 - *Conclusion*

People with severe mental illnesses such as schizophrenia die younger than expected, losing an average 15 years of their lives to cardiovascular and other diseases.¹ This has led to calls for a more integrated approach to care, with greater emphasis on physical health. In this article, we examine some current issues in the care of older people with severe mental illnesses such as dementia and delirium. We argue that existing systems compartmentalise care and lack the sophistication to deal with the complexity of these illnesses. We suggest that a more collaborative approach between old age psychiatry and geriatric medicine in both hospital and community settings could yield benefits.

Geriatric medicine occupies a position of unfashionable scepticism about the ‘medical model’ of care and its corollary of single-mode interventions. Under the banner of ‘comprehensive geriatric assessment’ attention is paid to function, mental health, and social and environmental factors as well as (usually multiple) acute and chronic medical diagnoses. Elements of prevention, rehabilitation, palliation and mental health models are used flexibly. Care often includes cessation of medicines, recognition of burdens placed on patients by medical intervention, and the prioritisation of comfort, rather than an expectation that death is delayed.² Old age psychiatry can learn from geriatric medicine by embracing complexity, comorbidity and the ultimate inevitability of deterioration, signalling a return of old age psychiatry to its origins.³

What is a geriatric syndrome?

Geriatric syndromes are states of ill health which occur with high frequency in older people but which do not fit into discrete disease categories. They are typically explained by a range of organ dysfunctions and diseases, have functional and social implications, and therefore require care that is complex and traverses traditional disciplinary boundaries. Delirium, falls, immobility and urinary incontinence have been described as geriatric syndromes, but the term is loose and may also include pressure sores and sarcopenia. Dementia and other mental health problems can be thought of in similar terms.⁴

Dementia as a geriatric syndrome

Dementia is common towards the end of life; 6% of people who die aged 65–69 years and 58% of those who die aged 95 or over have dementia.⁵ The aetiology of late-onset dementia is often multifactorial.⁶ Dementia causes functional decline, and contributes to falls and incontinence. Multi-morbidity is usual⁷ and the symptom burden in the last year of life of people with dementia exceeds that of people dying with cancer.⁸ Dementia causes problems with safety awareness and loss of independence, and is a source of much carer strain. Crises are frequent, and usually have physical, mental, social or care-system contributors. People with dementia frequently transit between home, hospital and care home. These ‘unique and changing personal, psychosocial and physical needs’ are acknowledged in the Memory Services National Accreditation Programme,⁹ but secondary care memory clinics are unlikely to be the only way to address them.^{10,11}

A more comprehensive and accessible form of engagement is needed, in the form of primary care liaison psychiatry or

rapid response community mental health teams (CMHTs). CMHTs for older people led the way in delivering dementia care within communities (long before community geriatrics was a tangible entity).¹² These teams are under threat, with proposed merger into 'ageless' community teams. This would require increasing focus on psychopathology and behaviour, with a likely prioritisation of single (psycho)pathologies. Failure to recognise and appreciate the special needs of patients with dementia and the skills of CMHTs in addressing them risks diminishing patient care.¹³ At the same time, the need to address physical and functional comorbidity suggests that an overt alliance between old age psychiatry and geriatric medicine is needed.

Delirium as a psychiatric syndrome

Delirium and dementia frequently co-occur in older people in the general hospital. Dementia has achieved a high national profile in the UK. By contrast, delirium barely enters public discourse. Two-thirds of elders acutely admitted to hospital with delirium have underlying dementia^{14,15} and half of people with dementia in acute hospitals have delirium.¹⁶ Informant history is vital in identifying the two syndromes, but persistent, subacute and subsyndromal delirium is common and the syndromes can be difficult to distinguish, especially where prior dementia was undiagnosed, leading to the coining of the term 'cognitive spectrum disorders' to cover both.¹⁷ Between 10 and 20% of delirium in older people does not have an identifiable precipitant¹⁸ and the cognitive impact of delirium may persist for months or merge into the onset of a dementia syndrome.¹⁹ Some survivors develop post-traumatic stress disorder. Uncertainties also exist as to the division of clinical responsibility between geriatricians and psychiatrists. Arguably, neither specialty can do it well in isolation.

The development of health services in the UK over the past 20 years has seen psychiatrists focus on patients in the community while geriatricians have increasingly assumed responsibility for the acute medical intake, militating against collaboration. The diagnostic uncertainties and sequelae of delirium imply the need for systematic follow-up, which geriatric medicine is poorly placed to provide. Psychiatry has a role in working with the third sector and primary care to highlight the malign effects of delirium even in the context of successfully treated acute physical illness.

The publication of delirium guidelines from the National Institute of Health and Care Excellence (NICE) has been a major advance in the promotion of delirium management,²⁰ but evidence is weak that any specific intervention or programme of delirium care improves outcomes.²¹ Conversely, there is evidence that multi-component interventions aimed at preventing delirium can reduce its incidence and improve outcomes.^{22,23}

Establishing a role for delirium prevention in hospitals and community settings is a challenge given the low profile of delirium training in medical and nursing schools, poor recognition by clinicians, and competing imperatives for healthcare organisations. Conceptualising delirium as both a safety risk to individual patients and an organisational risk due to increased length of stay and adverse health outcomes provides an incentive for change. Old age psychiatrists, with their emphasis on the importance of assessing mental health alongside physical health, can valuably contribute to both delirium care and education.²⁴

Why is delirium prevention not taken more seriously in community psychiatry?

Prevalence studies of delirium in any setting are fraught with the problem of distinguishing delirium from dementia.²⁵ A Swedish study of very elderly people found that 52% of people with dementia had experienced delirium within the previous month compared with 5% of those without dementia.²⁶ Work in the Netherlands revealed a delirium prevalence of 9% in care homes.²⁷

The evidence for the value of delirium prevention programmes in care homes has yet to be established, but there is evidence that coordinated programmes to reduce the prescribing of culprit medications are effective in preventing delirium.²⁸ A trial of the effectiveness of multi-component delirium education in preventing the disorder in care homes is underway in the UK.²⁹

People with dementia who are living in their own homes and are in receipt of care from CMHTs are also at high risk of delirium. Behavioural and psychological symptoms in dementia (BPSD) are associated with morbid – ities that contribute to delirium, such as falls, nutritional deficits and polypharmacy. Delirium can cause a similar range of symptoms, which may become chronic and constitute BPSD.³⁰ Delirium is triggered by physical illness, injury,

medications or medication withdrawal, and rightly remains the domain of primary care and geriatricians, but unless psychiatry co-owns the delirium agenda, the cross-over of skills from the management of BPSD will fail to shape delirium prevention, assessment and management. The similarities between delirium prevention programmes and those for the non-pharmacological management of BPSD are striking.^{31,32}

Frailty

Frailty is a state of vulnerability to decline in the face of stressors, in the context of precarious multisystem physiology and social adversity.³³ Epidemiological evidence highlights the importance of frailty in elderly populations. It has proven difficult to operationalise, but recognisably overlaps with dementia in cross-sectional studies.³⁴ One view conceptualises it as the effect of cumulative deficits³⁵ and the other as a phenotype characterised by three or more of the following factors: unintentional weight loss, self-reported exhaustion, poor grip strength, slow walking speed and low physical activity.³⁶ However, geriatricians recognise that frailty will often manifest through geriatric syndromes – falls, immobility (‘off legs’), delirium (‘more confused’), urinary or faecal incontinence (often associated with delirium, dementia and immobility) and susceptibility to drug side-effects (antidepressants making a patient ‘very drowsy’).³⁷ The maturation of old age psychiatry as a specialty has been facilitated by the advent of specific therapies for Alzheimer’s disease, but an emphasis on prescribing for Alzheimer’s disease has selected against attendance by frail elders and those with non-Alzheimer pathology (particularly vascular dementia) and cognitive deficits outwith a full-blown dementia syndrome.

Comprehensive geriatric assessment aims to consider the full range of factors contributing towards frailty (*Table 1*). Its implementation is linked to better outcomes.³⁸ It has parallels with biopsychosocial assessment, although this does not have similar evidential weight behind it, and indeed has been criticised by the psychiatric profession as ‘mere eclecticism’.³⁹ The accusation of vagueness laid against biopsychosocial assessment suggests that it needs to find a home within an operationally defined, evidence-based structure such as comprehensive geriatric assessment. The two processes differ only in the emphasis and differential expertise of the clinicians undertaking them. Geriatricians recognise that they tend to neglect the mental health dimension, which may be reduced to a brief cognitive assessment or screening test for depression. There is therefore a fertile opportunity for mutual learning between geriatrics and psychiatry in the area of the assessment of frailty.

Components of comprehensive geriatric assessment

Domains	Items to be assessed
Medical	Co-morbid conditions and disease severity
	Medication review
	Nutritional status
	Problem list
Mental health	Cognition
	Mood and anxiety
	Fears
Functional capacity	Basic activities of daily living
	Gait and balance
	Activity/exercise status
	Instrumental activities of daily living
Social circumstances	Informal support available from family or friends
	Social network such as visitors or daytime activities
	Eligibility for being offered care resources
Environment	Home comforts, facilities and safety
	Use or potential use of telehealth technology etc.
	Transport facilities
	Accessibility to local resources

Sustainable integration

The needs of older people with mental health disorders are not well served by a retreat to psychiatric specialisation, restrictive referral criteria or commissioning models based on activity alone. Geriatric medicine recognises and embraces complexity and uncertainty, and responds by flexibly utilising a variety of models, albeit at times with tensions between them. Old age psychiatry can learn from comprehensive geriatric assessment. Geriatric medicine needs to take mental health more seriously, to increase the depth and sophistication with which it assesses the mental state, and can learn from person-centred care and recovery models. The logical future for both disciplines is in collaboration and integration that transcends organisational and cultural barriers.

A sustainable integration of physical and mental healthcare for older people will require more than cooperation between clinicians. The joining of forces between psychiatrists and geriatricians can take place at an organisational level when mental health and community trusts merge. However, we also need a flexible, accessible, consultative model of psychiatry that seeks to empower a broad range of community practitioners and will be the means to generate influence on problems that are just too common and multi-morbid to be addressed solely by clinic-based approaches or a single professional discipline. This reinforces the need for CMHTs for older people, and highlights the need to change the commissioning model from one based on activity defined by clinic attendances. Crises in care homes, for example, often represent a complex interplay of medical, mental, social and environmental issues best addressed by timely multi-disciplinary input rather than transferring responsibility on to a single discipline. Accessible advice on a broad range of cases managed primarily by other teams ('liaisons') allows for teaching and upskilling while preserving specialty provision for patients with more severe, less tractable mental health problems. These teaching and support roles need a commissioning model.

CMHTs are in a good position to identify dementia and promote delirium prevention measures. Working alongside community geriatrics will strengthen old age psychiatry by allying it with the developing evidence base and increasing its workforce.

The Rapid Assessment Interface and Discharge (RAID) model developed in Birmingham has captured the attention of policy-makers through its widely publicised potential financial savings. But it also demonstrates the total immersion of mental health practitioners in the multi-professional melee that is acute hospital care.⁴¹ Why not import this style of working into primary care and scale down the centralised psychiatric clinic? This has been tried in Gnosall, Staffordshire, where a model of primary care liaison psychiatry has created a well-received, effective service for people with dementia.⁴²

Conclusion

Psychiatrists must lobby commissioners to recognise the plight of those frail, elderly patients who are not living well but dying with the multiple comorbidities of dementia within a healthcare system that fails to accommodate complexity. People with dementia are prone to crisis and comorbidity, necessitating attention to physical health (parity of esteem) equal to that developing for other severe mental illness. Emphasising geriatric syndromes (and the importance of sound mental health assessment within comprehensive geriatric assessment) is a good way to defend old age psychiatry while at the same time developing integrated physical and mental healthcare for older people. An invigorated liaison psychiatry, underpinned by a re-forged alliance between old age psychiatry and geriatric medicine, gives a pointer to how integration might work, and enables parity of esteem for mental and physical health.

1.6.25 Police liaison and section 136: comparison of two different approaches

Abstract

Aims and method Two police liaison and section 136 schemes were developed alongside police services at different sites within the same NHS trust. In one, a mental health nurse worked with frontline police attending incidents related to mental health. The other involved nurses providing advice from the police control room. Section 136 detentions were measured over two 6-month periods (6 months apart) before and after practice change. Data analysed included total numbers of section 136 assessments, outcomes following subsequent assessment, and relevant diagnostic and demographic factors. Association of any change in section 136 total numbers and proportion subsequently admitted was investigated in both sites.

Results The model involving a nurse alongside frontline police showed significant reduction in section 136 numbers (38%, $P < 0.01$) as well as greater admission rates ($P = 0.01$). The scheme involving support within the police control room did not show any change in section 136 detention but showed a non-significant ($P = 0.16$) decrease in subsequent admission.

Section 136 of the Mental Health Act 1983 enables an individual police officer to remove any person found in a place to which the public have access appearing to have a mental disorder and to be in immediate need of care or control to a place of safety, such as a hospital, police station or a purpose-built section 136 unit. The section can only be used if the officer believes it is in the interests of that person or necessary for the protection of others. Although section 136 can be an important care pathway to enable an individual to receive appropriate support, it can also be a very distressing experience for them – some report feeling criminalised and punished for having a mental illness.¹ Its use is also costly given that it requires the input of an approved mental health professional (AMHP) and two doctors for the assessment, plus police and often nursing time to manage the detained person and staff the place of safety.

Background and aims

The Mental Health Act Commission has highlighted the challenge of collating data on the use of section 136,² but figures have only been gathered at a national level by the Health and Social Care Information Centre over the past 5 years.³ These combine police and mental health records on section 136 detentions but have limited detail on outcomes. At a national level the rates of section 136 detentions to places of safety between 2010/2011 and 2014/2015 increased from 14 111 to 19 406.³ Attempts to combine inconsistently recorded data have shown a steady upward trend at a rate greater than has been seen with use of the other Mental Health Act sections for detention.⁴

Significant variation is seen regionally in section 136 use. Outcomes from such detentions, often seen as markers of how appropriately the detention has been applied, are also seen to vary from region to region: from areas where around 60% are admitted to hospital⁵ to those where 68% are discharged.⁶ While theories to explain these variations have included a rural/urban divide, police culture, socioeconomic deprivation and diagnostic factors,⁷ the available data have been limited in both accuracy and detail.

In response to concerns about the growing use of this police power and regional variation, there has been a national drive to improve inter-agency working between police and mental health services. Both the Bradley Report⁸ and the Crisis Care Concordat⁹ placed emphasis on local agencies working more closely to improve the experience of individuals in a mental health crisis and to intervene as early as possible within the criminal justice system. Areas have responded differently to the challenge. This paper analyses various aspects of section 136 and changes observed with different ways of inter-agency working within two areas of the same National Health Service (NHS) trust, in Ipswich and Norwich.

The local response in Ipswich has been a Commissioning for Quality and Innovation (CQUIN)-funded pilot scheme developed in partnership between Norfolk and Suffolk NHS Foundation Trust (NSFT) and Suffolk Constabulary. The scheme commenced in April 2014 and involves two experienced mental health nurses working on alternate shifts alongside frontline police officers, 7 days a week from 14:00 until 00:00, to help assess and appropriately divert members of the public who present with potential mental health-related emergencies. Accompanied by a police officer (individuals vary with police rota), they are seen as the initial point of contact for officers attending a potential mental health-related event. They are able to perform face-to-face assessments in a dedicated police car but can also provide advice to other officers over the phone.

Norwich was chosen as the control site as it was closely matched by size, ethnicity and measures of deprivation (*Table 1*). Norwich also established a police liaison service (funded by the police service) to address the same national concerns. It employed 4 mental health nurses on rotation providing support to the local police force between 8:00 and 22:00, 7 days a week. However, they were based in the police control room and offered telephone advice to police officers without face-to-face contact with the public.

Lower value indicates higher deprivation.

The aims of this study were to examine changes in and between Ipswich and Norwich regarding section 136 detentions and hospital admission rates of detained individuals. This would enable us to build on past research and consider what factors were driving the use of section 136 locally, and in turn better understand any impact the police liaison projects may have had.

Method

This retrospective study compared numbers and outcomes of section 136 assessments, characteristics of detained individuals and some follow-up data. Information was obtained prior to and following differing changed practices within the trusts for the two areas. Numbers of section 136 detentions were gained from local section 136 suite records and cross-referenced with data gathered at trust level in an attempt to capture all section 136 assessments in Ipswich and Norwich. Further data pertaining to each individual were then collected retrospectively from hospital records using electronic notes (Epex in Ipswich and Carenotes in Norwich). Data were gathered for two 6-month periods: 1 June – 30 November 2013 and 1 June – 30 November 2014. This was to limit any impact on results of the preparation for and introduction of services. This also allowed for comparison of the same 6-month cycle (a year apart) pre- and post-intervention in both areas and between areas.

The project was viewed as service evaluation by the trust's research and development department and thus did not require ethics approval. The exact information gathered and hypotheses to be tested were agreed at the planning stage. Data were entered into Minitab (version 16) to allow for appropriate statistical analysis. The exact data collection questions can be found in *Box 1*.

Such a study set-up meant that each location had a control group prior to intervention and an experimental group post-intervention. Analysis was conducted pre- v. post-intervention in both locations and between the locations. Null hypotheses were that there were no differences between locations or between pre- and post-intervention. Population

sizes covered by each section 136 suite were established by combining police force estimates of the locality from which officers were detaining people and the 2011 census local authority population sizes.¹⁰ Chi-squared statistical tests were used where appropriate. We used *t*-tests when comparing section 136 numbers per 100 000 population, Fisher's exact test for comparing proportions, and the Mantel–Haenszel procedure to identify possible confounding factors.

Results

Demographics

As seen in *Table 2*, there were no significant differences in the study participants' age or gender pre-intervention compared with post-intervention in either area individually or between the areas. There were no significant differences in ethnicity either, with the overwhelming majority of individuals assessed being of White British background.

Numbers of section 136 assessments

There was strong evidence to suggest, over the total time periods, that Norwich had proportionately fewer section 136 assessments per 100 000 population than Ipswich ($P = 0.01$). This difference was greater in the pre-intervention period. Between the two 6-month periods there was a small, non-significant increase in those detained under section 136 in Norwich but a large reduction in section 136 assessments in Ipswich post-intervention ($P = 0.01$) (Table 2 and Fig. 1).

Fig. 2: Section 136 assessments and subsequent admissions.

Box 1 Survey questions

1. Pre- or post-intervention?
2. Ipswich or Norwich?
3. Date of assessment?
4. Time of assessment?
5. Gender?
6. Age?
7. Ethnicity?
8. Broad ICD-10 category?
9. Number of section 136 assessments the individual had in the previous 6 months?
10. Any contact with mental health services in past 2 weeks?
11. If so, what type of contact?
12. Main reason for section 136?
13. Any specified location?
14. Was the individual admitted?
15. If so, was this under detention?
16. If admitted, what was the length of admission?
17. If not admitted, was follow-up offered by secondary mental health services?
18. If so, was the first appointment complied with?
19. If not admitted, was the individual subject to a further section 136 assessment within the subsequent 4 weeks?

Admission

Over all the data collected, there was no significant difference in admission to hospital following section 136 assessment between Ipswich and Norwich. Prior to intervention, although admission was less likely in Ipswich than in Norwich, this was non-significant. In Ipswich there was a significant change in admission post-intervention ($P = 0.01$), with a higher conversion to admission. Post-intervention, there was a difference between Ipswich and Norwich ($P = 0.04$), with higher admission in the former. Thus the interventions were associated with a proportionate increase in admissions following section 136 in Ipswich. Although data suggested that the admission proportion decreased in Norwich, this was non-significant ($P = 0.16$).

Apart from weak, non-significant evidence to suggest that in Norwich those admitted post-intervention were more likely to have been detained than pre-admission ($P = 0.10$), there was no other association between detention under the Mental Health Act following admission and pre- and post-intervention status.

Contact with community mental health services

Any contact with community mental health services (CMHS) in the 2 weeks prior to section 136 assessment was measured. In Norwich, data provided strong evidence that in the pre-intervention period there were more individuals who had some contact with CMHS than in the post-intervention period ($P = 0.01$) and when compared with Ipswich ($P = 0.01$). In Ipswich there was no evidence of any difference between contact pre- v. post-intervention.

For those individuals who were not admitted to hospital following section 136 assessment, the proportion that had at least one subsequent 136 assessment in the following 4 weeks decreased in both sites, but the change was significant only in Norwich ($P < 0.01$ v. $P = 0.14$ in Ipswich).

In Ipswich there was moderate evidence to suggest that, if not admitted, people were more likely to be offered follow-up from secondary mental health services post-intervention than pre-intervention ($P = 0.04$). If follow-up was offered in Ipswich, there was strong evidence to suggest that the first follow-up contact was more likely to be kept post-intervention than pre-intervention ($P < 0.01$). In Norwich there was evidence that a person was more likely to be offered follow-up prior to as opposed to after the intervention ($P = 0.02$), but no evidence to suggest any difference between compliance rates pre- v. post-intervention.

Diagnosis

There was weak non-significant evidence to suggest that people assessed in Ipswich were more likely to have been deemed to have 'no mental illness' prior to the intervention compared with post-intervention ($P = 0.08$), but in Norwich there was strong evidence to the contrary ($P < 0.01$).

Counts of pre- and post-intervention broad ICD-10 categories of individuals assessed from each site are shown in *Fig. 2*.

Time of day

We were unable to obtain the exact time of implementation of the actual section 136 order for individuals. Time between implementation and assessment following the order is influenced by many factors. Trust policy states that this should happen within 3 hours.

In Ipswich the triage service was funded for 10 hours per day (between 14:00 and 00:00). As an estimate within this study, following implementation of the order, individuals who were assessed between 15:00 and 03:00 were deemed to have been assessed in a time period in which the triage service was operating. Within these time periods, the numbers assessed and numbers admitted are shown in *Table 2* (numbers admitted following assessment out of these time periods are also shown). Thus, a similar proportion were assessed within the triage hours both pre- and post-intervention (72.2% and 69.2%).

As stated above, admission following section 136 in Ipswich was more likely after the triage service commenced. On further analysis this effect was seen to be confounded by assessment within/outside triage times (Mantel-Haenszel odds ratio 5.44, $P = 0.02$) with a significant association in the triage times ($P = 0.05$). This indicated that the triage service intervention had most association with differing admission rates within the triage times.

Unfortunately, due to a large number of missing assessment time data in Norwich, a similar analysis was not deemed feasible.

Discussion

This retrospective study evaluated the impact of two recently developed police liaison schemes based in closely matched semi-rural areas within a single mental health NHS trust, with a focus on section 136 rates and outcomes before and after the projects were established.

The pre-intervention findings show that Suffolk Constabulary was detaining significantly higher numbers of people for assessment in the Ipswich area than the police force in Norwich. This difference matches the only data available prior to 2013/2014 on section 136 rates for the two regions, from 2005/2006, in which the Independent Police Complaints Commission (IPCC) analysed regional variation across England and found Suffolk to be a medium-rate user and Norfolk a low-rate user of section 136 detentions to police custody.¹¹

Well-matched local population demographics and demographic profiles of those detained would indicate that differences are not linked with variation in race, gender or age. The diagnostic profiles of those detained also show little variation between sites. These observations are significant given that a number of studies have identified common factors pertaining to those detained under section 136, such as Black men being over-represented, and the typical individual tending to be a young male, unemployed, with a psychiatric history and diagnosis of schizophrenia.¹²

As police officers are the sole implementers of S136 detentions, their attitudes and training around mental health can be considered an important variable. Qualitative studies have identified high rates of concern among police officers over inadequate training in relation to mental illness,¹³ and poor understanding of their role in relation to section 136.¹⁴ Informal feedback from the two police forces involved in this study indicates that mental health training is similar and thus would be an unlikely source of variation.

The IPCC report also observed that low-rate forces used alternative powers such as breach of the peace and that well-known 'suicide spots' such as seaside cliffs were observed in police force areas with high rates.¹¹ Data we have gathered on both police forces show a similar arrest rate (15 v. 16 per 1000 population) but a slightly higher crime rate (49.76 v. 43.98 per 1000 population) in Suffolk compared with Norfolk.¹⁵ However, there are also lower levels of policing per 1000 of population in Suffolk (3.11 v. 3.33).¹⁵ The impact of these slight differences is hard to interpret. Ipswich has a locally well-known 'suicide spot' but numbers of detentions relating to its locality were not significant.

Findings from the post-intervention data support the theory that a mental health liaison service to the police can have a significant impact on section 136 rates and also suggest which model is more effective. The Ipswich site showed a 38% reduction in the use of the police power during the post-intervention study period. In that time, there were no other significant changes to police or mental health policy or resourcing locally. This reduction is in contrast to the steady increase in the use of section 136 nationally.¹⁶ The Norwich site with support based solely in the police control room, by contrast, showed no significant change in overall numbers of section 136 detentions. The data provide some possible explanations for this observed difference between the sites.

It could be speculated that the impact of a liaison service with experienced mental health nurses in Ipswich, where rates were higher 10 years ago¹¹ and pre-intervention rates were high in this study, was to enable the local constabulary to achieve a greater level of confidence in dealing with mental health-related crises that is already present in Norwich. The detention outcome data in Ipswich may be seen to lend weight to this idea. Post-intervention we observed a proportionate increase in admission rates, an increase in offer of community support if discharged and a reduction in those deemed to have 'no mental illness'. These outcome measures can be interpreted as markers of a service better able to identify those with mental health needs and, combined with an increase in engagement, suggest it is better at signposting to appropriate services.

By contrast, the Norwich data post-intervention show a proportionate decrease in admission rates, decrease in follow-up being offered and increase in 'no mental illness' assessments despite overall numbers remaining approximately the same. It could be inferred that support based in the police control room is only effective for individuals known to mental health services, whereas members of the public unknown to services need to be assessed face-to-face to provide effective input from a specialist service. Our recording of those who had contact with mental health services in the 2 weeks prior to detention showed that for both areas approximately 50% were either known to or actively open to mental health services, which is lower than estimates from previous research of around 75–84%.¹² The near equal percentage of those in contact with mental health services prior to detention in Ipswich could further suggest that the face-to-face liaison service is able to affect detention rates for both those known to mental health services and those not known.

The data relating to time of assessments in Ipswich suggested that while the liaison service had a greater impact on conversion to admission rates during their working hours, there was a near-even drop in section 136 rates across all hours. This could indicate that multi-agency working has promoted an ability among the local police force to better identify those who should be detained for further assessment. Lending further weight to this perception is the fact that the service in Ipswich was only in operation 76% of the time due to planned leave and sickness.

A follow-up to the Bradley Report claims that similar schemes are producing positive results, including reduced section 136 rates.¹⁷ We believe that our study provides an evidence base for these as yet unpublished findings, and lends weight to the value and impact of closer inter-agency working between police and mental health services. The breadth of data and comparison of models available in this study may help to guide the development of future schemes and their refinement.

Limitations

Within this study we gathered data regarding individuals detained to places of safety under section 136 within the two main urban areas in Norfolk and Suffolk, namely Norwich and Ipswich. There will have been a few occasions where these sites were occupied and people were subsequently taken to other localities. Although we can say that both areas are equally resourced and from experience know these numbers to be small, this should be acknowledged as a weakness. Estimations of section 136 rates per population size in each area must be viewed with caution as the local authority boundaries do not equate to areas that the 136 suites serve, and it was difficult to achieve clarity on this. The study could not define the areas where the section 136 detention was made and this may have been outside the area covered by the triage services, which may have led to an underestimate of the impact of either service.

While this study builds towards a better understanding of the model that is most effective in police liaison work, it lacked a detailed analysis of the work done directly by the mental health nurses and police officers involved. Any future studies should include these data alongside qualitative feedback from relevant professionals and individuals to enable a fuller understanding of the impact of such a service.

1.6.26 Online media reporting of suicides: analysis of adherence to existing guidelines

Abstract

Aims and method To assess the compliance of contemporary online media output with guidelines for the responsible reporting of suicidal acts. A search engine was used to identify online media reports of suicide from UK sources over the course of 1 month. Each article was assessed against guidelines for the responsible reporting of suicide produced by the Samaritans, a UK mental health charity.

Results We identified 229 articles, of which 199 failed to comply with at least one of the Samaritans' guidelines. Failure to mention support sources, excessive detail about the method used and undue speculation about the trigger for suicide were the most commonly breached guidelines. Significant differences were found between the quality of local and national media sources, with local media sources being broadly more compliant with guidelines.

Clinical implications This study highlights the urgent need for the implementation of responsible reporting guidelines in online media articles as a component of suicide prevention efforts.

Responsible media reporting of suicide is considered to be key to current international suicide prevention efforts.¹ Previous studies suggest that media reports of completed suicide can influence the rate of future suicidal acts and the method chosen.²⁻⁶

Guidelines to promote responsible reporting practices exist in a number of countries.⁷ Studies suggest that they can alter the content of media reports,⁸ although the general awareness and use of the guidelines has been found to be poor.⁹ In the UK, the 2012 Editors' Code of Practice from the Press Complaints Commission prohibits the reporting of suicide with excessive detail about the method used,¹⁰ but established responsible reporting guidelines tend to include additional features in an attempt to prevent copycat behaviour.¹¹

After a detailed literature review, no studies could be found comparing a significant number of contemporary UK media reports of suicide against responsible reporting guidelines, despite the fact that the media have been implicated in the phenomenon of 'suicide clustering' observed in the UK.¹² Other studies have focused on newspaper and television

the original work is properly cited.

reports, and scant attention has been paid to online media sources, despite the fact that 84% of households in the UK have access to the internet and 55% of adults use the internet to access news.¹³ This is the most rapidly growing method of accessing news media, particularly for younger individuals,¹³ who may be more vulnerable to the content of media reporting.^{14,15}

This study sought to evaluate the compliance of online media reports of suicidal acts from UK-based sources with responsible reporting guidelines, and to identify the prevalence of the inclusion of other potentially harmful features of online media, namely comments sections and links to other internet features, for example pro-suicide websites.

Method

A search was performed on the Google News UK search engine using the keyword ‘suicide’ with the location filter set to include articles of UK provenance only. The analysis included reports which made reference to an attempted or completed suicide published by local and national media sources during 28 consecutive days in November 2014. Articles about suicide bombing and euthanasia were excluded, as were those behind a media paywall.

Each report meeting the inclusion criteria was assessed against an adapted version of the ‘Ten things to remember when reporting suicide’ contained in the document issued by the Samaritans.¹⁶ This is one of the more prominent and widely used sets of guidelines for journalists in the UK.¹⁷ As a direct search for articles was undertaken, it was not possible to assess whether each article was given undue prominence, for instance a homepage splash, so this criterion from the Samaritans’ guidelines was not used, leaving nine criteria for article comparison (*Box 1*).

Data were collected on compliance with each section of the guidelines and those meeting all criteria were considered to be compliant with responsible reporting of suicide. Analysis was undertaken to determine the overall compliance with guidelines, the frequency with which each guideline was breached, and whether there were any differences based on whether articles originated from a local or a national media source. Differences between local and national media sources in the proportion of articles breaching any guidelines were calculated using the chi-squared test. Data analysis was performed in STATA 11 for Windows XP.

Box 1 Guidelines for the reporting of suicide assessed in the study. Adapted from the Samaritans¹⁶

1. Leave out technical details about the method of suicide, such as describing the type of ligature used or the number and types of pills taken in an overdose. Never suggest that a method is quick, easy, painless or certain to result in death.
2. Language matters. Avoid dramatic headlines and terms such as ‘suicide epidemic’ or ‘hot spot’.
3. Include references to support groups and places where suicidal people can find help.
4. Treat social media with particular caution and refrain from mentioning websites or networks that promote or glamorise suicide.
5. Avoid dramatic or sensationalist pictures or video. Refrain from including content from suicide notes.
6. Do not give undue prominence to photographs of a young person who has died and avoid repeated use of images such as galleries.
7. Do not brush over the complex realities of suicide and its impact on those left behind.
8. Speculation about the ‘trigger’ for a suicide, even if provided by a close family member, should be avoided.
9. Use statistics with caution. Make sure you have the most recent data and are comparing like with like.

In addition to comparison against the Samaritans’ guidelines, the inclusion of user-generated comments, threads and internet links to other articles was noted.

Results

Overall, 229 articles met the inclusion criteria: 68 articles from local media sources and 161 articles from national media sources. The majority (214 articles) came from media organisations which offer both a print and online platform, with national publications such as the *Guardian*, the *Telegraph* and the *Daily Mail* making up the bulk of national media output, and an array of smaller local outlets each contributing a smaller number of articles to the total. Fifteen articles were found in a range of online-only outlets such as the International Business Times, Yahoo UK, The Huffington Post and Wales Online. Ten articles were found on the websites of media network providers such as the BBC, ITV and STV.

Compliance with the responsible reporting guidelines

Of the 229 online articles included for analysis, 199 (86.9%) breached at least one of the Samaritans' guidelines. The mean number of guideline breaches per article was 2.2, with only a small variation between local and national media sources (2.1 v. 2.2 breaches per article, respectively; $P = 0.08$).

The most commonly breached aspects of the guidelines were a failure to include reference to sources of support for those considering suicide (69.4%), the inclusion of excessive technical detail about the method used (31%) and undue speculation about the reasons for suicide (30.1%) (*Table 1*). The other guidelines were breached in less than 25% of articles, with just 2 articles mentioning organisations that promote suicide and 1 article using statistics irresponsibly, telling readers the proportion of people completing suicide after jumping from a well-known landmark.

Compliance with reporting guidelines

	All sources	Local	National	Difference between local and national <i>P</i>
Articles, <i>n</i>	229	68	161	–
1 breach, <i>n</i> (%)	199 (86.9)	55 (80.9)	144 (89.4)	0.08
Breaches per article, mean	2.2	2.1	2.2	–
Specific guideline breaches, <i>n</i> (%)				
1. Excessive technical detail about the method	71 (31.0)	25 (36.8)	46 (28.6)	0.22
2. Sensationalist or irresponsible language	38 (16.6)	20 (14.7)	28 (17.4)	0.04* <#TFN1>`_
3. No sources of support	159 (69.4)	48 (70.6)	111 (68.9)	0.81
4. Mentioning places that promote or glamorise suicide	2 (0.9)	0 (0)	2 (1.2)	0.36
5. Dramatic pictures, videos, content of suicide notes	41 (17.9)	6 (8.8)	35 (21.7)	0.02* <#TFN1>`_
6. Picture galleries	30 (13.1)	1 (1.5)	30 (18.6)	0.001** <#TFN2>`_
7. Narrative brushes over the complex realities of suicide	20 (8.7)	5 (7.4)	15 (9.3)	0.63
8. Undue speculation about the triggers	69 (30.1)	18 (26.4)	51 (31.7)	0.43
9. Irresponsible use of statistics	1 (0.4)	0 (0)	1 (0.6)	0.52

P < 0.05,

$P < 0.01$.

