds. Nearly all disciplines, especially psychiatry, deliver care in a team manner, so without expansion of numbers across professions, how are the same levels of interactivity to be maintained outside Monday to Friday, 9-to-5 opening hours? If Donne's metaphor is apt, psychiatry is not an island, so where will children and families' Social Services be, and the police, occupational therapy, clinical psychology and investigative services, when required? Although the government has acknowledged this problem,⁶ it is evident that an initiative from the Department of Health will not be prioritised in the same way by other departments.

The financial and human resource implications appear to be largely not considered. Although there is evidence of better outcomes for patients seen during the week in non-psychiatric specialties, there is no clear costing of the changes required to raise weekend services to the same level as those provided during the week. Many NHS staff have premium rates for unsocial hours: fewer staff will be spread more thinly across weekends and evenings, so without additional recruitment, daytime services will shrink and likely worsen outcomes Monday to Friday. Whereas there are theoretical savings in physical medicine with extended use of surgical theatres or radiological facilities, such potential is not so easy to find in mental health services. For those drawn to community work in particular, reducing family time, a reason many choose the specialty in the first place, will affect recruitment and retention. Surveys of consultants show that the average time spent on NHS activity is already well in excess of contractual requirements, at 5.8 hours extra unpaid labour a week,⁷ thereby further increasing the challenge of doing more with less.

We are aware that that several NHS trusts are attempting to alter Standard Operating Procedure to specify what consultants will do while on call, including mandating non-emergency tasks out-of-hours. Consultants, in particular, have the reasonable expectation that on-call work will be for tasks that require their level of experience and skill, rather than for bureaucratic reasons.

The 2003 Consultant Contract⁸ contains an important provision at Schedule 3, Paragraph 6: "Non-emergency work after 7 pm and before 7 am during weekdays or at weekends will only be scheduled by mutual agreement between the consultant and his or her clinical manager. Consultants will have the right to refuse non-emergency work at such times. Should they do so there will be no detriment in relation to pay progression or any other matter." To the government, this is a major impediment to an imposition of 24/7 working in the absence of agreement. To negotiators, it is an important safeguard against excessive and antisocial hours with the compromise of patient safety. For either side, its meaning could become totemic.

There may be much discussion over what an emergency is. We suggest a framework where the most important categories are akin to those used in time management:⁹ emergencyurgentimportantnot urgent not important.

Emergency is defined as 'a serious, unexpected, and often dangerous situation requiring immediate action'. So, a non-emergency is anything that is not an 'emergency'. An urgent problem may later become an emergency, but that is a separate issue.

The Cassandras among us may worry about litigation where an action is delayed. However, it is the commissioned service's responsibility to ensure that there are appropriate care arrangements in place, not the individual consultant's. Of course, the General Medical Council provides help on this matter when stating that: "If patients are at risk because of inadequate premises, equipment or other resources, policies or systems, you should put the matter right if that is possible. You must raise your concern in line with our guidance and your workplace policy."^{10:para.25} Many will agree that acute suicidal ideation, an acute dystonic reaction and attempted self-harm are all emergencies. Likewise, while administrative procedures that allow leave while detained, or medication to be administered lawfully, are very important, they are not 'emergency' situations. Military training includes the mantra that 'A failure to plan on your part does not constitute an emergency on mine', something we would do well to remember.

So where do practitioners sit on the urgent category? There will be some that lie outside our comfort zone, for humanitarian or other reasons, such as advice to a trainee about medication for psychotic phenomena where few would not readily offer advice even when not deemed an emergency. However, where is the boundary with the Human Rights Act? Many NHS trusts have a seclusion review policy where after 24 h in seclusion a review in person by a consultant

must occur. Now this may be good practice according to the Mental Health Act Code of Practice, but an infringement of best practice is not an emergency.

It may well be that the solutions of other countries may help. Greenland, part of the Kingdom of Denmark, runs practically all of its psychiatric services over videoconferencing facilities.¹¹ In Los Angeles, time constraints and skills shortages have led to a parallel approach (R. Mendoza, personal communication, 2015). The British ‘special hospitals’ have used the same technology to reduce loss of clinical time to travel to disparate sites or courts.

The discussion about what is an emergency should rage, and it should rage hard. It is a point around which consensus would allow us to protect that which we cherish – a service delivered in a considered and coordinated manner, where there is a fair exchange of time and labour for salary and security. In a politically driven, evidence-poor initiative, psychiatrists should stand firm on whether the proposed changes hold merit. If they do, at what cost should we accept them?

1.8.72 Mindfulness for Health: A Practical Guide to Relieving Pain, Reducing Stress and Restoring Wellbeing

Thomas A. Ernst¹

date

2015-12

Contents

- *Mindfulness for Health: A Practical Guide to Relieving Pain, Reducing Stress and Restoring Wellbeing*

This book leads the reader through a journey of how to deal with suffering from bodily symptoms-related illness and injury. It clearly describes the differences between primary suffering due to injury and secondary suffering largely created within the mind through learnt views, behaviours and fears the person has experienced in their life or through their illness. It then gently describes how, by engaging with the secondary suffering, much of the suffering can be relieved or brought down to the primary pain and suffering which is generally easier to manage within traditional medicine. The book also points out that traditional medical models of pain often miss secondary suffering, whereas traditional therapies often fail to address secondary suffering or can even make it worse. It is to the great credit of authors that they deal with this sensitive issue with compassion and empathy.

The book then turns into a step-by-step practical guide on how to approach secondary pain and suffering. The guide is complete with audio recordings of practices that the reader can easily follow and this will not require excessive time. Real-life experiences of people who were helped by following this guide are included.

The problem of dealing with pain and suffering is as old as humanity and the readers would have come across many hopes and promises made by medicine, alternative medicine and the spiritual sector among others. This book outlines not only anecdotal evidence in the form of testimonies from people engaging in mindfulness but also benefits from a wealth of research which it refers to.

As a doctor having used mindfulness successfully to manage my own pain and suffering from illness, I found reading this book was somewhat challenging, as it would be to many other readers. However, I have not yet read a book on mindfulness so sensitive and gentle with the issue of pain and suffering as this one.

1.8.73 Should psychiatrists ‘Google’ their patients?

G. Alice Ashby Aileen O’Brien Deborah Bowman Carwyn Hooper Toby Stevens Esther Lousada

2015-12

Abstract

Since its beginnings in the 1980s the internet has come to shape our everyday lives, but doctors still seem rather afraid of it. This anxiety may be explained by the fact that researchers and regulatory bodies focus less on the way that the internet can be used to enhance clinical work and more on the potential and perceived risks that this technology poses in terms of boundary violations and accidental breaches of confidentiality. Some aspects of the internet’s impact on medicine have been better researched than others, for example, whether email communication, social media and teleconferencing psychotherapy could be used to improve the delivery of care. However, few authors have considered the specific issue of searching online for information about patients and much of the guidance published by regulatory organisations eludes this issue. In this article we provide clinical examples where the question ‘should I Google the patient?’ may arise and present questions for future research.

- *Mental health monitoring using social media*
- *Safeguarding vulnerable adults online*
- *Only Googling when there is no other option*
- *To consent or not to consent?*
- *Mental health specific concerns*
- *Conclusions and proposals for future research*

Background

The internet is a part of everyday life and access to it is growing at a startling rate. According to the United Nations' specialised agency for information and communication technologies (the International Telecommunication Union), by the end of 2014, 3 billion people, approximately 43% of the world's population, will have access to the internet, compared with 60 million people in 2000. The number of mobile-broadband subscriptions will reach 2.3 billion globally by the end of 2014, almost five times as many as in 2008.¹ Social media has also weaved its way into people's lives over the past decade. There were 802 million daily active users and 1.28 billion monthly active users of the social media site Facebook in March 2014, and over 80% of the daily users of Facebook are based outside the USA and Canada.² According to the Office for National Statistics, the UK has one of the highest rates of social media use in Europe, with almost half of all adults (48%) using social networking sites such as Facebook and Twitter.³

Some aspects of the internet's impact on medicine have been better investigated than others. Various authors have looked at whether email could be used as an acceptable form of communication between doctor and patient.^{4,5} Psychiatrists have also looked into the possibility of using video conferencing for psychotherapy.⁶ The use (and misuse) of social media by doctors, in terms of professionalism and boundary violations, has been studied.^{7,8} This has led to a plethora of professional regulatory bodies and other medical organisations publishing guidelines to help doctors navigate the internet in general and social media in particular.⁹⁻¹³ The published guidance is reasonably thorough: guidelines concentrate on the advice given to professionals about their use of social media sites, and their profile on them. Professionals are advised against forming friendships with patients online. However, professional bodies are often behind the curve in doing this. For example, the UK's General Medical Council guidelines were first published on the 25 March 2013,⁹ a full 9 years after Facebook was founded.¹⁴

The issue of searching online for patient information has caught the imagination of doctors and ethicists writing in the blogosphere.¹⁵⁻¹⁷ Many raise concerns about the potential ethical 'slippery slope' of Googling your patient, but raise examples where it may be justifiable. However, there has been little discussion in formal medical ethics and law literature about this issue. There is also a paucity of official guidance to help doctors navigate their way through this particular online minefield. For example, the British Medical Association's guidance on social media does not refer to this issue at all and the Royal College of Psychiatrists in the UK has not yet issued any guidance in relation to this kind of online activity. Where professional guidance does touch upon the issue of 'online searching' it focuses on the problems that can arise when patients 'Google' their doctors rather than the other way around. We are not aware of any legal cases in this particular area either. In sum, there is an apparent regulatory lacuna in terms of whether and if so, how, doctors should use the internet to dig around in their patients' digital backyards.

The lack of research and guidance in this area is increasingly problematic because a great deal of information about patients is now available at the click of a search box button. Many of us are documenting our lives online far more than might have ever been expected 20 years ago and doctors and patients can now find out a huge amount about each other online with relatively little effort.¹⁸ In addition many patients post personal information online that could potentially harm them or have an impact on clinical assessments by their healthcare professionals and a growing number of doctors admit to using the internet to search for general clinical information.¹⁹

Clinton *et al* provide the only comprehensive review of the literature on the ethical difficulties surrounding searching online for information about patients, something they term 'patient-targeted Googling' (PTG).²⁰ They provide a list of questions for psychiatrists to consider before deciding whether to use PTG, shown in Box 1.²⁰ They argue that PTG can be an acceptable clinical tool but warn against 'unbridled PTG simply because online information is legally available in

the public domain'. They describe possible conflicts, such as using 'Google Earth' to look at photographs of a patient's large house, when the person has not paid for psychotherapy (the authors are based in the USA), and compare this with driving past the patient's house, which would be considered by many to be a boundary violation.²⁰ This raises questions about whether such media reconstitute the meaning of boundary violation: is looking at 'Google Earth' as intrusive as going to look at someone's house in person? The internet, whether we like it or not, has caused pre-existing boundaries to blur.

In this paper we will look at the potential benefits and harms related to internet searching being used as a clinical investigative tool and propose some questions for future research. In this article we use the word 'Google' as a verb intentionally, as it has become part of our everyday English language, meaning 'to use an internet search engine to find information'.

Checking conflicting and falsified information

Internet searching for information about patients may mean finding things you did not expect, that the patient had not shared or had even lied about. Should we use the internet to investigate factitious disorder or malingering?

Volpe *et al* discuss a case involving a 26-year-old patient who had requested a prophylactic bilateral mastectomy with reconstruction because of an extensive family history of cancer, where there was suspicion among the clinical team that some of the history was fabricated.²¹ In the paper Volpe, Blackall and Green argue that 'uninvited patient Googling' is bad practice for three reasons. First, it bypasses the personal relationship and makes it too easy to terminate a relationship with a patient, and to avoid discussion of personal topics. Second, it erodes provider-patient trust. Third, it represents an invasion of privacy. They also make the point that it is unclear why a healthcare professional would not just ask the individual in person if they had any concerns about them. In the same paper, George, Baker and Kaufmann argue for the opposite position.²¹ They note that it would be 'irresponsible not to exhaust all resources in learning about a patient with such troubling red flags'. They argue that the finding of a factitious disorder via the patient's two Facebook pages 'saved a team of professionals from aiding and abetting a fraudulent, deceptive and self-injurious scheme', stopping them from breaking their oath to first 'do no harm'.²¹

Clinton *et al* ask how the discovery of important information found online would then be broached with the patient and how this information should be documented in the medical notes.²⁰ Interestingly, no author we could find in a literature search had considered whether an online search could be performed with the patient's informed consent and, perhaps, in the patient's presence. In the Volpe *et al* case, for example, the surgical and genetics teams used an internet search in what they believed to be the patient's best interests, without telling her beforehand. What is also not explained is how the patient was told she would not be having surgery and what reasons the patient was given for this decision.

Uncovering dangerous lifestyle choices

Doctors could Google their patients in order to investigate concordance with advice about treatment and lifestyle changes, including advice about not driving or misusing various drugs. Psychiatrists, in particular, might be interested in discovering whether a patient with psychosis is drinking alcohol heavily or using other substances, which might cause or exacerbate psychotic symptoms.

Farnan *et al*'s main concern is that 'digitally tracking the personal behaviours of patients, such as determining whether they have indeed quit smoking or are maintaining a healthy diet, may threaten the trust needed for a strong patient-physician relationship'.²² The violation of trust might occur because patients assume that doctors do not perform such searches (i.e. the violation relates to a real, or perceived, deceit) or because they feel that such activity violates important boundaries. Gabbard *et al* note that the boundary violation may be the nub of the problem.²³ It is hard to imagine how the doctors in the Volpe *et al* case, described above, approached their patient with the information found on her Facebook accounts. If the information was related to her – as it presumably was – it is hard to see how this could have led to a positive, therapeutic, outcome. Indeed, the patient may well have felt betrayed by the team caring for her.

Of course, if a doctor can find out about such things as alcohol and drug misuse by searching in the 'online public domain', the same holds true for other people. Accessing information on an internet search engine or social media site would be much easier for a patient's future employer than accessing a person's medical records without their

consent. In an era of recovery-oriented medicine, including supporting people to return to work, perhaps we should be proactively and openly discussing online presence, for example as part of the employment support provided by a community psychiatry team?

Mistaken identity

Another problem may arise from the fact that many people have the same names. How do we know information found on Google about a patient is actually about them? If you Google one of our names (G.A.L.), an online namesake is a character from the film ‘The Devil’s Advocate’, in fact ‘Alice Lomax’ in the film is Satan’s child’s mother. We doubt anyone is actually confused by this, but clearly less obvious confusions might happen, and the simple answer is that identities online cannot be absolutely confirmed. Furthermore an individual may use pseudonyms, or internet information might obviously be wrong, as anyone can post anything.

If, however, we had asked for informed consent from the patient to do the search in the first place, especially if they were present during the search, the potential for confusion could be reduced because they could identify any obvious errors with ease. The patient could also more openly discuss with their doctor any negative – and potentially defamatory – comments posted about them online by other people and it would also help doctors identify situations where the patient was the victim of ‘cyber-bullying’.

Delusions of grandeur or reality?

An internet search can act as a form of collateral history. For example consider a man who presents with an exuberant, energetic persona, speaks rather quickly and loudly, and then tells his doctor he knows some Royals and has written a famous book or been in a film. Googling his name might immediately clarify whether these were grandiose delusions and this information might also make a difference in determining whether or not the patient is diagnosed with mania in the context of bipolar disorder.

Clearly the difficulty with this is that something being online does not mean it is true. It is possible to ‘be who you want to be’ online; to invent an ideal persona or avatar is almost as simple as revealing information about yourself that ‘you did not want to be made public’. However, we suspect that many clinical psychiatrists have used Google for this purpose before, as often multiple references, or references on trusted sites, can give reassurance that what someone is saying is true. There is a clear negative side to this however. Patients in psychiatry may be particularly vulnerable to not being ‘believed’ and routine Googling to check what the person has said might reinforce this tendency and stigma.

Mental health monitoring using social media

Consider a long-term patient with severe depression, who has regular appointments with a community psychiatry team. Could someone from the mental health team monitor the patient’s mental state via their social media feed or blog, with their consent? Assuming people write honestly and use the same websites regularly, social media can give a unique, time-relevant insight into a person’s mental state. For example a Facebook ‘status’ or a ‘tweet’ on Twitter might often include information about how a person is feeling. The posting of certain pictures and videos or even ‘emoticons’ (cartoon faces depicting different emotions) might also reveal important insights into the patient’s current frame of mind.

Clearly, if psychiatrists were to monitor mental state in this way, it would fundamentally change how mental health systems work, but it is not as far fetched as it sounds. It would not necessarily involve a person constantly watching the millions of messages streaming via a forum, Facebook or Twitter feed, which would clearly be impossible. The technology to automatically flag the use of certain phrases in emails or on social media already exists, and a team at Dartmouth University in the USA, involving computer scientists and psychiatrists are developing this technology to help prevent suicide, as part of *The Durkheim Project*.²⁴

Familiarity with the internet does depend on age. Marc Prensky describes ‘digital natives’ as compared with ‘digital immigrants’, born before the ‘rapid dissemination of digital technology in the last decades of the 20th Century’.²⁵ He, fairly terrifyingly asserts that today’s average university graduate has ‘spent less than 5,000 hours of their lives reading,

but over 10,000 hours playing video games [and] 20,000 hours watching TV' and that 'as a result of this ubiquitous environment and the sheer volume of their interaction with it ... think and process information fundamentally differently from their predecessors'. There is evidence that young people who self-harm find it easier to express their feelings honestly and openly in an online forum than during a face-to-face consultation and would prefer this.²⁶

This suggests to us that we should be open to different methods of communication with different age groups, as not doing so means we may miss vital information. In the mastectomy case described above, George, in the paper with Volpe and colleagues, goes further, and suggests we should use all the resources we have where there are 'red flags', and that not using an internet search would be negligent in some cases.²¹ This tracking would, potentially, allow interventions to be made, for example to intervene urgently if a patient was suicidal. Clearly the difficulty with this is that doctors cannot check the online 'statuses' of all their patients all the time, and it would be difficult to gauge where responsibilities would stop and what the standard duty of care amount to in such cases. In addition, tracking a patient's blog, or social media feed might actually, quite rightly, increase a sense of paranoia.

Safeguarding vulnerable adults online

Given that anyone and everyone can read what is openly online, an online search can sometimes protect vulnerable adults from abuse from others. Cyber-bullying, for example, involves threatening or derogatory messages posted on social media sites or online chat forums. It might also include things like encouragement to lose weight in anorexia nervosa or messages inciting self-harm or violence. Discussing this issue openly with patients and carers, in the same way that psychiatrists would openly discuss other risk issues, seems sensible. Also imagine a young man with paranoid schizophrenia who is in hospital, very unwell with psychosis, and finds it frustrating that no one 'believes' what he is experiencing. He tells his psychiatrist to look at his blog online, in order to fully understand what he means. The team agree that with informed consent it is acceptable to do this search and they proceed with the online search. In the process they find that the blog, which has almost daily entries, gives good information about when the patient started to become unwell since there is marked evidence that his thought disorder and delusional beliefs increased in severity over the course of the past few weeks. However, the team also see that in one blog post, the patient has included sensitive personal information about himself, including his home address. They discuss this with him, and how vulnerable this might potentially make him, and arrangements are made for the blog post to be taken down.

In this situation the patient has given permission for the online search and has, in fact, asked the team to specifically read his online blog. In such cases searching online for information seems reasonable. However, this kind of scenario raises deeper ethical questions about whether mental health professionals should be proactively discussing online presence with patients, not just to find out information about deteriorating mental state, or to help holistically with recovery, but also to safeguard vulnerable individuals and potentially assess risk to others, for example by discovering threats made online in the context of illness.

Only Googling when there is no other option

Searching for information about a patient online should also clearly be done on a 'need to know' basis and not purely out of curiosity or voyeurism. Imagine a core trainee being called to a forensic psychiatry in-patient unit on-call, which they do not usually work on, to examine a patient who might have a chest infection. We would not expect this doctor to search online to find out what crime was committed by the patient because this information has no bearing on the patient's physical problem and will not help the doctor to provide whatever treatment the patient may need. In fact, the internet search might even have an impact on the ability of the doctor to treat the patient in an impartial and non-judgemental manner, especially if the crime was especially heinous.