Additional features of online media

Sixty-four articles included additional features which could contribute to readers encountering unsuitable material, such as the inclusion of user-generated comments sections and links to other articles which may similarly be poorly adherent to reporting guidelines (Table 2).

Articles with additional adverse features

	All sources <i>n</i> (%)	Local <i>n</i> (%)	National <i>n</i> (%)	<i>P</i>
Articles with additional adverse features	64 (27.9)	11 (16.2)	53 (32.9)	*0.01
Links to other articles about suicide	37 (16.2)	5 (7.4)	32 (19.9)	*0.02
User-generated comment threads	39 (17)	7 (10.3)	32 (19.9)	0.08

$P < 0.05$.

Discussion

This study evaluated the compliance of 229 online reports of suicide with the guidelines issued by the Samaritans. To our knowledge, this is the first study looking at the content of online media reports of suicide and the first in the UK looking at a selection of contemporary media output. Of note, the majority of articles included in the study failed to meet the Samaritans' guidelines for the responsible reporting of suicide. The results support findings from the limited number of studies undertaken elsewhere in the world that suggest media reporting of suicide is poorly compliant with available guidelines.^{18–21}

Of particular concern is the finding that 69.4% of reports failed to include a reference to a potential source of support for those readers who may be experiencing suicidal thoughts themselves; this was consistent across local and national sources. Lack of responsible information awareness and signposting support undermines suicide prevention efforts and fails to provide an alternative perspective to the often distressing narrative of articles. The finding that most articles omit references to support groups has been replicated in other studies from around the world: just 1% of Indian newspaper sources,¹⁹ 3% of US sources²¹ and 8.6% of Chinese sources⁸ included a reference to a support group.

Our finding that 31% of articles contained an excessive level of detail about methods used to complete a suicide is a significant cause for concern. The experience in other countries supports the idea that publication of suicide methods can perpetuate attempts and trends in methods chosen by others in 'copycat suicides'.^{2–5,22} In the course of assessing media reports for this study, the inclusion of details about the blood concentration of cyanide to achieve death, and the exact location and time of suicides by train, as well as details of places where suicides by jumping were completed, were all noted.

The finding that 30.1% of articles engaged in speculation about the reason for suicide was also a cause for concern. The journalistic tendency to simplify the reasons behind a suicidal act or engage in undue speculation about the surrounding circumstances can have a damaging impact on the bereaved family¹⁷ as well as readers who may over-identify with the person mentioned in the article, potentially increasing the deleterious impact for vulnerable individuals. This tendency to make articles more 'readable' may also be reflected in the fact that 8.7% of articles brushed over the complex realities of suicide, often failing to mention the family left behind or the impact of the suicidal act on others.

That being said, only one report included the irresponsible use of statistics and only two reports directed readers towards pro-suicide websites.

A qualitative observation was that where a particular fact about a suicide attempt is known, it will usually feature in other articles from other outlets about the same act. For example, very specific details about a method used were usually re-reported in all articles discussing the same event without due regard for the reporting guidelines.

Local v. national media sources

When comparing reporting by national and local media sources, local sources were overall more compliant with guidelines, with significant differences in the use of sensationalist language, dramatic pictures, videos or the content of suicide notes and the use of galleries, as well as the use of additional features of online media. The exact reason for the broadly better compliance with guidelines among local sources is not fully understood, but it may be because local media sources are closer to the subject of the article and local reporters may be more sensitive to the feelings of the bereaved family and local community.

Additional features of online media

The unique additional features of online media (compared, for example, with newspaper articles or television reports) could also compound their negative impact on readers; 16% of articles included links to other reports of suicide. Our finding that a majority of articles about suicide fail to meet responsible reporting guidelines and that the mean number of guideline breaches is 2.2 per article raises the possibility that the negative impact of irresponsible reporting is likely to be amplified by the inclusion of links to other potentially non-compliant reports.

Previous findings that discussion forums can increase suicidality among younger users²³ suggest that the addition of comments sections which can facilitate discussion should be avoided with online reports of suicide. Despite this, 17% of analysed reports had a comments section for user-generated content, and concerning comments such as the deceased person being 'brave' or 'at peace now' were frequently a feature of these.

Policy considerations

There is an evident need to evaluate the reasons for journalistic non-compliance with the existing guidelines of suicide reporting in the UK. Given the increasing use of online media and the apparent poor quality of reporting, there is a need to focus efforts on increasing the compliance of reports with responsible reporting guidelines. Suitable measures should also be established for non-compliant and potentially harmful articles to be flagged for urgent review.

Limitations

Although a standardised tool was used to identify breaches of media guidelines, judgements about breaches were not cross-checked between researchers. In addition, although the search sought to capture publications over a period of time, this work cannot account for potential seasonal changes in data.

Next steps

The present study uncovers an urgent need to address the fact that the majority of online articles assessed do not comply with existing guidelines on the responsible reporting of suicide. It highlights a significant public health concern because potentially vulnerable people have access to material which may provoke suicidal behaviours and which does not signpost them to support resources. Given the increasing weight of evidence that media reporting can affect suicide rates, there is an urgent need for the implementation of responsible reporting guidelines in online media articles. We propose that work be done to clarify and publicise the guidelines, and to train and encourage journalists to use them, and that a strong consideration be given to the role of more formal regulation and monitoring.

1.6.27 Caregiver burden and distress following the patient's discharge from psychiatric hospital

Abstract

Aims and method Caring for someone with a mental illness is increasingly occurring within the community. As a result, family members who fulfil a caregiving role may experience substantial levels of burden and psychological distress. This study investigates the level of burden and psychological distress reported by caregivers after the patient's admission.

Results This study found that the overall level of burden and psychological distress experienced by caregivers did not differ according to the patient's legal status. However, the caregivers of those who were voluntarily admitted supervised the person to a significantly greater extent than the caregivers of those who were involuntarily admitted. Approximately 15% of caregivers revealed high levels of psychological distress.

Clinical implications This study may emphasise a need for mental health professionals to examine the circumstances of caregivers, particularly of those caring for patients who are voluntarily admitted, a year after the patient's admission.

One in four families worldwide is affected by mental illness.¹ With the onset of illness, a family member may assume a caregiver role for their unwell relative, which may result in positive and negative experiences for the caregiver.² While caregivers convey a sense of satisfaction and well-being from their caregiving relationship, they also report feeling burdened.³ Such burden may be characterised by both objective difficulties, such as being unable to leave the family home and work, and subjective difficulties, such as psychological distress.⁴

Should a patient become severely unwell, it is often the caregiver who intervenes to initiate emergency psychiatric treatment.⁵ Caregivers can experience significant obstacles in gaining the assistance of a mental healthcare team for their relative⁶ and involuntary admission in particular can be associated with high levels of caregiver burden.⁷ This is important, as the level of burden experienced by caregivers can significantly predict treatment adherence and outcome in the patient.⁸ Furthermore, caregivers who experience high levels of burden reveal an increased incidence of physical and mental health problems and health-related risk behaviours.⁸ However, less is known about the level of burden or psychological distress that caregivers experience in the period following admission. Additionally, the limited research to date has focused on caregivers of involuntarily admitted patients and there is very little known about the caregivers of those admitted voluntarily.

For this reason, we aim to determine the level of burden and psychological distress reported by caregivers approximately 18 months after the patient's admission to an acute mental health unit. We also aim to determine whether clinical (specifically legal status) and demographic factors were associated with the level of burden and psychological distress reported by caregivers.

Method

Participants

Participants consisted of caregivers of either involuntarily or voluntarily admitted patients. Caregivers were recruited from two concurrent studies: the Service Users' Perspectives of their Admission (SUPA) study⁹ and the Prospective Evaluation of the Operation and Effects of the Mental Health Act 2001 from the Viewpoints of Service Users and Health Professionals study. The former was conducted in south-east Dublin and North Wicklow and involved both involuntarily and voluntarily admitted patients. The latter was conducted in Galway and Roscommon and included involuntarily admitted individuals and individuals who were brought to hospital under the Irish Mental Health Act, 2001, but were not subsequently involuntarily detained (i.e. they accepted a voluntary admission).

As patients were recruited before caregivers in these studies, our inclusion and exclusion criteria for caregivers stemmed from those applied to patients (*Fig. 1*). Patients were excluded if they could not provide informed consent, had a diagnosis of dementia or had a moderate to severe intellectual disability that rendered them unable to participate in the study. Patients who received a sole diagnosis of a personality disorder or substance misuse were also excluded from participating, as these individuals cannot be admitted involuntarily under the Irish Mental Health Act, 2001. Caregivers who were younger than 18 at the time of interview or who had a moderate to severe intellectual disability that impeded their ability to consent were similarly excluded from participation in the study.

Informed consent

Informed consent was obtained from all individual participants included in the study. The consent process consisted of three steps. First, patients were asked to consent to their caregiver being contacted and informed of the study approximately 1 year after their discharge. Second, caregivers were contacted by telephone by a researcher who introduced the study and arranged a time of interview. Finally, informed consent was sought from caregivers at interview.

Psychometric instruments

The Involvement Evaluation Questionnaire (IEQ) was employed as a measure of caregiver burden and caregiving.¹⁰ It consisted of 27 core items divided into four sections: urging, supervision, tension and worrying. Scores on the IEQ ranged from 0 to 108, with larger figures representing a higher level of caregiver burden. The IEQ is a reliable instrument, with Cronbach's alpha 0.74–0.85 for each subscale and 0.90 for the total score.¹¹ The IEQ also included a short, 12-item General Health Questionnaire (GHQ-12) that measured psychological distress. Scores on the GHQ-12 ranged from 0 to 12, with higher scores indicating that the caregiver was experiencing emotional difficulties.¹² The GHQ-12 is a reliable measure of psychological distress with an alpha coefficient of 0.87.¹³ Finally, diagnostic and clinical information pertaining to the patient was taken from a Structured Clinical Interview for DSM-IV-TR Axis I Disorders (SCID).¹⁴

Setting

The study included caregivers of individuals admitted to an acute mental health unit in one of five hospitals in Ireland that covered a combined urban and rural catchment population of over 590 000 individuals.

Ethical approval

The study received ethical approval from the governing ethical committees in all of the study sites: St John of God Hospitaller Order Provincial Ethics Committee, Newcastle Hospital Ethics Committee and University Hospital Galway Ethics Committee.

Statistical analysis

All data were entered into a Microsoft Access database and analysed using SPSS Version 22 for Mac. As the data were not normally distributed, multiple Mann–Whitney U and Kruskal–Wallis tests were used to determine whether burden and psychological distress scores differed between caregivers of involuntarily and voluntarily admitted individuals, and according to clinical and demographic factors. Effect sizes (r) were used to measure the magnitude of differences between scores. A small, moderate or large effect size corresponded with values equal to or less than 0.10, 0.30 and 0.50, respectively.

Results

Demographic and clinical characteristics

Sixty-five caregivers participated in the study; 42 (65%) were female. The mean age of caregivers was 54 years (s.d. = 15). The majority of caregivers were married ($n = 49$, 75%), 5 (8%) were single, a further 5 (8%) were divorced and the remaining 6 (9%) were widowed. Most caregivers were the person's parents ($n = 37$, 57%), 11 (17%) were spouses or partners, 8 (12%) were siblings, 6 (9%) were children and 3 (5%) were other relatives. The mean length of time between caregiver and patient interviews at baseline was 584 days (s.d. = 165). The median duration of the index admission was 34 days (interquartile range (IQR) 17.5–50) and 24 (36.9%) patients were readmitted within 1 year of the index admission.

Forty-six (71%) individuals were involuntarily admitted and 19 (29%) were voluntarily admitted. The majority were male ($n = 33$, 51%). The mean age of patients was 39 years (s.d. = 12). The majority of patients were single ($n = 41$, 63%), 16 (25%) were married and the remaining 8 (12%) were divorced.

Caregiver characteristics across legal status are given in *Table 1*.

Comparison of caregiver characteristics across legal status

Characteristic	All caregivers	Caregivers of involuntarily admitted patients	Caregivers of voluntarily admitted patients	Statistical test	<i>P</i>
Age, years: median (IQR)	54 (43–67)	54 (43–66)	54 (39–68)	$U = 340$	0.94
Gender, <i>n</i> (%)					
Male	23 (35)	14 (30)	9 (47)	$\chi^2 = 1.7$ d.f. = 1	0.19
Female	42 (65)	32 (70)	10 (53)		
Marital status, <i>n</i> (%)					
In relationship	49 (75)	34 (74)	15 (79)	$\chi^2 = 0.2$ d.f. = 1	0.67
Not in relationship	16 (25)	12 (26)	4 (21)		
Education, <i>n</i> (%)					
Primary/secondary	16 (30)	12 (33)	2 (13)	$\chi^2 = 2.8$ d.f. = 1	0.09
Tertiary	37 (70)	24 (67)	13 (87)		
Household, <i>n</i> (%)					
Living together	37 (57)	23 (50)	14 (74)	$\chi^2 = 3.1$ d.f. = 1	0.08
Living separately	28 (43)	23 (50)	5 (26)		
Relationship, <i>n</i> (%)					
Parent	34 (71)	25 (78)	9 (56)	$\chi^2 = 2.5$ d.f. = 1	0.12
Partner	14 (29)	7 (22)	7 (44)		

IQR, interquartile range.

Caregiver burden

The median level of burden in the sample was 13.00 (IQR 6.00–22.00). The median level of burden in caregivers of involuntarily admitted patients was 11.50 (IQR 6.25–20.75) and in caregivers of those voluntarily admitted it was 18.00 (IQR 5.00–34.00). Caregivers' overall scores of burden did not significantly differ ($U = 328$, $P = 0.18$, $r = 0.17$). However, caregivers of voluntarily admitted patients supervised the person to a greater extent than caregivers of involuntarily admitted patients (median IEQ supervision scores 2 v. 0, $U = 258$, $P < 0.001$, $r = 0.38$). The particular items of the subscale of supervision on which caregivers of voluntarily admitted individuals scored higher were ensuring that the person had enough sleep ($P = 0.02$) and that they did not drink too much alcohol ($P = 0.05$).

Factors associated with caregiver burden

There was no significant association between the level of caregiver burden and the caregiver's gender, patient's gender, diagnosis, level of functioning, relationship to caregiver or living in the same household as the patient (*Table 2*).

Involvement Evaluation Questionnaire (IEQ) and General Health Questionnaire (GHQ-12) scores according to demographic and clinical characteristics

	IEQ					
Ca regiver gender

GAF, Global Assessment of Functioning; IQR, interquartile range.

P 0.05. On applying a Bonferroni correction, no variable reached significance.

Psychological distress

Nine caregivers (15%) reported high levels of distress (defined as a score of 4 on GHQ-12). The median score of psychological distress was 1.00 (IQR 0.00–2.50): 1.00 (IQR 0.00–3.00) in caregivers of involuntarily admitted patients and 0.00 (IQR 0.00–1.00) in caregivers of voluntarily admitted patients. Caregivers of involuntarily or voluntarily admitted patients did not significantly differ in their levels of psychological distress ($U = 302, P = 0.19$).

Factors associated with psychological distress

No significant association was found between the caregiver's level of psychological distress and the caregiver's gender, patient's gender, diagnosis, level of functioning, relationship to caregiver or whether they lived in the same household as the patient (*Table 2*).

Post hoc analysis

We hypothesised that subsequent admissions from the index admission could affect the burden and psychological distress of caregivers and therefore further analysis examining this was performed. Caregiver burden was higher when the patients had been readmitted (16.0 *v.* 9.5, $U = 281.5, P = 0.04$) and there was a trend for a higher level of distress (1.0 *v.* 0.0, $U = 277, P = 0.06$). Legal status for the index admission was not associated with readmission ($\chi^2 = 0.28, n = 61, P = 0.60$).

Discussion

Summary of findings

The findings indicated that overall levels of burden and psychological distress did not differ between caregivers of involuntarily and voluntarily admitted patients at approximately 18 months after discharge from an acute mental health unit. However, caregivers of voluntarily admitted patients engaged in significantly higher levels of supervision than caregivers of those involuntarily admitted. Such supervision focused on, for example, ensuring that the patient slept sufficiently. *Post hoc* analysis also suggested that caregiver burden is associated with readmission to hospital.

Comparison with previous research

To our knowledge, no study to date has examined whether differences in the patient's legal status at admission accounted for differences in caregiver burden (objective and subjective) at more than 1 year follow-up. Our findings, however, support those of Boydell *et al.*,⁷ who also emphasised that overall burden was not linked to involuntary admission in caregivers of patients with first-episode psychosis. Our scores of burden and psychological distress are substantially lower than those reported by other authors.¹¹ Thus, the similarity in scores between caregivers in this sample may be due to a reduction in overall caregiver burden following the person's admission to hospital regardless of legal status.¹⁵

Implications

The finding that caregivers of voluntarily admitted individuals supervised the person to a greater extent is interesting and warrants discussion. It is possible that this additional supervision is a positive experience and that it results in an earlier detection of warning signs and prevents potential relapses from progressing to an involuntary admission. This finding highlights the need for caregivers of both voluntarily and involuntarily admitted individuals to receive support and psychoeducation. Interestingly, the *post hoc* analysis suggests that it may be the frequency of admissions that results in higher burden, as opposed to the legal status of the admissions. Furthermore, a longitudinal replication of this study assessing burden at various time points may provide us with a clearer picture of the caregiver's experience of burden.

Strengths and limitations

The study encompassed a number of strengths and limitations. Our sample included caregivers of involuntarily and voluntarily admitted individuals from both rural and urban geographical locations. Another strength of the study was that the caregivers did not self-select to the study. Nonetheless, our process of consent may have introduced bias, as those who consented for their caregiver to be interviewed may have had closer family relationships. Additionally, there was a significant gap between the index admission and the caregiver interviews, which introduces a number of potential confounders, such as readmission to hospital.

We thank Alastair Fetherston for designing the database for this study.

1.6.28 Unlocking an acute psychiatric ward: the impact on unauthorised absences, assaults and seclusions

Abstract

Aims and method The acute psychiatric in-patient service in Christchurch, New Zealand, recently changed from two locked and two unlocked wards to four open wards. This provided the opportunity to evaluate whether shifting to an unlocked environment was associated with higher rates of adverse events, including unauthorised absences, violent incidents and seclusion. We compared long-term adverse event data before and after ward configuration change.

Results Rates of unauthorised absences increased by 58% after the change in ward configuration ($P = 0.005$), but seclusion hours dropped by 53% ($P = 0.001$). A small increase in violent incidents was recorded but this was not statistically significant.

Clinical implications Although unauthorised absences increased, the absence of statistically significant changes for violent incidents and a reduction in seclusion hours suggest that the change to a less restrictive environment may have some positive effects.

- *Unlocking an acute psychiatric ward: the impact on unauthorised absences, assaults and seclusions*
 - *Method*
 - *Results*
 - *Discussion*
 - * *Strengths and limitations*
 - * *Final consideration*

The locking of psychiatric institutions is an important topic because detention involves significant restrictions on human rights, enshrined in the Universal Declaration of Human Rights. However, studies that have evaluated the impact of unlocking a psychiatric ward are rare; we were only able to identify four such studies spanning 7-decade-long assessing in this area. Lang *et al*¹ evaluated a policy change that resulted in a ward changing from being largely locked for 6 months to being largely open for 6 months and found that negative outcomes were more common during the closed time period. Other studies are considerably older^{2,3} and were largely positive in their findings, with the exception of the study by Molnar *et al*,⁴ which reported an increase in the frequency of ‘elopement’ (unauthorised absence) from 2.5 to 7% of admissions in the context of changing ward policy to allow a largely unlocked environment.

Any consideration of locked psychiatric wards must be viewed in the context of emerging policy that recommends minimising the use of locked psychiatric wards⁵ and emphasises a duty to provide psychiatric care in the least restrictive environment. A desire to provide least restrictive care created the impetus for our local psychiatric service to shift from an acute in-patient environment consisting of two locked wards and two unlocked wards to four largely unlocked wards. It also provided the opportunity to evaluate the impact of the change through reporting of long-term data detailing adverse events, such as unauthorised absences, ward violence and rates of seclusion, prior to and following the changes in ward environment.

Method

Data for this study were taken from the acute in-patient service in Christchurch, New Zealand. The service is the sole provider of acute in-patient services to adults aged 18–65 in the city of Christchurch, outlying towns and rural areas, with the exception of forensic patients, patients with an intellectual disability and in-patients requiring planned detoxification from substances, who are admitted elsewhere. The acute in-patient service receives admissions from community and emergency psychiatric services when care in the community is no longer feasible, with a typical case mix consisting of patients with affective disorders, psychotic disorders and personality disorders.

The service underwent major architectural change in 2013. Before, the service was configured with two locked wards (totalling 20 beds), two wards (totalling 44 beds) that were predominantly unlocked except overnight, and a seclusion area with 3 seclusion rooms. In response to service development initiatives and the desire to provide less restrictive care, the wards were reconfigured into 4 largely unlocked 16-bed wards (except overnight when the wards remain locked). At the end of each ward is a zone called the ‘high care area’, which is quieter than the general ward and provides care for up to three of the more unwell patients. Each high care area is continuous with its adjacent ward and can be designated ‘high care’ when doors are closed or locked, or be regarded as part of the general ward when extra clinical input is not required. The décor and bedrooms of the high care area are identical to the adjacent ward, but an

additional lounge, bathroom and courtyard are provided in order for the high care area to act as a self-sufficient unit when required. All wards, including the high care areas, are intended to be unlocked as much as possible but each ward or high care area can be locked separately in order to detain a patient if this is deemed necessary. The high care area bedrooms were not outfitted for seclusion but the seclusion area remained unaltered and could still be used if required. *Figure 1* presents details of the ward layout. If the ward or a high care area is locked, it is recorded in the restraint register as an environment restraint, and is therefore available for review.

In addition to these structural changes, nursing staff numbers increased, from 27 nurses routinely rostered on the wards to 34 nurses. However, if a nurse was required to provide one-to-one supervision after the change, this needed to occur within existing staff levels, whereas previously this was not the case. The frequency of one-to-one supervision pre- and post-change was not systematically recorded and is not readily available for review.

The acute in-patient service routinely records data on unauthorised absences, seclusions and violent incidents. Unauthorised absences include patients who are under involuntary mental health legislation and leave the ward without permission or fail to return from authorised leave, and voluntary patients who leave the ward outside of their agreed treatment parameters or fail to return from agreed leave. Nursing staff follow procedures when absences occur, including filling out a form documenting the absence which is then collated in a central database.

Violent incidents are assessed clinically and categorised into a number of subcategories including verbal abuse, threats of violence and assaults; all are recorded and collated centrally.

Seclusion is initiated by nursing staff as an intervention of last resort for managing a situation of imminent or actual violence. In response to international and New Zealand initiatives,⁶ seclusion reduction initiatives became embedded into the routine care environment of the acute in-patient service from 2010 and the goal of reducing seclusion occurred alongside the plan to provide a less restrictive environment through the ward redevelopment. Although seclusion rates are likely to be reduced by the seclusion reduction initiatives, the change in ward environment had the potential to hinder or assist the goal of reducing seclusion. As a consequence, we report seclusion rates which are collated centrally on a database and are therefore available for review.

The AWOL (absent without leave), violent incidents and seclusion databases have all collected data over an extended period. In de-identified form, they provided the opportunity to examine rates of unauthorised absences, seclusions and violent incidents for 18 months prior to the change in ward configuration and compare this to 18 months following the change. The mean rates and standard deviations of the monthly adverse events were calculated for the pre- and post-change 18-month intervals. As the data were non-parametric in nature, the Mann-Whitney *U*-test was used to compare the 18 months prior to the change with the 18 months following the change. The change in ward environment was staggered during June and July 2013; this time period was therefore not included in any data analysis as our goal was to examine a longer-term impact of the policy change as opposed to short-term effects during and following the transition.

We also report frequency and duration of the use of environmental restraint to clarify whether or not the intended change to a largely unlocked environment was successful or resulted in frequent locking of the newly configured wards. The frequency of Safety Assessment Code (SAC) 1 and 2 incidents (adverse events involving serious, major or extreme harm to patients) involving psychiatric in-patients is also provided pre- and post-change and examined for the possibility of a change in more serious adverse events that would not be detected by previous methods.

Ward occupancy data are routinely collected by means of a census taken at midnight every 24 hours. Admission data to the acute in-patient service and the forensic service are also recorded daily. Forensic in-patients are predominantly admitted from forensic out-patient services, courts and prisons, and not from general out-patient services. However, we examined admission and occupancy data for these services to test for the possibility that changes in outcome data were confounded by variations in occupancy or transfer to the more secure environment of the forensic service. The rate of monthly admissions pre- and post-change was compared using the Mann-Whitney *U*-test.

Although this was a study of group data and individual files were not accessed, ethics approval was sought and granted by the local University of Otago ethics committee (reference number HD 14/21).

Results

Longitudinal data on monthly unauthorised absences are presented in *Fig. 2*. The mean rate for the 18 months prior to the new ward configuration (December 2011-May 2013) was 16.9 (s.d. = 7.7) compared with 26.7 (s.d. = 11.2) for 18 months following the change in ward configuration (August 2013-January 2015). This represented a mean increase of 9.7 unauthorised absences per month and a percentage increase of 58% that was statistically significant ($P = 0.005$). As some literature suggests unauthorised absences may be seasonal, means were also calculated for the year pre- and post-change to ensure identical calendar months were compared, and the results were similar (16.6 (s.d. = 9.1) v. 29.6 (s.d. = 7.5), respectively).

Violent incidents were examined through the extraction of data recorded under the category of aggression, which includes verbal abuse, verbal threats, physical threats and physical assaults. Specific data were also extracted on physical assaults to assess for more significant violence. *Figure 3* shows the longitudinal data for all violent incidents and the mean monthly rates for 18 months pre- and 18 months post-ward changes, which were 72.3 (s.d. = 34.5) and 78.2 (s.d. = 43.1), respectively. This represented a mean increase of 5.9 violent incidents/month, or an 8% increase in incidents, which was not statistically significant ($P = 0.696$). With regard to physical assaults, the mean difference of 2.8 assaults/month, from 11.5 (s.d. = 5.9) before to 14.3 (s.d. = 10.1) after, was also not statistically significant ($P = 0.628$) (*Fig. 3*).

Another assessed variable was the longitudinal data on monthly seclusion hours over the study period as well as the mean rates of monthly seclusion (hours/month) (*Fig. 4*). The mean length of seclusion prior to the change was 391.5 (s.d. 203.0) compared with 185.2 (s.d. 135.6) following the change. This represented a mean drop of 206 hours/month or a percentage drop of 53% that was statistically significant ($P = 0.001$).

Occupancy was recorded according to bed nights/month and converted to a percentage of available bed nights. Occupancy varied between 80 and 101%, with a mean occupancy of 91% over the study period. It is likely that the single month that experienced more than 100% occupancy was very busy and included extra persons in rooms (e.g. partners, who do not routinely stay) being entered in the census data. Percentage occupancy data were largely stable over the study period and were without systematic trends that could account for the significant increases in unauthorised absences or significant reduction in seclusion hours. In keeping with the occupancy data, the rate of new admissions to the acute in-patient service was also largely stable over the study period (mean monthly admissions for the 18 months pre-change 100.4 compared with 107.8 for the 18 months post-change, $P=0.071$). The mean number of monthly admissions to the forensic service increased from 3.1 before the new ward configuration to 4.4 after; however, the increase was not caused by in-patients from the acute in-patient service as a total of 3 patients were transferred from the acute in-patient service to the forensic service for the 18 months prior to the ward change compared with 4 patients in the 18 months following the change.

The frequency of environmental restraint (locking of the high care areas or whole wards) revealed that, on average, there were 16 times per month when either a high care area or a whole ward was locked following the change in ward configuration. This meant that on average, each of the four wards had 4 periods each month in which part or the whole of the ward was locked. The frequency of locked periods/month varied from 0 for some wards to a maximum of 19, when the high care area of one ward was locked on multiple occasions in response to a single patient's multiple attempts to leave. In 37% of the environmental restraints, just the high care areas were locked as opposed to whole wards (affecting only 1–3 patients at a time). The mean time an area was locked was 120 minutes, and the range varied from 1 minute to 920 minutes. These results can be compared with the period prior to the new ward configuration, which had two wards (affecting up to 20 patients) constantly locked and occasional periods when the two open wards were locked in response to clinical pressure.

The total number of SAC1 and SAC2 events involving in-patients was 14 over the study period. Of these, 10 occurred before the change in ward configuration, 0 occurred during the transition period, and 4 occurred after the changes were made. For SAC1 incidents resulting in the death of a patient, 7 occurred prior to the ward changes (4 deaths occurred on the ward, 2 while patients were on granted leave, and 1 while on unauthorised absence from the ward) and 4 deaths occurred following the ward changes (3 on the ward and 1 while on granted leave). No SAC2 incidents occurred for patients who were on leave in the community or during an unauthorised absence.

Discussion

This study examined a range of adverse indicators over an extended time period in order to clarify whether or not a change in ward environment from two locked and two unlocked wards to a largely unlocked environment was associated with an increase in adverse events. The principal finding was that a significant increase in unauthorised absences occurred. However, significant decreases in the use of seclusion and non-significant increases in violent outcomes were also observed, although the reduction in seclusion occurred alongside national and local initiatives to minimise the use of seclusion.

The new ward configuration still made provision for the locking of wards. However, this was only done for relatively short periods (mean 120 min) and less often than prior to the ward redevelopment, when 2 wards affecting 20 patients were continuously locked. In addition, in 37% of the occasions when locking occurred, only a high care area was locked, meaning that 3 or fewer patients were affected. These numbers suggest that the unlocking of two wards and the change in ward environment did not result in wide-spread or prolonged locking of the new ward configuration.

The occupancy and admission data were without systematic trends to explain the changes noted. In addition, there was minimal flow of patients from the acute in-patient service to the forensic service, suggesting that more difficult patients who may be over-represented in adverse incident data were not transferred to forensic services after the wards were reconfigured.

Previous studies of unauthorised absences from psychiatric wards have raised concerns about rare but serious adverse events that have occurred while patients are absent.⁷ Although the low base rate of these events makes analysis difficult, it is reassuring for those considering a transition to the provision of a largely unlocked environment that of the 14 SAC1 and SAC2 events occurring over the study period, 10 occurred prior to the ward change and only 4 occurred afterwards. In addition, of the adverse events resulting in the death of a patient, 7 occurred before the ward changes and 4 afterwards. Although total numbers of unauthorised absences increased, there was only one death involving a patient who had left the ward without being granted leave, and it occurred prior to the ward change. All other community deaths over the study period involving in-patients occurred for patients who had been granted leave.

Strengths and limitations

One strength of the study was the routine collection of outcome data by hospital staff who were unaware that the data would later be used for study purposes. As a consequence, changes in reporting behaviour could not arise as a result of study influences because of the retrospective nature of the study conception and design. A further strength is the longitudinal nature of the data-set that allowed us to make before-and-after comparisons and consider longer-term effects, as opposed to solely focusing on the transition period during which staff are adapting to changes. These longer-term effects were thought to be more important in evaluating the impact of the change in environment and can be taken into account by service leaders in other locations considering similar changes. Although the longer-term outcomes were our primary area of interest, it is also reassuring that the transition period did not coincide with any SAC1 or SAC2 events, or a spike in the other adverse events evaluated by the study.

Our main limitation was that the study design was not experimental in nature. As the study was uncontrolled, our methodology allows comments to be made on associations between adverse events and the ward changes, but demonstrating causation is not possible. In particular, there was a service initiative to reduce seclusion that started prior to the study period. There were also increases in the numbers of routinely rostered nursing staff on the acute in-patient service after the ward change. This means that the relative influences of the change in ward configuration, the seclusion-reducing initiatives and the changes in nursing numbers on the adverse event rates are hard to quantify. It is therefore possible that increases in seclusion might have been observed if the changes in ward configuration had occurred in isolation. However, it is also reassuring to note that no such increases were seen in the presence of the seclusion reduction focus and nursing number changes that also occurred over the study period.

Final consideration

Studies such as ours that have evaluated the impact of unlocking psychiatric wards are rare. We were only able to identify 4 previous studies over 7 decades in our literature review. These studies were largely supportive of unlocking psychiatric wards, although the Molnar *et al*⁴ study also identified an increase in unauthorised absences following changing ward policy. However, after the initial increase, the rate subsequently decreased following an intervention to better manage risk and absconding.⁴

As stated, the unlocking of our in-patient ward should not be viewed in isolation. Although the findings were mixed with respect to adverse outcomes, we suggest that clinical attention and adaptations to nursing practice and clinical care have the ability to mitigate adverse outcomes when changes in environment occur. This conjecture is supported by the ability of some psychiatric units to markedly reduce seclusion rates⁸ in the presence of administrative and clinical support, and scrutiny of seclusion practice. It is likely that the reduction of seclusion hours demonstrated in this study occurred largely as a result of nursing and management strategies already in place to reduce seclusion in our service. However, seclusion hours continued to fall despite the change in ward configuration, meaning that the less restrictive environment did not have a negative impact on seclusion rates or supported the continued reduction of seclusion. Further support for the ability of service improvement initiatives to minimise adverse outcomes is given by the studies of Bowers *et al*,^{9,10} who trialled anti-absconding interventions in acute psychiatric wards with positive results, and the study by Nijman,¹¹ who demonstrated a reduction in aggressive incidents through a systematic focus on aggression alongside an intervention to reduce aggression. These studies suggest the importance of nursing practice interventions in addition to any environmental measures for reducing rates of absconding and aggression.

Adverse outcomes varied after the change to a largely unlocked environment, with increases in absconding, reductions in seclusion and non-significant increases in violent incidents. The real-world nature of this study does not allow clear inferences to be made regarding whether or not the unlocking of the ward was causally linked to these changes in adverse outcome rates. However, the longer-term nature of the database, with the ability to scrutinise the adverse outcomes pre- and post-change in ward configuration, strengthened the ability of this study to examine the change. The change to a largely unlocked environment was stimulated by a desire to provide care in the least restrictive way possible. Our findings constitute a cautious endorsement of this approach. Although unauthorised absences increased, other adverse outcomes were stable or improved. Thus, providing acute in-patient psychiatric care in a largely unlocked environment appears feasible, particularly in the presence of other service improvement strategies.

1.6.29 Psychiatry trainees' experiences of cognitive-behavioural therapy training in a UK deanery: a qualitative analysis

Abstract

Aims and method To explore core psychiatry trainees' experiences of cognitive–behavioural therapy (CBT) training by using interpretative phenomenological analysis of semi-structured interviews conducted with seven core trainee psychiatrists in Yorkshire and the Humber Deanery.

Results Four key themes emerged: (1) barriers to training; (2) guidance, with emphasis on the importance of supervision groups; (3) acquisition of new skills and confidence; (4) personal influence on the training experience.

Clinical implications Many trainees in Yorkshire have a positive experience of CBT training; however, some also experience barriers to acquiring the relevant skills. Further research should build on the positive factors and barriers identified here, with a view to guiding improvements in training nationwide.

In 2009 the Royal College of Psychiatrists revised the curriculum for psychiatric training to include specific psychotherapy elements within the core curriculum for all psychiatry trainees.^{1,2} The curriculum outlines general and specific competencies.² To achieve these competencies, trainees must complete a psychotherapy Assessment of Clinical Experience (ACE) as a workplace-based assessment (WPBA), attend case-based discussion (CBD) groups and undertake two psychotherapy cases in two modalities.² This revision was an attempt to ensure that core trainees get sufficient experience of psychological treatments to be able to utilise them accurately, evaluate their effects intelligently and, where appropriate, deliver them competently. Cognitive–behavioural therapy (CBT) is one of the recommended modalities of psychological treatments. Psychiatry trainees are expected to be competent to deliver CBT effectively, and CBT is a valuable skill that enriches and informs their practice.^{3–5}

The current literature suggests that prior recommendations for training in psychotherapies have not been widely implemented,^{6–8} despite trainees expressing an interest in acquiring such skills.⁸ Historically, trainees have been unaware of new curriculum guidelines^{7–9} and barriers to the training have been identified. These include lack of supervision,¹⁰ limited availability of suitable cases for training,⁹ and lack of protected learning time.^{4,11–16} A small study¹⁷ suggested working with low-complexity patients in the primary care setting as a way of overcoming these barriers, with protected time to do so. However, this has not been trialled on a wider scale, and limited data are available about whether this is a preferred route of training.¹⁷ Indeed, little qualitative research exists on the experiential accounts of psychiatric trainees undergoing the current training programme.

Aims

This study aims to explore the experiences of CBT training, delivery and supervision in core trainee psychiatrists who have trained in Yorkshire and the Humber Deanery. This work aims to identify barriers that lead to negative experiences of CBT training and identify the factors that facilitate a positive training experience. We also hope this study will guide improvements to CBT training for core trainee psychiatrists to enable trainees to meet the Royal College of Psychiatrists' objectives and, ultimately, become more competent and psychologically minded psychiatrists.

Method

This was an exploratory, qualitative study. Semi-structured telephone interviews and face-to-face interviews were used for data collection, and interpretative phenomenological analysis (IPA) was employed. IPA is a qualitative tool that enables the exploration of an individual's perception of events and how they 'make sense' of experiences.^{18,19} Approval for the study was granted by the Research and Development Department, Faculty of Medicine and Health, University of Leeds.

Recruitment

Twelve core trainee psychiatrists in Yorkshire who had recently completed CBT cases under supervision were invited to participate in the study via email. One trainee declined participation as they were no longer working in the area and four trainees did not respond to the recruitment emails. Seven participants consented to take part in the study.

Participants

The participants were a small, purposeful sample of seven core trainee psychiatrists (CT2 and CT3). Three participants were male. Two participants had worked in a psychotherapy post and one expressed an interest in specialising in psychotherapy.

Procedure

The semi-structured interviews were guided by a review of the pre-existing literature concerning psychotherapy training experiences. This was piloted and amended as necessary. The questions concerned core trainees' experiences of CBT training and the generalisability of acquired competencies, the feasibility of training, the impact of supervision, the emotional aspects of training, and understanding of the College's curriculum. The interviews lasted between 12 and 24 min and were recorded. The recordings were transcribed verbatim to produce the raw data for the study.

Analysis

The process of IPA¹⁹ was conducted by both interviewers, who listened to interview recordings and read and re-read the transcripts to familiarise themselves with the data. Initial interpretations of the data (descriptive summaries and points of interest) were entered as annotations in the margins of the transcripts. Emergent themes were then drawn and recorded in a table after cross-checking them against the transcript. This process was repeated for each transcript. Initially, the researchers searched for connections between the themes within the transcripts, and then between the transcripts. Thematic connections were identified and emergent themes were clustered, and a list of subordinate themes was compiled. Subordinate themes were clustered into superordinate themes. The superordinate themes and sub-themes were verified against the transcripts to ensure that they were grounded in evidence and then they were organised into a master table (*Table 1*). Last, quotations which best encapsulated each theme were identified.

Themes

Superordinate themes	Subordinate themes
1. Barriers	a. Time b. Cases c. Patients d. Access to learning resources
2. Guidance	a. The role of supervision b. Learning from peers c. Sticking to the curriculum
3. Acquisition	a. Gaining new skills b. Models of mental illness c. Personal influence d. Confidence

Results

Three superordinate themes were identified, with three or four subordinate themes each, and are described below.

Barriers

Barriers to CBT training and the impact that this had on learning was a prominent theme across all of the interviews. Some participants had personally experienced barriers to training and others described the impact that barriers had had on their peers.

Time

The impact of insufficient time for learning was a theme that occurred across all seven interviews. Participants disclosed how shift work caused disruption to their CBT training.

‘if we were on-call that day or on nights or on leave, um, you ended up missing some of the sessions because of that and I think because CBT is quite structured, so you learn one thing in one session and then progress on to the next bit in the next session, so if you miss a bit I think it becomes a bit more difficult to get your head around it’ (participant 2).

One participant described the challenges encountered in maintaining protected learning time amidst other work commitments: “‘Because I was working in the ward [...] it’s quite difficult to get out of that to get supervision and do other things’ (participant 6).”

Conversely, another participant perceived that colleagues respected protected learning time, suggesting that trainees’ experiences varied depending on where they were working: “‘There’s no problem getting time away from your day job to go [to] the CBT training’ (participant 7).”

One participant, who had worked in a psychotherapy job, acknowledged that this job provided more time for training than other jobs: “‘I did a psychotherapy job in my last 6 months, so I was able to spend a lot more time and pick up a

lot more cases than perhaps other people have experienced' (participant 4)."

One participant expressed concern that lack of time may prevent the use of CBT in future practice: "depending on the workload you're not always able to provide the adequate time per patient' (participant 2)."

The time delay between beginning CBT training and being allocated a patient case was identified as a barrier.

Cases

Participants felt that there was a shortage of CBT cases available for trainees and this had a significant impact on their CBT training.

'I think the barrier is there is a big waiting list and that is a problem, like you have to wait to get a case [...] and obviously if there [aren't] enough patients [...] you [won't] get a case and there's loads of trainees and this is kind of a mandatory thing, everybody has to have a case' (participant 3).

Participants felt that it would be beneficial to have more than one case: "I would say if we had at least two cases that might be better but again it is very difficult to get a CBT patient because we have got loads of trainees and, um, not a lot of CBT we do, we get for trainees because [...] if it is not simple for trainees they do not consider it, to give it to us, and there is a long waiting list, I think you know that, there is a big waiting list for CBT, so like I had to wait for nearly ... more than a year actually' (participant 3)."

A participant who had worked in a psychotherapy post observed that one case would not have provided sufficient CBT experience: "I work in psychotherapies so I have had more than one case and [I] have had good exposure to CBT. I just don't know whether if I hadn't had this job, this exposure would be enough' (participant 1)."

Patients

Six of the participants discussed the impact of the patient on their experience of CBT. First, participants felt that completing a CBT case was more challenging if the patient did not engage. Second, they discussed the impact of patients not attending sessions or discontinuing with treatment; this was perceived to be a substantial barrier to training that was not taken into account by the College's curriculum.

'if the patient doesn't engage or doesn't complete therapy – this could potentially be a problem. In fact [the trainee] might not have the time to undertake another case and complete it' (participant 7).

However, participants acknowledged that the impact of the patient on CBT training was a factor that is difficult to control.

'It's totally up to the [patient] whether he or she will continue or not and if she leaves before you complete the full therapy then you have to wait for the next patient so that is a problem but I don't know the way to change it because it's totally up to the patient if they will continue or not' (participant 3).

Conversely, one participant acknowledged that a good doctor-patient relationship could have a positive impact on the experience of CBT training.

'seeing results from patients as well has been really good' (participant 4).

Access to learning resources

Participants expressed concern about keeping skills up to date as time elapsed.

‘I think the Royal College [of Psychiatrists] run a CBT module, but it’s all things that you have to pay for [...] and I think that most people feel like they pay for enough exam material [and] for the Royal College exam, and probably don’t have [a] mountain of spare cash to be spending on more e-learning stuff, so it might be good if the trust wanted to sort of do something with CBT, or if the Royal College will give out [an] e-learning module – I think that would be quite useful, and for people who are not seeing cases that regularly – I think it might kind of just update you with CBT’ (participant 4).

Conversely, others thought that the time and experience was ‘ample’: “‘I’ve been given adequate texts to read and stuff in my spare time. I have ample opportunity to discuss any complications that arise with my case so [...] all in all it’s been really good’ (participant 2).”

Guidance

The participants perceived that supervision was an important feature within their experience of CBT training. The superordinate theme of guidance was identified across all interviews, with the subordinate themes of supervision, peer learning and curriculum.

The role of supervision

There was an overall satisfaction with supervision from all the participants, who felt that they had continued support and advice. Feedback and reassurance from supervision encouraged the trainee to gain confidence and it was highlighted that the participants felt able to ask their supervisor for advice.

‘I would say that the supervision was really good, it was tailored down to trainees’ need [...] the supervisor was approachable’ (participant 5).

‘there were quite a few things that needed improvement and I felt that supervision enabled me to identify these areas and work on improving these sets of things’ (participant 1).

It appeared that the expertise of the supervisor themselves was respected and was useful to the majority of the participants. All of the participants had a consultant psychiatrist as their supervisor.

‘expert opinion on where you are going with your cases, so you feel like you do a good job with the patient’ (participant 4).

‘has a lot of experience on this ground so that was quite helpful’ (participant 3).

In terms of emotional support, there appeared to be a consensus that, if required, emotional support from supervision would be present.

Interviewer: ‘And, do you feel like you had enough emotional support if needed during your training?’

Participant: ‘I suppose I would, yes. It was never an issue, but I would imagine that if I had felt stressed I would have found support’ (participant 1).

Learning from peers

Three of the participants discussed how helpful peer learning was in their training, in particular as regards case supervision conducted in group sessions.

‘Well, I actually used to love and look forward to [...] supervision, because every time – because our supervision was a group sort of supervision – I learn not only from my case, but [I] also learn from other people’s cases. Because people have different aspects they need supervision [for], so I will kind of learn quite generally because it’s quite enjoyable to keep on listening to different cases, including mine – and following it up through week after week. So I really enjoyed it’ (participant 6).

Sticking to the curriculum

In contrast to the optimism surrounding supervision, the participants did not consider the College curriculum to be a sufficient source of guidance.

I: ‘Also, how aware were you of the Royal College guidelines before you started your CBT training?’

P: ‘Um ... not very.’

I: ‘And do you feel that there is any way in which they could be accessed more easily?’

P: ‘I wouldn’t even know how you access them now to be honest.’

I: ‘Okay, that’s okay. Okay.’

P: ‘I’m assuming that you look on the Royal College website but I never have’ (participant 7).

This lack of awareness of the Royal College of Psychiatrists’ curriculum guidelines was found in other participants, who reasoned that the guidelines are too extensive and incomprehensible. However, it transpired that six participants had acquired the competencies outlined in the curriculum despite the fact they were unaware of what these were.

‘The curriculum for core training is huge and extremely vague mostly – so you need to trawl through that document, probably most people haven’t’ (participant 4).

P6: ‘I’ve been able to explain to the patient what CBT is and what it is used for and also, sometimes I’ve been able to use the skills I’ve learnt in CBT, to offer treatment to the patient.’

I: ‘Do you feel like you are able to deliver CBT?’

P6: ‘I think I feel that way’ (participant 6).

One participant relayed that the curriculum needed to be more flexible owing to the nature of the therapy itself being unpredictable and time consuming.

‘I do think they need to be a bit flexible, because say if a patient drops out of therapy and say you have done 10 sessions that now doesn’t count as a case!’ (participant 4).

Acquisition

The participants felt that they acquired a great deal via their CBT training, in terms of gaining specific CBT skills, but also in learning generic skills that could be applied to psychiatric practice and learning which patients would be suitable for CBT. They acquired a new insight into models of mental illness and learnt to conceptualise mental illness in accordance with the CBT model. Trainees also discussed their personal influence on their experience and thus their acquisition of CBT skills. Last, they grew in confidence as they gained experience working with their CBT case.

Gaining new skills

The trainees felt that they gained a great deal from their CBT training, in terms of both specific CBT skills and also broader transferable skills that could be applied to their psychiatric practice.

‘I enjoyed it. I think basically it’s really important [...] for [a] psychiatric trainee or for a psychiatrist to have experience in CBT’ (participant 1).

Most of the participants felt that they gained a greater understanding of what CBT entails and how it works. This enabled them to confidently explain CBT to patients.

‘it gave a clear understanding for me of what exactly CBT involves and how it has a beneficial effect on patients’ (participant 5).

Three participants described how the training helped them to identify which patients would be suitable for CBT. They felt confident in referring patients for CBT. However, others felt that they needed more experience to accurately assess patients for CBT.

‘I mean, now like when I will refer patients for psychotherapy I would now know what are the categories that I need to check before referring and whether the patient is suitable for CBT or not because I have practical experience of doing it and I know that I’ve some idea whether the patient [would benefit] from CBT or not’ (participant 3).

Some of the participants felt confident using CBT techniques. However, they acknowledged that they had limited experience and that they were not fully equipped to deliver formal CBT.

‘And do you feel like you would be able to deliver it as well?’ P: ‘Delivering, to be honest – no. Because, I think, err, having done only one short case of CBT, without any supervision, I won’t be able to take up a case on my own I guess ...’ (participant 5).

Although not all of the participants felt confident in delivering CBT, they felt that they had gained transferable skills that could be used elsewhere in their psychiatric practice.

‘Sometimes in my session now [...] I see people with [...] anxiety and other disorders; I am able to use the very same skills I used in my CBT session to kind of handle the situation around me’ (participant 6).

The participants hoped that they would continue to use the skills that they had gained. However, some expressed concern about losing skills over time, particularly if they did not use CBT regularly in their job.

‘if you’re not in touch then you may lose some skills. That may be a problem in the future because you’re not going, not actually keeping doing it, practising it, yeah, so maybe it can impact on practice in the future’ (participant 3).

Models of mental illness

Six participants talked of the training causing a shift in their understanding of mental illness, moving them away from the diagnosis exclusively, and focusing on the wider problems for their patient, allowing them to reach the criteria of the curriculum and develop their emotional intelligence.

‘what I found out is that [pause] maybe some of these people do not have defined mental illness but they definitely have a problem, and just basically move me away from having to diagnose a patient with something, so [I was able to] focus on the problem rather than the diagnosis, and sometimes the problem did not correspond to an ICD-10 diagnosis, and I think this is really useful because, eh, usually in everyday life, people have problems – rather than psychiatric diagnosis’ (participant 1).

‘Well it has given me the insight into looking at the behaviour and thoughts, in terms of how people are affected, and how to help them – that’s not what I was thinking before, because before I was thinking in terms of the medical model, and now I’m thinking more about other things like their thoughts and their

behaviour, and their emotion – and how all of that is part of their illness, and how to use that to treat their illness’ (participant 6).

The trainees described how this increased awareness affected the management of their patients.

‘it does change your thinking about your practice, and you know – what else is out there, other than, you know, medication and that kind of thing, there are other ways that people can benefit from secondary care’ (participant 4).

‘having done CBT training [pause] it helped me to identify that there are some mental disorders which need both medications and psychotherapy’ (participant 5).

The benefits of having time to reflect as part of psychotherapy training gave trainees a different perspective on the patient that they were treating.

‘and I think when you’re using CBT to make them think differently about their illness and their actions it makes you think differently about it as well [...] and you certainly see patients’ difficulties from a different point of view [...] and it gives you time to figure that out’ (participant 2).

Personal use of this new way of looking at models of mental illness was cited; the participants described how this changed how they see themselves.

‘within myself, it changed me in such a way, the way I am able to kind of evaluate my behaviour, with what I do and what I think – so I use it on myself quite a bit. If I find myself in a difficult situation, even in day-to-day life – I use the same principle on myself to kind of look at how things are done, and change things differently. So I think that’s how personally CBT has influenced me’ (participant 6).

Personal influence

Several of the participants acknowledged that they had a particular interest in CBT. Two had worked in a psychotherapy post and one hoped to specialise in psychotherapy. Furthermore, the participants acknowledged that their personal interest may have affected their experience of CBT training and they may have gained more from the training as a result.

‘Personally, I am interested in psychotherapy anyway, so I wanted – I want to be able to use CBT [pause] later on in my career, so [pause] so that’s one of the reasons why I think it was really useful’ (participant 1).

Confidence

The majority of the participants talked of increased confidence during their training and afterwards. This is in regards to their own skills and understanding, as well as recognition of when to refer a patient for CBT.

‘since my first case, [I] have got a lot more fluent [than] in the beginnings of therapy’ (participant 4) .

One participant expressed a lack of confidence in referring patients for CBT because their CBT supervision was still ongoing at the time of the study: “‘I don’t think I’m confident at the minute because I suppose I’ve been given a patient, I’ve not assessed someone for it as such but, um, I’m continuing to have CBT supervision [...] so I think by the end of it I will be able to, yes, to figure out who would benefit from it’ (participant 2).”

Overall, there was a positive association between experience and confidence.

‘Do you know, I feel much more confident about CBT ... because I know what it is, so I feel much more confident’ (participant 3).

Discussion

A number of barriers that affect trainees' experiences of CBT training have been identified here; chiefly a lack of protected learning time, a shortage of available cases for training purposes and difficulties arising due to problems with patient engagement and therapy completion.

Having protected time for CBT training was high-lighted as crucial for psychiatry trainees, who reasoned that the difficulty in completion and the formulaic structure of CBT require a regularity and dedication to carry it through. The 'inevitability' of work disruptions and shift patterns were the main source for these disruptions recognised in this study. As previous work suggests, there was variability within this, dependent on where one is a trainee and what jobs one is assigned. Trainees in a dedicated psychotherapy post were more positive about their ability to complete and transfer their CBT skills. We propose that this may be due to the trainee having a personal interest in 'talking therapies' in addition to the granted protected time to acquire these skills in a psychotherapy post, a proposition which resonates with previous work in this area.⁴ This variation resulting from chance permeates to the level of patient allocation as well – as each trainee is allocated a different patient, standardisation of experience becomes problematic. One aspect that helped with this was peer-group learning, insofar as the experience of each trainee is shared and hence multiple cases are acquired instead of just the one that each trainee has had. This echoes previous recommendations to utilise novel ways, such as peer-group learning, to assist CBT supervision and skills acquisition.³ Thus, ensuring that protected learning time is provided and that it is a feasible task is likely to improve the trainees' experience.

Concerning the shortage of cases, further enquiry would be beneficial to explore the feasibility of targeting the long waiting lists for both the patients and the trainees by enabling trainees to take on a broader range of patient cases. A larger study would be beneficial in exploring this, continuing with the idea to source cases from primary care.¹⁷ This could help to relieve the pressure for the trainee to complete one 'ideal' CBT case, and thus the patient being a barrier to learning could have less impact. It was also suggested that it could be beneficial to provide a follow-up course that can be accessed freely to ensure that skills are maintained over time. Furthermore, the training experience could be improved if the Royal College of Psychiatrists' curriculum took into account the effect of patients discontinuing with therapy and allowed a degree of flexibility for cases in which almost all sessions had been completed. Moreover, as prior literature suggests, further dissemination and accessibility of the College curriculum is still warranted.

A number of factors that facilitated a positive experience of CBT training in Yorkshire were identified. Supervision was highly valued and deemed to be an important facilitating factor during the training. Further research could be useful in order to elucidate how the benefits of supervision are mediated and thus enable similar supervision to be conducted elsewhere.

In accordance with the College curriculum, this study suggests that psychiatric trainees in Yorkshire report enhancements in their emotional intelligence and being able to refer for CBT accurately and evaluate its effect intelligently after the training. A broad positive association was relayed from the participants between exposure to CBT and confidence in recognition and delivery of skills learned. However, although trainees' overall confidence about psychotherapy increased, further experience is deemed necessary for the trainees to feel able to deliver CBT competently. On the whole, trainees gained a broader perspective of models of mental illness and learned transferable skills, which have now influenced their clinical practice.

Although a robust study design was employed and triangulation of the data was used to increase the validity of the findings, the qualitative nature of the study has inherent limitations.²⁰ Nonetheless, the study provides a valuable insight into the experiences of psychiatry trainees in Yorkshire and paves the way for further research in other deaneries across the UK in order to gain a clearer insight into the experiences of core trainee psychiatrists in general, with the aim of improving CBT training and ultimately enabling psychiatrists to become more emotionally aware, competent and confident.

1.6.30 Antipsychotic prescribing of consultant forensic psychiatrists working in different levels of secure care with patients with schizophrenia

date

2017-4

Abstract

Aims and method To detect any differences in the antipsychotic prescribing practices of consultant forensic psychiatrists working in different levels of secure care with patients diagnosed with schizophrenia, and to identify potential reasons for any differences. Prescribing data were collected from four secure hospitals within one National Health Service trust. A questionnaire was sent to consultant forensic psychiatrists working at those hospitals as well as those working in the trust's community forensic services.

Results Consultants working in high security prescribed more oral antipsychotics than consultants working in medium and low security, who prescribed more depot antipsychotics, as established via the prescribing data. The questionnaire provided insight regarding the reasons for these preferences.

Clinical implications There were differences in the antipsychotic prescribing practices of consultant forensic psychiatrists working in different levels of secure care, and, overall, the rate of depot antipsychotic prescribing was lower than might be expected. Although it was positive that the rate of polypharmacy was low when compared with earlier studies, the lower-than-expected rate of depot antipsychotic prescribing has clinical implications.

Schizophrenia is an enduring mental illness characterised by remissions and relapses. Treatment is available in the form of psychosocial interventions but the mainstay of effective management is antipsychotic medication.^{1–3} Antipsychotic efficacy is reduced by poor adherence and it is estimated that the risk of relapse is 2 to 6 times greater for patients not taking antipsychotic treatment.¹

Forensic psychiatrists working in secure hospitals are likely to have case-loads with high levels of comorbidity, non-adherence and risk;^{4,5} a history of aggression has been found to predict the use of high-dose antipsychotic treatment (total antipsychotic doses totalling greater than 100% maximum *British National Formulary* dose).¹

Paton *et al*⁶ reported on an in-patient census. Most (97%) of the 53.2% diagnosed with psychosis were prescribed an antipsychotic. Polypharmacy (the prescription of more than one antipsychotic agent) was common. Of those prescribed a regular antipsychotic, 51.6% were prescribed a first-generation agent, 11.3% were prescribed clozapine and 33% were prescribed a depot agent (80% of these patients had a psychotic illness). High-dose prescribing was more common when a depot agent was prescribed.

No previous studies have examined the prescribing patterns of forensic psychiatrists working in differing levels of security. It is important to identify such patterns to build on existing knowledge and to identify areas requiring change.

Aims

To detect any differences in the antipsychotic prescribing practices of consultant forensic psychiatrists working in different levels of secure care within a National Health Service (NHS) trust, and to identify potential reasons for any differences. We hypothesised that there would be no significant differences in prescribing patterns in this clinician group.

Method

Settings and sample

Covering a vast geographical area, the NHS trust studied is one of the largest in England and provides services in a variety of settings. Its secure hospitals feature one high secure hospital, two medium secure hospitals and one low secure hospital. Information on antipsychotic prescribing was collected on all in-patients with schizophrenia in these four hospitals in July 2014. A questionnaire was sent to the 34 consultant forensic psychiatrists based at the hospitals and 3 community-based consultant forensic psychiatrists working within the same trust.

Procedure

Prescribing patterns

In July 2014, the electronic healthcare records were used to produce a list of all current in-patients at the trust's four secure hospitals. The clinical records (electronic and paper healthcare records, and pharmacy records) were then used to ascertain which of these patients had schizophrenia. Further information was collected about patients with schizophrenia (gender, age, ethnicity, length of stay, antipsychotic medication prescribed), to produce an anonymised data-set detailing the percentage of patients diagnosed with schizophrenia at each hospital, and the proportion of patients with schizophrenia prescribed different types of antipsychotic medication.

Consultant questionnaires

Owing to the absence of a validated instrument, a semi-structured self-report questionnaire was developed to assess forensic consultants' attitudes to the prescription of oral and depot antipsychotic medications. The questionnaire was designed to take less than 5 min to complete. Consultants were asked in which level of security they worked and then three further questions: Disregarding the special case of clozapine, when treating a patient with schizophrenia do you have a general preference for either oral or depot antipsychotic medications? (Yes/No) Please indicate the strength of any preference on the scale below (0–100 anchored Likert scale: 0 – oral, 100 – depot). What are the reasons behind any stated preference? ((a) Improves adherence, (b) Better clinical outcome, (c) More convenient for the patient, (d) More convenient for the clinical team, (d) The next level of security/community team would expect/prefer it). There was also space for a free-text response. The three community consultants were asked two further questions: How important is the route of antipsychotic administration in your considering whether to accept a patient on to your caseload? (0–100 anchored Likert scale: 0 – very important, 100 – not at all important). How likely are you to accept a patient currently prescribed an oral antipsychotic (not clozapine)? (0–100 anchored Likert scale: 0 – very unlikely, 100 – very likely). The Likert scale is an ordinal psychometric assessment of attitudes or opinions, typically lacking concrete answers to accommodate neutral or undecided feelings. It was selected for this questionnaire owing to the speed and ease of completion, low cost, ease of distribution, and providing results amenable to analysis.

The Likert scale has been criticised for failing to measure the true attitudes of respondents, as it gives only 5 to 7 options of choice, and also for the space between each choice in reality possibly not being equidistant. In view of this, and in an attempt to further maximise freedom on behalf of the responder and to avoid railroading respondents into giving polarised responses, the Likert scale was amended to include some characteristics of an analogue scale.

The questionnaire was sent, with a cover letter, to all forensic consultants working in the four secure hospitals and in community forensic services in the NHS trust. After 3 months, the questionnaire was sent again to encourage non-responders. All data were supplied anonymously.

Ethical considerations

The project proposal was reviewed by the trust's research and innovations department and approved as service evaluation; research ethics approval was therefore not required. Patient anonymity was preserved throughout the study.

Analytic strategy

SPSS version 21 (Windows 10) was used for data analysis. Chi-square and ANOVA were used where appropriate. All tests were two-tailed and $P < 0.05$ was used to determine statistical significance.

Results

Demographic information

In July 2014, there were 556 patients detained at the four secure hospitals; 265 (48%) were diagnosed with schizophrenia. The sample characteristics are summarised in *Table 1*.

Sample characteristics of in-patients at each of the four secure hospitals

	High secure hospital	Medium secure hospital 1	Medium secure hospital 2	Low secure hospital	P	
Total number	339	69	85	63	–	
Schizophrenia, n (%)	139 (41)	53 (77)	33 (39)	40 (63)	** 0.001**	: sup:2 = 38.52, d.f. = 3
Ethnicity, n (%)						
White British	100 (72)	41 (77)	21 (64)	17 (42)	** 0.002**	: sup:2 = 15.23, d.f. = 3
White other	5 (4)	0 (0)	1 (3)	2 (5)	0.500	: sup:2 = 2.34, d.f. = 3
Black/Black British	19 (14)	3 (6)	4 (12)	11 (28)	** 0.026**	: sup:2 = 9.25, d.f. = 3
Asian/Asian British	9 (6)	5 (9)	2 (6)	3 (7)	0.902	: sup:2 = 0.58, d.f. = 3
Mixed/other ethnicity	6 (4)	4 (8)	5 (15)	7 (18)	** 0.024**	: sup:2 = 9.42, d.f. = 3
Age, years						
Mean (s.d.)	40.0 (9.8)	36.9 (8.7)	36.5 (8.8)	38.1 (10.3)	0.100	ANOVA $F_{(3,261)} = 2.10$
Median (range)	38.6 (21.9–66.3)	37.2 (19.6–60.0)	35.2 (21.8–58.2)	35.9 (19.8–62.0)	–	
Length of stay, years						
Mean (s.d.)	6.4 (4.5)	2.1 (1.9)	1.9 (1.4)	3.0 (3.9)	** 0.001**	ANOVA $F_{(3,261)} = 26.86$
Median (range)	5.9 (0.1–21.4)	1.5 (0.1–8.0)	1.4 (0.03–5.6)	1.5 (0.03–18.2)	–	
Female patients, n (%)	5 (3.6)	0 (0)	1 (3.0)	4 (10.0)	0.093	: sup:2 = 0.58, d.f. = 3
Age, years: mean (s.d.)	43.1 (5.9)	–	–	41.7 (13.4)	0.373	ANOVA $F_{:sub: (2,7)} = 1.14$
Age, years: median (range)	41.1 (36.9–54.3)	–	–	39.7 (25.7–62.0)	–	
Length of stay, years: mean (s.d.)	4.9 (2.4)	–	–	1.1 (0.4)	0.053	ANOVA $F_{:sub: (2,7)} = 4.62$
Length of stay, years: median (range)	6.5 (1.3–6.8)	–	–	1.1 (0.5–1.6)	–	

Bold denotes significance ($P < 0.05$).

As medium secure hospital 2 had only 1 female in-patient, means and medians for age and length of stay have not been calculated.

Medium secure hospital 1 provides a male-only service. The high secure hospital and medium secure hospital 2 have wards specialising in the care of patients with personality disorder, whereas medium secure hospital 1 and the low secure hospital do not, hence the differences in the rate of schizophrenia. The proportion of patients from Black and minority ethnic (BME) groups was high when compared with the general population⁷ (29% v. 14% respectively). The rate was highest for the low secure hospital (53%). This significant finding mirrors an earlier study⁸ which found an overrepresentation of BME groups admitted to low secure services across the UK.

There was little difference in mean patient age between the four hospitals, and expected differences in the mean lengths of stay.

Pattern of prescribing

Of all patients with schizophrenia, 3% ($n = 8$) were not prescribed antipsychotic medication and 12% ($n = 33$) were prescribed antipsychotic medication constituting polypharmacy. The most common polypharmacological combination was clozapine augmented with a second-generation oral antipsychotic. Data regarding the prescription of antipsychotic medication are summarised in *Table 2*.

Antipsychotic prescribing for patients with schizophrenia at the four hospitals

	High secure hospital	Medium secure hospitals	Low secure hospital			
Regular first-generation antipsychotic only, n (%)						
Oral	6 (4)	2 (4)	0 (0)	2 (2)	2 (5)	10 (4)
Depot	17 (12)	7 (13)	8 (24)	15 (17)	9 (22)	41 (15)
Regular second-generation antipsychotic only, n (%)						
Oral	59 (42)	8 (15)	10 (30)	18 (21)	11 (27)	88 (33)
Depot	1 (1)	9 (17)	0 (0)	9 (10)	6 (15)	16 (6)
Clonazepam only, n (%)	33 (24)	18 (34)	10 (30)	28 (33)	8 (20)	69 (26)
Total, n	139	53	33	86	40	265

Excluding clozapine.

Clozapine was prescribed to 26% of all patients, with the highest prescription rate observed in medium security hospitals (33%).

Excluding polypharmacy and clozapine use, more patients were prescribed a second-generation oral agent than a first-generation oral agent (33% v. 4%); this was true for all four hospitals. In general, this pattern was reversed for depot agents, with more patients being prescribed a first-generation depot agent than a second-generation depot agent (15% v. 6%). 70% of patients with schizophrenia in high security were prescribed an oral antipsychotic only (including clozapine), compared with 56% of patients in medium security and 52% of patients in low security (*Table 2*). It emerged that 13% of patients with schizophrenia in high security were prescribed a depot antipsychotic only, compared with 28% of patients in medium security and 37% of patients in low security. Owing to the relatively small sample sizes, data from the two medium secure hospitals and one low secure hospital were combined for statistical analysis, as shown in *Table 3*.

Oral and depot antipsychotic prescribing for schizophrenia in high security and the other hospitals

	High secure hospital	Other hospitals <i>a</i>	Total, <i>n</i>
One type of regular oral antipsychotic only, <i>n</i> (%)	98 (70)	69 (55)	167
One type of regular depot antipsychotic only, <i>n</i> (%)	18 (13)	39 (31)	57
Other, <i>b n</i> (%)	23 (17)	18 (14)	41
Total, <i>n</i>	139	126	265

Medium secure hospital 1, medium secure hospital 2, low secure hospital.

More than one type of antipsychotic prescribed regularly, no regular antipsychotic prescribed.

Chi-square testing revealed a significant difference in the rate of prescribing of oral and depot antipsychotic medication between the high secure hospital and the other hospitals ($\chi^2 = 12.78$, d.f. = 2, $P < 0.01$). The data suggest that more oral medication was used in high security and more depot medication was used in the other hospitals. *Table 4* shows the route of medication administration for patients with schizophrenia broken down by ethnicity. When medication was prescribed (i.e. excluding the 'no antipsychotic prescribed' category), chi-square analysis showed a statistically significant difference between the ethnic groups ($\chi^2 = 6.90$, d.f. = 2, $P < 0.05$); depot antipsychotics appear to be used more frequently for patients from BME groups.