Of course, doctors have the right to protect themselves from harm and the need to perform a risk assessment may mean that the doctor would need to know about any danger posed by the patient. However, there would be no indication for an internet search in this case as other members of the team would know the patient's history well and would be able to inform the doctor if the patient was dangerous. The doctor could also, of course, consult the patient's notes if no other team members were available to consult.

To consent or not to consent?

Would it be better practice to routinely ask consent and is informed consent possible for a Google search in psychiatry? The key elements of consent for an intervention in medicine usually include patient competence, the health professional giving clear information about potential benefits and risks and voluntariness. Many psychiatric patients fulfil all of these requirements and could, thus, consent to an online search. However, some of the patients in whom an online search may be a useful ‘investigation’ may not have the mental capacity to consent.

Likewise, patients on a psychiatry ward or in clinic may feel coerced into allowing an internet search, feeling that a ‘no’ will mean doctors will get suspicious or carry out a more ‘invasive’ online search without their consent. It is also worth pointing out that some patients might want to delete a few posts and images before the search is carried out because they deem some information to be ‘embarrassing’ (for example a photograph of them when they were an ‘awkward’ teenager). This does not seem unreasonable but it might be difficult if the doctor wants to conduct the search immediately. We are also concerned about the discussion about risks and benefits: if we do not know exactly what we will look for or find, is discussing the relative merits of a search possible? It is unusual for a doctor to discuss every possible finding of a magnetic resonance imaging scan or blood test with a patient before carrying it out, but of course the standard expected would be that relevant information is shared.

Informing patients would neuter the problem associated with deceit, however, it would not deal with the problem of potential boundary violations and it would not solve the potential for coercion either. The only way around these problems would be to seek consent from every single patient and make it clear that any refusal would be honoured. In other words, perhaps we should seek consent to search online for information about patients just like we ask for consent to speak to a relative or friend to discuss a patient’s condition? If we were to do this openly, perhaps the risk that patients might become upset or angry about the process might be reduced and, as Chretien & Kind note, this would help to limit foreseen harms.²⁷ There may be situations where risk to the patient, or to others, means that a Google search is appropriate without the patient’s consent.

Mental health specific concerns

Some of the ethical issues raised may be more pertinent to psychiatry than to other branches of medicine. Many patients will have experienced the validity of what they are saying being doubted by their doctors. If psychiatrists embrace PTG it could be seen as another paternalistic intervention. The capacity of patients in psychiatry will by the nature of their conditions be more likely to be impaired than in other branches of medicine. They may well lack capacity to understand the consequences of what they post on Facebook if, for example, manic and may cause damage to work and social relationships as a result. This raises difficult questions for concerned family and professionals about looking at posts on the internet, and even trying to get posted information removed.

Conclusions and proposals for future research

Many questions remain unanswered about the acceptability of Googling patients, especially those with mental ill-health, from an ethical and legal point of view. There is clearly an urgent need for this topic to be addressed in the ethics and medical law literature.

Should psychiatrists Google patients at all? Should they do it routinely, for all their patients? Should they ask for consent each and every time? Should they share the information with the patient? These kinds of questions urgently need to be addressed by ethicists and psychiatrists alike. We feel that when making a decision to Google a patient, it would be appropriate to work through a list of questions and reflect on how one would respond, the most important question being ‘why am I doing this internet search, and is it likely to help my patient?’

Further analysis of the legality of conducting Google searches is also needed. Given that the kind of online searches we are talking about here would only involve looking for information that is already in the public domain it is not clear that this activity could be considered unlawful. However, the lack of case law in this area makes the legality of the activity harder to judge.

We feel that clear guidelines are needed from the bodies that regulate health professionals on the use of internet searching, and where these newly emerging doctor-patient boundaries lie, especially within psychiatry. We propose that more empirical research is needed on this topic. For example, we would like to know how widespread the practice of PTG is among health professionals, and whether this varies depending on age, experience or professional group. Much more qualitative information is needed about the views of patients, their friends and families, and healthcare professionals about this kind of activity: the problems it might cause and potential benefits.

Failing to make use of modern technology when this technology can improve patient care is not an option. Failing to discuss the merits and demerits of using online searchers in an open and honest fashion is not really an option either. The reality is that the internet has become an integral part of our daily lives and medicine as a whole, and psychiatry in particular, need to get to grips with what this means for modern medical practice.

1.8.74 Bipolar Disorder

Lena Jawad¹

- *Bipolar Disorder*

Bipolar Disorder is a pocket-sized book whose target audience is any member of the multidisciplinary team involved in looking after a patient with bipolar disorder.

It begins with an interesting glimpse into the history of bipolar disorder and how the illness was documented in biblical texts as early as 1000 bc. Its key themes include the diagnosis of bipolar disorder, epidemiology, comorbidities, neurophysiology, genetics, psychopharmacological and non-psychopharmacological management, and managing 'special' populations with bipolar disorder (e.g. children, pregnant women).

The text is easy to read and key points are excellently summarised in boxes throughout. The book fulfils its aims (stated in the blurb) to a very high standard, covering all important areas of bipolar disorder in a way that is succinct and aids retention of knowledge. Although not fully comprehensive, it helpfully lists references after each chapter to guide the reader to further reading around the topic.

One of the main strengths of the book is its effective presentation of information, using a combination of prose, bullet points and diagrams to cater to the needs of a variety of learners. The chapter entitled 'A programmatic approach to treatment' takes readers through a thorough management plan, making the whole process more holistic – this is something I will most certainly take from the book and apply to the management of all my patients, regardless of their illness.

The only limitation is, perhaps inevitably, its emphasis on US Food and Drug Administration-approved medications in its pharmacological management chapter, which may not be as relevant to psychiatrists practising in countries other

than the USA. The book, however, does its best to incorporate global knowledge of bipolar illness, with references to a variety of countries.

I would wholeheartedly recommend this guide to anyone interested in learning more about bipolar disorder or who simply requires a revision of the key topics surrounding the illness.

1.8.75 The application of mental health legislation in younger children

Abstract

We review a case history of a young child who was admitted to an in-patient mental health unit due to extremely challenging behaviour and review the legal issues that had to be considered in ensuring that there was appropriate legal authority for the child's admission and treatment. In this particular case, the patient was detained for assessment under section 2 of the Mental Health Act 1983. This case demonstrates that all clinicians working in this area require a good understanding of the law in relation to treatment of children with mental disorder, which is extremely complex.

 - *Discussion*

Competence, parental responsibility and zone of parental control

Much of the debate around consent to treatment by young children has focused on competence. 'A child who has attained sufficient understanding and intelligence to be able to understand fully what is involved in the proposed intervention will be regarded as competent to consent'.¹ This concept is known as Gillick competence.²

However, especially for younger children, persons with parental responsibility are, in general, responsible for treatment decisions. Parental responsibility is defined by the Children Act 1989 as 'all the rights, duties, powers, responsibilities and authority which by law a parent of a child has in relation to the child and his property'. The Code of Practice for the Mental Health Act:^{sup: [2]_`} advises that the person responsible for the care and treatment of the patient must determine whether a person with parental responsibility has the capacity, within the meaning of the Mental Capacity Act 2005, to make a decision about the child or young person's treatment and whether the decision is within the 'zone of parental control'.³ The 'zone of parental control' is a concept derived largely from European Court of Human Rights case law and has become central to parent-related decision-making.^{3,4}

¹ Victoria Thomas is a specialty doctor, Barry Chipchase, Lisa Rippon and Paul McArdle are consultant psychiatrists, all at Northumberland, Tyne and Wear NHS Foundation Trust, Ferndene, Prudhoe, Northumberland, UK.

Although not a clearly defined concept,⁵ there are guidelines in the Code about whether a particular decision falls within the zone of parental control. There are two key questions.³ First, ‘is the decision one that a parent would be expected to make, having regard both to what is considered to be normal practice in our society and to any relevant human rights decisions made by the courts’? Second, ‘are there no indications that the parent might not act in the best interests of the child or young person’? The less confident a professional is that they can answer ‘yes’ to both questions, the more likely it will be that the decision falls outside the zone.

The zone of parental control and deprivation of liberty

The Code acknowledges that the parameters of the zone will vary from one case to the next, but the following factors should be considered: the nature and invasiveness of what is to be done to the patient (including the extent to which their liberty will be curtailed); whether the patient is resisting; the general social standards in force at the time concerning the sort of decisions it is acceptable for parents to make; the age, maturity and understanding of the child or young person; and the extent to which a parent’s interests may conflict with those of the child or young person. Certain treatments that could be considered particularly invasive or controversial, for example electroconvulsive therapy (ECT), are likely to be considered to fall outside the zone of parental control.³

Decisions that would result in a deprivation of liberty will be outside the zone, as detention engages the article 5 rights of the child (Convention for the Protection of Human Rights and Fundamental Freedoms right to liberty and security) and a parent may not lawfully detain or authorise the detention of a child.⁶ There is no specific definition of deprivation of liberty, but various factors have been identified that are likely to be relevant; for example, the use of restraint (including sedation) to admit a person to an institution where that person is resisting admission; staff exercising complete and effective control over the care and movement of a person for a significant period; and the person being unable to maintain social contacts because of restrictions placed on their access to other people. A recent judgment from the Supreme Court,⁷ commonly referred to as the Cheshire West case, has provided a clear ‘acid test’ on the meaning of deprivation of liberty. The Supreme Court has made it clear that, for a person to be deprived of their liberty, they must be subject both to continuous supervision and control and not be free to leave. The Supreme Court also held that, in all cases, the following are not relevant to the application of the test: (1) the person’s compliance or lack of objection; (2) the relative normality of the placement (whatever the comparison made); and (3) the reason or purpose behind a particular placement.

One of the matters the Court considered in the Cheshire West case was whether children could be deprived of their liberty in the family home. It was noted that all children are (or could be) subject to some level of restraint. The necessity for this adjusted with their maturation and change in circumstances. The Court expressed the view that ‘very young children . . . because of their youth and dependence on others, have – an objectively ascertainable – curtailment of their liberty but this is a condition common to all children of tender age. There is no question, therefore, of suggesting that infant children are deprived of their liberty in the normal family setting.’ In the case of children living at home with either birth or adoptive parents, Lord Neuberger said that: ‘what might otherwise be a deprivation of liberty would normally not give rise to an infringement of article 5 [of the Convention] because it will have been imposed not by the state, but by virtue of what the Strasbourg court has called “the rights of the holder of parental authority”.’ Foster placements were viewed differently because children would generally have been placed in this environment by local authorities and therefore if there was a deprivation of liberty it would be ‘imputable’ to the state.

Prior to the Cheshire West case, many clinicians viewed the level of supervision in place in a hospital environment as amounting to a restriction, rather than a deprivation, of liberty. Since the case, there have not been any reported cases specifically considering the position of children and young people in hospital. It is inevitable however that, in the wake of the judgment, a number of children and young people who lack competence or capacity to consent to their admission to hospital and who are being treated on an informal basis will need to be assessed to evaluate whether they are being deprived of their liberty.

Hence, there will be situations where neither the consent of the patient nor parental consent may be relied on and an alternative legal authority for treatment will be necessary. The following case example demonstrates how clinicians working with children and young people are now required to manage difficult clinical scenarios within a complicated legal framework. Here we describe the reasoning behind the use of the Mental Health Act 1983 in an unusually young patient. We have been unable to find a published example of use of the Act in such a young child.

Case study

B was an eight-year-old boy admitted to a child and adolescent mental health in-patient unit as an emergency, because of extremely challenging behaviour. He had been referred to his local community child and adolescent mental health service several months previously and was diagnosed with autism spectrum disorder. He also exhibited features of hyperkinetic conduct disorder. He was subject to a child protection plan and accommodated by the local authority on a voluntary basis at the time of admission. Because of episodes of extreme unprovoked aggression and sexualised behaviour B had been excluded from a special school and two foster placements had broken down.

On admission, B received a comprehensive package of care, which included assessments and interventions by nursing and medical staff, psychologists and other therapists. He received a carefully structured intervention involving nurses experienced with younger children, play therapy, education appropriate to his developmental level and medication (methylphenidate). B was nursed away from the older adolescents within a self-contained children's area of the in-patient ward. He had two members of nursing staff with him at all times because of his challenging behaviours, including highly sexualised behaviour, physical aggression and destruction of property. He required regular, difficult restraints involving up to four members of staff at a time, and occasional use of seclusion to maintain his own safety and the safety of others. The Code of Practice for the Mental Health Act advises that seclusion of an informal patient should be taken as an indication of the need to consider formal detention.³

With legal advice from trust and local authority solicitors, it was agreed that as long as B met criteria for detention under the Mental Health Act 1983, this was the preferred route. The 'least restriction' principle of the Act suggests that detention under the Act should be the last resort. However, it is undoubtedly necessary in cases where the option for informal admission is not appropriate or the risks in managing the child informally are too great. A patient may be detained under section 2 of the Mental Health Act 1983 for a period of assessment of up to 28 days. The application is based on the recommendations of two medical doctors, and an approved mental health practitioner is the applicant. The professionals must be satisfied that the following grounds are met: the person is suffering from a mental disorder of a nature or degree which warrants their detention in hospital for assessment (or for assessment followed by treatment) for at least a limited period; and the person ought to be so detained in the interests of their own health or safety or with a view to the protection of others (para. 4.2).³ In this case, B both had mental disorder (autism spectrum disorder and hyperkinetic conduct disorder) and was presenting in a way that put his own safety, and that of others, at risk.

Following a Mental Health Act assessment and close consultation with local authority and trust legal services, B was detained under section 2. B appealed to the mental health tribunal with the assistance of his independent mental health advocate and solicitor. His detention was upheld. During the period of detention, the local authority obtained an interim care order and acquired parental responsibility. The local authority questioned whether it would be able to agree to B being in hospital informally, however, the clinical team felt that the treatment decisions about restraint and seclusion required fell outside of the zone of parental control, regardless of who had parental responsibility. B's behaviours did begin to settle and he gradually ceased to require the restraint and seclusion that he had earlier in his admission. He was therefore discharged from section 2 shortly before the end of the 28-day period and remained on the ward as an informal patient while an appropriate community placement could be identified. Following several months' intervention it was possible to discharge B safely to a children's home, where he has not required restraint.

Discussion

Detention of such a young child using the Mental Health Act 1983 is unusual and we could find no published case that would discuss this, although, anecdotally, others have faced similar decisions.

In this case, the team was confident that B's age and immaturity prevented him from being regarded as Gillick competent and therefore he could not provide authority for his own admission and treatment. Both of B's parents had parental responsibility and were supportive of his admission to hospital. Initially, the clinical team had relied on their agreement. However, in the light of B's deprivation of liberty parental consent to treat him could not be relied upon. In addition, the child protection plan raised concerns about the parents' ability to act in the best interests of the child. The team therefore decided that the decisions that now needed to be made about B fell outside of the zone of parental control.

In emergency situations, a doctor can lawfully treat a child even if there is no time to obtain valid consent. This is known as the doctrine of necessity. The Code of Practice for the Mental Health Act advises that: 'In such cases, the courts

have stated that doubt should be resolved in favour of the preservation of life, and it will be acceptable to undertake treatment to preserve life or prevent irreversible serious deterioration of the patient's condition' (para. 36.51).³ In B's case, incidents of extremely challenging behaviour required urgent intervention, but these were frequent and repetitive and therefore the clinical team was unable to rely on the doctrine of necessity.

If a child is subject to a care order or emergency protection order under the Children Act 1989, the local authority acquires parental responsibility (Children Act 1989 s 33(3)(a) and s 44(4)(c), respectively). Section 25 of the Children Act 1989 can be used to detain a person with mental disorder under a secure accommodation order, but only if the primary purpose of detention is not to provide treatment for mental disorder, for example, if detention is required to maintain the safety of someone who exhibits severe behavioural disturbance. A child subject to a section 25 order does not have to be subject to an interim care order. The Children Act 1989 does not, however, specifically address mental disorder, does not provide specific powers to enforce treatment, and does not provide specific safeguards for the rights of the detained patient.⁸ B needed to be in hospital for further treatment of his mental disorder and therefore a secure accommodation order was not judged appropriate at that time.

In some situations, particularly if there are disputes between the family and the treating clinician or between family members, or if other authorities for treatment are not appropriate, there should be recourse to the courts. The High Court can use its inherent jurisdiction to make decisions that it considers to be in the child's best interests. Some issues may be resolved by section 8 orders made under the Children Act 1989. B met the criteria for detention under section 2 of the Mental Health Act and therefore the legal authority for B's assessment and treatment was provided without a court application needing to be made.

Detention under the Mental Health Act 1983 provides the child with a number of important safeguards, such as the right to appeal against detention. The 2007 amendments to the Act have resulted in greater protections for the rights of children and young people, for example the duty to ensure an age-appropriate environment (s 131A) and further safeguards for ECT (s 58A).

It is important that clinicians working with children with mental disorders equip themselves with a good understanding of the law and its application, in order that the appropriate legal authority for admission and treatment is used, taking into account all of the needs of the patient and the relevant factors of each case. The Mental Health Act 1983 can be appropriately applied to children, as this case illustrates.

We are grateful to B's parents for giving their consent for this paper, to the Redburn nursing staff, and to Camilla Parker and Anthony Harbour for their comments on an early draft of this paper.

1.8.76 Debate: Can and should psychiatrists use online information?

Elly O'Brien Christopher Pell

2015-12

Contents

- *Debate: Can and should psychiatrists use online information?*
 - *Yes*
 - *No*

Yes

When considering professional use of the internet, the focus tends to be on access to information. Yet the development of Web 2.0 and the growth of social media have transformed the internet from a largely read-only medium to one that facilitates interaction and user-created content. I will discuss some of the positive effects that online resources can have on professional practice, looking not just at access to information, but what we do with that information and how we interact online with fellow professionals and the public.

Doctors can access the best evidence online during consultations: using Google Scholar to identify relevant journal articles, consulting guidance using the NICE app¹ or checking doses and contraindications on the BNF mobile app (even when you have no mobile signal). Sites that aggregate high-quality content from elsewhere, such as NICE Evidence Search (www.evidence.nhs.uk) and Trip (www.tripdatabase.com), make searching for information and staying up to date quicker and easier. Trip's 'rapid review'² even allows you to search for primary studies for an intervention in a particular population, then compares the results to provide an overall score (although not designed to replace a full systematic review, it provides a useful and rapid overview of the evidence in an area).

The potential for variation in the quality of online information is often cited as a criticism of it. Using high-quality resources helps to reduce this risk, but the principles of critical appraisal apply to any information, regardless of the medium. Wikipedia has been shown to be as reliable as traditional textbooks in psychiatry,³ and 'comes close to' *Encyclopaedia Britannica* in accuracy.⁴ Wikipedia should not be written off as a resource in research, but its contents must be subject to scrutiny and facts always cross-checked.

Online patient information is useful for patients, who can read it in their own time and refer back to it if they have queries. NHS Choices⁵ offers a wealth of information for patients, and NHS England's Information Standard⁶ helps psychiatrists to identify high-quality patient information from a variety of sources (including the Royal College of Psychiatrists),⁷ reducing the need to produce leaflets in-house. Material with the Information Standard is also included in NICE Evidence Search – so doctors can retrieve high-quality patient information alongside clinical evidence.

Blogs can be used by patients much like a traditional diary, to express themselves and track the course of their illness. Psychiatrists can also direct patients to blogs that they may find useful to read. However, there is huge variation in blogs, and are prone to a type of response bias whereby only those with the most extreme experiences (whether positive or negative) will blog about them; therefore, blogs should be carefully vetted before being recommended to patients.

Educational and informative materials can also be shared and viewed online as videos via YouTube (see the Royal College of Psychiatrists' YouTube channel⁸) or presentations on SlideShare (www.slideshare.net). Following the 'do once and share' principle, this gives material greater reach as well as encouraging discussion and collaboration between professionals.