Medication administration for patients with schizophrenia by ethnicity

	Regular depot antipsychotic only	Regular oral antipsychotic only	Regular depot and oral antipsychotic	No antipsychotic	Total
BME patients, <i>n</i> (%)	23 (29.5)	48 (61.5)	5 (6.4)	2 (2.6)	78
White patients, <i>n</i> (%)	34 (18.2)	142 (75.9)	5 (2.7)	6 (3.2)	187
Total	57	190	10	8	265

Consultant questionnaires

The questionnaire was sent to the 34 consultant forensic psychiatrists based at the four secure hospitals in the trust (19 at the high secure hospital, 10 at the two medium secure hospitals and 5 at the low secure hospital), as well as to the 3 forensic consultants working in community forensic services within the same trust. The overall response rate was 78% (74% high secure, 80% medium secure, 80% low secure and 100% community). Limitations in the data collected leave us unable to comment on any differences (e.g. gender, age, years of experience) between consultants who did and did not respond.

Of the hospital-based consultants responding to the questionnaire, 35% expressed a preference for oral medication and 42% expressed a preference for depot medication; 23% did not express a preference. The mean score on the 0–100 scale, where 0 indicated a preference for oral and 100 for depot medication, was 37 (s.d. = 20) for respondents from high security and 74 (s.d. = 22) for respondents from other settings (medium security and low security); ANOVA demonstrated a significant difference between the two groups ($F_{(1,24)} = 19.759, P < 0.01$). Thus, those working in high security preferred oral medications and those working in other settings preferred depot medications.

Most (89%) expressing a preference for oral medications worked in high security. The following reasons were given: convenience for patient, adherence, safety, less invasive, improved engagement, increased patient responsibility and improved therapeutic relationship. Most (73%) expressing a preference for depot medications worked in medium or low security, and their reasons were: adherence, clinical outcome, expectation from next level of security, reduced side-effects, reduced tension between patient and team, easier risk management in community, ‘mental health review tribunal’/‘Ministry of Justice’ reassurance, and reduced adverse events.

All of the community-based forensic consultants expressed a preference for depot medication; stated reasons included adherence, clinical outcome and convenience for the patient.

Community-based forensic consultants were asked two further questions (see Method). It emerged that route of administration was important for consultants when considering whether or not to accept a patient (mean rating for question 1, where 0 was ‘very important’ and 100 was ‘not at all important’, was 31 (s.d. = 17)). Considering question 2, consultants were also likely to accept patients currently prescribed an oral antipsychotic (not clozapine) (mean rating 72 (s.d. = 21), where 0 – very unlikely, 100 – very likely).

Discussion

Findings

This study demonstrates a similar rate of antipsychotic prescribing (97%) as a previous study;⁶ 3% of patients were not prescribed antipsychotic medication. Consultant psychiatrists may opt not to prescribe antipsychotic medication in the context of a drug-free trial related to diagnostic uncertainty or severe side-effects, or because a patient has refused to take such medication.

This study reveals significant differences in the antipsychotic prescribing practices of consultants working in different levels of secure care. Consultants in high security were found to prescribe more oral antipsychotics, and those in medium and low security were found to prescribe more depot antipsychotics. It may be that the likelihood of high secure patients having an extended period of supervised care ahead of them reduces the bearing of adherence on antipsychotic selection.

The overall rate of depot antipsychotic prescribing was lower than that found by Paton⁶ and also lower than that quoted in the Maudsley guidelines.⁹ Polypharmacy was less prevalent than in Paton’s study;⁶ this finding was welcome but perhaps unsurprising as over a decade later the risks associated with polypharmacy are better understood and many trusts have guidelines restricting polypharmacy. The Care Quality Commission also actively discourages polypharmacy. The most common combination of clozapine augmented by a second-generation oral antipsychotic is in keeping with usual approaches to treatment-resistant schizophrenia.

BME patients with schizophrenia were significantly more likely than their White counterparts to be prescribed a depot antipsychotic. This finding builds upon existing research.^{10,11}

Significant differences in the opinions expressed by consultants were found: consultants working in high security preferred oral antipsychotics and consultants working in other settings preferred depot antipsychotics. Overall, 31% of all respondents expressed a preference for oral antipsychotics and 89% of these worked in high security, whereas 48% of respondents expressed a preference for depot antipsychotics and 79% of these worked in medium and low security and the community. Comments from community consultants suggest there is no expectation that patients should be prescribed a depot antipsychotic before they are deemed suitable to be managed by community services.

It is noteworthy that the presence of a community forensic team may mean that the area served by the NHS trust in this study is not typical of other areas in England and Wales. Community forensic services are not available countrywide and it may be that general adult psychiatrists accepting patients from secure services hold different views than their forensic colleagues.

Adherence

Both consultants preferring oral antipsychotics and those preferring depot antipsychotics listed 'adherence' as a reason for their preference. For patients with schizophrenia, poor adherence can be related to forgetfulness, disorganisation, complexity of regime, cost, lack of insight, ambivalence, poor relationship with therapist, stigma, side-effects and lack of perceived efficacy.^{3,12} Higher rates of non-adherence have been reported in patients with schizophrenia prescribed oral medication than those prescribed depot medication¹³ and patients treated with depot medication have been found more likely to continue medication, and to continue it for longer, than patients treated with oral medication. It has been suggested that improved adherence is likely to lead to better clinical and functional outcomes.¹⁴

Stone & Niz¹⁵ found that non-adherent patients with schizophrenia were more likely to enter the criminal justice system and suggest that consideration be given to using depot antipsychotics (or clozapine) as a first-line treatment for offenders with schizophrenia. Arango *et al*¹⁶ studied patients with schizophrenia and a history of violence. Of those who were violent again, those prescribed oral antipsychotics were violent sooner, and more frequently, than those prescribed depot antipsychotics. The authors link improved adherence to reductions in violence. It may therefore appear counterintuitive that the forensic population studied were prescribed less depot medication than patients in an earlier, mixed population, study⁶ and the rates quoted in the Maudsley guidelines.⁹

Efficacy

Reviews comparing the efficacy of oral and depot antipsychotics^{12,17} report that mirror-image and some large cohort studies have favoured depot preparations but randomised controlled trials (RCTs) have not.

Lafeuille *et al*¹⁸ compared outcomes in patients who relapsed on an oral medication and were then 'switched' to a depot antipsychotic with those who remained on an oral medication. 'Switched' patients had fewer readmissions and fewer emergency presentations. Johnson¹⁹ found that 33 months after being discharged from hospital, 40% of patients prescribed depot antipsychotics relapsed, in comparison with 60% of patients prescribed oral antipsychotics. David & Adams' review³ of non-forensic patients with schizophrenia identified little difference between oral and depot antipsychotics in terms of relapse rates or side-effects, but depot formulations were found superior in bringing about 'important global change'. Leucht *et al*²⁰ present a systematic review and meta-analysis of 10 RCTs carried out between 1975 and 2010; there were significantly fewer relapses in out-patients prescribed depot medication than in those prescribed oral medication.

Psychiatrist attitude

Haddad *et al*²¹ report that 50% of psychiatrists said that their use of depot antipsychotics had reduced in the previous 5 years, and 23% said that their use had increased (the 5-year time-span included the introduction of second-generation depot agents). Despite 89% opining that depot administration was associated with better adherence, and 98% opining that depot administration was associated with reduced relapse rates, only 4% said that depot was their 'first choice' route of administration for patients requiring long-term treatment. The findings from the current study may go some way in explaining the possible cognitive dissonance demonstrated by Haddad *et al*'s findings, i.e. consultant psychiatrists may consider many things other than adherence when deciding on antipsychotic treatment.

Potkin *et al*²² reviewed prescriber-patient conversations and found that depot antipsychotics were discussed only half of the time when a patient prescribed an oral antipsychotic wished to discuss a change in medication.

Advantages and disadvantages of depot antipsychotic medication

Previous studies have commented on perceived advantages and disadvantages of depot medications.^{1,3,12–14,19,22,23} Advantages have included a more constant plasma level, improved bioavailability, reduced availability of medication for overdose, improved adherence, more time to intervene when non-adherence is identified, reduction in family conflict and reduced treatment costs. Studies assessing patient attitude towards depot medication have revealed generally positive attitudes.^{3,22}

Disadvantages have included concern about side-effects, effect on therapeutic relationship, risk of high-dose prescribing, inappropriateness of use post-neuroleptic malignant syndrome, less flexibility and delayed response (i.e. mental state improvement on initiation, side-effect reduction on discontinuation). Potkin *et al*²² found that the usual reason for a patient declining depot medication was needle phobia.

This study adds to the existing literature by providing a forensic perspective on the advantages and disadvantages of depot medication.

Limitations

This study encountered a number of limitations which restrict the generalisability of the findings to wider forensic and indeed non-forensic settings. These include the small sample size, particularly with regard to the community consultants, the use of a non-validated questionnaire, and not including patients in the private sector (who in 2007 accounted for 35% of patients in England).²⁴

Clinical implications

Community teams caring for forensic patients with schizophrenia do not seem to have an expectation that patients should be prescribed a depot antipsychotic medication before they are deemed suitable for their service. It could be argued that given the relatively low rate of depot antipsychotic prescribing found in this study, and the superiority of depot preparations in terms of adherence, readmission and relapse rates, 'important global change' and, notably, risk of violence revealed through this literature review, consultants working with forensic populations should consider taking steps to increase their use of depot antipsychotic medications.

Directions for future research

Future research could attempt to evaluate the opinions of a more representative sample of consultant forensic psychiatrists, or the opinions of general adult psychiatrists and non-medical practitioners, particularly nurses,³ who may be expected to receive the handover of patients formerly known to forensic services. It would also be interesting to establish whether or not the perceived effectiveness of different types of antipsychotics influences prescribers' choices. Future research could further explore the finding that BME patients are more likely to be prescribed a depot antipsychotic than their White counterparts. It may also be useful to undertake a follow-up study, where patients stepped down from high or medium security are followed up some time after discharge and any changes in antipsychotic prescription are identified and investigated.

We are grateful to Dr Chris Clark, Dr Simon Gibbon, Dr Najat Khalifa and Sarah Brennan for their help and advice.

1.6.31 Niemann–Pick type C disease – the tip of the iceberg? A review of neuropsychiatric presentation, diagnosis and treatment

2017-4

Abstract

Niemann–Pick type C (NP-C) disease is a rare neurodegenerative lysosomal storage disorder. It is highly heterogeneous, and there is limited awareness of a substantial subgroup that has an attenuated adolescent/adult-onset disease. In these patients psychiatric features, often a psychosis, may dominate the initial impression, although often there is an associated ataxia and cognitive impairment. Typically, patients experience a substantial diagnostic delay. In this review we highlight the importance of early recognition and discuss the pathophysiology, neuropsychiatric presentation and recent changes in the investigation and work-up of these patients, and treatment options.

- *Summary*

Inborn errors of metabolism (IEM) are a collection of diseases that result from a deficiency in a metabolic pathway (usually an enzyme), leading to altered intracellular synthesis and catabolism.¹ IEMs are individually rare but collectively common. Most are diagnosed during childhood, but there is increasing awareness of later-onset variant forms that may present in adults, often with a mix of both cognitive and psychiatric problems.²

Niemann–Pick type C (NP-C) disease is a neurodegenerative, pan-ethnic, globally occurring lysosomal storage disorder. Lysosomal storage disorders are a subgroup of nearly 60 IEMs that also includes Gaucher’s disease, Tay–Sachs disease and the mucopolysaccharidoses. Although the lysosomal storage disorders are individually rare, their collective prevalence is 1:5000;³ they are usually the consequence of an enzyme deficiency and follow an autosomal pattern of inheritance. NP-C is rare, with a ‘classical’ clinical incidence of approximately 1:100 000.^{4–7} It follows an autosomal inheritance pattern, the result of mutations in one of two genes: *NPC1* (chromosome 18q 11–12) or *NPC2* (chromosome 14q 24.3),⁸ with *NPC1* accounting for 95% of cases.^{4,6} However, unusually, neither of these genes encodes an enzyme; they encode intracellular transporter proteins: *NPC1*, a late endosome/lysosomal transmembrane-bound protein and *NPC2*, a soluble protein.⁹

NP-C, like many other IEMs, has historically been considered a severe neurological and systemic disease of children, but this does not reflect the wide range of its presentations and severities. In a substantial subgroup of patients the illness has an adolescent/adult onset, with cognitive decline and neuropsychiatric symptoms predominating and survival that can extend even into their 7th decade.¹⁰ Most of these patients never receive an accurate diagnosis and for those who do, it is often after many years’ delay with frequent misdiagnoses.^{1,4,10–12}

This is a timely review of adult- and adolescent-onset NP-C. A recent publication suggests that the frequency of this late-onset disease may be far higher than the 1:100 000 ‘classical’ incidence.^{4–7,13} Wassif *et al*⁶ predicted a prevalence as high as 1:19 000–36 000, based on exome sequencing data of known disease-causing mutations. With easier and more readily available diagnostic tests, a disease-specific treatment⁴ and ongoing clinical trials, there has never been a more important time for a heightened awareness of NP-C.

Pathophysiology

The lysosome is an intracellular organelle, often termed the recycling centre of the cell. It has an acidic interior containing hydrolytic enzymes (hydrolases). These hydrolases, together with the integral transporter proteins (such as NPC1 and NPC2), traffic, break down and recycle cellular products. A defect in these results in the accumulation of partially metabolised substrates and a shortage of other lysosomal products. This ‘traffic jam’ leads to a complex chain of events, resulting in cell dysfunction and death and the consequent disease phenotype.

NP-C was described more than 100 years ago by Albert Niemann as an infantile disorder with hepatosplenomegaly and neurodegeneration,⁹ but the exact function of the NPC1 and NPC2 proteins has still to be fully elucidated. We know that a loss of function of either results in an identical clinical phenotype, suggesting a shared pathway for the two proteins. NPC1, a large transmembrane protein of the late endosome/lysosome and NPC2, a soluble lysosomal protein,⁸ work cooperatively to traffic intracellular lipids. Loss of function in either protein leads to the accumulation of cholesterol and a range of sphingolipids in the late endosomal/lysosomal intracellular compartment. This disrupts lysosomal calcium homeostasis, resulting in a host of secondary cellular trafficking defects.¹⁴ The neuropathological sequelae

of these defects include Alzheimer's-like neurofibrillary tangles, neuronal degeneration, neuroaxonal dystrophy and demyelination.⁶⁻¹⁸ Also, as endogenously synthesised cholesterol is necessary for axonal membrane maintenance and repair, white matter tracts are severely affected, with the corpus callosum showing the most striking axonal loss.^{18,19} Purkinje cells of the cerebellum, basal ganglia and thalamus are characteristically vulnerable in NP-C, leading to the often pronounced cerebellar dysfunction and ataxia in NP-C patients.¹⁵

Neuropsychiatric presentation

An organic cause can be found in a sizeable proportion of patients presenting with psychosis. For example, Johnstone *et al*²⁰ showed that a causative organic disease could be found in 6% of patients with a first episode of psychosis. Several IEMs are known to cause both psychoses and cognitive decline in adults. A recent systematic review² highlighted six metabolic disorders that should be considered in adult patients with psychosis: homocysteine metabolism disorders, urea cycle disorders, Wilson's disease, acute porphyrias, cerebrotendinous xanthomatosis and NP-C.

NP-C can vary widely in both age at onset and symptoms. A useful classification system subdivides NP-C into four groups based on the onset of neurological disease: early infantile/late infantile/juvenile/adolescent/adult onset.⁴

Typically, the earlier the onset of neurological disease, the more aggressive the disease process (*Fig. 1*).^{4,21,22}

Patients with adolescent/adult-onset NP-C have a neuropsychiatric disease involving varying degrees of cognitive decline, psychiatric and neurological symptoms.⁴ At presentation, psychiatric symptoms often dominate the clinical impression, and a substantial period may pass before neurological symptoms develop or are recognised by treating clinicians.²² In many patients this delay is confounded by early neurological features, commonly an ataxia misinterpreted as a side-effect of psychotropic medication, and the challenge of eliciting subtle cognitive decline in a depressed or psychotic patient.^{22,24} This diagnostic delay is often measured in years or sometimes even decades,^{10,24} with patients frequently receiving a range of incorrect neurological and psychiatric diagnoses before NP-C is confirmed. Incorrect diagnoses made in patients with NP-C include:¹² psychotic syndromes/Alzheimer's disease and frontotemporal dementia/progressive supranuclear palsy/Parkinson's disease/parkinsonism/spinocerebellar ataxia/Wilson's disease/multiple sclerosis/Creutzfeldt-Jakob disease/Wernicke encephalopathy.

Cognitive decline

The neurodegenerative disease leads to dementia in almost all NP-C patients. NP-C is sometimes referred to as 'childhood Alzheimer's'. Although this is used as an easy identifier rather than for its accuracy, the two diseases share some neuropathological features.

In patients with adult/adolescent onset, cognitive decline features to a greater or lesser extent in almost all cases. If found in combination with other disease features, further investigations should be performed.²⁵ To highlight a possible diagnosis, the three most useful clinical features are: cognitive decline, psychosis and progressive ataxia. Consequently, these have been utilised in a patient group-initiated awareness campaign 'Think again, think NPC' (<http://think-npc.com>). This clustering of symptoms to help identify patients has been further investigated by Wijburg *et al*²⁵ who have developed 'The NP-C Suspicion Index'. This index attributes scores to different clinical features to identify the likelihood of a patient having NP-C, with pre-senile cognitive decline (< 40 years) considered a strong indicator.²⁵

The cognitive profile in adult patients with NP-C usually starts with problems in word fluidity, working memory and executive dysfunction.^{4,8,26} There may also be a frontal lobe syndrome with perseveration and loss of interpersonal distance that manifests as excessive familiarity.²⁶ At this early stage of cognitive impairment, the Mini-Mental State Examination (MMSE) often fails to identify deficiencies in these areas. However, with disease progression, a more global impairment of function develops, meeting the diagnostic criteria for dementia.^{4,5,21,22}

Psychiatric symptoms

Psychiatric symptoms associated with NP-C can vary. In juvenile- and adolescent-onset patients, intellectual disability, behavioural problems and attention-deficit hyperactivity disorder (ADHD) have been reported.^{4,11,22} Many of these patients receive further psychiatric diagnoses at a later stage.⁴ One case report describes a patient with an autism spectrum-like disorder preceding a schizophrenia-like illness before eventually receiving their final diagnosis of NP-C.²⁷

In adult patients both affective disorders and psychoses are reported.^{4,5,22} An NP-C case series describes general psychiatric symptoms in 38% of early adult-onset patients,²² with the literature suggesting that a schizophrenia-like disorder is found in 25–40% of adolescent- and adult-onset NP-C patients.^{4,22} This psychiatric disease may initially be indistinguishable from schizophrenia, with auditory hallucinations, delusions and disorders of thought and behaviour; however, certain features are suggestive of an organic cause: neurological or visceral features, cognitive impairment, treatment resistance or even a paradoxical worsening of psychosis with drug therapy, visual hallucinations, unusual in classical forms of schizophrenia.⁴

Although the psychosis may be resistant to therapy, atypical antipsychotics can be useful, but caution should be taken to avoid worsening of any pre-existing dystonia.^{4,18}

Other major psychiatric illnesses described in NP-C include: depression generally susceptible to selective serotonin reuptake inhibitor (SSRI) therapy,⁴ bipolar disorder, often sensitive to mood stabilisers such as sodium valproate^{4,18} obsessive-compulsive behaviour, catatonia, often in younger patients and sometimes resistant to treatment, although electroconvulsive therapy (ECT) has been used successfully.^{4,18}

Neurological features

Adolescent- and adult-onset NP-C patients almost always have some neurological features at presentation, although these may at first be subtle and eclipsed by psychiatric features. In the more aggressive late infantile/juvenile-onset group, patients are often first described as being clumsy and struggling at school. This then progresses to the development of frank neurological disease that may include limb and gait ataxia, seizures, gelastic cataplexy (the loss of muscle tone with emotional stimuli), dysarthria, dystonia, dysphagia and dementia. Prognosis in these patients is poor, with death from the consequences of their advanced neurological disease typically in their late teenage years or early adulthood.^{4,7}

Adolescent and adult patients share some of these disease features, but in their case the illness is more insidious in its onset and slower in progression. Cerebellar dysfunction, especially ataxia, is the most commonly identified neurological feature, although dysarthria and dystonia are also frequently present.^{4,18,22} Interestingly, epilepsy, common in infantile and juvenile disease, and cataplexy (20% of classical NP-C patients), are both rarely seen.²²

The most important neurological sign in NP-C, as it is both highly prevalent and specific, is a vertical supranuclear gaze palsy (VSGP).^{4,7} VSGP is seen in only a limited number of other neurodegenerative diseases and rarely so early in their disease process. In NP-C it nearly always heralds the onset of the neuropsychiatric disease, regardless of the patient's age.^{4,22}

The gaze palsy, initially in the vertical plane, progresses to also involve horizontal eye movements as the brainstem pathology advances. Initially, the VSGP is subtle and may be missed. It involves vertical voluntary saccadic movements only, especially of downward gaze, and at this stage slow pursuit eye movements are preserved.⁴ If saccadic eye movements are not tested, the initial VSGP will be missed. Saccadic eye movements are easily tested by requesting the patient to look up and then down in quick repetition. (See <http://think-npc.com/could-it-be-np-c> for a video demonstrating saccadic eye movement testing in NP-C.)

Systemic features

NP-C is a neurovisceral disease, but in adolescents and adults the visceral component is rarely of clinical significance, although splenomegaly with or without hepatomegaly is usually present.⁴

In the perinatal and early juvenile forms, systemic manifestations may be pronounced, with severe and sometimes fatal liver and pulmonary disease.⁴ Interestingly, regardless of the patient's age, visceral disease, when present, always precedes neuropsychiatric features, often by years or even decades. The severity of this visceral disease offers little insight into the likely onset or severity of the patient's later neurological disease.^{4,5} There are cases of patients with paediatric liver disease who only develop neuropsychiatric features many decades later in adulthood.¹²

In adolescent- and adult-onset patients, hepatosplenomegaly – although frequently present – is often unrecognised. When present it is usually less pronounced and nearly always asymptomatic.⁴ The proportion of patients with hepatosplenomegaly in one case series was 85%, but within the adolescent/adult cohort it was reported lower, at nearer to 50%.⁵ However, another group reported that splenomegaly (with or without hepatomegaly) was found on abdominal ultrasound in closer to 90% of patients, regardless of the patient's age.^{4,22} Because of this, Bonnot *et al*² incorporate an abdominal ultrasound scan into their diagnostic 'work-up' algorithm for IEMs causing a schizophrenia-like illness.²

A patient with splenomegaly (especially in the absence of liver disease) with a co-existent neurodegenerative or psychiatric disorder is strongly suggestive of NP-C⁴ and should be appropriately investigated. A history of paediatric liver disease in such patients should also raise clinical suspicion.

Investigation and diagnosis

Rapid advancements in gene sequencing and liquid chromatography/tandem mass spectrometry (LC-MS/MS) have led to significant change in the available approaches to diagnosing NP-C, with both easier and more affordable tests available or in development.²⁸

Bonnot *et al*² suggest an algorithm for the work-up of a patient with a schizophrenia-like illness and a possible IEM. They suggest that with initial suspicion, a clinical and ophthalmological assessment and a cerebral magnetic resonance imaging (MRI) scan should be performed. Subsequent investigations should be performed based on these findings, with an abdominal ultrasound scan to identify hepatosplenomegaly if NP-C is considered. If this is positive, then disease-specific NP-C tests can be performed.² However, this pragmatic approach has some limitations: not all patients with NP-C have hepatosplenomegaly,^{4,5,22} and with easier plasma diagnostic tests available these should be performed earlier in the diagnostic process.

Historically, the diagnosis of NP-C was made histopathologically, by both cholesterol esterification studies and filipin staining of cultured skin fibroblasts,⁴ with most patients receiving a combination of different tests performed prior to this good, but costly and difficult, definitive investigation. These tests may have included: chitotriosidase measurements, white cell enzyme studies to exclude other lysosomal storage disorders, and fluorescent and electron microscopy of both bone marrow aspirate and liver biopsy specimens.²⁸ Because of the difficulties with the filipin staining test, the most widely performed and accessible definitive diagnostic test is now the sequencing of the *NPC1* and *NPC2* genes. Next-generation sequencers make this far easier to perform, especially if the genes concerned are included on a multi-gene panel appropriate for patients presenting with a certain disease phenotype – such as neonatal cholestatic jaundice.²⁹ But this approach is not without some limitations either. In 10% of patients only a single pathogenic mutation can be identified, and in some patients new mutations of uncertain clinical significance may be identified.

More recently, highly specific and sensitive oxidative cholesterol metabolites for NP-C have been identified.³⁰ This 'oxysterol test' can be performed on a plasma sample and is now used as the first-line diagnostic test with subsequent genetic confirmation at one of the principal UK reference laboratories for lysosomal storage disorders. Although it has a positive predictive value of > 97% in an NP-C enriched population such as infants with cholestatic jaundice,²⁸ its accuracy as a screen in broader populations is still being clarified. With the recent advances in LC-MS/MS, other candidate metabolites for diagnostic tests are being identified, with several in the pipeline. These are likely to be available in the near future as cheaper and widely accessible plasma or urine diagnostic tests.²⁸

Treatment options

Disease-specific treatments

Miglustat, a small iminosugar molecule, is licensed in the European Union for the treatment of the progressive neurological manifestations of NP-C in both adults and children.⁴ It reduces the accumulation of the downstream toxic metabolites, glycosphingolipids (GSL), by competitively inhibiting the first step in their synthesis.³¹ It has been shown to stabilise certain key neurological manifestations in a randomised controlled trial (RCT), a retrospective cohort study and in clinical experience.^{4,32,33} However, in adults it may take a year or longer to identify a discernible clinical benefit.⁴

Multiple other therapies are currently under clinical investigation for NP-C, of which two studies are at the Phase 2b/3 pivotal trial stage: arimoclomol, a small molecule that induces the heat shock protein response – a normal cellular stress response³⁴ cyclodextrins, ring-like sugar molecules that reduce lipid storage and in animal models have both substantially reduced the burden of disease and greatly prolonged lifespan.^{35,36}

Symptomatic treatments

Complex neuropsychiatric diseases have a profound effect on the patient, their family and carers. Consideration of the patient's nutritional status, swallow safety and toileting/bowel function, as well as their mobility and safety, is important, with a multidisciplinary team involved and access to appropriate agencies as needed. Timely discussions around issues of capacity, care and end-of-life planning are also necessary.

Cognitive impairment

Appropriate support services should be involved. Although miglustat may stabilise the cognitive decline, there is no evidence that cognitive-enhancing drugs such as cholinesterase inhibitors have a beneficial role.⁴

Psychiatric illness

Psychosis usually responds to antipsychotic medications, but some NP-C patients are resistant to treatment or even show (paradoxical) worsening with the initiation of drug therapy (a useful diagnostic red flag in unidentified NP-C). Atypical antipsychotics should be used and frequent neurological assessments performed to identify worsening of any pre-existing dystonia. If it occurs, dose reduction or an alternative antipsychotic may be used, supplemented if necessary with sodium valproate.⁴ Depression typically responds well to SSRIs,³⁷ and in some patients, when effectively treated, this leads to improvements not only in their mood but also their cognition and neurological disease. Bipolar disorder in NP-C has responded to mood stabilisers such as sodium valproate and catatonia has been treated successfully with ECT.^{4,18} Sleep disturbance in NP-C may manifest as sleep inversion, narcolepsy or obstructive sleep apnoea and can be treated with melatonin and continuous positive airway pressure ventilation (CPAP).⁴

Neurological disease

Patterson *et al*⁴ have published recommended treatment strategies for a range of different NP-C neurological complications.

Prognosis

Accurate prognostic predictions in NP-C are difficult. There is poor genotype-phenotype correlation in disease course, with affected siblings not infrequently following different disease trajectories. The extent and severity of visceral disease offers little insight into the severity of later neurological disease, an additional challenge when counselling parents of a newly diagnosed infant with liver disease.

The most useful prognostic indicator is the age at neuropsychiatric disease onset.

Summary

The largest subgroup of NP-C patients is likely to be an undiagnosed/misdiagnosed adult population with a neuropsychiatric disease. Consequently, NP-C highlights the need for continual diagnostic review in patients with psychosis, especially if there is coexistent cognitive decline and/or ataxia.

1.6.32 The mini-PAT as a multi-source feedback tool for trainees in child and adolescent psychiatry: assessing whether it is fit for purpose

Gill Salmon Lesley Pugsley

Correspondence

Gill Salmon (Gill.Salmon@wales.nhs.uk)¹

date

2017-4

Abstract

This paper discusses the research supporting the use of multi-source feedback (MSF) for doctors and describes the mini-Peer Assessment Tool (mini-PAT), the MSF instrument currently used to assess trainees in child and adolescent psychiatry. The relevance of issues raised in the literature about MSF tools in general is examined in relation to trainees in child and adolescent psychiatry as well as the appropriateness of the mini-PAT for this group. Suggestions for change including modifications to existing MSF tools or the development of a specialty-specific MSF instrument are offered.

- *Potential issues with using MSF tools*
- *Does the mini-PAT suit the needs of trainees in child and adolescent psychiatry?*
- *Conclusions*

Multi-source feedback (MSF) can motivate doctors to improve and change their practice.^{1,2} It gives doctors an overview of how others see them and compares this with their own view as well as the results of their peer group.³ MSF evolved in Canada and the USA out of a public demand for accountability to patients as well as an acceptance that assessments examining clinical decision-making and medical expertise do not address other essential competencies, such as interpersonal skills, professionalism and communication.³ MSF tools were originally designed to be formative, that is, to lead to awareness of and improvements in performance through feedback. More recently, however, they are being used for summative purposes, namely to provide information for revalidation and the annual review of competence progression (ARCP) which determines whether a trainee is considered fit to proceed with their training. As such, MSF tools need to be sufficiently reliable and valid. Reliability refers to the reproducibility of assessment measures or scores over repeated tests under identical conditions, and validity refers to the degree of confidence that an assessment measures what it is intended to measure. An associated term, feasibility, is a measure of whether an assessment instrument is practical, realistic and sensible given the circumstances and context.⁴

Research on the use of MSF for doctors

Ramsey *et al*⁵ published a landmark study showing that it was feasible for internal medicine physicians to obtain peer assessments about their humanistic qualities, clinical practice and communication skills. They also came to important conclusions about the reliability of MSF – for example, that 11 peer ratings were needed to ensure a reliability coefficient of 0.7 (the minimum acceptable for workplace-based assessments (WPBAs)) and that the results were not substantially affected by the relationship between the rater and the person being rated nor by the method used to select the raters. The findings of this study also suggested that a doctor's medical knowledge (determined by examination marks) was not predictive of how peers subsequently rated their interpersonal relationships or communication skills.

The finding that reliable and valid MSF questionnaires can be developed and be feasible to use for assessing doctors has been replicated across settings and specialties.^{2,6–9} A number of systematic reviews have also been published, all of which conclude that MSF as a method of assessing communication skills, collegiality, humanism and professionalism in doctors has high reliability, validity and feasibility.^{10–15}

The mini-PAT as an MSF tool

The mini-PAT is used by the Royal College of Psychiatrists as an MSF instrument for trainees. It is well known because of its widespread use in the Foundation Programme.^{16,17} The mini-PAT was derived from the Sheffield Peer Review Assessment Tool (SPRAT) following a mapping exercise against the foundation curriculum,⁶ thus ensuring its content validity. The SPRAT contains 24 questions assessing a doctor's competencies and professional attributes, and it maps directly on to General Medical Council (GMC) standards of good medical practice,¹⁸ again establishing its content validity. These standards include good clinical care, maintaining good medical practice, teaching and training, appraising and assessing, relationships with patients and working with colleagues. The SPRAT was the first MSF tool validated in the UK for use by paediatric consultants as part of their appraisal.¹⁹ It has also been shown to be reliable, needing as few as four raters to determine whether a doctor is in difficulty or not (more in borderline situations), and feasible, taking only 5–6 minutes to use with good return rates (more than 70%).²⁰ It can also discriminate between the more and less experienced trainee.²¹

In developing the mini-PAT, nine questions which did not map on to the curriculum for the Foundation Programme were removed from the SPRAT. These included questions relating to the management of complex patients and leadership. One question about probity and health was added while the free-text element and six-point scale (where 1 indicates 'very poor' and 6 indicates 'very good') remained unchanged.⁶ The resulting mini-PAT was thought to reflect the importance for foundation doctors of developing communication skills, team work and other humanistic qualities in relation to patient care in addition to their medical knowledge.³

In his critical analysis of the mini-PAT, while accepting its content validity and feasibility, Abdulla stated that it 'lacks sufficient field evaluation and has not gone through any stringent criteria that are required for the validation of an assessment tool'.³ Data on the reliability and validity of 693 mini-PAT assessments on 553 foundation year 1 and 2 (F1/F2) doctors have subsequently been published.⁶ The mean scores of the two groups were found to be significantly different when using the same criterion standard (i.e. expectation for F2 completion), with 19.6% of F1s and 5.6% of F2s being assessed as borderline or below the expectations for F2 completion. This was used as evidence of internal standardisation and construct validity, as was the finding that the trainees scored higher in the domains of working with colleagues and relationships with patients compared with the clinical skills domains. Overall, 53% of F1 doctors and 74% of F2 doctors could have been assessed by no more than 8 assessors based on their mean scores. Factor analysis revealed that the two main factors were humanistic qualities and clinical performance. The authors concluded that the mini-PAT was a valid and reliable MSF tool for assessing foundation doctors.