Twitter offers a forum for current awareness through discovering and sharing new evidence and useful resources. It also provides a medium for interactions between professionals, where they can discuss issues and, potentially, crowdsource solutions. The Department of Psychiatry at the University of Toronto runs the International Psychiatry Twitter Journal Club,⁹ allowing a large number of professionals from around the world to discuss a paper. Those who cannot attend can catch up or continue the conversation using the hashtag #psychjc. Conferences also increasingly promote tweeting, allowing those unable to attend in person to keep up with proceedings by monitoring the relevant hashtag. Storify is a free tool that can be used to draw together various media such as photos, videos and tweets from conferences (or anything with a hashtag) to produce a record of the conference.¹⁰

Twitter also allows interaction beyond fellow professionals; for example, the successful Twitter campaign last year that forced major supermarkets to stop selling 'mental health patient' Halloween costumes.¹¹ The campaign involved thousands of messages from members of the public, professionals, politicians and charities. Twitter also provides a valuable medium for promoting events such as World Mental Health Day, aimed at breaking down stigma, addressing misconceptions, advocating for patients' rights and giving patients a voice.

There is a lot of scaremongering about social media for doctors. However, arguably this is simply a new medium in which age-old problems can arise. Indeed, the General Medical Council (GMC) guidance states that: 'The standards expected of doctors do not change because they are communicating through social media rather than face to face or through other traditional media'.¹² So principles of patient confidentiality, respect for colleagues and maintaining appropriate boundaries with patients apply equally online and face to face. Accepting 'friend requests' and 'follows'

from patients or caregivers requires careful consideration, especially with vulnerable patients. But how different is this to psychiatrists having to decide how to deal with bumping into a patient at the supermarket? Social media can blur the distinction between the professional and the personal, but there are solutions, such as separating these personas into different accounts and increasing privacy settings (for example, having a protected account on Twitter). What should not be overlooked is the potential of social media for enabling interaction with patients and their caregivers, for new dialogues that challenge professionals' perceptions of service users' experiences and that create a more collaborative care model.

Psychiatrists must always question the information in front of them and the source from which it originates, regardless of the medium. Online resources enable psychiatrists to keep up to date with the latest research and to engage with it in a more interactive way. Psychiatrists now also have the opportunity to create and share their own high-quality media to raise the profile of the profession, and to combat misinformation and stigma. The use of online resources should not only be encouraged but be considered essential in contemporary psychiatry.

No

Social media and Web 2.0 are driving major social changes – one seventh of humanity has signed up for a Facebook account since its inception just a decade ago – and it would be naive to think that psychiatry would ignore the many advantages these changes bring.¹³ More than ever before we have access to the best-quality information, opportunities for professional and public collaboration and engagement, and multiple forums in which to raise awareness and standards in psychiatry. Or so it would seem.

In reality, our ability to use these technologies in professional practice has become fraught with difficulty as psychiatrists try to adapt to this shifting landscape. Indeed, new avenues for problems seem to crop up with alarming regularity, whether it be emerging legal trends, fresh ways to be censured by the GMC, or even novel clinical presentations such as addictive behaviour towards new technology.¹⁴ Such was the concern about professional use of the internet that the GMC update to *Good Medical Practice* now clearly defines the expected standards of practice that UK doctors use when going online.¹²

Whether we can access professional information online is often dependent on what is being searched for, and the location of the clinician. Many of the internet resources we take for granted at home are blocked or limited by internet filters. Websense and similar filters err on the side of caution to protect National Health Service networks from malware at the expense of many sharing and networking sites, rendering useful resources such as Dropbox, Slide-Share, Twitter and YouTube all but inaccessible from the hospital. Often, lack of hardware or mobile data access within the hospital can make accessing information online a frustrating exercise. Much more needs to be done to provide clinicians with smart devices and to open up wireless internet access within healthcare settings before we are truly able to take advantage of online information.

Even assuming this is achievable, there is an emerging opinion that doctors spend too much time staring at a computer screen and typing, rather than engaging with, actively listening to and carefully thinking about their patients. Furthermore, the illusion that such technologies improve our workflows by allowing us to multitask (for example, by searching for pertinent information during interviews or meetings) is severely challenged by the finding that our cognitive abilities and working memory are limited. The simple fact is that multitasking makes us more distraction prone – so we perform multiple tasks with an increasing lack of attention and efficiency.^{16,17}

Let us assume, though, that you have relatively unfettered access to the internet and have easy access to a computer in a distraction-free environment: should you use the internet to find professional information?

An initial problem is quality control. In the 'information age' critical appraisal is more than ever a vital skill, particularly with the proliferation of open access online journals with seemingly less-than-robust peer-review structures to safeguard article accuracy.¹⁸ This takes up time that you may not have, yet fails to provide the same level of coverage as a systematic literature search.¹⁹ Although we like to think that we can sift out the incorrect information, we are all prone to inherent biases when analysing multiple sources of data. Interrogating Google or other search engines for clinical information may compound this by selectively presenting data according to the search engine's own algorithms, rather than by the robustness of studies themselves.

The issue of quality of information costs us more time, as those attending our clinics and hospitals may now come armed with information they have uncovered online regarding their symptoms and treatments. In each case the validity and relevance of the information must be examined, before explaining to the individual why the ‘facts’ they have found may not be quite as they seem. This also extends to information that a patient may have learned online about their doctor, either through rating sites or informally via a Google search. Social media has considerably blurred the boundaries between our professional and private personas. While some professionals strive to separate these two aspects of their lives online, this is hard to achieve fully in practice. Psychiatry is no stranger to boundary issues, however. As our patients and their carers enter cyberspace, online interactions require care and attention in order to avoid difficulties in subsequent clinical interactions.

Although doctors are generally becoming more experienced at safely managing their digital identities, many still do not fully understand or adjust privacy settings on social media sites. Still other doctors fall foul of expected professional standards in terms of what information they make available online.^{20,21} With the increasing integration of location-sharing functions to such sites, this opens up new avenues for access and contact not previously available and may lead to unwanted communication or harassment. Some go as far as to suggest that professionals may wish to limit their use of social media so as to reduce the risk of stalking.²² All of this places considerable onus on psychiatrists to be at least aware of their digital footprint; better still, to actively curate their web presence and privacy settings so that oversharing and misinformation are swiftly identified and tackled. This same challenge extends to the specialty as a whole, as any search of Google or YouTube for terms such as ‘ECT’ or ‘psychiatry’ can yield reams of misinformation.

And what of reciprocity? Can patients expect to have their online identities scrutinised by healthcare staff prior to attending clinics, or should this information (however publicly available) require their explicit consent before being used in clinical decision-making?

It is questions such as this that highlight the rapidity with which these technologies have changed the landscape of interpersonal interactions within our society. With a mere decade of experience and with new social media trends and websites constantly emerging, no-one yet has a clear idea where the ethical, legal and professional sensibilities will eventually settle. What is clear is that using online information will necessarily change our practice, both by requiring greater attention to and scrutiny of the information yielded, and by changing the parameters of the doctor-patient relationship.

With our seeming acceptance of the erosion of personal privacy and our constant searching, editing and sharing of information, we may unwittingly be setting up as yet unknown difficulties and challenges for professional practice in the future. Whether we can skillfully navigate the minefields of professional information in the online world remains to be seen.

1.8.77 Mobile telephone apps in mental health practice: uses, opportunities and challenges

Justin Marley Saeed Farooq

Correspondence

Justin Marley (Justin.Marley@nepft.nhs.uk)¹

date

2015-12

Abstract

Smartphones are used by patients and clinicians alike. Vast numbers of software applications (apps) run on smartphones and carry out useful functions. Clinician- and patient-oriented mental health apps have been developed. In this article, we provide an overview of apps that are relevant for mental health. We look at clinician-oriented apps that support assessment, diagnosis and treatment as well as patient-oriented apps that support education and self-management. We conclude by looking at the challenges that apps pose with a discussion of possible solutions.

Mobile telephones are ubiquitous and have more recently evolved into the smartphone, a combination of a handheld computer and mobile telephone. Smartphones support software applications (apps) with specialised functions. Some apps may be pre-installed on the telephone but many apps are downloaded. Downloading apps (either free or for a nominal fee) is straightforward. Apps are available for a large number of mental health conditions and are also known as mHealth apps. Many of these apps have already been investigated by researchers and include apps for psychosis,¹ depression,² anxiety,³ alcohol use disorders,⁴ smoking cessation,⁵ sleep disturbance⁶ and weight loss.⁷ In this article we will avoid the more generic productivity apps (e.g. email apps) and will instead focus on general clinical and mHealth apps as well as regulated apps where possible.

Clinician-oriented apps

Assessment and diagnosis

Smartphone apps can aid in diagnosis in two main ways: by supplying clinicians with diagnosis-related information and less commonly through data acquisition. Apps can be used in clinical encounters or remotely, although the latter overlaps with self-monitoring. Apps have proven useful in assessment and diagnosis in clinical practice. In one study, 50% of doctors reported that apps facilitated diagnosis during on-call work whereas 43% reported apps helped them interpret laboratory values.⁸

As an example, Lab Tests Online UK (www.labtestsonline.org.uk) is a peer-reviewed online resource for clinical laboratory tests with corresponding apps for the iPhone and Android (*Fig. 1*). The app enables the clinician to look up explanations of test results through a search facility or an index. The explanations are intended for the general public but there is enough information there to be useful for clinicians. Other useful features include news updates, information on screening for populations and an index of conditions.

Fig. 22: Screenshot from the desktop version of Lab Tests Online-UK

There are a large number of apps relating to the diagnosis. Many of these are American apps that supply ICD-10 coding information for billing purposes. There are a number of variations including apps that convert between ICD-9 and ICD-10. The American Psychiatric Association has produced a DSM-5 app that contains detailed information on the DSM-5 diagnostic categories as well as ICD-10 coding equivalents. The app includes a series of instructive videos on many of the diagnostic categories.

Less commonly, apps can also be used in conjunction with hardware devices that connect to the smartphone. These apps may acquire and process data from external appliances such as digital stethoscopes, ophthalmoscopes and electrocardiogram (ECG) monitors. A similar principle can be seen with the self-monitoring apps that can provide clinicians with patient-collected data. Storing patient data on mobile apps brings additional complications relating to the Data Protection Act 1998 as well as principles of patient confidentiality that need to be worked through appropriately.

Treatment

Treatment-related mHealth apps can be broadly divided into medical and psychosocial and may be professional or patient-focused.

Medical apps

In terms of UK practice, the National Institute for Health and Care Excellence (NICE) produces both the *British National Formulary* (BNF) app and an app for NICE guidance (www.nice.org.uk/about/what-we-do/nice-apps-for-smartphones-and-tablets). The NICE BNF app offers a search facility to rapidly locate drug information and contains the contents of the paper version of the BNF. The app ensures that clinicians are able to access an up-to-date BNF even in the busiest clinical environments. This is contingent on the accessibility of the smartphone as well as regular updating of the app. The NICE guidance app features indexed evidence-based guidance from NICE on the management of a range of conditions. This app effectively utilises the large storage capacity of current smartphones.

Apps to assist in psychosocial interventions

There are many psychology-related apps, including those listed on the NHS Choices apps site (<http://apps.nhs.uk>) such as Phobia Free. Phobia Free supports the use of exposure therapy for the treatment of phobias in the form of games and augmented reality. Rizvi *et al* described an app called DBT Field Coach that provided instructions, exercises and reminders to help patients with borderline personality disorder manage emotional crises.⁹ The researchers found that the app helped patients to self-monitor and complete homework assignments.

Another group of apps support patient education. One example is the Brain Tutor 3-D/HD (online Fig. DS1) which features a 3-D magnetic resonance imaging (MRI) reconstruction of a brain (www.brainvoyager.com/Mobile/BrainTutorHD_iOS.html). The clinician is able to select views of a virtual brain or an MRI reconstruction of the head including the brain. All views support 3-D manipulation of the images. For instance, the clinician may explain the MRI findings to a patient and then proceed to demonstrate these on the 3-D models on their smartphone.

Patient-oriented apps: education and self-management

A large proportion of mental health apps are directed towards the public. One example of this is Moodscope from NHS Choices (<http://apps.nhs.uk/>), which enables a person to track their mood. The scores can be stored and a patient may allow the clinician to access their records to facilitate assessment. SAM (Self-Help Anxiety Management) supports patients in managing panic attacks. These apps support self-management of conditions including chronic illnesses through diary functions and education. Such apps may be particularly useful after discharge from specialist services or in-between appointments.

Self-monitoring apps create personal health records which are fundamentally different from clinical patient records in their function and composition. Patients will be more empowered by holding their own records and managing access rights to professionals. However, this is accompanied by a variability in the quality of information held in the records,¹⁰ an expanding number of record systems and the potential for further use of these records by third parties. The divergence of app-based personal health records and clinical records will generate complex interactions between these two systems.

Challenges

Smartphone apps present many challenges (*Box 1*). One of the primary difficulties is the regulation of mental health apps due to their abundance. A number of studies have highlighted evidence of unsafe medical apps¹⁰ and the US Food and Drug Administration (FDA), the UK Medicines and Healthcare Products Regulatory Agency (MHRA) and NHS England have started to regulate apps. The NHS Choices website identifies regulated clinical apps and lists a number of other medication-related apps intended for professionals and patients. The relevant regulator depends on the function of the app. For instance, the MHRA would regulate apps classed as medical devices.

Self-certification has been suggested as one solution for the regulatory challenges.¹¹ Lewis & Wyatt suggest a regulatory framework which addresses challenges intrinsic and external (e.g. hardware) to the app.¹⁰ Charani and colleagues go one step further, arguing that there needs to be a governance and legal framework in place for the use of apps in clinical practice.¹² If clinicians or subject matter experts have not been involved in app development this may influence its quality and effectiveness. An absent evidence base for an app may limit clinical uptake. Privacy and security are other challenges for the app market.

The effectiveness of apps may also depend on the characteristics of the patient population. In one study looking at smartphone apps for weight loss, young adults considered simple weight measurement alone too narrow in focus and advocated behavioural software features.¹³ Access to a smartphone was negatively correlated with age in one study looking at consecutive patients in a neuropsychiatry and memory clinic.¹⁴

Box 1 Challenges of mental health apps

Extrinsic to the app: hardware constraints that limit the apps.¹⁵

Intrinsic to the app

Relating to the patient or app user: concerns about how the data will be used by the app service.

Relating to the clinician: accuracy of clinically related processes¹⁶lack of medical involvement in app development¹⁷insufficient information to keep doctors or medical students interested.¹⁸

Relating to the healthcare service: deviation from or lack of evidence based practice recommendations³patient confidentiality issuesclinical risk emerging from use of apps.¹⁹

Conclusions

Mental health apps have expanded rapidly in number and regulation is playing catch-up. There are many useful apps that can support clinicians in the assessment and management of patients. There is also a burgeoning market of personal health apps that are reshaping the health economy. A sustained and multifaceted response from individual clinicians, health services and policy drivers is needed to adapt to this new health economy.

We thank Lab Tests Online-UK for their permission to include app screenshots in our article, Professor Rainer Goebel for permission to use the Brain Tutor HD screenshot and Dr Omer Moghraby for helpful discussions around the subject matter.

1.8.78 Commissioning neuropsychiatry services: barriers and lessons

Abstract

Aims and method

Previous studies have shown variations in commissioning of neuropsychiatry services and this makes access to neuropsychiatric services a post-code lottery. In this survey, we approached all mental health and neuropsychiatric service commissioners within London to map current funding and commissioning arrangements, and explored perceived barriers to neuropsychiatric service commissioning.

Results

83% of commissioners within London responded. There was significant variability between neuropsychiatric services commissioned through the mental health stream. Contracting arrangements were variable. Lack of earmarked fund for neuropsychiatry and disjointed funding stream for such

services were identified by commissioners as a barrier, as was the critical mass of neuropsychiatric cases.

Clinical implications

Neuropsychiatric service development continues to be hindered by lack of clear commissioning process. Strategic drive is needed to promote more equitable neuropsychiatric services. National or regional commissioning covering a large population will provide a better model for neuropsychiatric services to be commissioned.

 - * *Limitations*

Neuropsychiatry lies at the interface between neurology and psychiatry.¹ It is often debated that the narrow focus of neurology and psychiatry services fails to meet the need of patients from a broader neuropsychiatric perspective.² The Cartesian belief of the dualism of mind and body has had repercussions for neuropsychiatric training as well as service provision including commissioning.³ Being at the interface of neurosciences, neuropsychiatry services are commissioned through both physical health funding stream and mental health commissioning, though there is lack of clarity around this. This leaves this complex discipline vulnerable to falling between different funding streams.

In the UK, mental health services underwent significant growth under the *National Service Framework* (NSF) initiative for mental health, where the predominant focus was around community services.⁴ Although community models were recommended, neuropsychiatry services remained largely based within academic institutions.⁵ At the height of the NHS expansion, a national survey of neuropsychiatry services revealed them to be ‘patchy’ and ‘grossly inadequate’, and discovered that most of the neuropsychiatry services existed from pre-NSF days.⁶ Historically, neuropsychiatry services developed at certain national or regional centres, such as a national hospital, significantly before NSF or current commissioning arrangements. They continued to serve or were developed at certain regional centres in an *ad hoc* way dependent on local clinical enthusiasm or leadership. At times, such developments were not accompanied by specific commissioning initiatives. There were no systemic drivers or a comprehensive plan to meet the population need. Consequently, patients were often referred ‘out of area’ and services often struggled to meet demand, resulting in long waiting times. The reasons for lack of neuropsychiatry service development in recent years has not been examined, despite increasing recognition of need and demand for neuropsychiatry services and its impact on patients’ quality of life. Commissioning arrangements and awareness of neuropsychiatry among commissioners and managers could be one of the reasons behind this.³

The aim of this study was to explore commissioning arrangements for neuropsychiatry and perceived barriers for neuropsychiatry commissioning from the perspective of managers responsible for commissioning neuropsychiatry services. We based this study in London as the city is unique in having a significant concentration of neuropsychiatric services along with recognised variability in service provision.^{5,7} At the time of carrying out the study, the Greater London area came under the regional commissioning unit or strategic health authority (SHA), which also made London a regional unit. Therefore, London provided a unit of regional commissioning that could be studied and compared with previous literature. Primary care trusts (PCTs) are local units within the SHA that cover well-defined geographical areas, usually

within an administrative unit called a borough. In London there were 31 boroughs and 30 PCTs during our survey. Two boroughs collaborated and acted as one unit.

Apart from mapping current practice, the survey explored perceived barriers for neuropsychiatry service provision from commissioners and providers.

Method

Two surveys were carried out. One approached all mental health commissioners based at the 30 PCTs in London and the other was a separate survey of neuropsychiatry service providers. See the accompanying paper for details.¹⁰

All local mental health commissioners (within the PCTs) were contacted electronically with the survey questionnaire and this was followed up by a telephone call. The commissioners were asked whether they were aware of a different route of commissioning neuropsychiatry in their PCT. We were directed to the specialist commissioning unit for neurorehabilitation for the London area and they were contacted for the survey. The specialist neurorehabilitation commissioning forms a non-mental health commissioning route. We were not directed to any other funding or commissioning stream for neuropsychiatry.

The survey mapped commissioning arrangements for neuropsychiatry and provision of services. It was factor-analysed for emerging themes from providers' and commissioner' responses for 'perception of neuropsychiatry' and 'perceived barriers to neuropsychiatry service commissioning'.

Results

Overall, 30 mental health commissioners from 25 PCTs responded. There was no information from 5 PCTs; response rate for commissioners was therefore 83%. The specialist mental health commissioner for neurorehabilitation for London also responded. There was response from all 9 mental health trusts (specialist mental health providers), although 1 returned an incomplete response; thus, response rate for providers was 100%. Data were also gathered from a tertiary neuropsychiatry centre embedded within an acute hospital trust and one in the voluntary sector catering to patients from London but based outside London. Two independent-sector specialist neurorehabilitation centres were identified and contacted with provider questionnaire, and one of them responded.

The commonest mode of commissioning of neuropsychiatry services was to tertiary services followed by local services. This was followed by 'national' services which are essentially tertiary services which are open to referrals from across the country. Funding streams for certain conditions were identified to be other than mental health. Although neuropsychiatry services were tertiary services, they were often also open to direct referral from primary care. Brain injury or neurorehabilitation was commissioned through pan-London specialist commissioning group, i.e. from a 'specialist' commissioner across a larger geographical area and services provided by specialist tertiary providers. Commissioning for young-onset dementia and cognitive difficulties was often aligned with other health services for 'older adults'.