Use of the mini-PAT in child and adolescent psychiatry training

In child and adolescent psychiatry, the process when using the mini-PAT is as follows: twice a year, the trainee provides contact details of between 8 and 12 co-workers who see them on a frequent basis in a range of situations. These people and the trainee then complete the mini-PAT online. Presumably based on the findings of Archer *et al*,⁶ it is suggested that at least 8 forms must be completed to ensure the assessment is reliable. There is, however, no research specifically related to the mini-PAT on the minimum number of assessors required to give a valid result.³ The form uses a 6-point Likert-type rating scale. Trainees are rated according to the standard expected at each stage of training. A score of 4 corresponds to the expected standard, with higher or lower scores suggesting the trainee's performance is better or worse.²² The responses are analysed centrally and a report is then sent to the trainee's educational supervisor who delivers the feedback in person.²³

Potential issues with using MSF tools

Several issues that have been identified in relation to the use of MSF tools for medical practitioners in general are also relevant to their use in child and adolescent psychiatry. One is the trainee's choice of rater. Although several authors have found that MSF assessment is not necessarily biased by allowing the doctor to select their own raters,^{5,24,25} others have found that factors such as the seniority, gender and profession of raters can significantly influence the assessment. For example, Archer *et al*²¹ found that consultant raters using the SPRAT gave significantly lower mean scores to paediatric trainees than more junior doctors did; similarly, Bullock *et al*²⁶ found that consultants and senior nurses were more likely to give 'concern' ratings when assessing junior doctors than were peers or administrators. Thus, there is a trend for assessors to be more critical with increasing seniority. When considering the mini-PAT, Archer *et al*⁶ found that assessors' scores were affected by their occupation, the length of time the trainee had been working with them, and the working environment. They suggested standardising the number of consultants used as raters by each trainee. These findings support the need for more detailed guidance in rater selection from the Royal College of Psychiatrists. Trainees are currently only advised that raters be chosen from a broad range of co-workers.⁴ In addition, Abdulla³ suggests that selection bias can be reduced if the list of raters is discussed and agreed on beforehand with the trainee's supervisor.

Measurement errors, such as the central tendency and halo effect, can also occur and are particularly likely when behaviours which cannot be easily observed are being assessed.²⁷ A particular issue for non-doctor raters is knowing what standards they should expect for a doctor at that stage in their training. In an attempt to reduce measurement errors, Abdulla³ suggests better education for mini-PAT raters. This could be provided by the Royal College of Psychiatrists as part of their online mini-PAT package.

It has been shown that doctors' self-assessments do not correlate well with peer or patient ratings.^{7,28} Violato & Lockyer²⁹ studied psychiatrists, internal medicine physicians and paediatricians, and found that all were inaccurate in assessing their own performance. Those psychiatrists who were rated by peers to be in the bottom quartile saw themselves as 'average', whereas the psychiatrists in the top quartile significantly underrated themselves. This indicates that poorly performing doctors often lack insight, not always accepting negative feedback from others and querying its validity.³⁰ Overeem *et al*³¹ advise that trained facilitators should encourage trainees to reflect on MSF results and help them set concrete goals for improvement. Offering coaching to help trainees identify their strengths and weaknesses

may help facilitate changes in performance.³² Making the feedback highly structured can help trainees acknowledge feedback from all sources rather than just the medical scores which they tend to value more.^{5,33–35} Although taking the mean of the scores may be the most reliable approach,³⁶ attention should also be given to the free-text comments which might highlight specific performance issues and which may also make the feedback more acceptable.³⁵ These findings highlight the importance of the MSF feedback process, which should include the development of a relevant action plan in collaboration with the doctor.

It has been proposed that a single, generic MSF tool be used in the UK.³⁷ Research supporting this includes Violato & Lockyer's^{29,38} study of the use of one MSF tool for internal medicine physicians, paediatricians and psychiatrists. Although they found no specialty differences in response rates or reliability, it is of note that of the items clustered into the same four factors across the specialties, for psychiatry the most discriminating factor was communication whereas for the other two specialties the most important was patient management. By contrast, Mackillop *et al*³⁹ evaluated the use of a generic MSF tool across specialties and concluded that, although the generic content was appropriate for most specialties, some would benefit from specialty-specific content.

Does the mini-PAT suit the needs of trainees in child and adolescent psychiatry?

In child and adolescent psychiatry, the mini-PAT is currently used to assess trainees. Although the mini-PAT has content validity for foundation doctors, having been mapped against their curriculum, this does not necessarily mean it is also a valid tool for other grades or for use across specialties. In the making of the mini-PAT, some questions were removed from the SPRAT, namely those relating to management of complex patients and leadership.⁶ However, these items are highly relevant to trainees in child and adolescent psychiatry. Davies *et al*⁴⁰ modified the SPRAT for trainees in histopathology following a blueprinting exercise against the histopathology curriculum to establish content validity. They concluded that specialty-specific MSF is feasible and achieves satisfactory reliability. A similar approach blueprinting the SPRAT against the child and adolescent psychiatry competency-based curriculum⁴¹ could therefore be considered. The SPRAT also requires fewer raters than the mini-PAT in order for the results to be sufficiently reliable,⁶ thus adding to its potential suitability for child psychiatry trainees who often work in small teams.

Alternatively, a specialty-specific MSF instrument for child and adolescent psychiatry trainees could be developed, to reflect the differences in their practice compared with other specialties and the greater importance placed on communication, interpersonal skills, emotional intelligence and relationship building.⁴ Tools taking these attributes into account have been developed for use with consultant psychiatrists and have been found to be feasible to use as well as being reliable and valid.^{42,43} The child and adolescent psychiatry competency-based curriculum⁴¹ gives details of intended learning outcomes (ILOs), which are either mandatory or selective, some of which tap into these areas. The ILOs range from those that are predominantly clinical (e.g. managing emergencies (mandatory), paediatric psychopharmacology (mandatory) and paediatric liaison (selective)) to those that focus on more humanistic skills (e.g. professionalism (mandatory) and establishing and maintaining therapeutic relationships with children, adolescents and families (mandatory)). The ILO on professionalism includes: 'practicing Child and Adolescent Psychiatry in a professional and ethical manner; child and family centred practice; understanding the impact of stigma and other barriers to accessing mental health services and inter-professional and multi-agency working'.⁴¹ Some of the necessary associated skills which trainees are expected to attain include: supervising junior psychiatric staff, working with colleagues within the team and with other agencies to put the child's needs as central, and acting as an advocate for the child. There is scope to develop this area of the curriculum even further; the American Board of Pediatrics (ABP) published guidelines for the teaching and evaluation of professionalism in paediatric residency programmes⁴⁴ as well as standards of professional behaviour against which paediatricians, including those in training, can be evaluated.⁴⁵ Both are of relevance to child and adolescent psychiatrists.

If developed, a child and adolescent psychiatry specialty-specific MSF instrument would need to map on to the relevant ILOs. It could also include feedback from patients and families (which is not currently routinely collected as part of the WPBAs) to reflect the need to balance the views of the child (who is the patient) with those of their carers.

Conclusions

MSF tools such as the mini-PAT can provide reliable and valid information on areas of a trainee's performance such as communication skills and other humanistic qualities affecting patient care for which other forms of assessment, such as written examinations, are unhelpful. MSF tools have their predominant strength when used for formative assessment and were generally designed for this purpose. They are most appropriately used within a portfolio of other WPBAs and can help in making decisions about a doctor's fitness to practice or to continue training.⁴⁶ Rater bias and measurement error could be reduced by offering more detailed guidance to trainees in their choice of rater as well as to raters in the use of the tool. Measurement error could also be reduced by encouraging trainees to obtain a larger number of returns than the minimum of eight recommended by the Royal College of Psychiatrists.³ The quality of the feedback to the trainee is also important and educational supervisors would benefit from training in this area.

Although the mini-PAT is used widely across specialties, it has only been properly evaluated for use with foundation doctors. Interested researchers, clinicians or educationalists might now want to consider developing a modified version of the SPRAT or a specialty-specific MSF tool that is more appropriate for the needs of trainees in child and adolescent psychiatry. This would reflect the differences in their day-to-day practice compared with that of other trainees but would obviously need to be mapped to the curriculum and evaluated in practice to ensure content validity and reliability.

1.6.33 James Patrick Watson MD, FRCP, FRCPsych

: Formerly Professor of Psychiatry, King's College London and Honorary Consultant Psychiatrist, South London and Maudsley NHS Trust

- *James Patrick Watson MD, FRCP, FRCPsych*
 - *: Formerly Professor of Psychiatry, King's College London and Honorary Consultant Psychiatrist, South London and Maudsley NHS Trust*

James (Jim) Watson, who died after a stroke on 3 August 2016 aged 80, was among a small band of British psychiatrists who trained in the 1960s and 70s to take psychiatry out of the asylums and establish robust services in general hospital and community settings. They were also responsible for developing a wide range of specialist mental health services. Jim was deeply committed to improving the standards of clinical care, from early implementation of behavioural therapy through in-patient group therapies and the understanding and management of behaviour on hospital wards. He championed the relationship between staff and patient as key to recovery in psychiatry, deploring the move to ever fewer acute beds, reductions in staffing levels and organisational changes that resulted in fractured continuity of care and consequent erosion of the essence of good mental healthcare.

His clinical interest was reflected in his research, which included evaluations of community mental health, telemedicine and treatments for psychosexual disorders, for which he established one of the earliest specialist multidisciplinary clinics and training programmes in Britain. With his personal style, he led a vibrant, outward-facing, creative and very happy department, in which a serious commitment to excellence went along with a refreshing lack of pomposity and a keen sense of work being enjoyable. This was in no small part due to Jim's dedication to improving the quality of psychiatric services, not least by ensuring excellence in the education and training of psychiatrists and by making sure that medical students had a varied and stimulating exposure to psychiatry.

Under his leadership, Guy's Hospital Medical School had the enviable reputation of having the highest proportion of medical students opting for a career in psychiatry. In the postgraduate field, he was an inspirational leader of the South East of England training scheme for psychiatry, chairman of the Royal College of Psychiatrists' Specialist Training Committee and chairman of the Association of University Teachers of Psychiatry. In the mid-1990s he launched an MSc in mental health studies – a programme directed at professionals from all disciplines involved in delivering mental health services. This course was extraordinarily successful: consistently oversubscribed, with unprecedented numbers of applicants. Its success spawned further collaborations with university departments overseas, notably in Egypt and the Middle East, where he worked with colleagues to develop a diploma in psychiatric practice for wider dissemination across the region. His determination to improve mental healthcare led him to a lengthy involvement with mental healthcare in Pakistan. From the early 1990s, he collaborated with colleagues there, visiting regularly and helping to train staff for mental health clinics in rural settings that have now expanded to more than 15 centres, some of which are co-located with a mosque and madrasa. Jim was also connected with several other international projects involving, among other countries, Greece and the former Yugoslavia.

Jim was the eldest of three sons. His father was a teacher and his mother a doctor. He attended the Roan School for Boys in Greenwich, where he excelled academically and in sport. He studied medicine at Trinity College, Cambridge, where he was a senior scholar. In 1957 he transferred to King's College Hospital Medical School for clinical studies, qualifying in April 1960. It was there that he met his fellow student and future wife Christine Colley – they were married in April 1962.

After training in psychiatry at the Bethlem Royal and Maudsley Hospitals and Institute of Psychiatry, he was appointed as consultant and senior lecturer in psychiatry at St George's Hospital London in May 1971. He was appointed to the Chair of Psychiatry at Guy's Hospital Medical School in September 1974, steering his department through the union with St Thomas's Hospital in 1982 and onward to the final merger with King's College in 2000. In addition, he served as honorary consultant psychiatrist to the British Army from 1980 to 2000 and was the vice-president of the Royal College of Psychiatrists from 1998 to his retirement.

After retirement, Jim continued to contribute actively to the field, providing teaching and mentorship to psychiatrists in the Sussex Partnership NHS Foundation Trust. He maintained his collaboration with colleagues in Pakistan, advising on setting up a new School of Nursing as well as the development of a service and training resource for children with learning disabilities and autism. He took part in continuing education meetings with colleagues in Cheltenham, chaired a patient support group in a local general practitioner practice and was trustee of the Soundwell Music Therapy Trust which provides music therapy for people suffering from mental ill health.

Jim enjoyed a very happy family life, having four sons whose diverse careers in music, international school teaching, hospital medicine and clinical psychology were a great source of pride and affection. In 2002, he and Christine exchanged London life for a Cotswold home where he could indulge his enthusiasm for vegetable gardening – a throwback to his maternal ancestors who had traded as market gardeners, supplying mustard and cress to Queen Victoria.

Jim's passing will be felt as a great loss to psychiatry and by the many clinical and academic colleagues who had the privilege of knowing and working with him.

1.6.34 Irving Gottesman

: American psychologist and behaviour geneticist who radically changed traditional views of schizophrenia

Peter McGuffin

date

2017-4

Contents

- *Irving Gottesman*
 - : *American psychologist and behaviour geneticist who radically changed traditional views of schizophrenia*

The research and writings of the clinical psychologist and behaviour geneticist Irving Gottesman, who has died aged 85, radically changed the way psychologists and psychiatrists think about schizophrenia and, more generally, about what Irv called the ‘origins of madness’ (which was the subtitle of his 1991 book *Schizophrenia Genesis*).

His path to becoming a dominant figure in psychiatric genetics began at an international conference in 1961 when, as a psychology lecturer at Harvard University, he was introduced to Eliot Slater, director of the Medical Research Council (MRC) psychiatric genetics unit at the Institute of Psychiatry in London, and the doyen of psychiatric genetics of his day.

Slater agreed that Irv might join his unit provided he brought his own funding. Irv duly won a three-year grant from the US National Institutes of Health (NIH) and arrived in London in 1963. Slater was an austere and imposing figure and the building that housed his unit was equally austere, a makeshift postwar prefabricated building, affectionately known by staff as ‘the hut’, on the fringe of the campus of the Maudsley hospital in Camberwell. Although its physical environment was poor, the unit had much intellectual capital, provided by Slater himself, his deputy director Valerie Cowie, a psychiatrist trained in the new techniques of cytogenetics, and a brilliant if self-effacing senior research assistant, Jerry Shields.

The hut also housed another world-class asset, the Maudsley Twin Register. Begun by Slater in 1948, it contained the names of all patients entering the Maudsley and Bethlem Royal hospitals who had been born a twin. Irv’s successful NIH proposal was for a study of schizophrenia using the register and Slater paired him with Shields to carry out the work.

The principle of the classic twin method is straight-forward. Identical or monozygotic (MZ) twins share all their genes, whereas fraternal or dizygotic (DZ) twins share half their genes. MZ and DZ twins usually share the environment in which they are raised. Therefore if a disorder such as schizophrenia shows greater co-occurrence (‘concordance’) in MZ versus DZ twins this is evidence of a genetic effect. Similarly, absence of 100% concordance in MZ twins is evidence of environmental effects. The Gottesman-Shields Twin Study (1967) clearly confirmed the proposition that both genes and environment play a role in schizophrenia (at a time when theorists in the US and Britain were blaming parents, particularly mothers, for ‘causing’ the disorder).

One of Irv and Jerry’s major contributions was to propose a plausible mode of inheritance for schizophrenia. One of the big puzzles about familial common diseases at the time was that none (including physical disorders such as heart disease, diabetes, some cancers) showed the simple ratios of affected:unaffected within families predicted by Mendel’s laws.

The most widely accepted solution for schizophrenia was Slater’s model invoking the idea of a dominant gene with ‘incomplete penetrance’ (some people carry the gene but do not show the disorder). Irv and Jerry boldly proposed an alternative polygenic model, derived from the work of the Edinburgh mathematical geneticist DS (Douglas) Falconer, in which liability to develop schizophrenia has a normal ‘bell-shaped’ distribution in the population (like height or

weight) contributed to by many genes. But, unlike height or weight, there is a threshold effect, so that only the 1% or so of the population with the highest liability show the disorder.

The Gottesman-Shields polygenic model of schizophrenia eventually gained ascendancy, even though the final clinching piece of evidence emerged only in 2014 with the publication of a huge genome-wide molecular study of tens of thousands of subjects showing that more than 100 genes are involved.

Another far-reaching conceptual innovation was their idea of ‘endophenotypes’. Irv and Jerry proposed in their 1972 book, *Schizophrenia and Genetics*, that the genetic basis of psychiatric disorders could be better understood, and specific genes more readily identified, by the discovery of biological characteristics that lie a step closer to DNA than the clinically observable symptoms and signs, the ‘exophenotypes’, by which disorders are defined. Irv continued to elaborate the endophenotype concept over ensuing years and it provoked thousands of papers by others, a sort of Higgs boson for biological psychiatry. Unlike the Higgs particle, the existence of endophenotypes has yet to be proved experimentally for any of the major disorders.

Irv was born in Cleveland, Ohio, to Hungarian-Romanian Jewish emigre parents, Bernard, an insurance agent, and Virginia (nee Weitzner). He was a science enthusiast from an early age and began a physics degree while serving as an officer in the US navy, later switching to psychology. He completed his PhD at the University of Minnesota on the genetics of personality but initially had great difficulty in getting his findings published because of the prevailing orthodoxy in US academia in the late 1950s that behaviour was entirely due to nurture and nothing to do with nature.

After his postdoctoral fellowship in London, Irv returned in 1966 to the biology-friendly department of psychology in Minneapolis and set up one of the first behaviour genetics training programmes in the US. He thereafter held chairs in Washington University in St Louis (1980–85), where I first came under his mentorship as a visiting MRC fellow, and at the University of Virginia (1986–2001), where he set up a clinical psychology doctorate, before returning to Minnesota, where he remained for the rest of his career.

He won many plaudits and prizes worldwide but retained particular affection for and gratitude to the UK, where his recent awards included honorary fellowship of the Royal College of Psychiatrists and King’s College London.

Irv is survived by his wife, Carol (nee Appen), whom he married in 1970, and their sons, Adam and David, and grandchildren, Josh, Ava and Fiona.

Irving Isadore Gottesman, clinical psychologist and geneticist, born 29 December 1930; died 29 June 2016

1.6.35 The Other Side of Silence: A Psychiatrist's Memoir of Depression

Tom Brown¹

date

2017-4

Contents

- *The Other Side of Silence: A Psychiatrist's Memoir of Depression*

Linda Gask is an eminent academic psychiatrist with an outstanding international reputation. I state this upfront because it is none too obvious from this book – owing to her self-effacing style – and in my opinion, it is very relevant. I should also declare an interest as Linda and I were in the same year at Edinburgh University's medical school and I have heard small snippets of this story from her over the ensuing years.

In this excellent book Linda Gask shows what may be achieved despite living with a recurrent depressive illness; hope emerges even from her darkest moments and this work should encourage many. It is striking for its frankness and honesty – no small achievement given that she clearly must have known it would be read not only by colleagues, but by patients past and present, some of whom would have known little about her. She even mentions her failure to pass the MRCPsych exam at the first attempt and describes her – surprising to some! – experience of how sensitive and supportive a very senior academic colleague was at this time.

The book chronicles her life and career and the impact of her illness, including thoughtful reflections on its roots (in her early life). She teaches us about depression through the mirror of her own illness and that of her patients, and brings this to life through the use of clinical vignettes. She emphasises the importance of both biological and psychosocial factors in the origins of this illness and her description of treatments is both fair and accurate. Her accounts of her interactions with patients are particularly helpful and should be of value to any doctor, whether trainee or senior. I especially valued her comments on those whose failure to improve is ascribed to personality disorder, which is, alas, an all too common tactic of many psychiatrists.

This is an exceptional book and should be read by many, both doctors and patients. The high-profile endorsements on the cover are entirely deserved. Some years ago Linda wrote another excellent book entitled *A Short Introduction to Psychiatry*. I gave it to many medical students to read. I will give this to many more.

1.6.36 Mentalisation-Based Group Therapy (MBT-G): A Theoretical, Clinical, and Research Manual

Gwen Adshead¹

date

2017-4

Contents

- *Mentalisation-Based Group Therapy (MBT-G): A Theoretical, Clinical, and Research Manual*

This book presents a challenge for a reviewer because it is both a theoretical text and a technical manual. The technique in question is mentalisation-based group therapy (MBT-G) and one of this book's functions is to assist supervisors of MBT-G in rating therapists on quality of technique and adherence to the MBT-G guidelines. So, at first sight, you might not be drawn to this publication unless you are a group therapist – and trained in MBT-G.

However, I encourage people who are not psychotherapists or trained in MBT to consider this manual as a useful introduction to the concept of mentalising. Mentalisation is an old concept in psychology and refers to our human ability to understand ourselves as agents who make choices and form intentions. This ability includes an understanding and perception of *other* people as having minds that form intentions, which are real and distinct from our own.

All psychiatrists need a valid and reliable model of mind with which to work clinically, and the concept of mentalisation fits the bill. Mentalising capacities are crucial to our social existence, across the lifespan; failure to mentalise successfully is a feature of all mental disorders. The healthy mind is constantly mentalising, with odd lapses in reasoning and dialogue that are neither too severe nor too frequent. When the mind is disordered – through any cause – mentalising fails and immature modes of thinking dominate, often with catastrophic results in terms of social identity and function. The restoration of mentalising then becomes a crucial aspect of all psychiatric treatment.

There are several books on mentalising and mentalisation-based therapy by Karterud's collaborators in the UK (Peter Fonagy and Anthony Bateman) and the USA (Jon Allen). I found this particular book of interest because it approaches mentalising from a philosophical perspective: that of hermeneutics and how we interpret the world. Karterud suggests that the way we interact with and interpret others comes before our experience of our own minds; that the social self is primary in developmental terms. Such a relational approach to mind is a vital complement to models of mind that are either atomistic or mechanical. We have no evidence that the mind works like a machine, but there is growing evidence that the mind is organic and dynamic, responding, developing and evolving in response to the environment – which, for human beings, is the experience of other minds.

MBT is recommended by the National Institute for Health and Care Excellence for the treatment of borderline personality disorder and treatment trials of MBT for antisocial personality disorder are ongoing. But understanding mentalising is a broader objective which all psychiatrists need to achieve. This work is obviously essential reading for trained MBT-G therapists, but it is a useful introduction to mentalising in its own right.

- *The Narcissist Next Door. Understanding the Monster in Your Family, in Your Office, in Your Bed – in Your World*

I find myself split in my thinking about this book. On the one hand, I can see its appeal as an airport read; requiring little effort to get through, and full of celebrity and political commentary as well as easily digestible chunks of scientific evidence.

At that level, it's enjoyable. Especially so when it allowed me to neatly project all my ugly narcissism into reports about Kanye West and Sarah Palin. Perhaps a first for them to be mentioned in the *Bulletin*, no doubt adding to their narcissistic satisfaction, should they or their agents be subscribers.

At another level – and this is where I'm split – it is an exercise in quite contemptuous character assassination. Kluger's portrayal of his example subjects is cold and sneering at times. Furthermore, he often seems to conflate the concepts of narcissism and psychopathy, leading to a sense that the more narcissistic of us are one step away from becoming serial killers or workplace tyrants.

There are only brief mentions of how the presentation of narcissism might be related to inner vulnerability, and this left me wondering if Kluger might have been looking at the mirror crack'd. Even as I write this I wonder if I too am succumbing to the narcissistic appeal to feel superior to what we read – this is hard to contain when I am a UK reader and the author mentions former prime minister 'Malcolm Browne' (referring to Gordon) and the football team 'Aston Vista'. Such mistakes feel sloppy, arousing my narcissistic contempt; perhaps a response to feeling as though the author does not care enough about the UK to check facts properly.

Coming from a psychoanalytic tradition, where this subject has been a preoccupation of clinicians since Freud's 1914 *On Narcissism: An Introduction*, Kluger's view on the dilemma of the narcissist saddened me. We are all narcissists to some degree; it's what allows us to get out of bed in the morning and feel like we are good people who might be loved. The pathological narcissist is someone who has found their early experiences to be lacking and who has lost their trust in acceptance by others. To manage this insufferable situation, they create an outer self that is contemptuous of need and full of itself, and project away their dependent, vulnerable selves onto others. Sometimes, they are contemptuous and dismissive of needy people. Sometimes, if society is lucky, and the person more creative, they will look after others who are vulnerable – to repair the damage they feel inside themselves.

1.6.38 The Vegetarian

Ginevra Read¹

date

2017-4

Contents

- *The Vegetarian*

This short novel, winner of the Man Booker International Prize 2016, is translated from Korean and tells the story of Yeong-hye, a young woman in modern day South Korea. It is a fascinating and thought-provoking narrative that starts with Yeong-hye choosing to become vegetarian. This seemingly unremarkable and straightforward choice turns out to be nothing of the sort – vegetarianism is almost unheard of in Korea but, more importantly, Yeong-hye is on the verge of serious mental illness. Yeong-hye's stance is challenged by all of those around her, but she remains steadfast. It transpires that becoming vegetarian is the prodromal seed of an all-encompassing psychosis which will take Yeong-hye on a journey from being vegetarian to believing that she is vegetal in nature and therefore food is superfluous to her needs.

Clinicians will be acquainted with the somewhat perplexing process by which this intricate and emotive story develops. Information appears not in neat chronological order but in a tangle that needs some work to unpick. Yeong-hye's story is told in three parts. We hear first from her husband, then her brother-in-law and finally her sister, all the while following the unravelling of Yeong-hye's internal and external world, in a tale that deepens in complexity and darkness as it unfolds. Interspersed italicised monologues allow us a brief glimpse of Yeong-hye's muddled (and muddling) mind. By portraying thoughts that mingle with dreams and memories in a way that confuses the reader as to what is real and what is not, Kang elegantly conveys something of Yeong-hye's mental state. We don't hear much about Yeong-hye's premorbid adult life, other than through her husband, who says she was 'ordinary' and functioned to his liking. We can, however, sense the weight of the oppression she is subject to and guess that although becoming vegetarian may have marked an important transition point in her illness, it is unlikely to have been the beginning of it. The husband's account of Yeong-hye's condition reveals, through the lens of his own narcissism, a shocking lack of concern for his wife beyond her role in satisfying his immediate needs. He views Yeong-hye as an object and a possession, and this is most apparent in his remorseless and matter-of-fact description of raping her. A meal with her husband's boss tells us something about society's inflexible expectations and demonstrates that the lack of compassion experienced by Yeong-hye is multifaceted. We see Yeong-hye's father in action and learn a little about her upbringing; as a result, the degree to which she has been repressed and forced to endure throughout her life becomes clearer, and the powerful, subversive resistance enacted through her illness begins to make sense.

The second part of the book is equally disturbing and leads us to the brother-in-law, a less than successful video-artist who becomes obsessed with Yeong-hye's pre-pubertal appearance and whose paraphilic behaviour uncomfortably exposes her vulnerability.

In the final part of the book, several years later, we join Yeong-hye's sister In-hye as she visits her in a psychiatric hospital. In-hye now faces the repercussions of preceding events and the resulting family disintegration. We hear more

about the sisters' childhood and the abuse which they experienced; we learn that In-hye continues to suffer her own anguish as a corollary and that she in some way envies her sister's position.

This is an astonishing book. Strange, surreal and beautifully written. The idea that people could find themselves surrounded by such brutal inhumanity and lack of connection that they reject their current existence and instead opt for transformation into a life form that does not involve thought or feeling is indescribably sad, but probably not beyond imagination for most psychiatrists. Readers will find that they must piece together the jigsaw of Yeong-hye's life, and as hard as they try, the image is not clear and the final pieces can never be found – an experience to which most of us surely relate.

1.6.39 The Psychedelic Policy Quagmire: Health, Law, Freedom, and Society

Adam G. Van Hagen¹

date

2017-4

Contents

- *The Psychedelic Policy Quagmire: Health, Law, Freedom, and Society*

The resurgence of psychedelic research has opened up a new realm of possibilities in consciousness research. However, public policy surrounding the use of psychedelics has struggled to acknowledge that they may be effective therapeutic treatments or tools for enhancing self-awareness and exploring consciousness. Highlighting the need for redress, this anthology argues that current international public policy is not scientifically or culturally informed and is thus divorced from the empirical evidence that is supposed to inform its construction and implementation.

The book examines the complex policy issues surrounding psychedelic-based healing modalities and calls for an urgent shift in policy regulating the research and application of psychedelic substances. At its core, it is a scathing criticism of legal frameworks and regulatory policies that control the use of and research on psychedelics, and goes so far as to suggest that current structures and mechanisms impose a status quo of consciousness, thereby preventing people from fully enacting their right to freedom of religion, thought and conscience. At the very least, policy makers and ethicists need to give due attention to medical and psychotherapeutic research on psychedelics and the role they have in facilitating direct spiritual experiences. This includes acknowledging the transformative effect that experience may have on the self, as well as the right of all people to freedom of religion, thought and conscience.

Any book that rates these substances highly as a connection between the individual, society and the human race as a whole will find its detractors. That being said, *The Psychedelic Policy Quagmire* presents a strong case for the notion that psychedelics have transcended seemingly outdated legal, academic, cultural and spiritual paradigms. Although – by the editors' own admission – this volume is by no means definitive, it will undoubtedly prove to be a lightning rod in the academic community. With its focus on research and policy that maximise the benefits of the use of psychedelics, reduce the potential dangers of misuse and remove impediments to achieving these ends, it is inevitable that this book will be a catalyst for lively and robust debate. Recommended to academics and researchers in various fields, including

psychology, psychiatry, anthropology and the arts, this work should challenge many long-held assumptions about these fascinating substances.

1.6.40 Spirituality and Narrative in Psychiatric Practice: Stories of Mind and Soul

Paramabandhu Groves¹

date

2017-4

Contents

- *Spirituality and Narrative in Psychiatric Practice: Stories of Mind and Soul*

Telling stories is probably as old as human culture. Our ancestors used storytelling to entertain, instruct and make sense of their experience. A psychiatric history, when well taken, should be more than a fact-finding mission to provide a diagnosis and treatment plan. To be effective in providing treatment, helping with healing and promoting recovery, we need to know what matters to our patients. This includes the realm of belief and practice encompassed by the broad term spirituality. A book then that explores both spirituality and narrative is welcome.

Spirituality and Narrative in Psychiatric Practice, like the term spirituality, is broad in its scope. On the one hand, we have agnostic atheist Jeremy Holmes describing in his chapter “Meaning without ‘believing’ ” the spiritual nature of mentalising. As he puts it, ‘an intensely practical and loving pathway to spiritual aliveness’. On the other hand, there are writers from a theistic background, such as mental health chaplain Beaumont Stevenson, who considers how God or a higher power may manifest in the everyday stories of patients, providing a greater frame of reference than the story of self that often limits a human’s potential. The early chapters give a range of perspectives on narrative. With characteristic clarity Andrew Sims indicates how through careful psychopathological appraisal from attending to the patient’s story, it is possible to distinguish between spiritual experiences and psychiatric symptoms. Later chapters explore narrative and spirituality in a wide variety of themes such as affective disorders, offending behaviour, psychosis and the end of life.

The subtitle of the book is *Stories of Mind and Soul* and it is the stories that really shine. To preserve anonymity some are composite – made up from several people’s histories or typical examples – and therefore feel somewhat artificial; nevertheless, they engage the reader and serve didactic purposes well. Others are the words of individuals who have been willing to share their stories, and these have a greater ring of authenticity. In particular, the chapter by Jo Barber stands out as an honest and moving account of someone who has struggled with mental health problems and for whom spirituality has been important – at times problematic but often a resource that has supported her ongoing journey of recovery.

As the editors note in their concluding chapter, pressures on service delivery may get in the way of the time and space to listen well to patients’ narratives. However, for good psychiatric practice, not taking a good history is a short-cut we can ill afford. This work is a timely reminder of the importance of the fundamental tool of psychiatry and a welcome enjoiner to attend to what is significant to our patients.

1.6.41 Big data in mental health research – do the *ns* justify the means? Using large data-sets of electronic health records for mental health research

Peter Schofield

Correspondence

Peter Schofield

(peter.1.schofield@kcl.ac.uk)¹

date

2017-6

Abstract

Advances in information technology and data storage, so-called ‘big data’, have the potential to dramatically change the way we do research. We are presented with the possibility of whole-population data, collected over multiple time points and including detailed demographic information usually only available in expensive and labour-intensive surveys, but at a fraction of the cost and effort. Typically, accounts highlight the sheer volume of data available in terms of terabytes (10^{12}) and petabytes (10^{15}) of data while charting the exponential growth in computing power we can use to make sense of this. Presented with resources of such dizzying magnitude it is easy to lose sight of the potential limitations when the amount of data itself appears unlimited. In this short account I look at some recent advances in electronic health data that are relevant for mental health research while highlighting some of the potential pitfalls.

Recent advances

The most extensive electronic health data available for research in the UK are collected in primary care. For example, the Clinical Practice Research Datalink (CPRD) covers approximately 5 million active patients, with longitudinal records going back to 1987. This in turn is now linked to hospital episode statistics (HES) and mortality data, providing one of the world's largest longitudinal health data-sets.¹ As with any big data project much depends on the quality of the data. This may be enhanced in primary care, as general practitioners (GPs) have a financial incentive to accurately record certain treatments and outcomes under the quality and outcomes framework (QOF).²

While there is no national equivalent for psychiatric care, HES data provide at least some information about psychiatric in-patient stays nationally. There are also examples of local schemes providing comprehensive psychiatric data for research use, often on a very large scale. For example, the Case Register Interactive Search (CRIS) system covers the full clinical record of over 250 000 patients from the South London and Maudsley (SLAM) catchment area.^{3,4} This can be linked with neighbourhood census data, primary care records, HES data and educational data from the National Pupil Database (NPD). A feature of CRIS is that it comprises the entire clinical record so that much of what is available is in the form of free text which, through recent advances in the use of natural language processing (NLP) techniques, is now accessible for large-scale research.⁴ For example, a recent project used free-text-mining algorithms to extract information about cannabis use to investigate the relation with clinical outcomes for just over 2000 patients with first-episode psychosis.⁵ Another recent study supplemented coded diagnostic and treatment data with data extracted from free text to look at delays in treatment and diagnosis for patients presenting with bipolar disorder.⁶

With over 50 publications to date using this data-set, CRIS has proved particularly useful for research into mortality outcomes for people with severe mental illness,^{7,8} hard-to-reach groups such as homeless people^{9,10} and, more recently, services for people in the early stages of psychosis.^{11,12}

These examples are, however, still limited to either specific geographical regions or a relatively small subsample of the population. We have, of course, recently come close to a universal data-set of health records with the, ultimately ill fated, care.data proposal. Originally intended to link primary care data with existing hospital records, this would have provided whole-population data for research use. Arguably, this was unsuccessful because it was presented in a way that failed to reassure the public their data would be safe.¹³ While this has now been scrapped, it is still the government's aim that something similar is implemented.¹⁴

Allowing whole-population health data to be made available for research has, however, long been an accepted part of life in Nordic countries. For example, since 1968 all Danish citizens have had a unique personal identification number allowing data linkage across a range of health, welfare, employment and education data.¹⁵ This arguably represents a gold standard for mental health research, with all psychiatric in-patient admissions (since 1969) and all out-patient contacts (since 1995) providing longitudinal data for the entire population over nearly five decades.¹⁶ Because of the scale of longitudinal data collected, register-based studies using data such as these have proved particularly useful for aetiological research into relatively rare disorders such as schizophrenia. For example, a number of landmark papers have highlighted urban/rural differences in psychosis incidence^{17,18} and also documented the increased risk of psychosis for migrants and refugees.^{19,20}

Do big data mean high-quality data?

All these developments in the resources available for research are to be welcomed. However, simply having the ability to access data on this scale is not enough. What we gain through the sheer volume of data and breadth of coverage could be offset by ill-informed analysis and interpretation that fails to account for the limitations of the data. One fundamental limitation is that almost all examples of what we think of as big data are collected for purposes other than research. Health records, just like any bureaucratic product, are shaped by administrative convenience rather than the search for scientific truth. For example, if we look at the way that depression is recorded in primary care, it would be a mistake to take this at face value.^{21,22} For some time, recording a diagnosis of depression on the electronic record has triggered a series of prompts and demands on the clinician, which many saw as unnecessarily burdensome. This became a disincentive to code a formal diagnosis and instead alternatives, such as 'low mood', would be entered, although treatment itself remained unaffected. This has meant that GP records can show an exceptionally low prevalence of depression compared with what we know from national survey data.^{23,24} In this case, a failure to understand what statisticians term

the data-generating process would lead to a fundamental misinterpretation of what these data represent. Furthermore, the quantity of data collected here makes no difference to the validity of our conclusions. In fact, having more data is likely to help reinforce any erroneous claims.

Looking at health informatics more broadly, a classic example of what can go wrong if we fail to understand the data-generating process is that much cited example of big data, Google flu trends. Here, the frequency and location of a selection of Google search terms, based on health-seeking behaviour, were used to predict where and when the next flu epidemic would occur.²⁵ This was shown to more accurately predict epidemics compared with previous epidemiological studies and was therefore held up as an exemplar of the ascendancy of big data in health research.²⁶ That is, until Google flu trends stopped predicting accurately and eventually proved no better than estimates based on flu prevalence from a few weeks before.²⁷ This was in part a result of changes Google had made to their search engine, including the introduction of the auto-complete feature that meant searches no longer worked in quite the same way as when the algorithm was first devised. This problem was further exacerbated as the original search terms were never actually made public so could not be externally validated. Clearly, electronic health records are not subject to the same technical issues as a search algorithm. However, as we outline above, changes in the data-generating process, such as how diseases are coded, could make an important difference to results. In some ways, Google flu trends is the perfect example of the hubris associated with big data; as one of the early evangelical accounts confidently stated, ‘society needs to shed some of its obsession with causality in exchange for simple correlations: not knowing why but only what’.²⁶ Although this might make sense if we are simply mining data looking for patterns, this approach alone has little to offer in the way of research evidence.

Are the data we routinely collect aligned with research agendas?

A further limitation of research using administrative data is that we rarely have any control over what is collected and therefore risk the research agenda being set by what data are available. One field in which there have been major advances in recent years is ethnicity and mental health, partly due to the availability of electronic health records where patients’ ethnicity is now routinely coded. In particular, large-scale case registers have been used to document the increased incidence of psychosis among Black and minority ethnic groups, as well as exploring possible risk factors to explain these differences.^{28–31} These findings have been validated using other methodologies. However, there is a risk that we now focus research attention on what are often fairly crude categories, while neglecting other forms of minority status or more nuanced definitions of ethnicity simply because of the available data. For example, it is likely that other forms of marginalised status may also be relevant as risk factors where individual characteristics (such as sexuality, social class or marital status) are at variance with what is usual in a locality.^{32,33} However, these are typically not recorded in register data and are therefore unlikely to receive as much research attention. Where relevant risk factors are not being recorded, research has the potential to inform the data collection process to not only benefit research but also enhance clinical care.

How complex is the analysis of big data?

Another inherent danger is in the way we analyse these data. Often, the more data we have to analyse the more likely it is that we miss patterns in the data that could confound the associations we are interested in. For example, there might be temporal patterns in longitudinal data, such as long-term disease trends, that make it difficult to distinguish effects in before-and-after study designs. Short-term events such as the shift from ICD-9 to ICD-10 in the 1990s could confound our results when comparing changes in rates of diagnosed psychiatric disorders. Data might also be spatially patterned, with different environmental risk factors operating in different areas. This might be further patterned by administrative structures where, for example, differences in mental health outcomes in particular areas may reflect the performance, and reporting practices, of different mental health trusts. Considerable advances have been made in recent years in the tools available for analysing data patterned in this way. In particular, multilevel modelling and Bayesian analysis techniques allow us to simultaneously account for effects operating at temporal, individual, spatial and administrative levels. However, these are still not easily accessible to many researchers, or research consumers, although their use and accessibility are increasing. Implicit in these methods is a fundamentally different approach to that of small-scale studies, such as randomised controlled trials, where the aim is to remove complexity from the data through random

allocation. With big data we can no longer rely on random assignment and rely instead on being able to model the complexity inherent in the data to account for possible confounding effects.

Do big data mean more or less transparency?

Admittedly, complex data of this kind can be difficult to analyse, but it also presents an ever-increasing number of choices about how the analysis could be conducted. We might use different diagnostic categories, we could follow our sample over different time periods and look at a variety of different subgroups. We might use different statistical methods for the same analysis and we could also adjust for different sets of covariates. This growing array of possibilities also increases the opportunities to pick and choose our analysis until we find the most impressive-looking *P*-value. This tendency, often termed *P*-hacking or *P*-fishing, can be found in any statistical analysis, unless of course the method is predetermined and published in an advance protocol. However, big data exacerbate this tendency by increasing the possibilities for analysis. Often this means that statistically significant effects, which appear to show something important, cannot then be reproduced and our analysis is ‘over-fitted’ to our data. The US statistician Andrew Gelman describes this potential as the ‘garden of forking paths’.³⁴ He argues that this need not necessarily mean deliberate deception on the part of the analyst, but is often the result of unconscious bias as reasonable analysis decisions are made but they are contingent on the data. The accumulation of these decisions, at different stages in the analysis, ultimately leads to a statistically significant result being more likely. What is required, argues Gelman, is greater transparency so that we are able to retrace the steps made in the analysis to assess for ourselves the significance of findings. A related problem with large data-set analysis is that often very low, highly statistically significant *P*-values can be found for what amount to clinically insignificant effects. It is argued that these tendencies have led to what has been described as a ‘reproducibility crisis’ in science.³⁵ In response, the American Statistical Association recently issued a statement calling for greater transparency in the reporting of results and a move away from simply reporting *P*-values below a certain threshold ($P < 0.05$).³⁶

Complementary methods

Clearly, there are some inherent problems in the analysis of large-scale health records data, both for the unwary and for the unscrupulous. However, there is nothing either inherently good or bad about the use of these kinds of data for mental health research. Ultimately, this comes down to understanding the human story behind how the data were created, having the analytical skills to best interpret the data and being transparent in the way results are reported. What big data can then give us is one version of the truth to complement what we are able to discover using other methods. In fact, one of the best examples of big data that we have in UK mental health, CRIS, also includes a parallel community survey component, the South East London Community Health Study (SELCoH).³⁷ This is intended both to provide a parallel sample of community controls to match the case register and to yield detailed information about individual circumstances and attitudes otherwise absent from medical records.

There are of course a number of well-established national community survey resources, such as the Adult Psychiatric Morbidity Survey and the annual Health Survey for England, that are not dependent on health service use or subject to the diagnostic bias that occurs in health records data.^{38,39} We must also not forget the potential for qualitative research to address many of the questions in mental health research that are beyond the reach of statistical analysis. With the increased emphasis on evidence-based medicine, qualitative methods have increasingly been sidelined. For example, the *BMJ* recently announced that, in future, qualitative studies would have a low priority in the journal.⁴⁰ In response, 76 senior academics from 11 countries wrote an open letter calling for the journal to reconsider.⁴¹ They cite the complementary role that qualitative research can have, particularly where there is a failure to reproduce the results of analyses of large-scale health data-sets.

Last, let us not forget that the research we do is only meaningful in that it relates to the, essentially individual, experience of mental disorder. Whatever volume of data we analyse, whether we look at $n = 100$ or $n = 1\,000\,000$, ultimately we are interested in what this can tell us about the experience of $n = 1$.

The author would like to acknowledge the contribution of Justin Lock, who provided the inspiration for the title of this editorial.

1.6.42 Vitamin D deficiency in adolescents in a tier 4 psychiatric unit

Neil F. Stewart Simon N. Lewis

Correspondence

Simon N. Lewis (slewis9@nhs.net)¹

date

2017-6

Abstract

Aims and method To review the current clinical practice and guidelines for testing and treating vitamin D deficiency in adolescents admitted to a tier 4 adolescent psychiatric unit in north London. The blood test results of 56 patients admitted between 2012 and 2014 were examined to determine whether vitamin D levels had been tested. For those individuals who were tested for vitamin D, results were analysed by gender and ethnicity.

Results Of 56 patients admitted, 48% were tested for vitamin D deficiency and in 81.5% of cases we uncovered deficiency or severe deficiency; 18.5% had the minimum levels of vitamin D for bone health as per our trust guidelines.

Clinical implications Adolescents within tier 4 adolescent mental health services may be at higher risk of vitamin D deficiency and so assessment of vitamin D levels should be considered as part of a standard physical health review for this group of young people.

It is well known that vitamin D plays a role in bone health. In addition, vitamin D receptors have been found in several areas of the brain and are reported to be involved in neuroimmuno-modulation, neuroprotection, neuro-plasticity and brain development.¹ Given that some of these receptors are found in brain areas implicated in mental illnesses such as depression,¹ it is plausible that vitamin D and/or vitamin D deficiency have a role in the pathogenesis of mental illness.

Existing guidelines identify risk factors for vitamin D deficiency²⁻⁴ (details available from the authors on request), although there is little that relates specifically to adolescents or individuals within mental health settings. We hypothesised that patients in a tier 4 adolescent psychiatric unit in north London may be at increased risk of vitamin D deficiency, potentially having had reduced exposure to sunlight as a result of their psychiatric presentations. Linked to this, according to data from the UK National Census in 2011,⁵ there is a higher proportion of individuals with increased skin pigmentation (black and minority ethnic (BME)) compared with the national average within inner London schools, which may reflect general population trends in urban areas.

Aim

We examined the blood test results of all patients admitted to Simmons House, a tier 4 adolescent psychiatric unit, to review our management of individuals with vitamin D deficiency, make recommendations for future practice and identify areas where further study is needed.

Method

The blood test results of patients admitted to the unit between 2012 and 2014 were examined after a clinical observation that a number of patients had vitamin D deficiency. Patient notes were checked to determine gender, ethnicity, whether they were tested for vitamin D levels and the result of the test. The results were classified according to local laboratory reference ranges at the Whittington Hospital NHS Trust in London: <25 nmol/L severe deficiency, 25–50 nmol/L deficiency and 50 nmol/L minimal vitamin D levels for bone health. The results were also mapped to other guidelines, such as National Institute for Health and Care Excellence (NICE) guidelines (<25 nmol/L ‘low vitamin D status’) and those outlined by the Endocrine Society and Society for Adolescent Health and Medicine (>75 nmol/L ‘adequate’).^{4,7}

Results

Of 56 patients on the unit between 2012 and 2014, 48% ($n = 27$) were tested for vitamin D deficiency. According to local laboratory reference ranges (Whittington Hospital NHS Trust), 81.5% ($n = 22$) were deficient or severely deficient (40.7% deficient and 40.7% severely deficient) and 18.5% had the minimum levels for bone health. Applying the NICE guidelines, 40.7% of patients had low vitamin D status. No individuals tested had levels of >75 nmol/L (a level recommended in other guidelines).^{4,7} The results are summarised in *Table 1*.

Vitamin D levels in the tested patient sample

	Pa-tients <i>n</i>	Tested for vitamin D levels (%)	D deficient or severely deficient (%)	Minimum level of vitamin D for bone health (%)	Vitamin D at > 75 nmol/L
Male	14	8 (57)	6 (75)	2 (25)	0 (0)
Female	42	19 (45.2)	15 (79)	4 (21)	0 (0)
White	39	18 (46.1)	13 (72.2)	5 (27.8)	0 (0)
BME	17	9 (52.9)	9 (100)	0 (0)	0 (0)
Total	56	27 (48)	22 (81.5)	5 (18.5)	0 (0)

BME, Black and minority ethnic.

<50 nmol/L

>50 nmol/L

Results by ethnicity

Nearly half of adolescents who were White were tested (46.1%, 18/39), and 72.2% ($n = 13$) were deficient or severely deficient in vitamin D. In individuals from BME groups, who were potentially at higher risk of vitamin D deficiency due to increased skin pigmentation, 52.9% (9/17) were tested for vitamin D levels and 100% were deficient or severely deficient. There was no significant statistical association between ethnicity and vitamin D deficiency ($\chi^2 = 3.07$, $P = 0.136$ (Fisher's exact test)).

Results by gender

Three-quarters of the sample were female ($n = 42$); 14 were male. Of the 57% ($n = 8$) males tested, 75% ($n = 6$) were deficient or severely deficient in vitamin D, whereas of the 45.2% ($n = 19$) females tested, 79% ($n = 15$) were deficient or severely deficient in vitamin D. There was no statistical association between gender and vitamin D deficiency ($\chi^2 = 0.05$, $P = 1.000$ (Fisher's exact test)).

Discussion

Are adolescents at risk?

There is emerging evidence that the adolescent population in general is at risk of vitamin D deficiency.⁸ Although risk factors may vary, depending on geographical location, seasonal changes, latitude and variations in ultraviolet light levels, there has also been a suggestion of a worldwide re-emergence of rickets in the paediatric population.⁹ The Royal College of Paediatrics and Child Health identifies adolescents as having an 'increased need' for vitamin D,¹⁰ and the draft NICE guidelines⁶ stated that young people undergoing rapid periods of growth are at an increased risk of vitamin D deficiency, although this did not appear in the final guideline.²

Which guidelines to use?

An update to the NICE guidelines regarding vitamin D deficiency was published in November 2014 with the aim of increasing vitamin D supplement use among at-risk groups.² The guidelines include the findings of the *National Diet and Nutrition Survey* showing that 8–24% of children (depending on age and gender) may have vitamin D deficiency (details available from the authors on request). It is also noted that up to 75% of Asian adults may be deficient in vitamin D. The groups at risk of vitamin D deficiency, including adolescents, are: people who have low or no exposure to the sun, for example those who cover their skin for cultural reasons, those who are housebound or confined indoors for long periods, and people with darker skin, for example people of African, African-Caribbean or South Asian origin.

There appears to be a lack of consensus between various guidelines in defining a biochemical vitamin D deficiency. NICE guidelines² give a level of <25 nmol/L as low vitamin D status, but local laboratory reference ranges and recommendations made in other guidelines vary. For example, the Endocrine Society⁴ and the Society for Adolescent Health and Medicine⁷ provide different recommendations regarding required vitamin D levels, which appear to be higher than those in the NICE guidelines.² *Table 2* summarises the guidelines.

Vitamin D levels by guideline

	Whittington Hospital NHS Trust laboratory interpretation	NICE guidelines	Endocrine Society and SAHM interpretation
< 25 nmol/L	Severe deficiency	Low vitamin D status	Deficiency
25–50 nmol/L	Deficiency	n/i	Deficiency
>50 nmol/L	Minimal levels for bone health	n/i	Recommended or 'adequate' level

SAHM, Society for Adolescent Health and Medicine; n/i, no interpretation offered in the guideline.

Prevention and treatment

Vitamin D deficiency can be treated with oral or intramuscular supplementation, usually in the D₃ form (cholecalciferol), as this may be more effective than vitamin D₂ in raising serum 25(OH)D levels.¹¹ NICE guidelines outline the daily vitamin D intake requirements to minimise the risk of deficiency in various age groups, with 400 IU for 'at risk' adults. Similar requirements have been suggested for adolescents.⁸ Medical causes of vitamin D deficiency, other than reduced sunlight exposure, should also be considered, for example reduced parathyroid hormone levels or malabsorption disorders such as coeliac disease. No single treatment recommendation for vitamin D deficiency is given in national guidelines.

How much sun exposure is recommended?

A recent NICE guideline, published in February 2016, outlines the risks and benefits of sunlight exposure.¹² It recognises that advice on sunlight exposure to date has been available from many sources and that the information has often been 'inconsistent and potentially confusing'.¹² Young people and their parents/carers could be confused, worrying about balancing advice to limit sun exposure, because of the increase in incidence of skin cancer and other skin disorders, with a need to have sun exposure for vitamin D production.^{13,14} The new NICE guideline acknowledges that, with a proviso that 'a simple definitive message telling different groups how often and how long they can be exposed to sunlight to ensure minimum risk but maximum benefit' is not possible because of the multiple biological, social and environmental factors that contribute towards an individual's risk-and-benefit profile.¹² Specific risk factors for skin cancer such as a family history of the disease should always be considered when giving sun exposure advice, and the NICE guideline also mentions groups who should take 'extra care to avoid skin damage and skin cancer'. This includes young people.¹²

It is suggested that skin colour charts may be helpful in making judgements about sun exposure advice. Individuals with naturally very light skin (skin types I and II) are at greater risk of sunburn and skin cancer and require shorter times of sun exposure to synthesise vitamin D compared with those with darker skin types (types V and VI), who are at increased risk of vitamin D deficiency in the UK.¹²

Advice should be tailored for the time of year and the time of day. For example, in the UK between March and October and between 11 am and 3 pm, short periods of sun exposure to the forearms, hands or lower legs are required to synthesise vitamin D, whereas longer times are required between 3 pm and 11 am.¹² Between October and March, there is 'very little of the ultraviolet B wavelength the skin needs to make vitamin D'.¹²

With so many factors to consider, it is perhaps not surprising that the general advice given in the NICE guideline remains equivocal, with an emphasis on providing consistent, balanced messages regarding the risks and benefits of sunlight exposure for each individual. It is suggested that: 'short (less than the time it takes for skin to redden or burn), frequent periods of sunlight exposure are best for vitamin D synthesis. In addition, this type of exposure is less likely

to result in skin cancer'.¹² This advice is broadly similar to advice published in a multiagency consensus document in 2010 (<https://www.cancerresearchuk.org/sites/default/files/vitamins-consensus.pdf>).⁷

Study recommendations

If it were assumed that all of the individuals in our study who were not tested – deliberately or by accidental omission – had 'optimum' vitamin D levels, then 39.3% ($n = 22$) of the total sample had vitamin D deficiency. However, it seems unlikely that all of the non-tested patients had optimal levels given that, for example, 8 BME patients were not tested and 100% of those who were tested were deficient or severely deficient in vitamin D.

Factors influencing whether patients on Simmons House Adolescent Unit were tested for vitamin D before 2015 have not been explored in this project. The apparent idiosyncrasy of testing is beyond the scope of the present study but was one of the reasons for the study and subsequent recommendations detailed in the *Appendix*.

The results could suggest that all individuals within Simmons House at risk of vitamin D deficiency were identified and their levels tested accordingly. Alternatively, it may be that a proportion of the 52% of individuals not tested had an undetected vitamin D deficiency, particularly those from BME backgrounds given that 100% of the BME patients who were tested had deficiency or severe deficiency. As increased skin pigmentation is identified as a specific risk factor for vitamin D deficiency in the NICE guidelines, it could be that all adolescents with increased skin pigmentation admitted to a tier 4 adolescent psychiatric unit should have their vitamin D levels checked. This may be particularly relevant in units with culturally diverse populations. Specific recommendations made for Simmons House are detailed in the *Appendix*.

Perhaps any adolescent with a mental illness of a severity that requires in-patient admission is at risk of reduced sun exposure and consequent vitamin D deficiency, no matter their ethnicity. It could be suggested that all patients within tier 4 adolescent psychiatric units should be considered at high risk of vitamin D deficiency and tested, unless there was clear evidence to the contrary, such as a confirmed history of adequate sun exposure and theoretically sufficient dietary intake.

Choosing a particular treatment regime depends on clinical need and consideration of local guidelines. Recommendations given in various London NHS trusts guidelines (St Bartholomew's and The London NHS Trust, Royal Free Hospital NHS Trust and The Whittington Hospital NHS Trust; details available from the authors on request) range from treating a deficiency with oral cholecalciferol in doses of 2000 to 6000 IU per day, or once-weekly doses of 20 000 IU, all for a minimum of 3 months before rechecking vitamin D levels. Once the serum 25(OH)D level has been normalised, the recommended maintenance doses range from 400 to 1000 IU of cholecalciferol per day, with NICE suggesting 400 IU per day as a prophylactic dose for those at risk of deficiency. Therefore, at the very least, it seems that prophylactic supplementation of 400 IU of vitamin D₃ per day should be considered for adolescents at risk of vitamin D deficiency, or treatment of a confirmed vitamin D deficiency initiated after discussion with the adolescent and/or their family/carers. Treatment regimens should be in line with local guidelines until a sufficient evidence base is established to provide national guidelines.

More research is needed into the prevalence of vitamin D deficiency in all age groups, both in the general population and in hospital settings (general and psychiatric hospitals). The topic is likely to appear in the medical literature frequently in years to come, with hypothesised links between vitamin D deficiency and a multitude of medical conditions ranging from cancer to psychosis,¹⁵ multiple sclerosis¹⁶ and the possibility of a worldwide re-emergence of rickets in the paediatric population.⁹ The relationship between vitamin D and mental illness is not known. A meta-analysis¹⁷ published in the *British Journal of Psychiatry* in 2013 supported an association between low vitamin D concentrations and depression, mostly based on observational studies. However, the nature of the association is not yet known to be causal and the paper also noted that the quality of evidence in this particular area to date is poor; no randomised control trials have been performed.¹⁷

If an association between depression and vitamin D deficiency were to be confirmed through future study, vitamin D supplementation could potentially be a cost-effective treatment adjunct with minimal adverse effects. In the meantime, the beneficial effects of vitamin D on bone health have been clearly demonstrated. Future research might include a nationwide project through the Royal College of Psychiatrists' Quality Network of Inpatient CAMHS Units (QNIC;

qnic.org.uk) to which almost all tier 4 units in the UK are allied for appraisal and accreditation. Additionally, consideration of whether the child and adolescent population attending tier 3 child and adolescent mental health services (CAMHS) should be tested for their vitamin D status requires further thought.

1. All admissions to Simmons House should be considered at high risk of vitamin D deficiency, especially individuals with increased skin pigmentation or with a history suggestive of a lack of sun exposure. Therefore, vitamin D levels should be included as part of the routine physical assessment.
2. If blood tests are refused or clinically inappropriate, prophylactic treatment should be considered with 400 IU cholecalciferol (vitamin D₃) orally once daily, assuming informed consent is gained.
3. If a vitamin D deficiency is detected, baseline corrected calcium levels should be tested, plus a full bone mineral profile and testing of parathyroid hormone levels, along with routine admission blood tests (e.g. full blood count, urea and electrolytes, liver function tests, random blood glucose, thyroid function tests and lipid profile).
4. Treatment of a vitamin D deficiency should consist of high-dose cholecalciferol (vitamin D₃) (5000–6000 IU) orally daily for 3 months. Vitamin D levels and corrected calcium levels should then be checked again and a maintenance dose of cholecalciferol (vitamin D₃) 400 IU commenced once daily when vitamin D levels have normalised. Continuation of treatment should be tailored to each individual, based on severity of the deficiency and ongoing risk factors for vitamin D deficiency. Longer-term management of supplementation should be discussed with primary care colleagues.
5. Patients and/or their families/carers should be made aware of potential side-effects of treatment i.e. vitamin D toxicity or hypercalcaemia, which may present with anorexia, weight loss, vomiting and polyuria.
6. Ongoing examination of blood test results (serum vitamin D levels) should take place and internal audit on clinical practice should continue.

1.6.43 Adherence to NICE guidance on lifestyle advice for people with schizophrenia: a survey

education programme in addition to usual care. However, it is difficult to define what constitutes 'usual care'. We aimed to define 'usual care' for lifestyle management in people with schizophrenia, schizoaffective disorder and first-episode psychosis in STEPWISE study sites. Ten National Health Service (NHS) mental health trusts participated in a bespoke survey based on the National Institute for Health and Care Excellence (NICE) guidance.

Results Eight trusts reported offering lifestyle education programmes and nine offered smoking cessation support. Reported recording of biomedical measures varied.

Clinical implications Although recommended by NICE, lifestyle education programmes are not consistently offered across UK NHS mental health trusts. This highlights missed opportunities to improve the physical health of people with psychotic illness. Our survey benchmarks 'usual care' for the STEPWISE study, against which changes can be measured. Furthermore, future studies will be able to identify whether any progress in clinical practice has been made towards achieving the NICE recommendations.

The prevalence of overweight (body mass index (BMI) >25 kg/m²) and obesity (BMI>30 kg/m²) in adults with schizophrenia is approximately twice that in the general population and while it has increased in both groups in the past 30 years, the rate of increase is greater in people with schizophrenia.¹ Weight gain often occurs after initiation of antipsychotic treatment: over 50% of individuals gain more than 7% of their initial body weight within the first 12 months of treatment, with up to 86% gaining weight with some types of antipsychotic.² Compared with the general population, people with schizophrenia consume more fat and refined carbohydrates and fewer vegetables,³⁻⁵ are less physically active and experience higher levels of deprivation,⁴⁻⁷ all of which are associated with obesity. The National Institute for Health and Care Excellence (NICE) recommends that people with psychosis or schizophrenia, particularly those taking antipsychotics, should be offered access to a combined healthy eating and physical activity programme

to aid in the prevention of weight gain and its related comorbidities, leading to improved quality of life.⁸ They should be supported by clinicians to make choices about antipsychotic medication, informed by discussions of likely benefits, possible side-effects, such as weight gain and metabolic disturbance, and impact on other aspects of their physical health. For those who smoke, help should be offered to stop smoking.⁸

The STEPWISE study (STructured lifestyle Education for People WItch SchizophrEnia, schizoaffective disorder and first episode psychosis; ISRCTN19447796) was commissioned to evaluate the extent to which a structured lifestyle education programme can support weight loss, compared with usual care, when delivered to adults with schizophrenia, including those with schizoaffective disorder or first-episode psychosis, in a community mental health setting. In pragmatic trials, practitioners are often allowed ‘considerable leeway in deciding how to formulate and apply’ the treatment in a control arm defined as ‘usual care’.⁹ While the result may be reflective of the care received by patients outside the trial, there is often variation in care in an active control arm, which may be difficult to document.^{10,11} For this reason, study teams often try to capture the active content of the control arm of their trials.¹² In this paper we describe a survey of ‘usual care’ for the management of weight and other lifestyle factors in people with schizophrenia, schizoaffective disorder and first-episode psychosis in the ten participating study sites.

Method

Research tool

The survey instrument consisted of 14 questions, which were a combination of closed and open design, with the aim of eliciting information about the implementation of the recent NICE guidance on psychosis and schizophrenia at National Health Service (NHS) mental health trusts in the UK, and consequently what is offered as ‘usual care’. The survey was developed for the research study, based on the physical health aspects of the NICE recommendations in clinical guideline 178.⁸ Questions followed the baseline assessment tool published alongside the NICE guidance. The instrument was piloted with one study site investigator (J.M.) on two occasions, and each led to substantial changes to the tool. For instance, the second iteration revised questions to ascertain proportions of patients to whom certain criteria apply, rather than closed questions such as ‘Are patients referred to a healthy eating programme?’ The final version of the tool also clarified which questions related to all patients with schizophrenia, schizoaffective disorder and first-episode psychosis, and which questions related to patients with first-episode psychosis only (the questionnaire is included in the *Appendix*). This is in line with the additional recommendations specified in the NICE guidance for patients with first-episode psychosis who have recently been prescribed antipsychotic medication; these additional questions were not applicable to the management of patients with established mental illnesses.

Survey structure

Trusts were initially asked whether they offered a healthy eating and physical activity programme. Subsequent questions asked for more information about these programmes, including whether they were combined or separate for healthy eating and physical activity; how patients accessed them; and how often patients were referred to such services. Additional information was sought on the availability of smoking cessation services in this population and whether discussions took place between patients and clinicians prior to antipsychotic treatment initiation, including benefits of treatment, interactions with other substances and other possible side-effects.

In addition, NICE recommend that a number of physiological measures should be recorded both prior to the patient starting antipsychotic medication and annually thereafter. Respondents were asked to comment on how likely it was that each measure would be recorded at both of these time points in their trust and how often patients on antipsychotic medication have their weight recorded.

Sample selection

The STEPWISE trial has ten centres in a variety of urban, suburban and rural locations across England: Sheffield Health and Social Care NHS Foundation Trust, Leeds and York Partnership NHS Foundation Trust, Bradford District Care NHS Foundation Trust, Greater Manchester West Mental Health NHS Foundation Trust, South London and Maudsley NHS Foundation Trust, Sussex Partnership NHS Foundation Trust, Southern Health NHS Foundation Trust, Devon Partnership NHS Trust, Somerset Partnership NHS Foundation Trust and Cornwall Partnership NHS Foundation Trust. A representative from each centre was invited to complete the survey.

Respondents

The principal investigators at each of the ten centres for the STEPWISE trial were initially approached. Some of them completed the survey themselves, while others delegated to trust physical health leads or equivalent as they were better placed to answer the questions. Contact was made via email in the first instance, with an invitation to attend a teleconference with the STEPWISE research assistant (L.S.) to complete the survey. Those who did not provide a response to the invitation within 4 weeks were contacted again by reminder emails and/or by telephone. Six of the ten sites' surveys were completed through discussion via teleconference. The remaining four sites' surveys were completed independently by a trust representative and written responses were provided to the STEPWISE research assistant.

No sites required more than one reminder email/telephone call in order to arrange completion of the survey. As the survey information was requested from members of a research team, a favourable ethical opinion from an NHS Research Ethics Committee was not sought and consent was unnecessary. Responses provided organisational data only and did not include any personal data. Responses from all sites were received between 22 May and 28 October 2015.

Analysis

Descriptive statistics in the form of counts were produced for quantitative variables. Supporting information provided by respondents and information yielded from qualitative questions was summarised in narrative form.

Results

Healthy eating and physical activity programmes

Eight respondents reported that their trust offered programmes on healthy eating and physical activity, which were mostly separate programmes. Supplementary information indicated that provision was *ad hoc* and interventions were rarely standardised. Most respondents reported routinely inviting patients to access services such as discounted local gym memberships, cooking groups and activity groups delivered by local authorities and third-sector organisations. Two trusts reported offering one-on-one advice sessions with healthy living advisors or health trainers, but the sessions were usually advice-giving and often more clinically focused rather than looking at the patient's physical well-being.

Those trusts that offered trust-led programmes reported that these were available in principle to all of their patients rather than specific groups based on diagnosis. However, interventions were often accessed only by certain groups of patients, usually through particular clinicians or clinics. One trust estimated that 70% of their eligible patients are referred to such services by mental health professionals, based on recent Commissioning for Quality and Innovation (CQUIN) results; other respondents were unaware of routine data from which they could quantify referrals. Six trusts reported offering lifestyle advice through open-ended group courses, three through courses delivered over a fixed period and four through drop-in sessions.

Smoking cessation advice

Six respondents indicated that patients who smoke were offered help to stop some of the time, three reported help was offered all of the time, and one said this was not offered at all. Respondents who selected 'some of the time' were unable to quantify this, but felt that this occurred most of the time. Although it varied whether smoking cessation services were offered by the trusts or external services, most offered a combination of the two. Seven trusts reported offering trust-led smoking cessation services, while others had trained smoking cessation advisors but had no formal trust-offered service. Most trusts reported signposting outpatients to external services, some of which were managed by primary care, with advice leaflets available within the trust.

Antipsychotic treatment initiation

Table 1 shows the reported levels of discussion about likely benefits of treatment, as well as potential weight gain, diabetes and metabolic side-effects and any other possible side-effects, across all respondents. Most trusts who reported that the recommended discussions took place 'some of the time' felt that this would be most of the time, but there was a lack of evidence to support this. One site reported that discussions would be dependent on the clinician, but that resources were available to clinicians to support the discussions. Another site suggested that such discussions may be part of an ongoing process rather than all happening in one session, depending on the patient's level of capacity.

Discussions with patients when deciding on antipsychotic treatment ($n = 10$ NHS trusts)

	All of the time	Some of the time	Not at all
Topic			
Likely benefits	7	3	0
Weight gain	5	5	0
Diabetes and metabolic side-effects	3	7	0
Other possible side-effects	5	5	0
Other substances			
Alcohol	5	5	0
Tobacco	2	8	0
Other prescribed medications	3	7	0
Non-prescribed medications	0	10	0
Illicit drugs	3	7	0

Table 1 also shows how often respondents reported discussions taking place regarding the use of alcohol, tobacco, prescribed and non-prescribed medications and illicit drugs, at the time of antipsychotic treatment initiation.

Table 2 shows how likely trusts considered that physiological measures would be recorded prior to treatment initiation.

Recording of physiological measures prior to antipsychotic treatment initiation ($n = 10$ NHS trusts)

	Very likely	Likely	Neither likely nor unlikely	Unlikely	Very unlikely
Weight	3	4	1	2	0
Weight plotted on a chart	1	3	1	3	2
Waist circumference	0	2	3	3	2
Pulse	3	4	1	1	1
Blood pressure	4	2	1	2	1
Fasting blood glucose	0	5	1	2	2
Random blood glucose	2	4	0	3	1
HbA1c	2	2	1	2	3
Blood lipid profile	2	4	0	2	2
A ssesment of any movement disorders	2	4	2	0	2
A ssesment of nutritional status, diet and level of physical activity	3	3	1	3	0

Ongoing monitoring of weight and other physiological measures

It was clear from the responses that there were variations in recording patients' weight at the time points recommended by NICE (first at 6 weeks post-treatment initiation, then at 12 weeks, at 1 year and annually thereafter), both between trusts and within trust services. Some confusion exists regarding responsibility for annual patient reviews in the community and whether these should be completed by the general practitioner (GP) or the trust. Half of those surveyed reported that it was neither likely nor unlikely that patients would have their weight recorded weekly for the first 6 weeks, with three other trusts reporting that this was very unlikely. There was an even spread across all response categories as to whether weight was recorded at 12 weeks, but at 1 year four of those surveyed reported that patients were very likely to have their weight recorded. Six respondents reported that weight was likely or very likely to be recorded annually thereafter, although this was where the confusion arose regarding responsibility for these reviews.