Figure 1 describes different modes of purchasing neuropsychiatry services. Block contract was the most popular method, closely followed by commissioning per patient but needing approval for all the patients. In only a small minority of cases referrals did not require commissioners' approval. Interestingly, the mode of commissioning was unclear in 4 cases. Some of the commissioners were using more than one method of purchasing neuropsychiatry services.

Fig. 23: Modes of purchase of neuropsychiatry services.

A whole range of neuropsychiatry services were commissioned and provided (*Fig. 2*). There appears to be a significant disparity in the range of provision and commissioning. This may indicate that some neuropsychiatry services were commissioned as part of a larger service without specific earmarked funding. There was a lack of clarity of commissioning processes in such cases.

Overall, commissioning interest and service provision for specific neuropsychiatric services did not mirror each other. The nine mental health trusts in London were asked about whether they provided neuropsychiatry services. Among

them, five identified themselves as providing some form of neuropsychiatry service while four reported not providing any neuropsychiatry service. One of the trusts that no longer provided neuropsychiatry service had a brain injury rehabilitation unit that was closed the year before the survey. There was significant interest in commissioning neurodevelopmental disorders such as autism spectrum and adult attention-deficit hyperactivity disorder (ADHD) (80% and 68% of responding commissioners, respectively), but only 33% of mental health trusts had provision for autism spectrum disorder and 22% provided service for adult ADHD. One of the commissioners reported they commissioned services for sleep disorder but none of the providers had service provision for sleep disorder. Similarly, one of the providers had service provision for stroke-related neuropsychiatry, though none of the commissioners we were able to contact were commissioning such a service.

Both service providers and commissioners identified lack of funds in general and lack of funds specifically earmarked for neuropsychiatry as a barrier to neuropsychiatric service development. Both identified the disjointed nature of commissioning funding streams for neuropsychiatry and lack of national strategic drive for neuropsychiatry as further barriers to commissioning such services. But there were variations in perceptions of commissioners *v.* providers. Of the 30 commissioners who responded, 23 perceived there was a barrier to commissioning neuropsychiatry services (77%). Commissioners were more concerned about lack of critical mass ($n=8$; 35%) of individual neuropsychiatric disorders in their commissioning units or areas (*Fig. 3, Box 1*).

Providers often perceived a 'lack of interest' in commissioning neuropsychiatric services as a barrier to setting up or providing neuropsychiatry services (*Fig. 4*).

Commissioners were asked if they were aware of new neuropsychiatry services that were commissioned (expansion) in the past 10 years. There were only 8 responses, suggesting some of the local mental health commissioners were unaware of how services had evolved in the past 10 years locally. We also explored whether there were plans for expansion for neuropsychiatry services locally in the future. From the responses we received, there were services being considered for certain conditions: adult autism spectrum disorder (6; 27%), adult ADHD (4; 18%), young-onset dementia (4; 18%), memory clinic/dementia services (2; 9%), other specific conditions in individual areas (3; 14%); 4 commissioners reported there were no plans to develop new services (18%)

Box 1 Some comments on neuropsychiatry services from commissioners:

- 'The numbers of patients requiring these types of services are small in comparison to other psychiatric services and the challenge is therefore being able to provide affordably and locally for this group.'
- 'Economies of scale for larger areas (e.g. across west London) are needed given that the service may not be sustainable at a borough level'
- 'The low volume affects local commissioning.'
- 'Neuropsychiatry is a relatively small field and not high up on the national agenda'.

Two of the nine mental health trusts reported expansion of generic neuropsychiatry services over the past 10 years; two trusts reported no expansion and two other trusts did not know whether there was any expansion. One trust reported there was some patchy development of adult ADHD and young-onset dementia services without commissioning support, largely led by the 'individual' interest of clinicians. Another trust also reported patchy (not across all boroughs) development of young-onset dementia, adult autism spectrum disorder and ADHD services. One of the trusts closed down a brain injury rehabilitation service. One of the specialist providers reported developing an adolescent brain injury rehabilitation unit while another reported expansion in the services for medically unexplained neurological symptoms, including in-patient facilities and services for Tourette syndrome.

Commissioners were also asked about future planning in the field of neuropsychiatry services. A third responded that there were no plans for expansion (11/30; 37%). Medically unexplained neurological conditions (along with generic medically unexplained symptoms) were being considered for commissioning in two PCTs while three more PCTs would 'review' their current commissioning in this field. Adult ADHD services were being considered in three PCTs while one borough was reviewing their commissioning in the field. Adult autism spectrum disorder service commissioning was being considered by one borough.

Three trusts (one with existing neuropsychiatry services, two without) were unsure whether there would be further expansion of neuropsychiatry services. Two of the mental health trusts had plans of developing generic neuropsychiatry

services. One trust reported plans to enhance psychological therapy (cognitive-behavioural therapy) services within the existing neuropsychiatry services. One of the trusts reported plans to develop services for adult ADHD. Two mental health trusts and one of the specialist providers had no further plans to develop neuropsychiatry services in the near future.

Discussion

This is the first detailed study of commissioners' and providers' views on neuropsychiatry services commissioning. Data were gathered from all the providers and 83% of commissioners, making a robust data-set.

This study shows significant variations and inconsistencies in commissioning of neuropsychiatry services. There is evidence of a disjointed approach towards commissioning neuropsychiatry, despite London being a relatively small geographical area. Certain themes emerged as major barriers which may have contributed to the current state of affairs.

Critical mass for commissioning neuropsychiatry services

Commissioners identified a lack of 'critical mass' as a common barrier to neuropsychiatry service commissioning. Providers also reported this to be a big barrier. In the UK, commissioning is changing radically. As the current structure of purchasing healthcare is reorganised, it can be replaced by a more localised and potentially fragmented system, mirroring the current system. This would be detrimental for neuropsychiatry commissioning as it may mean lower numbers of neuropsychiatry patients per neuropsychiatric condition per commissioning unit and further aggravate the problem of the lack of 'critical mass'. The barrier of critical mass can be addressed by commissioning neuropsychiatry services for a larger population. We believe a regional or national specialist commissioning panel would best achieve this purpose. This already exists for services such as neurorehabilitation. The specialist commissioning panel mentioned previously reduced variability in neurorehabilitation when compared with borough-based commissioning of neuropsychiatry services.⁸ With the current restructuring of health services in the UK, PCTs and regional commissioning units (SHAs) have been abolished and from 2013 neuropsychiatry is being commissioned by NHS England, although this is going to be reviewed in a few years' time. This might provide commissioners the critical mass to commission neuropsychiatry services more effectively, reduce variability and address unmet needs.

Knowledge and expertise of commissioners and integrated commissioning

Historically, neuropsychiatry has fallen between neurosciences and mental health commissioning.⁹ The vast majority of providers reported a perceived lack of knowledge and expertise among commissioners, disjointed or unclear commissioning processes, and lack of earmarked funds for neuropsychiatry as challenges to setting up neuropsychiatry services. Commissioners also found a lack of earmarked funds and negotiating multiple funding streams confusing.

Disjointed commissioning and fragmented funding streams without any clear resources earmarked for neuropsychiatry leaves neuropsychiatry at the periphery of multiple streams of funding, for example mental health, older adults' health, neurosciences, specialist neurorehabilitation. It has been hypothesised that there is a lack of adequate understanding of neuropsychiatry among commissioners and service managers, be it of mental health or physical health.³ To expect a high level of specialised expertise at every local commissioning unit for a range of neuropsychiatric disorders, each of which have a small local population, is unrealistic. Current restructuring also provides the opportunity for neuropsychiatry services to be commissioned through 'specialist commissioners' with earmarked funding. Specialist commissioning covering a substantial geographical area will address concerns of lack of understanding through specialist knowledge as well as ensure there are sufficient patient numbers (critical mass).

From our survey we gathered that very few mental health providers, apart from a few large neuropsychiatry centres, provided care for the vast range of neuropsychiatric conditions. We hypothesise that conditions such as sleep disorder or neuropsychiatric input into neurodegenerative conditions and epilepsy may be closely aligned with acute healthcare, which was possibly not wholly captured in this survey, as they are both far removed from mental health commissioning or mental health trusts and do not have earmarked funding stream that can be reliably traced. There was indirect

evidence that the commissioning of these services was possibly linked with generic acute hospitals and funded through physical health funds or a specialist neurosciences funding panel (*Fig. 2*).

Commissioning in neuropsychiatry needs to be integrated and streamlined. Funding and resources for neuropsychiatry need to be transparent and ring-fenced to allow services to be equitable across the country.

Need for strategic drive in neuropsychiatry

Commissioners and providers identified a lack of strategic drive as a barrier for neuropsychiatry commissioning. The study shows that where strategic drive exists, even if the condition is rare, it improved standardisation and access to services. The two conditions where this survey found a good degree of shared understanding from provider and commissioning perspectives were brain injury neurorehabilitation and young-onset dementia. Both were supported by the presence of strategic drive, for example the NSF for long-term conditions,¹⁰ a House of Lords report,¹¹ the Department of Health's dementia strategy,¹² or the National Institute for Health and Care Excellence (NICE) guidelines on dementia.¹³ Services for medically unexplained neurological conditions in London were possibly helped by the recognition of medically unexplained conditions as one of the four streams for which Healthcare for London started working on care pathways in 2008, which later evolved into the Darzi care pathways (the work has been summarised by the report from the Commissioning Support London).¹⁴ Unlike the NSF for mental health, the NSF for long-term conditions provided an opportunity to foster neuropsychiatric service development.¹⁰ It was recognised by neuropsychiatrists as a potential strategic driver,¹⁵ but so far its impact has been arguably limited. Adult ADHD and autism spectrum disorder services were boosted by their respective national clinical guidelines.^{16,17}

We believe there is an imminent need for a strategic drive for generic neuropsychiatry, both nationally and internationally. The Royal College of Psychiatrists' working group consensus paper provides an ideal platform to develop strategic drivers to foster neuropsychiatry services' development to meet population needs.⁹

Developing a shared understanding of what is neuropsychiatry

Different definitions and interpretations of the core neuropsychiatric territory are damaging to the development of neuropsychiatric services globally.³ This confusion is not new. In 2005, the International Neuropsychiatric Association identified 'defining of neuropsychiatry' as one of the key priorities and 'first and the most difficult challenge' to help identifying 'the legitimate territory of neuropsychiatrist'.¹⁸ This confusion around the remits of the discipline spills over to neuropsychiatry service provision. There was a significant variation in the familiarity of the different conditions and their commissioning and service provision (*Fig. 2*).

The perception of what constitutes neuropsychiatry varied significantly among both commissioners and providers. Assessment of local need for commissioning is affected by this uncertainty around prevalence of 'neuropsychiatric cases'. Through our survey we obtained direct and indirect evidence that neuropsychiatry services were highly non-uniform in what they provided.

It is important to look at neuropsychiatry as a discipline with more clear boundaries and foster development of specific drivers that promote uniform service provision that is both adequate and equitable. Neurodevelopmental disorders (such as autism spectrum disorder and adult ADHD), young-onset dementia and psychiatry of intellectual disability often require skill-sets similar to neuropsychiatry, but traditionally have not been considered its core business. In fact, they do not form part of the core Specialised Services National Definitions Set definition of neuropsychiatry.¹⁹

We believe the nature of the difficulties seen by neuropsychiatry services is by definition complex and beyond the service provision that could be delivered by either neurology services or mental health services alone. We suggest a basic model with four categories to define the core boundaries of neuropsychiatric disorders (*Box 2*).

Limitations

The study was carried out within the Greater London SHA. One can therefore argue that the results might not be generalisable to other areas. However, London was chosen as it had a high concentration of neuropsychiatry centres within a well-circumscribed geographical area located within an SHA where previous service mapping had been carried out.^{5,7} We believe that the problems identified in London can only be an underestimate of commissioning barriers across the country. This can be taken as a pilot study, as information and literature in this field nationally or internationally is very limited.

Box 2 Core neuropsychiatric disorders

Broadly speaking, neuropsychiatry services provide assessment, investigation and treatment for patients with: a neuropsychiatric disorder (cognitive, behavioural or psychiatric symptoms) associated with a recognised neurological condition or organic brain lesion such as Parkinson's disease, epilepsy, acquired brain injury a neuropsychiatric disorder or mental illness with a yet unrecognised neurological condition or probable organic aetiology (e.g. psychosis related to as yet undiagnosed epilepsy or encephalitis) functional neurological disorders (e.g. dissociative seizures, dissociative memory disorder or conversion disorder) excluding primary presentation with general somatoform disorders without prominent neurological symptoms, chronic fatigue and chronic pain disorders other neuropsychiatric conditions may include specific conditions such as neuropsychiatric sleep disorders, complex neurobehavioural disorders or neuropsychiatric manifestations of extracranial physical conditions.

The study looked into commissioning from the mental health commissioners' perspective and incorporated neurorehabilitation specialist commissioning. However, neuropsychiatry services are located at the interface of neurology and psychiatry and therefore the study may have failed to capture any neuropsychiatry services that are commissioned through and embedded within acute or psychical healthcare setting.

The study surveyed service providers and commissioners and can only comment on the responders' understanding, knowledge and perception of how services were aligned. For the purpose of this study these responses were taken to be proxy measures of the reality of service provision on the ground and the process of their commissioning. The data collected may have been contaminated due to confusion over 'caseness' of neuropsychiatry patients.

Neuropsychiatry commissioning remains disjointed and variable. This study identifies barriers for neuropsychiatry commissioning and service development. This makes a case for neuropsychiatry to be commissioned in its entirety through a national specialised commissioning group in the future. This should help to reduce inconsistent provision nationally and help respond to unmet need. There is urgent need for increasing collaborative working between national commissioners and national bodies of neuropsychiatric expertise such as the Royal College of Psychiatrists' Faculty of Neuropsychiatry in the UK. Such a joined-up approach is necessary to develop universally acceptable strategic drives that can foster real improvements in services and benefit patients with neuropsychiatric conditions. We must learn the lessons of the past to break the barriers we continue to encounter.

1.8.79 The changing face(book) of psychiatry: can we justify 'following' patients' social media activity?

Abstract

Individuals with mental health issues may post information on social networking sites that can provide an insight into their mental health status. It could be argued that doctors (and specifically psychiatrists) should understand the way in which social media is used by their patients to gain a better insight into their illnesses. However, choosing to actively monitor a patient's social media activity raises important questions about the way in which medical students, qualified clinicians and other healthcare professionals obtain information about patients. While this may be framed as a mere form of 'collateral history-taking', there are obvious practical and ethical problems with doing so. Here, a case is made against monitoring the social media activity of patients involved with psychiatric services.

Contents

- *The changing face(book) of psychiatry: can we justify 'following' patients' social media activity?*

In 2013, nearly one in four people worldwide actively used social networking sites, a statistic predicted to increase rapidly throughout this decade.¹ Given that so many people are using social networking sites, it may be no surprise to find that many people with mental health issues have a social media presence too. For example, there are a plethora of 'pro-ana' (pro-anorexia) websites, blogs and Facebook groups in existence for individuals with eating disorders. These have proven to have both therapeutic and potentially dangerous effects on illness behaviour.^{2,3}

People with mental illness may post information online that provides an insight into their current mental health. If this is the case, then doctors (and specifically psychiatrists) should understand the way in which social media is used by patients as it may allow them to gain a better insight and, subsequently, provide better care.

To explore these premises, I consider the act of looking at a patient's Facebook page, Twitter activity or personal blog as merely another form of 'collateral history-taking'. Focusing specifically on the Facebook 'status update' – a way in which individuals may post their current thoughts and feelings (with a time and date stamp) – I ask whether this is a way to access a patient's mental state in real time. Given that the majority of Facebook profiles are public (meaning that the profile owners have chosen not to opt into privacy settings), any updates posted are available to not only Facebook 'friends' but also others within the person's associated 'networks' and those outside, for instance healthcare professionals.

A study carried out in the USA aimed to assess the prevalence of college students' disclosures of depression symptoms on Facebook.⁴ Despite the potential for stigma surrounding mental health symptoms or diagnoses, a quarter of profiles observed publicly displayed depression references. However, should we take this statistic seriously? We may, wrongly, be talking about an overrepresented population. It might be that patients with particular mental health conditions or certain personality types are more likely than others to frequent the likes of Facebook, Twitter and other forms of social media more often. It has been suggested that there may even be a correlation between excessive internet use and social anxiety, depression and introversion.⁵ Furthermore, we cannot be sure that the information posted in an update is accurate. Creating a social media profile allows profile owners to be selective about the aspects of their identity they wish to display and those they wish to avoid putting into focus. The 'online disinhibition effect'⁶ states that when people are online, they tend to disclose more about themselves or act out more intensely or frequently than they would in person. This suggests that we should exercise a degree of caution when considering information posted online.

Nonetheless, even if the information posted online by individuals with mental health issues is accurate, there appears to be a 'fine line' between monitoring and being meddlesome. Once a doctor has demonstrated that their actions would be of benefit to the patient, the most pressing question to consider next is whether they should ask the patient for their consent. The Human Rights Act 1998 states that everyone 'has a right to respect for his private and family life, his

The Authors own the copyrights to the individual articles.

home and his correspondence'. This applies even if seeking a patient's consent will have an effect on their future activity online. The obvious response to this is that the information has already been made public, and so patients have waived any rights that they had to privacy. Yet, a survey of 492 bloggers demonstrated that people often disclose information online with a particular audience and time period in mind, even though the information may then become broadly available for an indefinite period.⁷ Medical students and qualified clinicians should be aware that accessing a patient's social networking profile through covert and unauthorised means may form a basis, at least in the patient's opinion, for the argument that they have infringed upon their patient's private life.

Finally, if we proceed without consent and the patient finds out, there may be serious effects on the psychotherapeutic relationship: a relationship based on the active engagement of the patient which can no longer happen if the patient does not trust the healthcare professional. This is likely to have implications for the patient's health. There is an implicit understanding that a patient's trust in their doctor is unconditional. In response to the new dilemmas that may arise in clinical practice due to the rise of social media use by both patients and clinicians alike, the General Medical Council has reiterated the importance of trust not only in a doctor's clinical practice but also in their online behaviour.⁸

If a psychiatrist takes it upon themselves to do further research on their patient online and finds conflicting information, it is difficult to see how this could be used without challenging the patient's narrative. This is further complicated by the question of what to do with any new discoveries about the patient that may surface. Options for the psychiatrist may include: documenting new information in the patient's notes, conferring with colleagues, telling the other members of the multidisciplinary team involved in the patient's care, or disregarding what they have seen for fear of future repercussions. It is, however, important to consider whether the psychiatrist has a duty of care to act on information of which they would have otherwise been unaware.

While not specifically social media, the internet has been used as part of risk assessment in accident and emergency settings before. The information obtained from a Google search proved to be crucial in a doctor's decision to classify a patient as high- rather than low-risk for future suicidal intention.⁹ However, it would be a slippery slope to suggest that one success justifies following the social media activity of all of our patients. Whereas in theory actively looking at a patient's social media profile might be advantageous, in reality it is unethical (particularly without consent). If doctors plan to use any information found for treatment, then they will have to disclose their intentions to patients before they do so.

I would like to thank Dr Angelika Luerhs for her support while researching this topic.

1.8.80 Mental health problems associated with female genital mutilation

2015-12

Abstract**Aims and method**

To study the mental health status of 66 genitally mutilated immigrant women originating from Africa (i.e. Somalia, Sudan, Eritrea and Sierra Leone). Scores on standardised questionnaires (Harvard Trauma Questionnaire-30, Hopkins Symptom Checklist-25, COPE-Easy, Lowlands Acculturation Scale) and demographic and psychosocial correlates were analysed.

Results

A third of the respondents reported scores above the cut-off for affective or anxiety disorders; scores indicative for post-traumatic stress disorder were presented by 17.5% of women. Type of circumcision (infibulation), recollection of the event (a vivid memory), coping style (avoidance, in particular substance misuse) and employment status (lack of income) were significantly associated with psychopathology.

Clinical implications

A considerable minority group, characterised by infibulated women who have a vivid memory of the circumcision and cope with their symptoms in an avoidant way, reports to experience severe consequences of genital circumcision. In terms of public healthcare, interventions should target these groups as a priority.

 - *Discussion*

Female genital mutilation (FGM) ‘comprises all procedures involving the partial or total removal of the external female genitalia or other injury to the female genital organs whether for cultural, religious or other non-therapeutic reasons’.¹ The procedure is performed within a wide range of mainly African ethnic groups. Appropriate estimations are that between 100 and 140 million women and girls have undergone the practice.² FGM is defined as a violation of human rights, and in many countries it has been outlawed. Nonetheless, FGM is still performed in a large part of Africa, particularly in Eastern regions. Currently, FGM is also performed in small migrant girls resident in European countries.³ The impact of FGM on social and psychological health is underresearched⁴⁻⁹ and knowledge of the psychosocial consequences in a migration context is even scarcer.¹⁰⁻¹² Moreover, reports vary from high prevalence of trauma-related and other psychiatric symptoms such as anxiety and depression,^{4,13} to no mental health problems at all¹⁴ or even positive feelings.^{15,16}

The aims of this study were to explore the relationship between FGM and psychopathology in circumcised women originating from an African country who have migrated to The Netherlands. Research questions were: What kind of mental health problems are reported by circumcised immigrant women? Which factors are associated with the presented psychopathology? Based on the literature,⁴⁻¹² we hypothesised potential predictors of psychopathology which could be

distinguished between demographic factors (e.g. country of birth, years of residence in The Netherlands, educational level), circumcision-related factors (type of circumcision, age at the time of circumcision, vividness of recollection of the circumcision), coping mechanisms and acculturation demands.

Method

Design

In a cross-sectional research design, a survey among a sample of circumcised immigrant women in The Netherlands was conducted. Topics were measured in a quantitative way by means of culturally sensitive standardised questionnaires (the complete study design is described in Vloeberghs *et al*¹⁷).

Procedure

The estimated size of the target population (women who have undergone FGM living in The Netherlands) is about 26 000 women.³ We involved representatives of this population actively in the research process, at the level of both data acquisition and data interpretation. Participants were recruited by means of snowball sampling, a sampling method that is being used to study hard-to-reach populations (see, for example, de Jong & van Ommeren¹⁸).

The first stage of snowball sampling involves selecting individuals using referrals by insiders within the target population. These individuals were asked to list others with identical characteristics. From this list at least one person was randomly selected and approached for an interview. The interviewee was then asked to list others and the same procedure was repeated several times. Attempts were made to maximise sociodemographic diversity. Approximately half to a third of the solicited women (depending on the interviewer and her network) agreed to participate. It was not possible to compare those who chose to participate in the interview with those who declined.

The interviews were conducted by seven interviewers (all females coming from the participants' countries of origin). We consulted various key persons in the different communities during the development of the measures and the interpretation of the results (e.g. during 'experts meetings'). Interrater reliability across the interviews was enhanced by means of a protocol that guided the interview process and a training concerning the way in which the interviews should be conducted, how to handle possible risks of (re-) traumatisation and ethical aspects concerning the process of personal data collection.

The respondents were informed about the aim of the study by means of an information sheet. The interviewers – who were awarded financial compensation – were instructed to read the information sheet to illiterate respondents. It was emphasised that they had to guarantee anonymity and that participation of the respondents was voluntary. Participants were reassured about confidentiality and told that they were not obliged to answer questions that they did not wish to answer. They were given the telephone number of a family doctor attached to the project (M. van den M.) whom they could contact in case of problems or questions concerning their well-being.

The interviews mainly took place at the respondents' homes. In some cases they were conducted at community centres or in public places, depending on the preference of the participant. The interviews were completed within an 18-month period in 2008/2009. The duration of the interviews varied from 40 to 180 min (mean duration about 90 min). The answers were recorded verbatim and later transcribed by the researchers (J.K. and E.V.).

Sample characteristics

A group of 66 women participated in the study (*Table 1*). The participants' ages ranged from 18 to 69 years, averaging 35.5 years (s.d. = 10.5); 43% were married, 79% had children (mean 1.78, s.d. = 1.6). The group included 36 (54%) heavily circumcised (infibulated) women, mainly from Sudan and Somalia. The other women had undergone less invasive forms of circumcision: 9 women got an excision (type 2), whereas 21 had undergone type 1 circumcision.¹⁹ The age at which the participants were circumcised ranged from 8 months to 16 years (mean 6.4, s.d. = 4.1).

Descriptive statistics of demographic variables of the FGM sample ($n = 66$)

Variable	
Age, years: mean (s.d.) range	35.5 (10.5) 18–69
Age at circumcision, years: mean (s.d.) range	6.4 (4.1) 0.8–16
Years in The Netherlands, mean (s.d.) range	10.9 (6.3) 2–29
Number of children, mean (s.d.) range	1.78 (1.6) 0–8
Country of birth, n (%)	
Somalia	18 (27)

Source of income, n (%)	
Job, education fee or social benefit	37 (66)
No income	19 (34)

FGM, female genital mutilation.

According to World Health Organization classification.¹⁹

Instruments

The survey consisted of four questionnaires including the Harvard Trauma Questionnaire (HTQ-30),²⁰ a 30-item transculturally validated screening instrument for post-traumatic stress disorder (PTSD) symptomatology (Cronbach's $\alpha = 0.96$ in the current sample); the Hopkins Symptom Checklist (HSCL-25),²¹ which measures anxiety (10 items) and depression symptoms (15 items) and has proven to be useful as a screening instrument in several cross-cultural studies and patient studies²²⁻²⁵ (Cronbach's $\alpha = 0.96$); the COPE-Easy,²⁶ which measures different coping styles by means of 32 items grouped under three theoretical head dimensions: (a) actively problem-directed coping, (b) support-seeking coping and (c) avoidance behaviour; the internal consistency of the subscales of COPE-Easy in this sample was satisfactory (Cronbach's α varying between 0.67 for avoidance behaviour and 0.91 for active problem-directed coping); and the Lowlands Acculturation Scale (LAS),²⁷ which assesses the level of cultural adaptation with 20 items and distinguishes between a global orientation towards the past (and land of origin) as opposed to the orientation towards the future (and country of current residence) in terms of integration skills and culture-bound traditions (Cronbach's $\alpha = 0.63$). All instruments were translated into languages spoken by the participants, applying a back-translation procedure. A preliminary version of the questionnaires was pilot-tested with ten women and both content and format were revised on the basis of results.

Statistical analysis

Hierarchical regression analyses were used to test whether demographic factors (country of birth, age, years of residence in The Netherlands, marital status, educational level, source of income and number of children), circumcision-related factors (type of circumcision, age at the time of circumcision, vividness of recollection of the circumcision), coping strategies (COPE-Easy subscales) and acculturation demands (LAS subscales) predicted symptom severity of PTSD (HTQ-30 total score), anxiety and depression (HSCL-25 total score).

Results

More than a third of the participants ($n = 24$, 36%) scored above the cut-off level for indicators of psychopathology: a fifth of the total sample ($n = 13$, 20%) met the criteria for PTSD (mean HTQ-30 score >2.5), a third met the criteria for depression ($n = 22$, 33%), nearly a third met the criteria for an anxiety disorder ($n = 20$, 30%; mean HSCL-25 score >1.75) and a sixth ($n = 11$, 18%) scored above the cut-off level for all three psychopathology indicators. Almost two-thirds of all participants ($n = 42$, 64%) did not report scores above the cut-off on indicators for PTSD, anxiety or depression.

Type of circumcision, country of origin, source of income, vividness of recollection and coping style were significant factors in a multivariate context concerning mental health symptoms. Infibulation, a 'vivid recollection' and a substance-misuse coping style were associated with enhanced PTSD scores, whereas originating from Somalia was associated with decreased post-traumatic symptoms ($R^2 = 0.67$, $F_{(4,38)} = 22.04$, $P < 0.0001$; Table 2). Associated with higher anxiety and depression scores were infibulation, substance misuse, avoidance coping and lack of income; however, women originating from Somalia reported less anxiety and depression ($R^2 = 0.59$, $F_{(5,39)} = 13.68$, $P < 0.0001$; Table 3).

Discussion

FGM is associated with a wide range of long-term health and psychological problems (e.g. Andro *et al*²⁸). Circumcised immigrant women in this study are likely to report emotional disturbances that relate to FGM, with about a sixth reporting scores above the threshold for PTSD and a third reporting severe levels of depression or anxiety. Specific factors, associated partly with FGM and partly with current life stressors, influence the severity of psychopathology. In particular, infibulated immigrant women who have a vivid recollection of the circumcision, who do not have a paid job, and who cope with their problems mainly in an avoidant way (substance misuse), may form a group at risk of severe psychological problems.

The majority of the sample reported mental health problems but did not meet criteria indicative of psychopathology. These relatively low percentages could be due to the common fact that the majority of the survivors of traumatic events are able to recover without developing mental health problems. The underreporting of symptoms could also be owing to different perceptions (not the circumcision but other stressors would be responsible for the current complaints/symptoms) or taboo (being ashamed to talk about the problems, feeling a sense of stigma). In addition, the reluctance to speak out can be related to the fact that thinking or talking about the mutilation may cause the pain experienced at the time of the ritual to reappear; chronic pain and traumatisation can have a mutually reinforcing effect.²⁹ Nonetheless, it may also be true that the majority of the women experience no substantial traumatic symptoms as a consequence of FGM (see Lockhat,¹² who showed that women who were circumcised according to the mild sunna variant (type 4) did not report PTSD-related problems).

The finding that infibulation and a vivid recollection may enhance symptomatology may not come as a surprise. Still, some findings do puzzle us, such as the finding that Somali background appears to have a protective effect.

Speaking openly about the trauma may only be beneficial when this is appropriate within a culture of recognition of the trauma and its psychological consequences. Somali respondents may have more problems communicating about FGM in their culture. Another explanation may be that Somali women assess the event less negatively than women from other countries. According to the Lockhat model,¹² a negative judgement is predictive of PTSD development. In fact, some Somali women refer to the Islamic teachings saying that sunna is not prohibited. To them sunna has a normative and positive connotation within Islam, whereas, for instance, Sudanese respondents reject the Somali reinterpretation (Idjihad) of what is being said in the Holy Writings.¹¹

Another finding concerns the relationship between symptoms, avoidant coping and substance misuse. Avoidance plays a pivotal role in PTSD symptom maintenance.³⁰ Accordingly, it is not surprising that avoidant coping is associated with PTSD symptom severity. Participants may develop substance misuse problems in an attempt to manage distress associated with the effects of FGM and related stress symptoms, or to numb themselves from the remembrance or experience of intense emotions. In our sample this coping style seems to exacerbate the problems in those experiencing anxiety and depression.

Our study has a unique character. The active participation of the target population and the way we obtained data provide sufficient ground for answering the research questions validly. For HTQ and HSCL excellent cross-cultural psychometric results have been reported. Some caution, however, is warranted in interpreting the results. Using a cross-sectional design, we can only employ a relatively passive approach to making causal inferences based on the findings – we may only speak about potential predictors. Moreover, the small group size, which is an inherent consequence of studying such a precarious topic, presents an important limitation as do the composition characteristics of the group (i.e. the high level of education and low marital state).

Incorporated in the clinical treatment of circumcised immigrant women should be providing them with coping mechanisms to help them come to terms with their experiences. Using therapy to equip women with instrumental skills to help them cope in day-to-day life and promote social integration to avoid social isolation (e.g. by enrolling the women

in education/training) is also a good starting point for improving mental health (see also Summerfield³¹). In addition, when treating women who experienced FGM one must be able to discern the various types of FGM, be knowledgeable about the related symptoms and the effects these may have on the woman, and have awareness regarding the taboo surrounding the practice. Finally, mental healthcare providers should be attentive to the fact that FGM is but one of a range of possible traumatising experiences the patient may have been subjected to. They should not only focus on FGM but check whether there are other factors, such as social or financial circumstances, that may be causing the symptoms presented by the patient.

On the basis of the empirical findings presented, our study shows that FGM is associated with psychological health problems for a substantial group of immigrant women. However, a considerable number of women are capable of coping with most impediments and may regard the ritual as 'normal' and therefore not sickening. Our data thus underline the diversity in interpreting the events and the level of remembrance as crucial for experiencing psychopathology. For future studies, it is important to elucidate the contextual factors that influence decisions about service utilisation. Prevention and clinical efforts should focus on the individual within its context and should be aware of potential hesitation among some women to seek psychological help. Clinicians are encouraged not to pathologise the consequences of FGM but to focus on the urgent psychological, social and psychosexual needs identified among a significant number of circumcised women.

1.8.81 YouTube and 'psychiatry'

Robert Gordon John Miller Noel Collins

Correspondence

Noel Collins (noel.collins@sabp.nhs.uk)¹

date

2015-12

Abstract

YouTube is a video-sharing website that is increasingly used to share and disseminate health-related information, particularly among younger people. There are reports that social media sites, such as YouTube, are being used to communicate an anti-psychiatry message but this has never been confirmed in any published analysis of YouTube clip content. This descriptive study revealed that the representation of 'psychiatry' during summer 2012 was predominantly negative. A subsequent smaller re-analysis suggests that the negative portrayal of 'psychiatry' on YouTube is a stable phenomenon. The significance of this and how it could be addressed are discussed.

– Discussion

* *Psychiatry fighting back*

YouTube (www.youtube.com) is a video-sharing website created in 2005, which now provides a platform for 2 billion clip viewings every day.¹ The website's viewership statistics are eye opening. More than 1 billion unique users visit YouTube each month. Over 6 billion hours of video content are watched each month and 100 hours of video are uploaded to YouTube every minute. It is available in 61 countries and across 61 languages, and according to Nielsen, YouTube reaches more US adults aged 18-34 than any cable network.²

Clip content is varied, uncontrolled and often anonymous. Whereas clips are uploaded and accessed by diverse individuals, groups and political bodies across the globe, universal access is restricted in some countries. In China, for example, YouTube access was blocked by the government in 2009 as a response to Tibetan content.³ YouTube website administrators also reserve the right to remove uploaded content should users violate specified terms and conditions. Video files that ignite social political unrest, violate copyright and intellectual property protection laws, or breach national security legislation are likely to be removed. According to the YouTube terms of service, material which is obscene, defamatory or unlawful must not be submitted.⁴ Despite these restrictions, the YouTube platform is largely an unregulated medium which is being used to circulate extraordinarily varied material. This includes sharing and disseminating health-related information, particularly among younger people.^{5,6} Against this backdrop, there is growing concern that internet social media are being increasingly used to communicate an anti-psychiatry message.⁷ However, to our knowledge, this has never been confirmed in any published systematic analysis of YouTube content. This descriptive study aimed to determine whether YouTube portrayed 'psychiatry' in a positive, neutral or negative light. In view of the enormity of the viewership statistics, we consider the implications of this.

Study

On 12 July 2012 we examined YouTube on default search settings using the solitary search term 'psychiatry'. We believed this to be the most appropriate description of the discipline as a whole and the most likely reductionist YouTube search term for the specialty. Other possible search terms such as 'mental health' were discounted owing to the conceptual overlap with psychopathology and other constructs and the likelihood of generating broad and irrelevant search results. YouTube ranks search results according to relevance gained from the title of the clip, descriptive language within 'relevant keywords' and 'video tags', and the video description itself. Furthermore, the higher the number of 'comments' a video possesses, the higher the 'authority signal' becomes (i.e. the inherent video popularity, which also promotes a higher ranking).⁸

The first 100 clips of more than 1000 ranked results were viewed independently by two researchers (R.G. and J.M.) and categorised as positive, negative or neutral in their representation of psychiatry. No explicit criteria were used in categorising clips, which were assigned to each category according to the global impression of reviewer regarding the overall theme of each clip. Clips were assigned 'neutral' as a default if no overall negative or positive theme was identified. Disagreements in clip category were arbitrated by a third reviewer (N.C.). The number of views and clip length were also recorded. Non-functioning, deleted or repeated clips were excluded from analysis. Browser software at the time of examination was up to date and there was no disagreement between non-functioning clips observed on different computers.

Study results

The kappa agreement between observers was 76%. The observers excluded 20 clips from analysis. The majority of eligible clips portrayed psychiatry negatively (51%) compared with neutrally (29%) and positively (20%) (*Table 1*). Negative clips were viewed more frequently and were longer than both positive and neutral clips. A subsequent smaller re-analysis of the first ten ranked clips on 14 July 2013 (five negative, two positive, three neutral) and 13 August 2014 (six negative, one positive, three neutral) revealed similar findings. A selection of analysed clips is provided in *Box 1*.

Characteristics of negative, positive and neutral clips on 12 July 2012

Clip type	Eligible clips, <i>n</i> (%)	Average number of clips views	Average clip length
Negative	41 (51)	77 035	14m 49s
Positive	16 (20)	54 234	9m 34s
Neutral	23 (29)	7244	7m 20s

Common themes of negative clips related to the process of diagnosis and treatment. In particular, psychiatric diagnoses were criticised for being invalid, unreliable and a non-scientific mechanism of social control. Other concerns included stigma and the ‘labelling’ of individuals with diagnoses, administering toxic psychotropic medication to children and the potential harm of psychiatric treatment. Themes of positive clips included the benefits of psychiatric research, improvements in treatment and an anti-stigma video (‘Beards and Bowties’ by Dr Kamran Ahmed: <http://www.youtube.com/watch?v=70loMcIqd9Q>). Neutrally themed clips were largely educational in nature, including a cartoon portrayal of the proposed neurotransmitter mechanism of bipolar affective disorder.

Discussion

This study reveals that the representation of ‘psychiatry’ on YouTube in July 2012 was predominantly negative. Subsequent clip analyses in 2013 and 2014 suggest that this is a stable phenomenon. The source of negative YouTube clips was unclear owing to blind authorship. However, there were three ‘regularly negative’ authors of clips promoting a seemingly ‘anti-psychiatry’ campaign.

What does a search term of ‘psychiatry’ mean? Content analysis of clips suggested the discipline of psychiatry itself was the implied meaning of ‘psychiatry’ in the majority of clips. Although other medical specialties also suffer from negative portrayals on YouTube, this is usually topic-specific such as paediatric immunisation or objections to tanning by dermatologists.⁹⁻¹¹ ‘Psychiatry’ as a medical discipline appears uniquely targeted on YouTube for negative representation.

Why is portrayal of psychiatry on YouTube negative? The YouTube medium itself is vulnerable to extreme content owing to blind authorship, presentation of opinion as fact and the distinct lack of any peer review or editorial process.³ The online anti-psychiatry campaign has been linked to Scientology, disgruntled patients and psychiatrists, critical social scientists, humanistic psychologists and journalists sceptical towards psychiatry.⁷ It has also been suggested that an anti-psychiatry group now exists as a patient-based consumer movement.⁷ This online antipsychiatry message may be increasing,⁷ with the release of DSM-5 being a particular nidus of further criticism.¹² The negative online representation of ‘psychiatry’ may also be an extension of long-standing societal scepticism of ‘psychiatry’ into a contemporary medium. It could also be symptomatic of the overall failure of psychiatry to promote itself more positively.

It is unclear whether information disseminated through social media platforms influences health-related attitudes and behaviours.⁶ More educated viewers appear relatively resistant to inaccurate information on YouTube, even when the message is framed as scientific reasoning.⁶ However, it does appear that social media websites are becoming an increasingly popular source of health information.¹³ The spiralling volume of uncensored information being uploaded to social video platforms such as YouTube makes it difficult for health consumers to discern reliable health information from misleading content. Certain patient groups, such as younger adults and people with anorexia, may be more

vulnerable to extreme content.¹³ It is also unclear how the negative online representation of psychiatry interacts with real-world stigma surrounding psychiatric illness and its treatment.