Table 3 shows trusts' consideration as to how likely it was that physiological measures would be recorded at least annually in patients taking antipsychotic medication. One site felt they were unable to answer this question, so we present data reflecting responses from nine trusts.

Recording of physiological measures at least annually for patients on antipsychotic medication ($n = 9$ NHS trusts)

	Very likely	Likely	Neither likely or unlikely	Unlikely	Very unlikely
Weight	3	4	0	2	0
Weight plotted on a chart	0	3	3	2	1
Waist circumference	0	2	2	3	2
Pulse	2	4	1	1	1
Blood pressure	3	4	1	1	0
Fasting blood glucose	1	2	5	1	0
HbA1c	2	2	4	1	0
Blood lipid profile	2	1	4	2	0
A assessment of any movement disorders	1	4	3	1	0
A assessment of nutritional status, diet and level of physical activity	3	1	3	2	0

There was no correlation between which of the recommended physiological measures were recorded by trusts prior to antipsychotic treatment initiation or annually thereafter, although generally those trusts who were likely to record particular measures prior to treatment initiation were also likely to record the same measures at least annually thereafter.

Discussion

Principal findings

It was clear from this survey that there was great variation between different NHS mental health trusts in the provision of healthy eating and physical activity interventions routinely offered to patients, as well as variation between clinicians within the same trust, with interventions often accessed only through particular clinicians or clinics. Commonly, trusts reported signposting or referring patients to programmes offered by external services, such as gym memberships and activity classes.

Most patients had access to a smoking cessation service should they require it, and referrals to such services were reported to occur most if not all of the time at nine out of the ten trusts surveyed, regardless of whether the service was offered within the trust or run externally.

When deciding on antipsychotic medication with newly diagnosed patients, there was also variability in the reported discussions that took place across trusts. All trusts reported that the likely benefits, weight gain, diabetes and metabolic and other possible side-effects were discussed with the patient at least some of the time; the possible interference of other substances with prescribed antipsychotic medication was also discussed.

Although at the early stages in the course of antipsychotic treatment it was reported unlikely that trusts would record a patient's weight, as recommended by NICE, by 1 year after treatment initiation a larger proportion of trusts reported weight recording, with an increase for annual reviews thereafter, despite the uncertainties regarding responsibility for undertaking annual reviews in the community.

Study strengths and limitations

A strength of this survey was that its design was based on the NICE guidelines to which mental health trusts should be adhering. This meant that trusts' compliance with these recommendations could be assessed, allowing us to elicit information on what programmes (if any) trusts were offering in usual practice and how these compared with what is recommended by NICE. This also allowed us to try to define 'usual care' in relation to the STEPWISE study, using a standard approach across all trusts.

The survey was, in principle, a suitable method to elicit the same information from all respondents; however, it was clear from the responses that owing to the variability of services offered it was often difficult to provide a succinct account using this survey tool. The narrative information provided by the respondents proved more useful in gaining a fuller picture of their usual care than the descriptive statistics, which in some cases were a best guess, as clear data were not always available.

Furthermore, responses were based on one member of staff's knowledge of usual care in practice, and although this person was usually best placed to answer the questions, from the survey responses received knowledge may have been limited, especially as some interventions offered were particular to a specific clinic or clinician and usual care may vary within and between community mental health teams in any given NHS organisation. In addition, how representative 'usual care' is in comparison with NHS trusts not taking part in the STEPWISE study remains unknown.

The levels of detail regarding the content of available services also varied, perhaps indicating that the respondent had more involvement with some programmes than others. Therefore, it was considered likely that additional interventions may have been offered within trusts of which the survey respondent was unaware.

In relation to implementation, a weakness in the survey was highlighted when some responses were received through telephone discussion while others were completed by the respondent and returned to the researcher. No systematic differences between telephone and paper copy responses were identified, although more supporting information was often provided through telephone responses, as these were elicited through more of a conversational discussion. This difference in response methods may have caused questions to be perceived differently, although all telephone participants had a copy of the questionnaire available to them at the time of completion. Perceptions of appropriate levels of detail can change with different methods of completion, which may lead to variation in results. However, as such variation was evident between practices offered as 'usual care' in the ten trusts surveyed, the impact of these differences in completion method is considered likely to be small.

The variability in the information elicited has not allowed for a common picture across all sites, as although a type of programme is recommended by NICE, a particular standardised programme is not available across all trusts. However, the survey did provide sufficient baseline information to allow any changes in usual practice during the course of the STEPWISE study to be monitored at a trust level, rather than across all study sites as a whole. This will enable assessing at the end of the STEPWISE study the extent of potential contamination between the intervention and control arms of the trial, based on changes in practice reported in the survey.

Context

Although there may be an increased awareness of the potential benefits of some treatments, this does not ensure that such treatments are implemented effectively. Evaluations and methods of improving the implementation of NICE guidelines often have limited attention.¹³ A systematic review undertaken by Berry & Haddock¹³ noted that the research around the implementation of NICE guidelines on schizophrenia is relatively limited, suggesting that these patients have poor access to psychological interventions such as cognitive-behavioural therapy (CBT). Some barriers to implementation of NICE guidelines were reported, such as insufficient support from trust management and the needs of organisations. The paper also highlights that whereas NICE considers randomised controlled trials (RCTs) to be the gold standard when developing an evidence base for its guidelines, RCTs have also been criticised for their poor ability to reflect the 'real world'. The authors suggest that targeting these barriers is key to facilitating successful implementation of the guidelines.¹³

It is therefore important to identify which aspects of the guidance are not currently being followed, in order to target these areas for implementation and improve clinical care. Not only is it important to consider the implementation of

guidance relating to monitoring of biomedical measures, but there is also likely to be a limited effect unless this is combined with sufficient intervention in behaviour or treatment. Similarly, the mere fact of guidance or a trial does not necessarily lead to substantive changes or better outcomes. Repeating the survey annually will allow identification of any substantive, systematic changes within the organisations, both since the introduction of the NICE guidelines and throughout the duration of the STEPWISE trial.

From a research perspective, the reported variation also has implications for our study when defining 'usual care'. If all trusts adhered to all recommendations in the NICE guidelines, we could be sufficiently confident that contamination between trial arms would be minimal. However, as different levels of compliance with different recommendations were evident, this does not allow for standardised 'usual care' across the study. This does mean that usual practice can be compared over time within each trust individually, in order to assess how much 'usual care' has changed throughout the course of their participation in the STEPWISE study.

The Royal College of Psychiatrists' National Audit of Schizophrenia includes standards on the monitoring of physical health in patients with schizophrenia. The audit report in 2014 noted that the provision of interventions is poor when there is evidence of physical health risks.¹⁴ It highlighted barriers to intervention, such as availability of staff time, facilities and equipment, the need for formal systems to conduct annual reviews, and the need for more formal arrangements regarding responsibility for physical health between primary and secondary care.¹⁴ Standard 5 in the audit specifically looks at interventions offered for particular physical health risks. The overall results show that intervention for BMI > 25 kg/m² was evident in 71% of patients, while interventions for smoking were reported in 59% of patients.¹⁴

For the ten trusts surveyed, the audit reported a range of 47–83% of patients receiving intervention for elevated BMI, and 33–67% receiving intervention for smoking. Overall, the audit also showed wide variation in the monitoring of physical health risk factors. For example, the range across all participating trusts for monitoring of BMI was 5–92% of patients and 16–99% for the monitoring of glucose control. This is supportive of the information yielded from the study survey and highlights variability in services offered across trusts.¹⁴

Implications for stakeholders

This survey indicates that the ten sites surveyed are not fully compliant with NICE physical health recommendations on the management of patients with schizophrenia. However, as the guidelines were published in March 2014, this is not surprising, because services require time to commission and set up. In some respects, this alleviates the concerns that the 'usual care' arm of the STEPWISE trial may converge with the intervention arm, as there are no reported standardised programmes offered across any of the trusts surveyed. However, there is such variability observed that it becomes clear that 'usual care' is not the same for all participants in the trial or in the wider population group.

We have not tried to assess the success or potential effect of any one aspect of the physical health programme in comparison with others. Although it may be argued that smoking cessation could have a greater effect on physical health than healthy eating or physical activity programmes, despite the lower compliance with NICE guidance, any discussion is likely to be subjective. Furthermore, NICE does not prioritise any one element, coming from an understanding that all aspects are important and contribute to improved physical health.

As a future direction, it may be useful to try to identify patients at higher risk of cardiovascular events, using recording of cardiovascular disease risk factors in combination with risk engines to calculate risk accurately. This identification process could then drive intervention. This may be of interest to trusts as a method of offering a physical health intervention to those patients who are likely to receive the most benefit clinically. A suitable risk engine to calculate this would be the PRIMROSE cardiovascular disease algorithm,¹⁵ as this has been developed specifically for people with severe mental illness. The PRIMROSE model includes additional variables for psychiatric diagnosis, psychotropic medication, harmful use of alcohol, antidepressants and social deprivation score, unlike similar prediction models used in the general population. This is perhaps why PRIMROSE performed better than some other available published risk models, which may overpredict the risk of cardiovascular disease in this population.¹⁵

Further research

The survey will be repeated with the same ten NHS trust representatives at 12 and 24 months after the first iteration. This will allow the STEPWISE study team to consider how trusts are implementing the NICE guidelines and, consequently, whether convergence has occurred between the two arms of the STEPWISE trial at an individual trust level. As STEPWISE progresses, the participating NHS organisations may become more aware of the need to undertake physical health interventions and so 'usual care' may improve, potentially diminishing the effect of the STEPWISE intervention.

date

2017-6

Abstract

Aims and method To examine gender differences in self-reported depression and prescribed antidepressants (ADs). The Hospital Anxiety and Depression Scale was used to assess depression, and information on prescribed ADs was obtained from the Swedish Prescribed Drug Register.

Results Depression was reported by 11.7% of the participants (12.3% men and 11.2% women). ADs were prescribed for 7.6% of the participants (5.3% men, 9.8% women). Among men, 1.8% reported

Depression is currently considered one of the largest and fastest growing health hazards.¹ Although only a small percentage of all those with mental health problems contact healthcare professionals and obtain a diagnosis, depression is one of the most common causes of sick leave and disability.^{2–5} Diagnosed depression was relatively unusual 20 years ago, but the incidence has increased remarkably with the introduction of new diagnostic guidelines and antidepressant drugs. What was previously considered psychological distress was then interpreted as a disease, with the risk of over-diagnosis and over-treatment.^{6–10} The point prevalence of depression in the general population is now estimated as 3–9%.^{1,11,12} There is an explicit gender impact on diagnosed depression, with a 2:1 ratio of women/men; about one in four women and one in ten men will develop depression severe enough to require treatment at some time in their lives.^{1,2,11,12} Moreover, depression may present differently in women and men. Women may be more prone to somatic symptoms of depression, whereas men appear to have more melancholic symptoms and to be more susceptible to drug misuse and aggressive behaviour.^{13–17} To date, however, there is no clear understanding of what causes these gender disparities in depression. They are considered likely to be a combination of several factors: biological, social and behavioural.^{18,19}

Depression is a long-lasting and, if left untreated, often chronic condition. Treatment usually lasts at least 6–12 months, and includes pharmacological therapy with antidepressants (ADs).²⁰ The use of ADs has increased dramatically in recent years.²¹ According to the national Swedish Prescribed Drug Register (SPDR), almost 9% of the Swedish population was prescribed ADs in 2014, and 65% of these ADs were prescribed for women.²² Similar patterns have been found in other countries.^{23–25} The explanation for this escalation, especially seen in women, remains unclear, but has sometimes been interpreted as a sign of inappropriate use.^{8,9} Nevertheless, despite the widespread use of ADs, depression has repeatedly been shown to be inadequately treated in the general population. Some studies have found that fewer than one in four patients with depression are prescribed ADs and that the duration of treatment is often shorter than recommended.^{26,27}

The ADs prescribed are primarily selective serotonin reuptake inhibitors (SSRIs), although others, for example serotonin–noradrenaline reuptake inhibitors (SNRIs), tricyclic antidepressants (TCAs) and monoamine oxidase inhibitors (MAOIs), are also used depending on illness severity, the patient's age and various adverse drug reactions.^{20,28,29} Gender impact has been observed not only on the number of ADs prescribed but also on their type. For example, women

are prescribed SSRIs more often than men.³⁰

We examined gender differences in the relationship between self-reported depression and prescribed ADs, in the prevalence of self-reported depression, and in the number and type of prescribed ADs.

Method

Participants

A questionnaire was sent to a random sample ($n = 16\,000$, aged 18–84 years) of the Swedish population (totaling 9.5 million); responses were received from 7725 people (48.3%), as presented in *Fig. 1*. The study complies with ethical research requirements, as approved by the Regional Ethical Review Board in Uppsala, Sweden (Dnr 2012/073). Participation in the study was voluntary and information about its purpose was sent out with the questionnaire. Filling in and returning the questionnaire was considered to be equivalent to the respondent giving their agreement to participate in the study.

Assessment of depression and prescribed antidepressants

Self-reported depression was assessed using the Hospital Anxiety and Depression Scale (HADS).³¹ Of the 7725 available participants, 7618 (3435 men, 4183 women) filled in the HADS form (*Fig. 1*) and all analyses were based only on these participants. The HADS was developed to detect patients with high levels of psychological distress and does not include assessment of somatic symptoms. It contains two subscales, one each for anxiety and depression, each consisting of 7 items (score range 0–21) capable of distinguishing between these diagnoses. Higher scores indicate higher levels of psychological distress. Each subscale has three categories based on the score: 0–7 (normal), 8–10 (borderline) and 11–21 (abnormal). In this study, a cut-off level of +8 was used on the depression scale; this level indicates at least mild depression and provides an optimal balance between sensitivity and specificity.³²

Information on depression obtained from the HADS was linked (through the participants' identification number, a unique lifetime personal identifier given to all Swedish citizens) to prescription data. Prescribed ADs were obtained from the SPDR, a national register held by the National Board of Health and Welfare, which gathers data on all dispensed prescriptions for patients in ambulatory care from the entire Swedish population.^{22,33} We collected information on ADs 0–6 months prior to the HADS evaluation. SPDR drugs are classified according to the Anatomical Therapeutic Chemical (ATC) classification system.³⁴ The ADs (N06A) were categorised as TCAs (N06AA, e.g. amitriptyline, imipramine), SSRIs (N06AB, e.g. citalopram, fluoxetine), 'others' (N06AX, including SNRIs (e.g. venlafaxine) and tetracyclic antidepressants (TeCAs, e.g. mirtazapine)), and monoamine oxidase inhibitors (MAOIs; N06AF, N06AG, e.g. moclobemide). The MAOIs were excluded due to few users.

Analyses

The Statistical Analysis System software (SAS9.2, Cary, North Carolina, USA) was used to perform chi-squared tests (χ^2 , P) to examine gender differences in the relationship between self-reported depression and prescribed ADs, and in prevalence of self-reported depression, prescribed ADs, and type of ADs prescribed. Logistic regression analysis (odds ratios (OR) with 95% confidence intervals) was used to examine gender differences in self-reported depression, controlling for age.

Results

In total, 11.7% of the study population (12.3% men, 11.2% women; ², n.s.) was classified as having self-reported depression. Logistic regression analysis showed that the difference between men and women was statistically significant, i.e. men reported depression more often than women (OR 1.226 (CI 1.062–1.414)). According to the SPDR, 7.6% of the study population had been prescribed at least one AD during the 6 months prior to the HADS evaluation. Significantly more women than men were prescribed ADs: 5.3% of the men and 9.8% of the women were prescribed at least one AD ($P < 0.0001$).

Table 1 presents gender differences in the relation between prescribed ADs and self-reported depression in the study population. Among the men, 1.8% reported depression and used ADs, 10.5% reported depression but did not use ADs, and 3.6% used ADs but did not report current depression, while 84.1% were neither depressed nor used ADs. The corresponding figures for women were 2.6%, 8.6%, 7.2% and 81.6%. The gender difference was statistically significant (² $P < 0.001$) in all age groups except the youngest, and was most marked in the groups aged 45–64 and 65–74 years.

Relation between self-reported depression (assessed using the HADS) and prescribed antidepressants (ADs) in the study population ($n = 7618$), Sweden 2012/2013

	Men	Women									
18–34	593	1.7	8.9	2.0	87.4	831	1.8	9.8	3.6	84.8	N.S.

² analyses comparing men and women.

The participants who had received at least one prescribed AD during the 6 months studied ($n = 592$: men $n = 182$, women $n = 410$) were analysed with respect to the type of AD prescribed (Table 2). SSRIs were the most commonly prescribed ADs for both men (62.8%) and women (71.0%), although women were prescribed them more often than men, particularly in the age group 45–64 years (² $P < 0.05$). By contrast, there was no statistically significant gender difference for the TCAs (men 14.8%, women 10.2%), except for in the age group 45–64 years. Further, men were prescribed ‘other’ ADs (e.g. SNRIs and TeCAs) significantly more often than women (men 39.3%, women 28.1%; ² $P < 0.01$).

For example, serotonin–noradrenaline reuptake inhibitors, tetracyclic antidepressants.

² analyses comparing men and women.

Discussion

The present study found that the relationship between self-reported depression and prescribed ADs differs by gender. As in several other studies,^{26,27} the majority of those who reported depression in our study did not use ADs, and overall, men used ADs to a lesser extent than did women, although they reported depression to a greater extent. This could have been caused by several factors. Many people, especially men, prefer not to seek healthcare.³⁵ Women are clinically diagnosed with depression far more often than men, probably not only because they are more depressed but also because they are more likely to seek healthcare, thus increasing the chance that their depression will be detected.³⁶ Also, diagnostic criteria for depression originate from a female norm and symptoms provided by women, leading to an increased likelihood that depression in women will be diagnosed.¹⁵ Depression in men has a different presentation than the classic depressive symptoms more often than in women, and this could lead to men's mental health problems not being recognised and therefore being under-treated.^{13,35}

In contrast to diagnosed depression, previous studies using HADS to assess depression have mostly found no gender differences or, like our study, found a higher prevalence of depression in men.^{37,38} Since men experience more melancholic symptoms and women more somatic symptoms (e.g. increased appetite and weight, and hypersomnia),^{13–17} the reversed gender differences in depression assessed with HADS compared with clinically diagnosed depression could be due to the fact that HADS's focus is more on melancholic rather than somatic symptoms. Whether the HADS might be more sensitive than other scales in detecting depression in men is as yet unclear.

Other factors that could explain the relatively low use of ADs in our study among the sample with depression might be that the depressed participants may have been reluctant to accept treatment with ADs, a choice that is possibly more common among men; they may not have needed drug treatment, perhaps because other treatments were used (in mild depression psychotherapy is considered as effective as drugs); or they may not have had the prescribed drug dispensed. Many patients do not adhere to treatment instructions, for example do not even obtain their prescribed drugs (primary non-adherence), and prior studies have suggested that both gender and illness severity affect adherence.^{39–42}

In our study, it was twice as common for women as for men to use ADs when not currently depressed. This could indicate that their depression was in remission, but it could also mean that women are being over-treated with ADs. Several studies have found AD use to be higher among women, and the increased prescription of ADs in recent decades is especially notable among women.^{23–25,30,43} The higher level of AD prescribing to women may in part be attributed to the greater consumption of healthcare among women in general.^{36,44} Apropos of this, there are studies that show that women are more likely than men to receive a prescription during their medical visits.⁴⁵ The lower threshold for prescribing ADs has led to a debate about the possibility of over-prescription or of ADs being sometimes prescribed where alternatives would be better.^{7–9} It seems that even mild symptoms are now considered indicative of disease and treated with medications, although the efficacy is often limited in mild to moderate depression.^{7,46,47} Further, an

expanding number of indications (e.g. neuropathic pain, anxiety disorders, eating disorders and sleep disorders) seen more often in women than in men are contributors to the increasing trend to prescribe ADs, and this could explain some of the AD use without depression seen in our study.^{9,48}

As in other studies, the SSRIs were the main drugs in our study.^{28,30} Because of gender differences in the pharmacokinetics and pharmacodynamics of ADs, and because depression may present differently in women and men, it has been suggested that men and women could differ in their response to treatment and that pharmacological treatments should therefore be chosen by gender.^{49–51} The women in our study used SSRIs more often than the men. It could be that somatic symptoms respond better to SSRIs than to TCAs. Another cause might be gender differences in adverse drug reactions. However, supporting data are limited and sometimes conflicting, and current treatment guidelines do not take gender into account.^{49,50,52} Regardless, it is important to continue to examine any differences between men and women concerning pharmacotherapeutic efficacy and adverse drug reactions.

Limitations

The SPDR offers complete data on all dispensed drugs; however, it does not give information on actual usage. Also, ADs during the 6-month period were analysed without distinguishing whether the drugs had been used for a long or a short time. Moreover, ADs are sometimes prescribed for indications other than depression, which we could not control for. However, previous studies have reported that depression remains the main indication for AD use.⁵³ Participation in the study was voluntary and there may have been selection biases. For example, non-responders were more likely to be men than women. It is also possible that people with current symptoms of depression would be less likely to respond, introducing further bias to participant selection. Depression assessed using the HADS (in the previous week) was not directly linked to prescribed ADs via the SPDR (0–6 months prior to the HADS evaluation). However, depression is often a prolonged state, and problems in this respect that were encountered in the previous week were probably not temporary. Finally, it is important to emphasise that a cross-sectional design does not permit evaluation of causality to be derived from the results.

Summary of findings

The relationship between self-reported depression and use of ADs differed by gender. Overall, men were prescribed ADs to a lesser extent than women, although they reported depression to a greater extent. By contrast, women were prescribed ADs without reporting depression more often than men. This may be a sign for under-treatment among men and over-treatment among women. Further, men and women were prescribed different types of ADs, possibly because of gender differences in treatment outcomes and adverse drug reactions. Although the causes of these findings remain unclear, diagnostic and treatment guidelines should benefit from considering gender in these respects.

1.6.45 An analysis of whether a working-age ward-based liaison psychiatry service requires the input of a liaison psychiatrist

date

2017-6

Abstract

Aims and method This article presents a 12-month case series to determine the fraction of ward referrals of adults of working age who needed a liaison psychiatrist in a busy tertiary referral teaching hospital.

Results The service received 344 referrals resulting in 1259 face-to-face contacts. Depression accounted for the most face-to-face contacts. We deemed the involvement of a liaison psychiatrist necessary in 241 (70.1%) referrals, with medication management as the most common reason.

Clinical implications A substantial amount of liaison ward work involves the treatment and management of severe and complex mental health problems. Our analysis suggests that in the majority of cases the input of a liaison psychiatrist is required.

- *An analysis of whether a working-age ward-based liaison psychiatry service requires the input of a liaison psychiatrist*
 - *Method*
 - * *Involvement of a liaison psychiatrist*
 - *Results*
 - * *Referrals which required the involvement of a psychiatrist*
 - *Discussion*

Liaison psychiatry services in England have recently seen considerable expansion, following the positive evaluation of the Rapid Assessment Interface and Discharge Team (RAID) service in Birmingham.¹ The independent evaluation suggested that this well-staffed multidisciplinary liaison psychiatry service returned considerable cost savings for people with mental health problems in that general hospital and those attending the emergency department.

The 2015 annual survey of liaison psychiatry in England demonstrated that many services are too poorly resourced to be delivering benefits to patients as envisaged by the RAID study,² while the recent *Guidance on Developing Models for Liaison Psychiatry Services* has shown great variability in service provision.³ The relative lack of consultant psychiatric input suggests that the specialist skills offered by consultant liaison psychiatrists may be poorly understood. To examine the multidisciplinary liaison psychiatry team, we aimed to determine the proportion of referrals to a ward-based liaison service which required the involvement of a psychiatrist in a busy tertiary teaching hospital in England. This project was carried out as part of a registered audit (Audit Project 2125) with Manchester Mental Health and Social Care Trust.

There are many descriptions of the activity of liaison services, but we believe this is the first time the role of a psychiatrist has been addressed in depth. We hope our findings will help inform decisions regarding staffing and the configuration of multidisciplinary liaison psychiatry teams. We focused on a ward-based liaison service for adults of working age.

Method

We carried out a case series of the electronic records of consecutive referrals to a ward-based liaison service at a large teaching hospital in Manchester, over a 12-month period from 18 June 2013 to 17 June 2014. The hospital has approximately 750 beds, with a large renal and critical care unit. There is also a maternity unit on site, with over 8500 deliveries per annum, and an eye hospital. Our liaison service reviews referrals covering an age range of 16–65 by the next working day. Routine alcohol referrals, covered by two specialist nurses, may also be received by our service.

The following details were recorded for each referral: age, gender, number of face-to-face contacts carried out by the team, amount of time the team had ongoing contact with the patient (days), reason for referral, referrer type, psychiatric diagnosis using clinical judgement according to ICD-10 criteria,⁴ employment of the Mental Health Act 1983, and disposal.

Involvement of a liaison psychiatrist

To determine the proportion of patients who required the input of a psychiatrist, we developed criteria for contacts or interventions that required medical input and could not be undertaken by a non-psychiatrist. We deemed the involvement of a psychiatrist would be necessary in any of the following scenarios: Mental Health Act employed, rescinded or considered; medication management; treatment with psychotropic medications commenced in the general hospital; complex diagnostic matters; behavioural disturbance in physically unwell patients where advice about appropriate sedation is required; complex capacity assessments; and a specific request for a consultant psychiatrist opinion. Each case was reviewed and rated by a member of the team. *Box 1* provides detailed criteria for each of these scenarios. We recognise that there are many other kinds of interventions a psychiatrist may carry out as part of liaison work, but we wished to focus solely on interventions which could not be carried out by someone other than a psychiatrist. Many of the interventions therefore require some kind of expertise involving medical knowledge or prescribing of psychotropic medication in patients who are physically unwell.

Summary scores for normally distributed data are presented as means and standard deviations (s.d.). The activity data were not normally distributed, so summary scores are presented in the form of medians and interquartile ranges (IQR). Comparisons of continuous activity data were carried out using non-parametric statistical tests. Mann-Whitney *U*-tests were used to compare continuous data. As in some cases we had few activity data, with only one or two patients in each group, groups with very small sizes (two patients or fewer) were not included in the statistical analyses.

Results

The service received 344 referrals over the study period and carried out 1259 face-to-face contacts with patients. The average number of ‘face-to-face’ contacts per patient was 3.7 (s.d. = 5, range 1–33). The median age of patients seen was 48 years (IQR 36–59), and 184 (53.4%) were female. At any one time, between 8 and 15 patients were under review by the team. The majority of referrals were from physicians (all medical departments) ($n = 227$, 66.0%), 59 (17.2%) were from surgery, 31 (9%) from the maternity hospital and 23 (6.7%) from the critical care unit. One referral came from the eye hospital and a further 3 were from the liaison service for older adults, but these patients were best managed by the adults of working age team.

Table DS1 in the online supplement provides a snapshot of the patients under the care of the service on one day in May 2014, and is typical of the kind of patients who are under review by the service at any given time. Five patients had severe mental illness (four had schizophrenia and one had bipolar disorder). Two had been treated under the Mental Health Act and there was a possibility that one more person may have needed treatment. One person was on a community treatment order (CTO). Four patients had voiced recent suicidal ideas, two had complex organic mental disorders, and three had psychological reactions to physical illness or difficulties with their behaviour in an acute hospital setting.

Referrals which required the involvement of a psychiatrist

Table 1 illustrates the number of referrals which needed a psychiatrist. Of the 344 referred patients who saw a psychiatrist, we deemed on the basis of our criteria that a psychiatrist was required for 241 patients (70.1%). Patients who required a psychiatrist needed more face-to-face contacts than those who did not require a psychiatrist (median 2 (IQR 1–5) v. median 1 (IQR 1–2)), and were under the liaison service for a greater period of time (median 7 days (IQR 1–14) v. median 1 day (IQR 1–7)).

Referrals and service workload depending on whether patient required a psychiatrist or not

		Face-to-face contacts	Days in contact with service, median (IQR)	
Requires psychiatrist	241 (70.1)	1039 (82.5)	2 (1–5)***	7 (1–14)***
Does not require psychiatrist	103 (29.9)	220 (17.5)	1 (1–2)	1 (1–7)
Total	344	1259	2 (1–5)	4 (1–13)

IQR, interquartile range.

$P < 0.001$ (requires v. does not require a psychiatrist).

According to our criteria, the most common reason for psychiatric input was medication management (Table 2): 77 patients (32.0%) required input regarding their current psychotropic medication use. Of interest, 10 of these patients were referred for clozapine management which required over 100 face-to-face contacts from the team. 56 patients were started on treatment for their mental health problems while they were in hospital (i.e. patient started on psychotropic medication). There were complex diagnostic issues in 38 patients and the Mental Health Act was considered in 23 patients, but only actually implemented in 18. In 14 cases the patient required a complex capacity assessment, 10 patients presented with challenging behaviour requiring advice about sedation, and a specific consultant opinion or involvement was requested in 6 patients. The categories are not mutually exclusive.

The number of patients who required a psychiatrist according to the categories in the study

Clinical categories	<i>n</i>	Percentage of total requiring psychiatrist
Medication management	77	32.0%
Treatment with psychotropic drugs	56	23.2%
Complex diagnostic issues	38	15.8%
Mental Health Act	23	9.5%
Management of severe mental illness	17	7.1%
Complex capacity assessments	14	5.8%
Management of behavioural disturbance	10	4.1%
Specific liaison consultant review	6	2.5%

Box 1 Definitions of categories used to determine whether the involvement of a liaison psychiatrist was required

- **Mental Health Act:** situations where the Mental Health Act has been applied or its potential use has been seriously considered
- **Medication management:** consultation in which there was a specific issue about psychotropic medication the patient was taking due to a change in their physical health. This may involve stopping, switching or another action.
- **Management of behavioural disturbance in the general hospital:** involving advice about medication, where a psychiatrist has provided assessment, advice and guidance about using sedating medication. The psychiatrist will have considered the patient's underlying physical health problems (e.g. renal failure) in making the decision regarding type and dosage of medication. Other non-pharmacological aspects for management of acute behavioural disturbance in physically unwell patients are not considered here, as they are not exclusively carried out by liaison psychiatrists
- **Complex diagnostic matters:** diagnosis or understanding of a clinical problem which required knowledge of specific medical disorders
- **Capacity:** requests for medically complex capacity assessments, where the patient has a history of a psychiatric condition which may be interfering with their judgement to give informed consent to potentially life-saving treatment
- **Treatment with psychotropic medications commenced in the general hospital:** treatment with a psychotropic agent that was commenced in the general hospital by the liaison team, in a patient who had ongoing physical health concerns
- **Specific request for consultant liaison psychiatrist opinion:** the referring consultant specifically requested a consultant psychiatric opinion or involvement

Box 2 Categories of clinical scenarios where we judged a psychiatrist was required (examples)

- **Mental Health Act:** Female (age range 50–60) with diagnosis of schizophrenia. Admitted with a ruptured oesophagus. Clozapine had been stopped prior to admission as she had refused to take it. Her psychosis had relapsed and she was floridly psychotic in hospital. Following repair of her oesophagus she required 6–8 weeks bed rest for the repair to heal. She was treated under Section 3 of the MHA with covert medication (clozapine). Her mental state returned to normal. She had a good physical and mental health recovery. She later agreed to continue to take clozapine on a voluntary basis.
- **Medication management:** Female (age range 30–40) admitted following collapse and found to have very low sodium. Diagnosis of schizophrenia. In discussion with medical team, all psychotropic medication was stopped. Haloperidol started cautiously. Usual medications re-started after physical recovery. Discharged to CMHT.
- **Management of behavioural disturbance:** Male (age range 40–50) who was admitted with delirium, barricaded himself and 3 other patients in a 4-bedded side room. History of hydrocephalus and other abnormal neurological signs. Input required sedation to manage the current situation and to facilitate medical investigations including brain MRI.
- **Diagnosis:** Male (age range 50–60) admitted from nursing home with a history of severe weight loss. History of schizophrenia and extrapyramidal side-effects attributed to neuroleptics. Huntington's chorea diagnosed by consultant psychiatrist.
- **Capacity:** Male (age range 50–60) with history of schizophrenia. Jumped off a bridge when 22 years of age, paraplegic following this. Psychosis treated well for years on clozapine. Developed bowel obstruction, multi-organ failure. Clozapine stopped. On regular haemodialysis. Chronically psychotic. Refusing dialysis. Complicating factors, low mood, chronic psychosis (at times he believes he is Christ and can be resurrected).
- **Treatment with psychotropic drugs commenced in the general hospital:** Male (age 60–70) admitted after stabbing his wife in the back and then stabbing himself 4 times in the abdomen. Diagnosed with depressive disorder. Treatment started with antidepressants while receiving medical treatment on ward. Mood improved.

- **Specific request for consultant liaison psychiatric opinion:** Male (age range 40–50) with a history of gastric problems and feeding difficulties. Had had gastrectomy and had been started on TPN. Had been in hospital for over a year. Staff suspected that reliance on TPN was far more than clinically indicated but all efforts to reduce it failed. Patient was aggressive on occasions with staff, made frequent complaints about staff and at times threatened self-harm. Consultant opinion was specifically sought regarding the risks of moving to home with TPN feeding.

CMHT, community mental health team; MHA, Mental Health Act; MRI, magnetic resonance imaging; TPN, total parenteral nutrition.

Table 2 shows the number of patients who required a psychiatrist according to the categories developed for this study.

Clinical illustrations of actions or interventions which were judged to require the involvement of a psychiatrist, according to each category, are provided in *Box 2*.

Table 3 shows the number and percentage of patients who required input from a liaison psychiatrist according to the most common psychiatric diagnoses. Patients with bipolar affective disorder, schizophrenia, Korsakoff's psychosis, amnesic syndrome and somatoform disorder required the involvement of a psychiatrist in over 80% of all cases, whereas for patients with anxiety/panic disorder, adjustment disorder or dementia the requirement was much lower.