Box 1 A selection of clips from the original 2012 analysis

Negative:

http://www.youtube.com/watch?v=y_AC-JhPOI (The psychiatric drugging of children & elderly)

<http://www.youtube.com/watch?v=hy79C0v8eIE> (Psychiatry)

<http://www.youtube.com/watch?v=PcuhhJ1BaMk> (The DSM: psychiatry's deadliest scam)

Positive:

<http://www.youtube.com/watch?v=dFs9WO2B8uI> (RSA animate – the divided brain)

<http://www.youtube.com/watch?v=tTCwihayOv0> (Peggy Rodriguez, MD for UNM Department of Psychiatry Residency Program)

<http://www.youtube.com/watch?v=89-LDCnP8qw> (Anthony Rothschild, MD: Brudnick Chair & professor of psychiatry)

Neutral:

<http://www.youtube.com/watch?v=5N8LJjGjsfI> (Ask the doctor: cardiology, psychiatry, geriatric medicine)

<https://www.youtube.com/watch?v=qVkYHioCHPk> (Psychiatry, Ain Shams University, basic interviewing skills 1.wmv)

<https://www.youtube.com/watch?v=jq5F2XRt6QM> (Psychiatrist vs psychologist (mental health guru))

Despite negative representation, viewing rates of YouTube 'psychiatry clips' are low compared with other content. The most popular 'psychiatry' clip, a music video by The Avalanches entitled 'Frontier psychiatrist', including a parody of the psychotherapist and patient encounter, attracted 2.3 million views. To give some perspective, 'Gangnam Style', a music video by the South Korean musician Psy, attracted 1.5 billion views, 'Charlie bit my finger again' 520 million and the Taiwanese 'Nyan cat' animation 101 million views.

Although the effects of negative representations of psychiatry on social media remain questionable, it is clear that YouTube content is capable of exerting global impact. Sceptics of this need only heed the story of Sonya the slow loris. In 2009, Dmitry Sergeyev uploaded a video of her being tickled. Although illegal to have a captive slow loris as a pet outside of Russia, this single viral video has increased the illegal pet trade of these animals and has now led to the near extinction of the species.¹⁴

Psychiatry fighting back

Accepting that negative representation of psychiatry on YouTube is a concern, how can it be addressed? Psychiatrists, their professional bodies and healthcare providers could start by recognising the influence of social media and its potential for disseminating health information, particularly in younger health consumers.⁵ Promisingly, the Royal College of Psychiatrists has launched its own YouTube channel (www.youtube.com/user/RCofPsychiatrists). This currently has low impact, with its introductory clip displaying a modest (2000) number of views, but it could eventually be a platform to provide unbiased and accurate information and to convey a positive message about psychiatry more generally. It may be as important to raise awareness among younger people and vulnerable patient groups about the trustworthiness of online information more generally.¹³ Others have suggested political leverage on YouTube to communicate more objective information⁶ or to carry explicit disclaimers when an extreme view is represented (in the same manner as television). Further options include the development of algorithms to automatically detect and filter extreme videos before they become popular.¹³ However, these proposals are somewhat at odds with the overarching YouTube ethos of free 'self-broadcast'.

The authors thank Alberto Pavanello for his advice and encouragement throughout.

1.8.82 ECT practices in Iraq: a national audit

Nesif Alhemiary Zainab Ali Mohammed J. Abbas

Correspondence

Dr Mohammed J. Abbas

(mohammed.abbas@leicspart.nhs.uk)¹

date

2015-12

Abstract

Aims and method

This national audit examined practice of electroconvulsive therapy (ECT) in Iraq against local standards. Data were collected by a questionnaire sent to heads of departments or medical directors in the 10 Iraqi hospitals which provide ECT and by examining case notes of all patients who had ECT in the first 6 months of 2013.

Results

Of the 26 psychiatric hospitals in Iraq, 10 provide ECT. There were some resource shortcomings in the ECT clinics (e.g. only 2 had a minimum of 2 rooms and all had no EEG monitoring). During the audit period, 251 patients had ECT. The mean age was 36.2 years and 51.8% were males. Bilateral ECT was used in all cases, general anaesthesia in 77.15%. The main indication for ECT was schizophrenia, followed by severe depression, resistant mania, catatonia and others.

Clinical implications

More work is needed to ensure all patients receive modified ECT. ECT is still used widely for schizophrenia. This needs further exploration and training.

Contents

- *ECT practices in Iraq: a national audit*
 - *Method*
 - *Results*
 - *Discussion*
 - * *Limitations*

Electroconvulsive therapy (ECT) is an effective treatment for a small number of patients who have severe mental disorders.^{1,2} Its use has declined in Western countries over the years³ and it has been associated with stigma.^{4,5} Unmodified ECT and its portrayal in the media might have contributed to that stigma.⁶

ECT practice varies across countries.^{3,7} In Asia, a survey of 257 institutions in 23 countries suggested that the practice may be seen as suboptimal, schizophrenia was the main indication, unmodified ECT is commonly used, electroencephalography (EEG) is not common and no formal training was given.⁸

International guidelines have been developed to ensure good practice in delivering ECT.^{1,2} In Iraq, the ECT Policy 2009 was produced by the Ministry of Health as part of a quality and standards project aimed at developing standards for care in psychiatric services. The project was carried out as a collaboration between the Royal College of Psychiatrists' Iraq Sub Committee and the Ministry of Health in Iraq using consensus conferences methodology.⁹ The aim of this audit was to assess the practice of ECT in psychiatric hospitals in Iraq by measuring the degree of compliance with the standards of the Iraqi ECT Policy 2009.

Method

Psychiatric services in Iraq are provided in 26 hospitals. Three of these are psychiatric hospitals and the rest are psychiatry wards or units within general hospitals.⁹ We contacted medical directors or heads of psychiatry departments by email or telephone to find out how many hospitals have ECT facilities: it transpired that only 10 provide ECT treatment.

The audit was designed to investigate compliance with the Iraqi ECT Policy 2009. The policy is written in Arabic and English. We divided the standards of this policy into two groups: the first group included standards related to the requirements of ECT clinics in terms of number of rooms, equipment, medicines, processes and staff. The second group covered the standards related to individual ECT treatments. The full policy is available from authors on request.

A self-completed questionnaire covering the first group of standards and a data collection form covering the second group were developed by the authors. The questionnaire was sent by email to medical directors or heads of departments in the 10 hospitals. The data collection form was completed by psychiatry trainees (students of the Iraqi Board of Psychiatry) in these hospitals providing data from case notes of all patients who had ECT in the first 6 months of 2013. The patients were identified from the ECT clinics' records. This audit was approved by the Iraqi Board of Psychiatry.

Data were analysed with SPSS version 19.

Results

All 10 hospitals returned the questionnaire regarding the first group of standards. For individual ECT treatments, data were available from 8 hospitals only. One hospital did not provide data and in the other no ECT treatment was given during the audit period.

Results showed that only 2 hospitals (20%) have a minimum of 2 rooms in their ECT clinics. Only 3 hospitals (30%) have an ECT machine which is less than 5 years old. No hospital has a machine which has EEG monitoring. Apart from one hospital, all machines used brief-pulse wave electrical current. Only in 4 hospitals (40%) was there an anaesthesia specialist attached to the department. There was a nurse responsible for the department in 7 out of the 10 clinics (70%). A nominated psychiatrist responsible for the department was available in 6 clinics (60%); all clinics (100%) train their ECT team and 4 (40%) conduct an annual audit of the work of the department (*Table 1*).

Responses to the questionnaire in relation to 10 ECT clinics requirements

	<i>n</i>		
Anaesthesia drugs are used according to Iraqi standards	5	0	5
Is there anaesthesia specialist in the ECT department?	4	1	5
Is there is a nurse responsible for the ECT department?	7	3	0
Has a minimum of two rooms	2	8	0
ECT device has EEG	0	10	0
ECT device has different doses	8	2	0
ECT device is less than 5 years old	3	7	0
A nominated psychiatrist is responsible for the ECT department	6	4	0
If yes, was the ECT team trained by the psychiatrist?	6	0	0
If yes, did the psychiatrist conduct annual audit?	4	2	0

ECT, electroconvulsive therapy; EEG, electroencephalography.

During the audit period, 251 patients had ECT: 130 male and 121 female. The average number of patients per hospital was 26.1 (range 0-47). The mean age was 36.2 years (range 17-67 years). The majority of patients ($n = 181$, 72.1%) were 18 to 44 years old, followed by the age group 45 to 64 years ($n = 67$, 26.7%). There was only 1 adolescent patient (<18 years old) and only 2 elderly patients (>65 years old).

The gender distribution was roughly equal with 51.8% of the patients male and 48.2% female. Only about a third (28.3%) were in-patients. Written consent by the patients or their relatives was obtained in all cases. ECT was given through bilateral electrodes placement in all patients. General anaesthesia was used in 77.15% of the cases. Unmodified ECT was given in three hospitals. Further correspondence with these hospitals revealed that the reason for using unmodified ECT was the unavailability of anaesthetists.

The main indication for ECT was schizophrenia (51%), followed by severe depression (31.5%), resistant mania (10.4%) catatonia (2.4%) and others (4.4%). In those diagnosed as having schizophrenia, only 5.5% had a second opinion before ECT was prescribed and in 40% the reason was poor response to other treatments (Table 2).

Demographic and clinical characteristics of the sample ($n = 251$)

	<i>n</i> (%)
Gender	
Male	130 (51.8)
Female	121 (48.2)
Service setting	
In-patient	180 (71.7)

continues on next page

Table 28 – continued from previous page

	<i>n</i> (%)
Out-patient	71 (28.3)
ECT prescriber: psychiatric specialist	251 (100)
Diagnosis	
Severe depression	79 (31.5)
Resistant mania	26 (10.4)
Catatonia	6 (2.4)
Puerperal psychosis	1 (0.4)
Schizophrenia	128 (51)
Other	11 (4.4)
In schizophrenia, reason for ECT	
Previous good response to ECT	3 (1.2)
Poor response to other treatments	102 (40.6)
Risk to self or others	20 (8.0)
Other	3 (1.2)
In schizophrenia, second opinion was obtained: Yes	7 (5.5)
Written consent by patient or relatives: Yes	251 (100)
ECT was done under general anaesthesia: Yes	176 (70.1)
Patient was informed to fast 10 h before treatment: Yes	251 (100)
ECT dose given according to Iraqi standards: Yes	251 (100)
There was a prolonged seizure: Yes	0 (0)
Bilateral ECT: Yes	251 (100)
Patient had ECT previously: Yes	102 (40.6)
Patient notes had documentation about response to previous ECT: Yes	62 (24.7)

ECT, electroconvulsive therapy.

All of the 251 patients (100%) received a physical health examination. However, investigations were done more often in the patients who had modified ECT than those who had unmodified ECT (*Table 3*).

Investigations

	Unmodified ECT (<i>n</i> = 75) <i>n</i> (%)	Modified ECT (<i>n</i> = 176) <i>n</i> (%)	<i>P</i>
Complete blood count	21 (28.0)	171 (97.2)	***
Fasting blood sugar	17 (22.7)	168 (95.5)	***
Urea and creatinine	8 (10.7)	170 (97.1)	***
Liver function test	8 (10.7)	171 (97.2)	***
Chest X-ray	11 (14.7)	176 (100)	***
Electrocardiogram	12 (16.0)	176 (100)	***

$P < 0.001$, chi-squared test.

There were no statistically significant differences between males and females across clinical and demographic variables.

Discussion

As far as we know, this is the first national audit of ECT practice in Iraq against clear and explicit standards. We collected data through two routes, a health professional questionnaire and a review of patient case notes. The audit highlighted areas of good practice and areas which need further improvement.

The majority of our patients were young (72.1% were 18 to 44 years old), which is very similar to Asian patients having ECT⁸ but different from trends in Western countries, where patients are usually elderly.¹⁰ Chanpattana et al¹⁰ suggested that this difference in age group trends could be caused by Asian population demographics and the fact that schizophrenia (with higher prevalence in younger patients) is the main indication for ECT in Asian patients. These explanations could also be valid for our Iraqi sample.

The gender distribution of our sample was roughly equal. This is slightly different from what is known in Asian countries, where more males receive ECT,⁸ and from Western countries, where more females do.¹¹⁻¹⁴ A possible reason for this near-equal gender distribution is that, in Iraq, there was found to be no gender difference in depression;¹⁵ however, it is also possible that our finding was accidental.

Another finding which was very similar to Chanpattana et al's⁸ was that schizophrenia was the major indication for ECT (51% v. 41.8% in their sample). This finding is slightly different from what Iraqi psychiatrists report about the indications for ECT. In a recent survey which included 73 Iraqi psychiatrists, the first indication mentioned was depression, followed by schizophrenia.¹⁶ The use of ECT in schizophrenia could raise a number of questions about the appropriateness and reasons for its use. International guidelines do not recommend ECT in general cases of schizophrenia, but as an option where clozapine has already proved ineffective or intolerable.² A review concluded that ETC might be an option in patients who show poor response to medication¹⁶ and this was also cited as the main reason for ECT in our sample. The lack or unavailability of clozapine and the difficulties associated with blood monitoring in Iraq might be one reason for poor treatment response. The practice of having a second opinion for the use of ECT in schizophrenia is still very rare in Iraq (5.5%) and needs to be encouraged.

It is encouraging that the majority (70.1%) of ECT in our study was modified ECT. This figure indicates a significant improvement in this area: although we do not have exact figures, we are aware that prior to 2003 ECT was mostly given in an unmodified way. This also seems better than the practice of ECT in Asian countries in general, where 55.7%

of patients still receive unmodified ECT,⁸ but is below the 100% standard stipulated by the Iraqi ECT Policy and the practice in high-income countries.^{1,2} Unmodified ECT was applied only in three hospitals and the unavailability of anaesthetists was the only reason. Measures to address this resource issue need to be taken by the Ministry of Health. Closure of ECT clinics where general anaesthesia is not available might be one, albeit the last resort, option. In this context, we are aware that the biggest psychiatry hospital in Iraq (which has 1200 beds) has stopped ECT treatment because of the unavailability of anaesthetists and patients who need ECT are transferred to an acute hospital where a modified ECT is given. This has led to a significant reduction in the number of ECTs (Tamimy J, 2011, personal communication).

In addition to human resources, this audit identified other shortcomings such as the number of rooms, the age of the ECT machine and the lack of EEG monitoring facilities. Improving these areas could lead to an improvement in the quality of care patients receive. For example, EEG monitoring, which was absent in all clinics, could mean lower doses being given and subsequently, fewer cognitive side-effects.¹⁸ One way of improving these areas could be by nominating a consultant psychiatrist (in our sample, this happened in only 60% of the ECT clinics) and a nurse who are responsible for ECT delivery, oversee its practice and audit it.

Bilateral ECT was performed on all patients in compliance with the Iraqi ECT Policy, which stipulates that bilateral ECT should be used except in patients under the age of 18 (only one patient in our sample) or in elderly patients with cognitive impairment. Bilateral use of ECT seems to be the norm in many countries.^{8,10,19,20}

Limitations

One limitation of our study is that we did not collect data about the number of ECT sessions given to each patient. This information could inform us about Iraqi practice in that area, but not necessarily in measuring compliance with the policy, which does not include a standard about the number of ECT sessions. Another limitation is that we did not record how many of the consent forms were signed by patients as opposed to relatives. This could have shed light on transcultural differences in that area. In Iraq, giving consent by the family on behalf of the patient is seen as acceptable. This is something which needs to be explored further in the absence of an active mental health act. This audit has not covered ECT practice in private clinics. We know from personal contact that this is not uncommon but it is not governed by any policy. Regulations might need to be enforced to ensure good practice. We did not collect data about who administered the ECT treatments; however, we know that in Iraq ECT is administered by a psychiatry specialist or a trainee.

The recent history of Iraq has been very traumatic, with three wars, years of economic sanctions and more than 11 years of civil unrest. These major events have affected the health services', including mental health services', infrastructure. Since 2003, there have been attempts to improve and modernise mental health services in collaboration with international bodies such as the Royal College of Psychiatrists through its Iraq Sub Committee. This subcommittee has contributed to many projects,⁹ for example drafting the ECT standards. This audit has examined the practice of ECT in Iraq against these standards and identified areas for further improvement. There are resource issues that need to be addressed by the Ministry of Health and areas which could be improved by training or research. In particular, the use of ECT in schizophrenia needs further exploration.

We thank the medical directors and heads of departments who answered the questionnaire. We also thank the trainee psychiatrists in the Iraqi Board of Psychiatry who helped in the data collection: Dr Ghada Adeeb, Dr Tharaa Wadaah, Dr Lava Dara, Dr Haeffa Ahmed, Dr Akeel Ibraheem, Dr Sadoon Abid, Dr Yassir Saad, Dr Ashwan A. Shwan, Dr Arafat Aldujaili.

1.8.83 Chemotherapy for Hodgkin's lymphoma in a patient receiving clozapine for treatment-resistant schizophrenia: use of the Mental Capacity Act 2005

Florence Elizabeth Chamberlain Nicholas Walsh Jan Falkowski

Correspondence

(florencechamberlain@doctors.org.uk)¹

date

2015-12

Abstract

Treatment resistance occurs in approximately 30% of individuals with schizophrenia and is commonly treated with clozapine. Nodular sclerosing Hodgkin's lymphoma is a subtype of Hodgkin's lymphoma predominantly affecting those under 50 years of age. In this case report, an individual with treatment-resistant schizophrenia developed nodular sclerosing Hodgkin's lymphoma and is treated with concurrent clozapine and systemic chemotherapy. The aim of this case report is to act as guidance for clinicians and to outline the difficulties of treating individuals with psychiatric illness under the Mental Capacity Act 2005 when the proposed treatment could lead to high levels of morbidity and mortality.

Contents

- *Chemotherapy for Hodgkin's lymphoma in a patient receiving clozapine for treatment-resistant schizophrenia: use of the Mental Capacity Act 2005*
 - *Case presentation*
 - *Discussion*
 - *Conclusion*

Nodular sclerosing Hodgkin's lymphoma is the commonest subtype of Hodgkin's lymphoma.¹ It is characterised by proliferation of malignant lymphocytes in the reticuloendothelial system and presenting with lymphadenopathy or systemic 'B' symptoms.² It affects men and women equally and predominantly those under 50 years.¹ There are 3 cases of Hodgkin's lymphoma per 100 000 people in England,³ and without treatment 5-year survival ranges from 40 to 95%.^{2,4} Treatment includes radiotherapy, systemic chemotherapy or both² and is curative in 90% of cases.¹ Risks from systemic chemotherapy treatment include myelosuppression, febrile neutropaenia and thrombocytopenia.² The mortality rate from febrile neutropaenia is 9.5%.⁵

The Mental Capacity Act 2005 is a legal framework in England and Wales for making decisions on behalf of adults who lack capacity to make particular decisions for themselves. All adults are presumed to have capacity for a particular decision unless it can be proven otherwise. Patients who lack capacity require their nearest relative or an independent mental capacity advocate (IMCA) to make a decision on their behalf. Under certain circumstances, decisions are made

by the Court of Protection. Treatment under the Mental Health Act 1983 does not include the treatment of physical illness except in cases where the mental illness is a consequence of a physical illness.

Treatment resistance is found in approximately 30% of patients with schizophrenia.⁶ Clozapine is currently the most effective management option in schizophrenia, but because of its side-effect profile it is reserved for use only as a third-line agent.⁶⁻⁹ This includes a 0.3-2% risk of potentially fatal agranulocytosis,⁸⁻¹⁰ which is higher among the Asian population^{8,11} and carries a mortality rate of 5-10%.¹² Despite this, a delay in starting clozapine in those with treatment-resistant schizophrenia has been shown to lead to poor outcomes.^{9,13}

To reduce the risks associated with the development of agranulocytosis, blood parameters should be monitored closely¹⁴ and clozapine should be discontinued permanently if leukocyte counts drop significantly.¹⁰ During clozapine treatment clinicians should avoid prescribing drugs that depress leucopoiesis.¹⁰ Here we describe an unusual case where a patient was successfully treated for nodular sclerosing Hodgkin's lymphoma using the Mental Capacity Act 2005 while concurrently treated with clozapine under Section 3 of the Mental Health Act.

Case presentation

A Bangladeshi patient with a 20-year history of treatment-resistant schizophrenia was treated with clozapine. Since diagnosis, the patient has had frequent admissions to acute psychiatric hospitals due to non-adherence, leading to rapid relapse of psychotic symptoms within days of cessation. However, when adherent to clozapine, the patient remains relatively independent with only mild residual delusional ideas persisting in the background.

An abnormal swelling developed in the patient's neck, but believing this to be a side-effect of clozapine, the patient refused to comply with further treatment. While admitted as an in-patient under Section 3 of the Mental Health Act 1983, the patient was diagnosed with stage IIA nodular sclerosing Hodgkin's lymphoma and managed expectantly. However, the patient developed severe leg oedema secondary to inferior vena cava syndrome. Meanwhile, the lymphoma progressed to stage IIIB, with a very poor prognosis if untreated.

The patient refuted the diagnosis of Hodgkin's lymphoma and accounted for symptoms using a multitude of delusional ideas. These included being 'incriminated by someone – who tried to get into my blood and body' and saying that their neck was 'just bloated'. It was deemed that the patient did not have the capacity to consent to or refuse treatment for Hodgkin's lymphoma at that time. The patient was unable to make use of the information that without treatment, a likely outcome would be death, but with treatment the prognosis was excellent. They were not able to understand the gravity of their illness, or why treatment was being offered, as well as continuing to deny the diagnosis. The patient could not weigh up the information provided but was, however, adamant that they did not want their life to end.

The risk to the patient and to others from a prolonged schizophrenia relapse if clozapine was withheld during chemotherapy treatment was weighed against risk of death from myelodepletion. Switching to an alternative antipsychotic agent was considered but not possible due to failure of multiple first- and second-line agents in the past. A literature search failed to provide any evidence of agranulocytosis from treating patients with clozapine and systemic chemotherapy previously.¹⁵ It was therefore deemed in the patient's best interests to give systemic chemotherapy and clozapine concurrently.

The urgency of treating the Hodgkin's lymphoma took precedence over waiting to see whether capacity could be regained with sustained clozapine adherence. In the absence of a nearest relative to consult, an IMCA was appointed, who agreed that systemic chemotherapy treatment should progress immediately against the patient's wishes in their best interests. Application was successfully made to treat the patient with clozapine off-licence.

Before commencing systemic chemotherapy, haematological parameters and clozapine level were within normal range. The patient was treated with six cycles of systemic chemotherapy. Each cycle consisted of doxorubicin 25 mg/m², bleomycin 10 000 iu/m², vinblastine 6 mg/m² and dacarbazine 375 mg/m² on day 1 and day 15 with a 28-day break between cycles. During the first cycle of systemic chemotherapy the patient became agitated and required sedation. It was decided that continuing with further treatment should be decided by the Court of Protection, which granted permission.

The patient completed treatment successfully and obtained complete remission from Hodgkin's lymphoma 6 months after treatment completion.

Discussion

This case illustrates some of the practical difficulties in treating patients under the Mental Capacity Act 2005. Although the probable outcome of not treating this patient's lymphoma was death, the proposed treatment also carried a high risk of morbidity and mortality and the administration of cytotoxic agents requires total compliance on behalf of the patient to avoid causing unnecessary harm to the patient and staff administering the treatment.

Any proposed intervention should be the least restrictive of the patient's basic rights and freedoms and the patient must be given all appropriate help to restore capacity to make such a decision. In this case, there was no time to spare to see whether reinitiating clozapine would restore the patient's capacity to consent to treatment and avoid application to the Court of Protection to treat without the patient's consent.

Since a third of the general population will be diagnosed with cancer in their lifetime¹⁶ and the population prevalence of schizophrenia is 0.30-0.66%,¹⁷ the concurrent use of clozapine and systemic chemotherapy in Hodgkin's lymphoma and other malignancies needs formal investigation. Our current knowledge base is from a handful of case reports which are not necessarily relevant to the malignancy in question.^{15,18} There is, however, a growing body of evidence from case reports that it may be safe to reintroduce clozapine treatment to control psychotic symptoms once the patient is established on systemic chemotherapy treatment.¹⁹⁻²¹ One case report exists where clozapine was reinstated in a case of Hodgkin's lymphoma when other antipsychotic agents failed to maintain psychotic symptom remission.²² But there is a lack of clear national and local guidelines as to the safe monitoring of these two potentially lethal treatments when prescribed concurrently. In the case of the patient we have described, blood parameters and clozapine levels were measured twice weekly and physical observations conducted 4-hourly throughout treatment.

It is widely established that patients are at greatest risk of agranulocytosis in the first 6 months of treatment with clozapine. A few cases of delayed-onset agranulocytosis have been described.^{23,24} The mechanism remains unknown, and thus physicians and psychiatrists are reluctant to prescribe concurrent myelosuppressing medication.²¹ Whether those well established on clozapine therapy are less likely to develop agranulocytosis while receiving systemic chemotherapy than those within 6 months of treatment needs also to be investigated.

Lithium has been used to increase neutrophil counts in those with neutropaenia during systemic chemotherapy and also in those with neutropaenia from clozapine therapy.^{8,9,25} The mechanism is poorly understood and may lead to an increased risk of lithium toxicity despite levels being within the therapeutic range.⁸ There is also some evidence that granulocyte-colony stimulating factor (G-CSF) can be used to treat agranulocytosis associated with chemotherapy and clozapine.⁸ However, whether lithium and G-CSF can be used prophylactically in cases where systemic chemotherapy and clozapine are concurrently prescribed has not been examined.

Conclusion

Despite the fact that none of the haematological parameters fell below critical levels in our patient, further research is needed before full conclusions with regard to safety during concurrent clozapine and systemic chemotherapy treatment. This case demonstrates the importance of regular immune and haematological parameters monitoring when such treatments are proposed.

1.8.84 Newspaper reporting of homicide-suicide and mental illness

date

2015-12

Abstract**Aims and method**

To explore the portrayal of homicide-suicide in newspaper articles, particularly how mental illness was reported. We carried out a qualitative study in England and Wales (2006-2008). Data from newspaper articles obtained via the LexisNexis database were used to examine a consecutive series of 60 cases.

Results

A fascination with extreme violence, vulnerable victims and having someone to blame made homicide-suicides newsworthy. Some offenders were portrayed in a stereotypical manner and pejorative language was used to describe mental illness. The findings showed evidence of inaccurate and speculative reference to mental disorder in newspaper reports.

Clinical implications

The media should avoid speculation on people's mental state. Accurate reporting is essential to reduce stigma of mental illness, which may in turn encourage people to seek help if they experience similar emotional distress.

– *Discussion*

- * *Newspaper interest in homicide-suicide*
- * *Reporting mental illness responsibly*
- * *Speculating on offender's mental state*
- * *Limitations*

Homicide-suicide refers to an individual who commits homicide and subsequently takes their own life. There is no standardised definition regarding the time between the two incidents. A 3-day period has previously been taken as a cut-off point, the rationale being that a 24-hour cut-off is too restrictive. Mental state is likely to remain the same over a period of days and the two events are therefore connected, but reasons for the suicide may begin to change in excess of 3 days.^{1,2} These incidents attract widespread coverage in local and national newspapers. Consequently, the way they are reported informs both the general public's understanding of these incidents and their attitude towards offender and victim.³⁻⁵ Therefore, it is important that the circumstances are reported accurately, particularly when incidents involve people with mental illness. For instance, there is an association between certain methods of reporting suicide and increased suicide risk in young people and vulnerable adults (i.e. contagion).⁶⁻⁸ In addition, it has been uncovered that 14% of articles in the print media in 2011 referred to people with mental illness as a 'danger to others',⁹ reinforcing the stereotype that people with mental illness are violent. Speculating on a person's mental state without evidence is as stigmatising as the use of derogatory language. The UK 'Time to Change' campaign, led by the charities Mind and Rethink Mental Illness, aims to encourage the media to promote positive attitudes towards mental illness.¹⁰ If successful, this may encourage people to seek help.

This is the first study to examine newspaper reporting of mental illness in homicide-suicide. We aimed to explore how UK newspapers reported incidents of homicide-suicide and how mental illness was reported in relation to these cases.

Method

Study design

The findings presented are from a larger, mixed-method study of homicide-suicide undertaken by the National Confidential Inquiry into Suicide and Homicide by People with Mental Illness (NCISH) (details available from the authors on request). In brief, 60 cases of homicide-suicide were reported to NCISH by the Home Office Statistics Unit of Home Office Science and by individual police services. The offences occurred between 1 January 2006 and 31 December 2008 in England and Wales. The inclusion criteria for these incidents were that the suicide occurred within 3 days of the homicide and that a coroner returned a verdict of unlawful killing for the victim and suicide/open verdict for the offender. Additional information on each case was sought from coroner's files, police records, newspapers, general practitioner medical records and mental health service records. A diagnosis of mental disorder was determined from the offender's medical records.

Data collection and sample

A search was undertaken for newspaper articles pertaining to the 60 cases of homicide-suicide. The LexisNexis database (www.lexisnexis.com) was consulted to locate articles published between January 2006 (the date of the first offence) and September 2012 (the date when analysis commenced), allowing time for the legal process to be concluded and reported in the media.

Searches of all local and national UK newspapers were undertaken, including tabloid and broadsheet publications, which ensured the data were representative and encapsulated a range of journalistic styles and biases. The victims' and offenders' names were used as search terms rather than the generic phrase 'homicide-suicide'. In instances where individual searches yielded thousands of returns owing to common names, the term 'suicide' or 'homicide' was added to the search. In instances where there were no returns or the count was low, alternative spellings, name variants or

known aliases were used. In six incidents where no articles were returned on LexisNexis, an additional search of online news media was undertaken.

Missing data

After an extensive search, newspaper reports were obtained on 54 incidents (90%); no articles were found on 6 incidents (10%). It is possible that these events were not reported in the media; a previous study found only 62% of homicide-suicides were reported in national newspapers.¹¹ Consequently, we felt that 10% missing data was within an acceptable range that would not bias the findings and would retain the generalisability of the results.

Quantitative analysis

Descriptive statistics were generated to provide context for these homicide-suicide incidents and limited information has been presented. The results were reported using 95% confidence intervals. The analysis was undertaken using Stata version 12. If an item of information was not known for a case, the case was removed from the analysis of that item; the denominator in all estimates was the number of valid cases for each item and it indicates the number of missing cases per item.

Qualitative analysis

The analysis of documents was undertaken in accordance with the principles set out by Hodder (2003).¹² A systematic and comprehensive approach was adopted by applying framework analysis which involves five key stages: familiarisation, identifying a thematic framework, indexing, charting, and mapping and interpretation.¹³ Each article was read and an iterative coding process was undertaken until saturation was reached. The themes were subsequently refined into three domains. The coding was carried out by S.F. and themes were discussed with L.G. and J.S.. Data were analysed using MAXQDA version 10 (www.maxqda.com). The approach differs from other qualitative analysis methods in stages four and five as it enables the data to be managed into a series of matrices whereby the data can be explored by theme and by case.¹⁴ This systematic, yet flexible, approach was preferred to other methods owing to the volume of data collected. Alternative methods to analyse media coverage used in previous research, such as content analysis with predetermined 'deductive' coding structures,¹⁵ latent class analysis¹⁶ or multivariate analysis,¹⁷ were not considered appropriate for this data.

Confidentiality and anonymity

The main data source were newspaper articles. Details of these incidents are therefore in the public domain.

Ethical approval

The study received the Medical Research and Ethics Committee (MREC) approval on 9 April 2008 and is registered under the Data Protection Act. The study was granted exemption under section 251 of the National Health Service Act 2006 (formerly Section 60 of the Health and Social Care Act 2001), enabling access to confidential and identifiable information without informed consent in the interest of improving patient care (approved 23 October 2008).

Results

Description of the sample

Over a 3-year period (2006-2008), 60 incidents of homicide-suicide were identified in England and Wales. Newspaper articles were obtained on 54 (90%) of these cases. Overall, 16 323 articles were found on these incidents. Duplicate articles (repeated in later editions) were excluded and the content was filtered for relevance. A total of 1163 articles were used in the analysis, an average of 22 per incident (range 0-115). The characteristics of offenders and victims are presented in *Table 1*. Most offenders were male, with a median age of 44, and over a quarter were from a Black and minority ethnic group. The victims were most commonly the offenders' spouse/partner or ex-spouse/partner, or their child. Nearly two-thirds of the offenders had a history of mental disorder.

Characteristics of offenders and victims

	<i>n</i> (%)	95% CI
Offender (<i>n</i> = 60)		
Median age, years (range): 44 (18–85)		
Gender: male	53 (88%)	80–97
Black and minority ethnic group	17 (29%)	17–41
History of mental illness from medical records	33 (62%)	49–76
Victim (<i>n</i> = 70)		
Median age, years (range): 38 (1–85)		
Gender: female	54 (77%)	67–87
Black and minority ethnic group	14(18%)	10–30
Relationship to the offender:		
Spouse/partner or ex-spouse/partner	45 (64%)	53–76
Child	20 (29%)	18–39

Three themes emerged from the qualitative analysis: characteristics that made these incidents newsworthy: how homicide-suicides were reported and the accuracy of newspaper reports of mental illness compared with the information contained in the deceased's medical records (*Table 2*).

Themes emerging from newspaper analysis

	Sub-theme
Theme 1: What makes homicide-suicide newsworthy?	Fascination with extreme violence and personal tragedy Characteristics of victims and offenders Having someone to blame
Theme 2: How are homicide-suicides reported?	Offender stereotypes The offender's personality Mental illness
Theme 3: Accuracy of newspaper reports of mental illness	Speculation that the incident was motivated by mental illness

What makes homicide-suicide newsworthy?

Fascination with extreme violence and personal tragedy

Tabloid newspapers exhibited a fascination with the level of violence involved in the incident. More often this referred to the violence against the victim in the homicide rather than the suicide. Graphic descriptions were used in the headlines, presumably in an attempt to attract readers. An example of a headline that illustrates the sensationalist nature of the reporting is: ‘CRAZED; EXCLUSIVE: Dad hacks toddler son to death and then kills himself’ (*The Mirror*, 2 September 2006).

Characteristics of victims

The newsworthiness of these incidents was also associated with the characteristics of the victim. The deaths of vulnerable or innocent victims added a further tragic element to the story. In addition to labelling the victims and offenders as good or evil, the status of the victim was elevated due to their profession. When reporting on the deaths of two police officers, one in the line of duty while responding to a serious incident, the language used emphasised the bravery of the victim while simultaneously showing disdain for the offender: “HERO cop [victim] was shot dead yesterday when a gunman went berserk during a furious row with his girlfriend. [The victim] was part of a police armed response unit called out to a domestic dispute after crazed [offender] armed himself with a hunting rifle (*The Sun*, 4 October 2007).”

Apportioning blame

There was increased newspaper coverage when the details of the homicide-suicide were used to highlight failure by services. In one article, the offender’s personal responsibility was marginalised and the focus turned towards perceived institutional failings, for which the newspaper blamed the prime minister: “Perhaps our PM and members of his government might like to imagine some inept social services bod bursting into THEIR home uninvited and removing their partner by force, saying: “It’ll be better for everyone.” What’s better for old people is that they feel safe and secure, and how the hell can they feel that when social-services Nazis tear them away from the one person left in the world who loves and understands them? The only person who remembers them as they were – strong and vibrant – not dependent on a state that doesn’t give a stuff about them?” (*News of the World*, 18 May 2008)”

How are the homicide-suicides reported?

We found markedly different styles of reporting between broadsheet and tabloid newspapers. A considerable number of articles reported short, factual accounts of the incident. By contrast, where the reports were opinion-based, these articles provided valuable insight as to how the offenders were perceived and portrayed to the general public.

Offender stereotypes

The portrayal of homicide-suicide in the media seemed to reinforce stereotypes and oversimplify the context of these events. For example, it was common for elderly couples with declining health to be described as being ‘devoted to each other’. Journalists assumed an empathic attitude toward the offender and the couple’s situation in general. Commonly referred to as ‘mercy killings’, a similar sympathetic tone was observed in cases of filicide by mothers where a child was killed for perceived altruistic reasons. However, fathers who killed their children did not receive the same level of sympathy, even when they experienced similar emotional distress before the homicide. In one article, the newspaper reported a mother’s defence of her son’s actions, in which two of her grandchildren died. This sentiment was subsequently criticised in the article, presumably to reinforce the message to the reader that there was no excuse for the offender’s actions and he did not deserve any sympathy.

The offender's personality

Direct quotations from family and friends were commonly used to generate a profile of the offender. These descriptions provided insight into how the person was perceived, and consequently, the image created of the offender in the media. Each case of homicide-suicide generated numerous articles in a range of publications. The witness descriptions of the perpetrator differed depending on the newspaper and the informant quoted. The contrast in the portrayal of the same offender is demonstrated: “‘Everyone is stunned and no one can believe it. He was such a nice bloke, he’d do anything for anyone and was very helpful and he absolutely loved his children.’ (*Daily Telegraph*, 23 September 2008) ‘There was something weird about him. I knew [he] wasn’t right in the head. He was an attention-seeking control freak who had a thing about teenage girls.’ (*News of the World*, 28 September 2008)”

Mental illness

Comments regarding the offender's perceived mental state were prominent in several newspaper headlines. Whereas most descriptions were written with sensitivity, there were some exceptions to this, notably from the tabloid press: ‘Nut free to kill for 3rd time’ (*The Sun*, 18 March 2006), ‘PSYCHO DADDY; Father strangled mum of his 4 kids then hung himself at home’ (*The Mirror*, 12 March 2009).

Accuracy of newspaper reports of mental illness

Speculation that the incident was motivated by mental illness

Newspapers are produced for commercial reasons and articles are written for specific audiences. We found the majority of the homicide-suicide incidents involving people with a history of mental illness were reported responsibly and newspapers did not stigmatise the offender. However, it was observed that some newspapers published speculative comments concerning the offender's mental state, without being able to substantiate these claims: “‘She must have had a very troubled mind to do what she did. We can’t imagine why she said to people she had cancer; she may have been suffering from some sort of mental illness. We are not aware of any mental health issues but that is something we shall be looking into.’ (*Birmingham Evening Mail*, 12 December 2007) ‘I would describe him as a psychopath. I saw him attack his brother with a hammer then run after him with a knife in the street.’ (*Yorkshire Post*, 9 March 2009)” In addition to the speculation regarding diagnoses, reporters often seemed to select quotations from witnesses that provided a default assumption of mental illness when there was seemingly no other plausible explanation. For example, they referred to the offender having ‘cracked’, ‘snapped’, ‘flipped’ or ‘gone berserk’. Although these terms appear in direct quotations from witnesses who knew the offender, the words imply the offender had experienced a mental health crisis at the time of the offence, yet no supporting evidence was provided to substantiate this.

Discussion

Newspaper interest in homicide-suicide

We found that homicide-suicides were highly newsworthy, with 90% reported in national and local newspapers, an average of 22 articles per incident. There are aspects of these offences which made them of public interest, notably they involved multiple victims, the majority of whom were intimate family members, consistent with previous research.¹⁸ Our data showed that extreme violence towards the victim, characteristics of the victim and the perceived failure of services to intervene in certain circumstances added to their media appeal. Emotive language, particularly in headlines, was used to attract the attention of the reader, which was consistent with findings from previous studies.^{17,19}

Reporting mental illness responsibly

In this study, we found the complexity of the events was often lost in the reporting. People who committed these acts were often assigned labels and portrayed in a stereotypical manner. We found evidence of derogatory language used to describe mental illness, such as ‘nut’ or ‘psycho’, although the majority of articles referred to people with mental illness more sensitively. This finding is consistent with a recent study undertaken by researchers at the Institute of Psychiatry in the UK which showed a decrease in the number of articles using pejorative language and referring to people with mental illness as being dangerous. The data also showed a simultaneous increase in anti-stigmatising newspaper articles and positive mental health promotion. However, the research reported no overall change in the proportion of stigmatising articles between 2008 and 2011.¹⁵

Speculating on offender’s mental state

Evidence of newspaper speculation on an individual’s mental state without any corroborating medical evidence was an important finding of this study. Labelling offenders as ‘psychopaths’ not only stigmatises the deceased, it also causes distress to the surviving family members. Previous research has shown how relatives of people who carried out a homicide or suicide experienced additional anguish due to the person’s portrayal in the media.^{20,21} Even where the evidence is lacking, reporters chose to reinforce the perception that mental illness is the only credible explanation for the offender’s actions. This conjecture promotes a widespread belief that ‘all’ people who commit homicide-suicide must have been mentally ill, when in many cases mental illness was not a feature. Data from the larger study of homicide-suicide have shown that 38% of offenders had no history of mental illness, consistent with a similar study in the USA.²² Guidance published by the American Foundation for Suicide Prevention and partners suggests that careful newspaper coverage could help to change these misconceptions.²³ Similarly, guidance for the media by Time to Change¹⁰ suggests to journalists: ‘Don’t speculate about someone’s mental health being a factor in the story unless you know it to be 100% true’. A further ‘reporting tip’ asks journalist to consider: ‘Who are your sources? Can you rely on eyewitnesses or neighbours to provide facts or has an assumption been made about someone’s mental health status?’ Examples of language that should or should not be used to avoid the perception of dangerousness are also detailed.

Limitations

Newspaper databases such as LexisNexis have been criticised for not being comprehensive and have been described as inconsistent and incomplete.²⁴ Previous research has shown that content (i.e. news wire stories) could have been removed before archiving; consequently, the original news content could be different from the archived version, which can introduce error.²⁴ Restrictive search terms could also lead to articles being missed. However, in this study the use of the individuals’ names in the search in conjunction with terms such as homicide or suicide made missing data less likely.

It is possible that mental illness was underreported, either through the reporter’s lack of interest in the offender’s mental health history or because they were unable to access medical information. Websdale & Alvarez²⁵ suggested that at the time of the incident the pivotal features of an article for journalists are ‘the crime-scene, the victims, and the aftermath of these killings’.

Homicide-suicide attracts a disproportionate amount of media attention. Although the number of incidents per year may be relatively small, the excessive and prominent newspaper reporting will inevitably influence our perception of these incidents and inform our understanding of the motivation for these acts. Previous research has shown an association between mental illness and homicide-suicide and this remains an important risk factor.¹⁸ Consequently, we would encourage the accurate reporting of mental illness in the media and advocating help-seeking behaviour in people who may be experiencing similar emotional distress. This is particularly important for men following the breakdown of a long-standing intimate relationship.²⁶

The study was carried out as part of the National Confidential Inquiry into Suicide and Homicide by People with Mental Illness. We acknowledge the help of HM Coroners, Police Services, particularly Greater Manchester Police, and primary care trusts for providing access to data.

1.8.85 Provision of neuropsychiatry services: variability and unmet need

Abstract

Aims and method

Neuropsychiatry services remain underdeveloped and underprovided. Previous studies have shown variability in service provision in the UK. In this survey we approached all mental health and neuropsychiatric service providers within London to map current neuropsychiatric service provision and explore perceived barriers.

Results

All the specialist mental health service providers responded. There was huge variability in neuropsychiatric service provision within different parts of London. There was evidence of significant unmet need and variability in service pathways. Lack of earmarked funds for neuropsychiatry and disjointed funding stream for such services were identified by providers as a barrier.

Clinical implications

This study provides further evidence of an ongoing lack of adequate neuropsychiatric service provision. Reasons for variability and unmet need are discussed. Adoption of a previously proposed hub-and-spoke model of service provision and the removal of commissioning barriers through uniform national commissioning may help deal with this problem.

- * *Continued lack of equitable care*
- * *Reasons for variability and inadequate provision*
- * *Limitations*

Neuropsychiatric conditions are frequently encountered in neuroscience settings and are not uncommon in mental health services. However, the provision and development of neuropsychiatric services has lagged behind in the UK and globally.^{1,2} Attempts at establishing the neuropsychiatric needs of the general population have taken two different routes. Researchers have either assessed ‘mental health needs’ in neurology patients or have searched for ‘organic’ problems in general psychiatric patients. A number of studies from Europe have estimated psychiatric morbidity in neurology patients at 40-55%.³ A study from London looking at neuroscience in-patients found a prevalence of neuropsychiatric conditions of 55%.³ Similar figures were reported from Scotland (47%) and additionally, a 30% prevalence of conditions ‘not explained by organic cause’ in neurology out-patients was described.⁴ A study from Scandinavia reported the prevalence of psychiatric conditions in neurology patients as 55.1%.⁵ However, referral rates to mental health services in this study were only 4.6%. Therefore, one should not assume that these relatively high needs are always addressed. Data on assessment of neurological or organic conditions in mental health patients are poor, but these are estimated to be around 10%.⁶

Estimates of the prevalence of neuropsychiatric presentations in specific neurological conditions range from 20 to 75%, depending on the nature and severity of the condition, method of assessment and the population studied.⁷⁻⁹ Rates of neuropsychiatric problems are generally higher in the specialist or tertiary centre settings.

What constitutes a neuropsychiatric condition and which of those conditions require specialist neuropsychiatric service input has also been open to interpretation. We have defined neuropsychiatric conditions under four broad categories in the accompanying paper.¹⁰ Not all patients in those categories would require specialist neuropsychiatric input. Neuropsychiatry services would see patients that are complex and beyond the service provision capacity of either neurology services or mental health services alone. Patients accessing neuropsychiatry services should have problems that fall within one of the four categories that define neuropsychiatric conditions¹⁰ and should meet at least one of the criteria described in *Box 1*.

Information on neuropsychiatry need and demand at a clinical services level is available from two large-scale audits carried out in south England, led by two of the most established providers of neuropsychiatric services in the UK.^{11,12} The authors concluded that geographical distance from a specialist service was the most significant barrier to access to care. They also suspected there was a lack of localised service provision for neuropsychiatry, both of which contributed to unmet need. Both studies found unmet neuropsychiatric need, particularly in areas geographically distant from neuropsychiatry centres. It was concluded that there was emerging consensus that a referral rate of less than 20 per 100 000 population per year possibly signified unmet need in terms of service provision.⁶

Box 1 Criteria for referring a neuropsychiatric condition to a specialist neuropsychiatry service.

- Complex
- Requires specialist investigations
- Requires specialist assessment
- Requires specialist treatment
- Requires neuropsychiatric clinical expertise, which lies outside of that which may be expected in either mental health or neurology services.

Neuropsychiatric care pathways and commissioning are not standardised and are highly variable across the UK. We suspect that neuropsychiatry service provision and access to care for patients are likely to be influenced by other complex factors over and above the well-established ‘geographical distance’ from a centre of neuropsychiatry. In this study we aimed to explore whether there is still geographical variation in neuropsychiatry service usage. Rather than exploring this from a purely service provider perspective, we invited both service providers and service commissioners to share their views. Through this process we aimed to minimise potential bias of data on variability obtained in previous studies solely from tertiary referral centres. The ‘top-down’ approach of assessing variability purely from one specialist service

provider perspective may be prone to bias as more than one provider may be catering to the needs of the population in an area and indeed some services may be provided locally outside large tertiary centres.

Method

Two separate regional cross-sectional surveys were carried out. R.B. and N.A. devised two standardised questionnaires: one for commissioners and the other for service providers. The questionnaires were developed through iteration and in consultation with the national questionnaire survey into neuropsychiatry services.¹⁴ Questions were very broad and open ended to establish the current state of affairs rather than to prove or disprove an *a priori* hypothesis. Mapping of existing neuropsychiatry services in London was completed. Mapping of services was carried out by an electronic search for neuropsychiatric services by inputting words 'neuropsychiatry' and 'London' into a generic search engine. In addition, information on existing neuropsychiatry services was obtained through the Faculty of Neuropsychiatry at the Royal College of Psychiatrists and by calling all the major mental health trusts in the London area. All specialist mental health providers were identified within the target geographical area. National or tertiary level referral centres providing neuropsychiatry services and neurorehabilitation to the population of London, including public and private or independent providers, were also identified. Senior management for each provider were contacted electronically with the questionnaire and this was followed up by a telephone call.

All local mental health commissioners from primary care trusts (PCTs) were contacted using a similar method. The survey attempted to assess existing provision and service usage for neuropsychiatry to capture variation within the well-defined geographical units (boroughs covered by PCTs). We discovered there was a centralised regional (strategic health authority (SHA) level) specialist commissioning panel for neurorehabilitation in London that commissioned services related to acquired brain injury across the city. We approached it with the commissioning questionnaire for our survey. We also explored the commissioners' and providers' perceptions of neuropsychiatry and perceived barriers to neuropsychiatry service and commissioning. Data were verified and cross-checked between providers and commissioners, although it was recognised that commissioners often went to more than one provider for different elements of neuropsychiatry services. Data captured were subjected to descriptive analysis and no inferential statistics were used.

Results

Data were collected from the local PCT commissioners and from the London-wide specialist commissioning group referred to above. Most local commissioners reported on commissioning that took place through generic mental health streams, as opposed to the specialist stream referred to by the specialist commissioning group. Mental health commissioners were requested to report actual figures, however, if these were not available they were asked to offer estimated figures based on the available data. There were 31 boroughs and 30 PCTs in London, which covered a population of 185 000 to 399 000 each (average 284 000). Response rate from the PCTs was very good (83%) and 100% responses were received from the providers of neuropsychiatric services in the area. We were not made aware of any patients going out of area from London for neuropsychiatric need, on the contrary, providers in London see a number of patients from outside the local area.

The number of patients for the specialist commissioning group ranged from 3 to 76 per year (*Fig. 1*). Therefore, there was a 25-fold variation in incidence among the 30 referring geographical units within London. About half the PCTs ($n = 15$) were able to provide an estimate of the number of neuropsychiatry patients they funded: from 4 to 472 per year. The variation of incident referrals at the unit PCT mental health commissioning level was a staggering 118-fold. The variation in population between the 31 boroughs and the PCT catchment areas was approximately two-fold. In *Fig. 1*, bars 6 and 19 represent patients commissioned through specialist panels from two PCTs. For commissioning of neuropsychiatry through local commissioning they functioned as one unit and are represented as bar 7.

Fig. 24: Breakup of neuropsychiatry cases funded.

The commonest mode of commissioning of neuropsychiatry services was to tertiary services followed by local services. Funding streams for certain conditions were identified to be other than mental health, for example through acute care, physical health, neurosciences or older adults, or even Improving Access to Psychological Therapies (IAPT).

Brain injury rehabilitation was commissioned through the pan-London specialist commissioning group referred to earlier. Certain services, which were not specifically commissioned, were provided by mental health trusts (therefore commissioning of these services remains unclear).

Discussion

Variability in service pathways

Neuropsychiatry is a complex discipline which requires a highly skilled workforce dealing with a range of conditions. Different service models have been proposed to meet neuropsychiatric needs. In one of the models, neuropsychiatry services are based at a 'tertiary level', accepting referrals from psychiatry, neurology, geriatrics and general medicine.¹⁵ In London, though most neuropsychiatric service provision was at a tertiary level (*Fig. 2*), no clear service models or pathways of neuropsychiatry services emerge from the data. The lack of consistency of neuropsychiatry service provision in a relatively small geographical area is quite striking.

Internationally, different models for neuropsychiatry service provision have been reported. In Ireland, an in-patient neuropsychiatric service is closely aligned to neuroscience services and receives referrals from neurology and neurosurgery.¹⁶ Although neuropsychiatric services are commonly aligned to large neuroscience centres, successful neuropsychiatric services have been set up aligned to district or local general hospitals. There is a published report of such a service from the UK.¹⁷ Although there has been mention of community outreach model in line with stroke-related rehabilitation,¹⁸ there is little evidence that neuropsychiatry has adapted to such a service model. Most neuropsychiatry service models from outside the UK refer to a liaison consultation model.^{10,19} In the UK, the College's Faculty of Neuropsychiatry working group proposed a hub-and-spoke model, with the hub closely allied to the neurosciences centre but the spokes working closely with services in the community.⁶ Currently, there is no evidence that this model has yet been adopted consistently in London. There is an urgent need to create clear neuropsychiatry service pathways and a hub-and-spoke model is likely to be the best option.

Continued unmet need in neuropsychiatry

This study found huge variability in annual rates of funded neuropsychiatry cases in the London area. This may to some degree represent poor data collection, or it may reflect real variability in the provision of neuropsychiatry services. The rate of referral in some areas was as low as 2 per 100 000 population, and estimates of referral below 20 per 100 000 have been proposed to represent an unmet local need for neuropsychiatry services.⁶ This study once again found evidence that there continues to be very significant unmet need in neuropsychiatry within London, despite the presence of a number of well-recognised neuropsychiatry services. There appears to be very little progress in meeting neuropsychiatric need in recent years.^{11,12} Barriers to commissioning, which may be responsible for the current state of affairs and are proving to be persistent, need to be explored.¹⁰

Continued lack of equitable care

This survey continued to find significant variation in the number of patients accessing neuropsychiatry services in the different London areas served by different PCTs. Earlier audits by tertiary referral centres for neuropsychiatry had identified a significant variation in service usage from different areas. A south London study showed up to 34 times' variation in neuropsychiatry cases per 100 000 population, ranging from 0.910 to 30.8.¹² A north London audit also discovered variation, although on a slightly smaller scale ranging from 1.7 to 25, which amounted to almost 15 times' variation between the highest and lowest referring boroughs or counties.¹¹

Whereas these previous studies took a provider-facing approach, our study examined variation in service usage from both secondary and tertiary provider perspectives as well as local and specialist commissioner perspectives. It revealed a more acute variation in neuropsychiatry provision in London. There was approximately 25-fold variation across boroughs for head-injury-related admission for neuropsychiatric rehabilitation. This is similar to the variations noted above. This is in spite of the relatively homogeneous 'caseness' for acquired head injury, a relatively well-established

service provision across London and the specialist commissioning panel dedicated to brain injury rehabilitation. Variability for out-patient neuropsychiatry provision was much more marked. The level of variability of provision in different areas of London cannot be explained by differences in demographics, which at best can explain a small degree of variation in a relatively small geographical area. This study shows that there is lack of equitable access to neuropsychiatry care in different parts of London that requires careful exploration and explanation.

Reasons for variability and inadequate provision

This study concurs with the findings from the other two London studies that geographical distance from neuropsychiatry centres does adversely affect service usage. However, it indicates that there are other factors that contribute to this variability, given that the geographical distance from a centre of neuropsychiatric provision in London is not excessive.

We hypothesise that factors that present as barriers to care in neuropsychiatry include contractual arrangements, funding streams, awareness of neuropsychiatry among commissioners and providers, and national strategic drivers which have an impact on service provision. Areas local to tertiary or national neuropsychiatric services may have better communication with commissioners to overcome these barriers and more favourable contractual arrangements to minimise barriers to funding approval, compared with services located at a distance. Local mental health commissioners were more aware of neuropsychiatry as a discipline, its boundaries, funding streams and local needs when they were working in areas in close proximity to tertiary or national service provider. We also found that, in areas located in close proximity to neuropsychiatry centres, 'secondary' mental healthcare was sometimes provided by the same provider as the neuropsychiatry service, which may have minimised funding and pathway barriers.

Limitations

The study was carried out within the area of Greater London, which may raise concerns about generalisability of the data to the rest of the UK. London traditionally has a better level of neuropsychiatry service provision and has well-known services that received referrals from outside London. Data from previous studies^{11,12} show that the provision of neuropsychiatry services outside London is not as good and the variability and unmet need is likely to be even more acute. Hence, the data from this study are pertinent to the whole of the UK and any solutions to deal with unmet need and variability should be applicable country wide. Indeed, given that a similar state of affairs has been reported anecdotally elsewhere in Europe,⁵ we believe the lessons learnt from this work are global.

The study looked into commissioning and provision from the mental health perspective and incorporated neurorehabilitation specialist commissioning. However, neuropsychiatry services are located at the interface of neurology and psychiatry and therefore the study may have failed to capture any neuropsychiatry service provisions that were embedded within acute healthcare setting. However, evidence of huge variability, unmet need and the fact that some boroughs had no local neuropsychiatric commissioning arrangements reasonably close to areas of neuropsychiatric service provision strongly suggests that provision for neuropsychiatry in London remains inequitable and inadequate.

The study surveyed service providers and commissioners and can only comment on the responders' understanding, knowledge and perception of how services were aligned, and provides proxy measures as opposed to real ones. The participants' responses might be affected owing to a lack of coherent understanding around caseness in neuropsychiatry. We have proposed a clearer definition of what constitutes a neuropsychiatric condition in Box 2 in the accompanying paper,¹⁰ and have defined the threshold criteria for when a referral should be made to a neuropsychiatric service for such conditions in Box 1 in this paper. In our opinion, a combination of a clear definition of neuropsychiatric condition and the threshold criteria will help resolve the issue of caseness.

This study provides further evidence of a continuing unmet need, significant variability of provision and lack of consistent service models and pathways in neuropsychiatry in the Greater London area. We believe this is representative of the situation in the rest of the UK, where the problem may be even worse given that London has a higher level of neuropsychiatric service provision with a few regional and national centres. The reasons for such variability need to be explored and minimised. Barriers to commissioning and provision¹⁰ need to be explored and removed. A hub-and-spoke model of neuropsychiatry provision closely allied with neurosciences centres⁶ should be adopted widely to bring

consistency of pathways. National commissioning with a mandate for abolishing undesirable variability and unmet need is the real solution, but one that is not without significant challenges.

- *BJPsych International: new name, new strategic focus*

With this issue of our journal we are beginning a new chapter in facilitating communication between psychiatrists throughout the world. *International Psychiatry* was established in 2003, as the *Bulletin of the Board of International Affairs* of the Royal College of Psychiatrists. It continues to be provided free of charge, both in paper and online, thanks to the generosity of the members of the Royal College of Psychiatrists. Our potential readership is enormous: over 15 000 members of the College receive the print edition regularly, and all issues can be downloaded from the College website. We need to address both the clinical interests and the needs of this diverse readership, and in so doing we will be redirecting the focus of the journal over the next few months and years. Publication of articles in the journal will remain cost free to contributors and rigorous refereeing will be sustained.

The time has come to review our strategic aims. Over the past decade, there has been a gradual evolution in content. We have focused increasingly on issues that have practical application in countries that do not have the resources to be adequately supporting psychiatric services.

First, we published accounts of the infrastructure of psychiatry provided worldwide in ‘Country Profiles’, a series that began with our first issue and emphasised diversity in mental health policies. We will continue with this policy and we have added an important section on international aspects of ‘Mental Health Law’, which is curated by George Ikkos, Deputy Editor.

Second, since the very first issue, we have reviewed diverse ‘Themes’, with a brief editorial and three papers that address the same topic from different perspectives. We intend to continue to address themes that have real practical relevance to supporting patients, with a particular, but not exclusive, focus on the needs of low- and middle-income countries as well as the mental health needs of the poor and socially excluded in high-income countries. Contributors who can provide examples of innovative practice, which could be emulated elsewhere at minimal cost, are especially welcome, as are papers on public mental health. Most articles in this thematic section are commissioned.

We receive a regular stream of uncommissioned articles, including some that concern original research findings. In future, we will not be publishing research articles of this type. The journal’s identity will be focused on practical issues, rather than theory or scientific studies that have no immediate relevance to the delivery of clinical services. We will pass such submissions on to the *British Journal of Psychiatry*’s new online sister journal, *BJPsych Open*, for consideration for publication there. We will continue to accept uncommissioned ‘Special Papers’, on subject matter that does not necessarily fit within a theme, but which is consonant with our aims.

There was a pressing need to address our limited online presence, and we have done so principally in the form of a blog. As we will no longer be publishing a Correspondence column, we will arrange for submitted comments about published articles, and also other relevant material, to be placed in the blogosphere, at <http://www.BJPsychInternationalblog.org>. A new member of the Editorial Board, David Jimenez, will be managing it, along with a social media presence with the journal’s new Facebook page (<https://www.facebook.com/BJPsychInternational>) as well as a Twitter account ([@BJPsychInt](https://twitter.com/BJPsychInt)). We will also be changing the face of ‘News and Notes’. In a journal that is published quarterly, it was inevitable that most news was out of date by the time it appeared in print. Accordingly, a change of focus was needed. Eleni Palazidou will be managing the new commentary section of the journal, ‘Pandora’s Box’, which will take as its theme important developments in psychiatric practice over the previous few months that have direct clinical relevance to the non-specialist.

Finally, we have reviewed membership of the Editorial Board. We are keen for Editors to be active ambassadors for the journal, and we have consulted with members over the past few months about their roles. We have assigned specific tasks to many members of the revised Board, who will, we hope and anticipate, be actively eliciting contributions to the journal from colleagues in their region of the world. An important innovation is the appointment of new regional Associate Editors, who will help ensure the increasing local importance of the journal to psychiatrists worldwide. We have a new Associate Editor, Daniel Maughan, with responsibility for 'Psychiatry and Sustainability', a subject that is of increasing importance to all psychiatrists.

We trust the changes we have introduced, in the relaunched and renamed *BJPsych International*, will be welcomed by our readership. We look forward to hearing your comments.