Patients who required input from a liaison psychiatrist according to diagnosis

Psychiatric diagnosis	Required psychiatrist (% of total seen)
Somatoform disorders	9 (100.0%)
Bipolar affective disorder	23 (92.0%)
Amnesic syndrome	11 (91.7%)
Korsakoff's psychosis	11 (91.7%)
Schizophrenia	42 (82.4%)
Depression	100 (74.1%)
Miscellaneous including eating disorders, intellectual disability	5 (71.4%)
Personality disorder	9 (69%)
Substance misuse	11 (68%)
Delirium	15 (65.2%)
Anxiety/panic disorder	6 (50.0%)
Dementia	2 (33.3%)
No diagnosis	8 (32.0%)
Adjustment disorder	2 (20.0%)

Discussion

Our findings suggest that a ward-based liaison psychiatry service for working-age adults in a large teaching hospital requires the input of liaison psychiatrists. We deemed that a psychiatrist was essential in the assessment or management of approximately 70% of all referrals to the service, whereas approximately 30% could be reviewed by other members of a liaison team. We based this judgement on clear, definable actions or aspects of care that necessitated the involvement of a psychiatrist. A consultant liaison psychiatrist would of course have many other roles, but for the purposes of this study we limited our focus to interventions or actions where the role of a psychiatrist was unequivocal.

Many of the patients seen by the service had complex physical and mental health needs. Table DS1 provides a snapshot of the work, and illustrates that it is necessary to involve a psychiatrist in the management of a large proportion of referrals. Out of the 12 patients under the care of the team on one day in May 2014, 9 required the input of a psychiatrist.

Certain patients with diagnoses such as adjustment disorder and dementia were unlikely to require psychiatric input, whereas high rates of psychiatric involvement were required for patients with severe mental illness and somatoform disorders. Psychiatric input was also needed in the management of patients with Korsakoff's psychosis, because locally a formal diagnosis from a psychiatrist is required in order to access particular kinds of Social Services support.

This study has three major limitations. First, data were based on routine clinical entries made using a National Health Service (NHS) electronic record system. It is possible that this may have led to an underestimation of the numbers of patients requiring psychiatric input due to a lack of recording certain data (e.g. details about psychotropic medication). It is very unlikely that it would have led to an overestimate of our findings. Second, this study was undertaken in a teaching hospital, with a large critical care unit, a large renal unit, a very busy maternity hospital and other specialist centres. It may not reflect the work of a liaison service in a district general hospital, but it emphasises the need to take account of local variations in acute hospital services when planning a liaison service. Third, this liaison service is a ward-based service only. Approximately a third of liaison services run out-patient clinics for complex cases requiring psychiatric time. Clinics can take psychiatrists away from acute ward cover and require different planning and staff resources compared with a ward-based liaison service.

The methods we employed, however, can easily be used by other services to estimate the requirement for input from a liaison psychiatrist, and this is likely to vary depending on the setting and age range of patients seen. As this research team consisted entirely of psychiatrists, we may have overestimated the need for the skills of our own discipline when creating the criteria and applying them. However, we have provided clinical examples to illustrate our decision-making process and thus expose it to critical examination.

Our results suggest that liaison psychiatrists have a pivotal role in ward-based liaison services for adults of working age, and this may be particularly important in a teaching hospital setting. Our work also provides support for the recent commissioning guidance for liaison psychiatry services in England developed by the Department of Health, which suggests that liaison psychiatry services in a teaching hospital/inner city setting may require additional consultant psychiatric input.⁷

1.6.46 Civil and forensic patients in secure psychiatric settings: a comparison

Abstract

Aims and method To evaluate differences between male patients in secure psychiatric settings in the UK based on whether they are detained under civil or forensic sections of the Mental Health Act 1983. A cohort of patients discharged from a secure psychiatric hospital were evaluated for length of stay and frequency of risk-related incidents.

Results Overall, 84 patients were included in the study: 52 in the forensic group and 32 in the civil group. Civil patients had more frequent incidents of aggression, sex offending, fire-setting and vulnerability, whereas forensic patients had more frequent episodes of self-harm.

Clinical implications Secure hospitals should ensure treatment programmes are tailored to each patient's needs. Civil patients require greater emphasis on treatment of their mental illness, whereas forensic patients have additional offence-related treatment needs. Regular liaison between forensic and general adult services is essential to help ensure patients can return to appropriate settings at the earliest opportunity in their recovery.

Further to the closure of the asylums and subsequent rare but high-profile failures in community care, forensic psychiatry in the UK has rapidly expanded, with the development of high, medium and low secure in-patient services across the country as well as specialist forensic mental health teams in the community.¹ Alongside its expansion, an ongoing debate related to its interface with general psychiatry has persisted.² In England and Wales, the forensic v. general psychiatry divide extends to the subdivision of in-patients detained under the Mental Health Act 1983 into those affected by civil and forensic sections. Patients detained under Part II of the Act are termed 'civil patients'. They can be detained under Section 2 for assessment and treatment for up to 28 days where there is suspicion of a mental disorder. Section 2 can be converted to Section 3 for further treatment. Alternatively, patients can be admitted directly under Section 3 when there is a known mental disorder. Patients detained under Part III of the Act are termed 'forensic patients', given their involvement in the criminal justice system through the courts and prisons.

While forensic units have expanded, there has been an overall reduction of in-patient bed numbers in the UK, which have fallen from 155 000 in 1954 to just 18 166 as of 31 March 2014. The number of patients detained in all settings under civil sections during 2013/2014 was 32 781, of which 25 300 were under Section 2 and 7481 were under Section 3. During 2013/2014 there were 1847 detentions under forensic sections: 99 under Section 35 or 36, which is admission for assessment or treatment via the courts; 763 under Section 37 hospital orders, allowing detention in hospital instead of a prison sentence; and 457 under Section 47, which allows transfer of a serving prisoner to hospital.^{2,3}

Secure psychiatric hospitals are generally geared towards providing assessment, treatment and rehabilitation for forensic patients, since they are the majority group in such hospitals. In particular, Coid *et al* found that 69% of patients in

medium security were detained under forensic sections.⁴ Despite this discrepancy in distribution, research into whether there are differences between these groups is limited. The only study we could identify was that by Reed (2004),⁵ who evaluated the differences between civil and forensic in-patients in a low secure intellectual disability setting and found, surprisingly, that the forensic patients were less likely to be aggressive or use weapons but more likely to harm themselves.⁵ It is not known whether these findings are isolated to intellectual disability settings. Therefore, we present findings from our evaluation of male patients discharged from a secure psychiatric hospital (excluding intellectual disability – the hospital does not cater for such patients) and suggest recommendations on how to meet the differing clinical needs identified in each group.

Method

The study was conducted as part of a service evaluation into length of stay at St Andrew's Healthcare, Birmingham, and registered with the St Andrew's Clinical Audit Team. In keeping with previous similar evaluations, ethical approval was not required as the study evaluated retrospective, non-patient-identifiable data from health records as part of service evaluation.⁵ Data were retrospectively collected for all discharges from the two medium and three low secure wards since the opening of the hospital in March 2009 to the study end point of 30 December 2014. The source of data were patients' electronic health records, including medical reports, Historical Clinical Risk Management-20 (HCR-20) assessments, Care Programme Approach records, electronically recorded risk incident logs and discharge summaries.

Summary statistics were calculated for all patients evaluated. Patients were then grouped by whether they were initially detained under a civil or forensic section at the start of their admission to St Andrew's Birmingham. In order to evaluate illness severity between the two groups, Health of the Nation Outcome Scales for Users of Secure and Forensic Services (HoNOS-secure) assessment scores taken at admission and discharge were noted.⁶ A power calculation was not performed but all available data were used in the analysis. The average length of stay was calculated for each group. SPSS version 16 for Windows was then used to calculate independent *t*-test statistics to examine any between-group associations and frequency of various types of incidents.

Results

In total, 93 male patients were discharged from the hospital during the data collection period; 9 patients were excluded from the study: 7 were excluded as their admission was less than 3 months and unlikely to be representative of the treatment phase being evaluated, and discharge would also have occurred prior to the standard Care Programme Approach meeting held 3 months after admission, where a formal diagnosis would have been made. One patient was excluded as they were informal during the course of their admission and one was excluded due to death from natural causes. Therefore, 84 patients were included in the study, with 32 in the civil group and 52 in the forensic group. In the civil group, 16 patients were admitted from general adult services, 1 from a police station, 7 from low secure services and 8 from medium secure services. The legal status of patients in the civil group remained unchanged during the course of their admission, apart from one patient who became informal in the days prior to discharge. None of the patients in the civil group switched to being forensic patients following convictions in court. Regarding the forensic group, 4 patients were admitted from general adult services, 3 from low secure services, 16 from medium secure services, 28 from prison and 1 from a high secure hospital. In this group, 14 patients changed their legal status prior to discharge; 11 changed from being sentenced prisoners under Section 47/49 to being detained under a notional Section 37, as they had gone past what would have been their automatic release date from prison. Two patients switched from being remanded prisoners under Section 48/49 to being sentenced under a Section 37 hospital order at court and one patient switched from Section 48/49 to a Section 37/41 hospital order with restrictions after sentencing at court.

Table 1 outlines the baseline characteristics of each group, including diagnosis, age, ethnicity and Mental Health Act status on admission. All patients were male, with a mean age of 37 years (range 20 to 63 years). *Table 2* shows the mean length of stay, HoNOS-secure scores on admission and discharge, and frequency of risk-related incidents.

Discussion

The study found no significant difference in length of stay or severity of illness based on HoNOS-secure scores at the start or end of admission between the civil and forensic groups. However, it should be noted that HoNOS-secure is not a specific measure of mental state, since it also evaluates behavioural functioning and a range of security measures. This study identified that civil patients in secure settings have more frequent incidents of aggression, sex offending, fire-setting and vulnerability, whereas forensic patients have more frequent episodes of self-harm. This finding challenges the preconception that forensic patients are more ‘dangerous’ and difficult to manage.² One explanation for this may be that the civil patients in this study represent a cohort of general adult patients that have been placed in forensic services due to their frequency of aggressive and difficult to manage behaviours, whereas the more stable forensic patients have been admitted due to severe but more isolated offences.

The higher frequency of incidents in the civil group may make engaging with specialist treatment programmes practically more difficult for this group, which may in turn become a factor that limits their motivation to engage. Secure hospitals should be aware that civil patients, due to higher frequency of risk incidents, may have differing needs to forensic patients. Therefore, we suggest that civil patients who present with a high frequency of incidents will benefit from a greater emphasis on treatment of their mental illness combined with behavioural interventions, with less of a requirement to engage in specialist treatment programmes or to complete formal psychological therapy programmes that are often required in forensic settings. Further research is needed to explore whether the higher frequency of incidents among civil patients affects the therapeutic milieu on the ward and has an adverse impact on outcomes for forensic patients engaging in specialist treatment interventions. The higher frequency of vulnerability incidents among civil patients highlights the difficulty they experience in forensic settings and suggests a greater need for vigilance and robust safeguarding for this patient group, who may be at risk of reprisal assaults by their forensic peers. The findings of our study must also be considered in light of the Schizophrenia Commission report,⁷ which comments that patients stay too long in secure services, and highlights funding cuts and acute bed closures in general adult services as part of the problem.

We conclude that our study supports the need to focus more on preventive interventions, such as avoiding delays in assessment, ensuring early treatment and supporting alternatives to admission such as crisis and home-based treatment teams, to help avoid admissions. Regular liaison between forensic and general adult services is essential to help ensure patients can return to appropriate settings at the earliest opportunity in their recovery. This may only be possible with careful consideration when commissioning services at all levels of care.

The finding that forensic patients have a greater frequency of self-harm incidents should be treated with caution as the numbers in this study are small and self-harm is a rare outcome. One possibility is that forensic patients may find the criminal justice system and their conviction distressing, leading to a greater risk of self-harm and potentially suicide. We suggest that clinical teams should be aware of this risk in these patients and ensure careful monitoring, risk management and support for patients during criminal proceedings.

Limitations

This study has a number of limitations. Most significantly, it is a comparison of forensic and civil patients conducted in a secure mental health hospital and the findings cannot be used to compare differences between forensic and general adult patients in non-secure settings. In addition, the civil patients in the study are likely to represent patients with greater treatment resistance whose aggressive behaviours have led to them being transferred to secure settings. It remains possible that the section status assigned to the patient on admission may be misleading, as quite often patients who commit offences when unwell are not prosecuted.⁸ The study is reliant on accurate recording of risk incidents in patients’ records. Although some degree of inaccuracy in recording of incidents may have occurred, it is anticipated that this would have occurred evenly between both groups and thus not affected the validity of the results. This study, in line with previous work, evaluates data for a cohort of discharged patients in order to evaluate comparable groups. It is possible that the study may underestimate the severity of risk incidents, since the most challenging patients would not have been included in the analysis as they have not yet been discharged from hospital. It is anticipated that the impact of this factor would be evenly distributed between each group.

Practice recommendations

Secure hospitals should ensure all treatment plans are based around the individual. There should be an emphasis on managing the mental illness of civil patients and tailoring treatments based on this goal, which will help reduce risks and hopefully shorten length of admission. Forensic patients are more likely to have additional offence-related treatment needs which would require specific interventions. Regular liaison between forensic and general adult services is essential to help ensure patients can return to appropriate settings at the earliest opportunity in their recovery. This can only be possible with careful consideration when commissioning services at all levels of care.

We thank Catherine Clarke, Psychology student at the University of Birmingham, for her help in the study.

1.6.47 Known unknowns and unknown unknowns in suicide risk assessment: evidence from meta-analyses of aleatory and epistemic uncertainty

Matthew Large Cherrie Galletly Nicholas Myles Christopher James Ryan Hannah Myles

Abstract

Suicide risk assessment aims to reduce uncertainty in order to focus treatment and supervision on those who are judged to be more likely to die by suicide. In this article we consider recent meta-analytic research that highlights the difference between uncertainty about suicide due to chance factors (aleatory uncertainty) and uncertainty that results from lack of knowledge (epistemic uncertainty). We conclude that much of the uncertainty about suicide is aleatory rather than epistemic, and discuss the implications for clinicians.

Contents

- *Known unknowns and unknown unknowns in suicide risk assessment: evidence from meta-analyses of aleatory and epistemic uncertainty*
 - *Can knowing about suicidality reduce uncertainty about suicide?*
 - *Can knowing about a wider range of risk factors reduce uncertainty about suicide?*
 - *Implications of the limits to epistemic uncertainty*

Uncertainty is the psychological state of being unsure, of having doubt, of not fully knowing. Uncertainty is central to modern medicine, where its recognition drives diagnostic efforts and leads to the pursuit of evidence-based practice.

All medical decision-making occurs under conditions of varying uncertainty about diagnosis, optimal treatment and prognosis. This is true in the assessment of suicidal patients.

Uncertainty has two underlying components: epistemic uncertainty that results from a lack of knowledge, and aleatory uncertainty that results from random or chance events.¹⁻³ In medical practice, both types of uncertainty are at play. A teenage tobacco user might or might not develop cancer later in life. This is mostly a matter of chance, a chance that will increase with heavier and longer tobacco use. This longitudinal cancer risk is probabilistic, akin to the throw of a die, and further knowledge might not greatly reduce uncertainty about what will eventually happen. In middle age, the same smoker might develop haemoptysis. A chest X-ray would reduce uncertainty about the presence or absence of lung cancer, but it might be more clearly resolved by a biopsy. Uncertainty in this case is not probabilistic – the smoker either has or does not have cancer. This is now a question that can be resolved with more information. Chance is no longer playing a part.

It is generally considered that uncertainty in suicide risk assessment can be greatly reduced by a detailed assessment of the patient's suicidal thoughts, plans and actions, and attention to other demographic and clinical factors. Suicide risk assessment guidelines and relevant peer-reviewed publications often contain long lists of questions to ask and factors to consider.⁴⁻⁷ This approach assumes that more substantial knowledge of the patient, their illness, circumstances and intentions will reduce the epistemic uncertainty in the assessment. Few would doubt that chance also plays a major part in suicide. The course of underlying illness, the vagaries of individual decision-making and impulsivity, and the patient's future circumstances are all sources of aleatory uncertainty.

In this article we consider the uncertainty surrounding suicide using the framework of epistemic and aleatory uncertainty. In order to do this, we use recent meta-analytic research to interrogate the proposition that uncertainty about suicide risk can be reduced by knowing more about suicidal thoughts and behaviours, or by the knowledge of a wider range of suicide risk factors.

Can knowing about suicidality reduce uncertainty about suicide?

No small number of references could begin to do justice to the importance that suicidal ideation and behaviours have assumed in suicide research. Several recent systematic meta-analyses have synthesised the quantitative peer-reviewed literature on the statistical relationship between suicidality and suicide. Each of these meta-analyses has cast doubt on the notion that knowing more about suicide ideas, or suicidality more broadly, reduces uncertainty about suicide.

Two meta-analyses published in 2011, one examining risk factors for suicide by psychiatric in-patients⁸ and the other examining risk factors for suicide by recently discharged patients,⁹ found that the association between suicidal ideation and suicide was statistically weak, with diagnostic odds ratios (OR) of less than 3. In 2015, Chapman *et al*¹⁰ published a meta-analysis finding that suicidal ideation was significantly associated with suicide among patients with schizophrenia spectrum conditions. However, suicidal ideation was not significantly more likely to lead to suicide than no suicidal ideation among patients with mood disorders (OR = 1.49, 95% CI 0.92–2.42).

A 2016 meta-analysis¹¹ examined the broader question of whether self-injurious thoughts and behaviours deserve their status as strong predictors of future suicidal behaviour. This study found that self-injurious thoughts and behaviours are only weakly associated with later suicide attempts (OR = 2.14, 95% CI 2.00–2.30) and death from suicide (OR = 1.54, 95% CI 1.39–1.71). The authors concluded that assessments of suicidality provided an improvement in prognostic accuracy that was only marginally above chance.

Another 2016 meta-analysis examined the psychometric properties of both individual risk factors and suicide risk assessment scales (the Beck Hopelessness Scale, Suicide Intent Scale and Scale for Suicide Ideation) among populations of people who self-harm.¹² The authors found a modest statistical association between previous self-harm and suicidal intent and later suicide, concluding that individual risk factors are 'unlikely to be of much practical use because they are comparatively common in clinical populations'. With respect to use of suicide risk scales they considered that they 'may provide false reassurance and [are], therefore, potentially dangerous'.

Thus, five recent meta-analytic summaries of the peer-reviewed literature have each reached similar conclusions – knowing about suicide thoughts and behaviours can only reduce uncertainty about future suicide to a modest extent.

Can knowing about a wider range of risk factors reduce uncertainty about suicide?

If enquiries about our patients' suicide ideas, plans and actions do not help very much, what else should mental health professionals do to reduce uncertainty? The most common and obvious answer is to consider a comprehensive range of other suicide risk factors. Again it is simply not possible to describe the full range of articles, guidelines and peer-reviewed papers that consider the range of potentially important risk factors for suicide. A weakness of this literature is that although very large numbers of risk factors for suicide have been identified, there is no widely accepted way in which this information can be combined to improve the predictive strength of suicide risk assessment. Further, despite widespread recommendations for a comprehensive consideration of suicide risk factors, there are doubts as to whether combining risk factors can ever produce clinically useful predictive models. More than 30 years ago, Pokorny¹³ concluded his paper describing a landmark prospective suicide prediction study with the statement that it 'is inescapable that we do not possess any item of information or any combination of items that permit us to identify to a useful degree the particular persons who will commit suicide, in spite of the fact that we do have scores of items available, each of which is significantly related to suicide'.

We recently published a meta-analysis that further examined the dilemma posed by Pokorny.¹⁴ We synthesised the results of all the published longitudinal prospective studies that used multiple risk factors to model future suicide among cohorts of psychiatric patients. We included experimental studies that employed multiple regression or survival analysis and studies that validated suicide risk prediction instruments. Our main outcome measure was the odds of suicide in high-risk patients compared with lower-risk patients. One of the aims of the meta-analysis was to determine if the observed between-study variability in this OR could be explained by the number of risk factors used in the predictive modelling. The results were very clear. We found a pooled OR of 4.84 (95% CI 3.79–6.20) derived from 37 studies and 53 samples of patients. This indicates that the rate of suicide among high-risk patients can be expected to be about 5 times the rate of suicide of low-risk patients. While this sounds like it might be a clinically useful finding, these odds do not meaningfully improve on the pooled ORs of about 4 that are associated with some individual suicide risk factors among psychiatric patients – factors such as depression, hopelessness and prior suicide attempts.^{8,9} The meta-analysis also found that 56% of suicides occurred in high-risk groups (sensitivity) and 44% occurred among the lower-risk group. Over an average follow-up of 5 years, 5.5% of high-risk patients, but 1% of low-risk patients, died by suicide. This 5.5% suicide mortality over a period of 5 years means the probability of suicide of high-risk patients over clinically important durations is extremely low. For example, the weekly probability of suicide of a high-risk patient over the 5-year follow-up can be estimated at $0.055/(5 \times 52) = 0.0002115$ or 1 in 4700 people. In practical terms, what this means is that if a patient is deemed at higher risk of suicide because of the presence of one or more risk factors (recall that the number of risk factors seems unimportant), our best estimate of the incidence of suicide in the following week is about 1 in 4700. Even if there was a hypothetical dynamic risk factor that transiently increased the next-week risk of suicide by 10 times, strict supervision of almost 500 high-risk people for 1 week would be needed to prevent one suicide – assuming that such supervision were 100% effective.

Relevant to the present paper, the meta-analysis found that the predictive models that used more suicide risk factors had no more statistical strength, and no better discrimination between high-risk and lower-risk groups, than studies that used fewer factors (slope 0.007, 95% CI 0.016 to 0.03, $P = 0.53$). In fact, studies that employed two factors had a similar predictive strength to studies that employed ten or more factors. *Figure 1* plots the diagnostic odds with 95% confidence intervals effect size of models using 2 or 3 factors (8 samples), 4 or 5 factors (11 samples), 6 or 7 factors (7 samples), 8 or 9 factors (5 samples) and 10 or more factors (22 samples) with obviously overlapping confidence intervals. We concluded that multivariate models offered little advantage over single risk factors and that multivariate models that relied on more suicide risk factors performed no better than those that use fewer risk factors.

Implications of the limits to epistemic uncertainty

The findings of these recent meta-analytic studies undermine one of our profession's main assumptions about suicide risk assessment. Suicidal ideation,¹⁰ suicide behaviour^{11,12} and more complex modelling¹⁴ offer predictive advantages only a little better discrimination than chance. Hence, most of our uncertainty about suicide risk is aleatory; knowing more does not help because epistemic uncertainty plays only a minor part.

So what should clinicians do? First, we believe that this fundamental problem with suicide risk assessment needs to be acknowledged. We need to acknowledge our powerlessness to usefully classify individuals or groups of patients according to future suicide risk. We need to acknowledge this to ourselves, and communicate this to health departments, to the courts, and most importantly, to our patients and their families.

Second, we need to provide a more universal standard of care, involving a complete and sympathetic assessment of every patient, their illness and their circumstances. Such assessment is needed to guide individualised treatment plans, and might also have the intrinsic benefit of reducing suicidality.¹⁵ Where modifiable risk factors are found, we need to try to modify them. For example, patients who present with suicidal ideation when intoxicated should not be summarily discharged when sober and denying suicidal ideation, but should be offered access to addiction services that have some prospect of reducing suicide risk and improving their lives, irrespective of their overall risk category.

Third, we need to be very sparing in our use of involuntary treatment as a reaction to suicide risk. It is likely that very few patients who we admit to hospital would have died by suicide as out-patients over the period of time usually associated with a contemporary length of stay. Patients making ongoing immediate threats might still be admitted to hospital, as such threats are a crucial communication and legitimate focus of care without recourse to notions of probability. However, suicide risk is simply not a sufficient warrant for making paternalistic decisions about involuntary hospital care. Equally, we should be careful not to automatically deny low-risk patients voluntary in-patient treatment when they want it. Many suicides are by low-risk patients and we should not pretend we are able to peer into their future any more than we can discern the future of a higher-risk patient.

1.6.48 Drug information update. Unconventional treatment strategies for schizophrenia: polypharmacy and heroic dosing

patients will require more heroic measures that include antipsychotic polypharmacy and high-dose monotherapy. Indeed, research has shown that roughly 30% of patients with psychosis are prescribed multiple antipsychotic medications. We discuss the potential benefits and challenges of these approaches and provide a rationale for why and when they should be utilised.

 - *Summary*

Schizophrenia is one of the most challenging psychiatric disorders faced by clinicians today, affecting roughly 1% of the population.¹ Many out-patient clinics and virtually all in-patient facilities manage these often complex clinical cases. Since the introduction of the first-generation antipsychotics (FGA) and subsequent development of the dopamine hypothesis, blockade of dopamine 2 (D₂) receptors has been the primary goal of pharmacological intervention. Even with the development and proliferation of the second-generation antipsychotics (SGA), D₂ blockade remains central to effective control of positive symptoms whereas serotonin 2A (5-HT_{2A}) plays an important but secondary role in the modulation of dopamine, theoretically improving negative symptoms while reducing the risk of extrapyramidal symptoms.²

The term ‘dopamine hypothesis’ of schizophrenia is slowly being phased out, as more sophisticated imaging studies have identified the nature of the dopamine dysfunction and its locus within the striatum. The striatum is a major component of the basal ganglia, and is divided functionally into the dorsal sensorimotor portion, the central associative striatum, and the ventral limbic striatum. Recently it has been found that the best correlation between positive symptoms of psychosis in schizophrenia and levels of D₂ activity is in the rostral caudate, a portion of the central associative striatum.^{3,4} We thus have *in vivo* confirmation of excessive D₂ neurotransmission and the relationship to the positive

symptoms of schizophrenia. In the limbic striatum low dopamine release is directly related to the severity of negative symptoms; the lower the dopamine levels, the greater the negative symptom severity.³

While the goal of treatment is normalisation of D₂ neurotransmission in the striatum, a subset of patients do not respond to traditional treatment algorithms which include antipsychotic monotherapy at dosing levels defined in registrational trials. Consequently, many patients continue to exhibit uncontrolled positive and negative symptoms as well as manifesting aggressive and impulsive behaviours.⁵ It has been argued that ‘unconventional’ strategies for better management of treatment-resistant psychosis should be employed.^{6–8} The two primary methods we discuss in the following pages include antipsychotic polypharmacy and high-dose monotherapy.

Why do standard treatments sometimes fail?

To effectively treat the positive symptoms of schizophrenia it is important to achieve at least 60% striatal D₂ blockade with antipsychotics.⁹ The exception is clozapine, which has been shown to have some antipsychotic effect at as little as 20% blockade.¹⁰ Beyond 80% D₂ occupancy, risk of extrapyramidal side-effects (EPS) increases, leading to non-adherence and treatment failure. Therefore, the ‘sweet spot’ of D₂ receptor blockade for most patients is between 60 and 80%.⁶ However, in some treatment-resistant cases, particularly when aggression and impulsivity are of concern, moving beyond 80% may be necessary.^{6,8,11–14} Moreover, there is significant evidence from the literature that a substantial portion of patients tolerate plasma antipsychotic levels consistent with >80% D₂ occupancy.

One of the early imaging studies from 1997 noted that a large fraction of patients stabilised on low-dose oral haloperidol had plasma levels associated with >80% D₂ occupancy;¹² however, prior clinical studies found that even at a plasma haloperidol level of 6 ng/ml (predicted 90% D₂ occupancy), only 30% experienced adverse effects.¹³ A similar pattern is seen with risperidone. The pivotal trials studied doses of 10 mg and 16 mg, which correlate with a plasma active moiety level of 70 ng/ml and 112 ng/ml, respectively.¹⁵ The plasma level of 70 ng/ml would correspond to a D₂ occupancy of 85%;¹⁴ however, despite this high level of predicted D₂ occupancy, the proportion of patients on 10 mg who required anti-Parkinsonian treatment was only 31%.¹⁶

Pharmacokinetic failure

Pharmacokinetics is the umbrella term that covers drug absorption, bioavailability, distribution, metabolism and excretion. The role of pharmacokinetics in antipsychotic treatment failure is relatively simple. Through abnormal pharmacokinetic processes such as poor absorption, rapid metabolism and enzymatic polymorphisms, antipsychotic plasma levels do not reach the threshold associated with 60% striatal D₂ occupancy. This leads to continued psychotic symptoms. It also leads to frustration and confusion for clinicians in that the patient does not sufficiently respond to standard treatment algorithms.

Pharmacodynamic failure

Pharmacodynamics encompasses receptor binding and sensitivity, postreceptor effects, and chemical communication. Pharmacodynamic treatment failure with regard to antipsychotics is the inability to provide significant amelioration of psychotic symptoms in spite of achieving plasma levels associated with at least 60–80% D₂ occupancy.¹⁷ Although adequate drug plasma levels are achieved, patients with treatment-resistant psychosis present with continued positive, cognitive and aggressive symptoms. The treatment failure associated with pharmacodynamic influences is hypothesised to be related to lack of D₂ receptor sensitivity or hypersensitivity. When patients manifest a lack of extrapyramidal adverse effects or akathisia, increasing drug doses to achieve plasma levels that are associated with >80% D₂ blockade may be necessary to provide symptom control.^{18–20} The overriding principle is that there are a subset of patients who both tolerate and require high levels of D₂ antagonism for symptomatic relief.

The importance of being patient

While recent studies have demonstrated that minimal response after 2 weeks on a particular antipsychotic dose portends a low likelihood of week 6 response on that dose, the full therapeutic effects of adequate D₂ receptor blockade in schizophrenia may not be apparent until many weeks or months later.⁷ Therefore, patience in pharmacological treatment of psychosis is critical when a patient exhibits partial response.^{7,11} For example, Robinson and colleagues found that in a sample of 118 first-episode patients with schizophrenia or schizoaffective disorder only 20% responded to treatment at 4 weeks. The picture was quite different at 52 weeks; roughly 87% responded to treatment.²¹ Other studies of ziprasidone, risperidone and olanzapine have shown continued improvement over several months of treatment.¹¹

Strategies to use prior to heroic measures

We believe polypharmacy and high dosing should not be the initial approach to treating schizophrenia. However, considering that roughly 30% of patients with psychosis are on multiple antipsychotics, the practice is far from rare.^{22,23} In an effort to address the growing practice of antipsychotic polypharmacy and high dosing of antipsychotics in spite of little support in the literature, Stahl provides 12 case-based recommendations.⁷ We review several below.

Utilise monotherapy first to include clozapine

Sequential trials of at least two SGAs are recommended. If both trials fail, consideration of an FGA is appropriate. Also, it is important to not overlook clozapine as monotherapy. The efficacy of clozapine in treatment-resistant schizophrenia, particularly with regard to aggression and violence, is well documented.²⁴⁻²⁶ However, some clinicians may be hesitant to initiate a trial of clozapine owing to fear of side-effects such as agranulocytosis.

Monitor blood levels

Securing drug plasma levels is the only way to know whether treatment failure is due to a pharmacokinetic issue such as rapid metabolism or a cytochrome P450 polymorphism, or simply poor adherence with oral therapy. Likewise, blood levels can alert you to pharmacodynamic abnormalities which occur when treatment response does not correlate with adequate dosing. Blood level monitoring of both FGAs and SGAs can provide the clinician with important information which can guide the treatment plan for patients with treatment-resistant psychosis. This is supported by the recent work of Lopez & Kane as relevant to haloperidol, fluphenazine, perphenazine, risperidone, olanzapine and clozapine.²⁷

Time may not be on your side

As noted above, it takes some patients longer than others to respond to antipsychotic treatments. Granted, it may not be possible to wait several weeks (and certainly not months) in acute settings or when a patient's behaviour is potentially harmful to self or others, but when possible, allowing adequate time for full response may be all that is needed when a patient has exhibited a partial response. The result of impatience is that a second antipsychotic may be prescribed or a single medication may be dosed in an unnecessarily aggressive manner.

Double-check the diagnosis

It is common practice to rethink the primary diagnosis if the treatment plan appears ineffective. Once pharmacokinetic, pharmacodynamic or time-course failures have been ruled out, the presence of substance misuse or a personality disorder or neurological illness should be considered.

Antipsychotic polypharmacy

Although a number of published treatment guidelines for schizophrenia are available, some of which conflict with each other, it is clear that clinicians should utilise a monotherapy approach to antipsychotic medication use.²⁸ Multiple trials of antipsychotic medications, generally SGAs to include clozapine, are recommended. In fact, divergence from this sequential clinical progression has historically been met with scepticism, caution and outright criticism.^{29–36} It is certainly understandable why this is the case. The literature is replete with evidence supporting the efficacy of monotherapy for schizophrenia. Furthermore, the pitfalls associated with combining antipsychotics are well documented. Increased side-effects, higher medication costs, scant information supporting efficacy, and suboptimal outcomes are all problematic with regard to antipsychotic polypharmacy.^{29–36} So, why the need to even review the topic? The reality is that patients included in research studies are generally those who are able to give consent, exhibit less violence and less impulsivity, have lower rates of chemical dependency, and are less likely to have histories of sequential trials of antipsychotics at documented therapeutic levels.^{7,8} In other words, consistent with much of psychiatry research, they are healthier and not mirror images of the patients seen in clinical practice. Therefore, we believe a strict adherence to a treatment guideline based on highly selective samples does not necessarily translate well to community-based out-patient clinics and in-patient facilities.

We acknowledge that antipsychotic monotherapy is sufficient for the majority of patients with schizophrenia and that adherence to established guidelines should generally occur. Indeed, recent studies support this position. A 2004 study by Suzuki and colleagues revealed that when patients with schizophrenia were switched from multiple antipsychotics to monotherapy, roughly half maintained gains whereas a quarter showed improvements. Another quarter of the sample decompensated.³⁷ In a similar study by Essock and colleagues it was found that patients switched to monotherapy maintained gains, but also showed improvement in metabolic effects assumed to be caused by antipsychotic polypharmacy. It should be noted that approximately a third of patients required multiple antipsychotics.²³ However, some evidence supports the use of antipsychotic polypharmacy. A recent meta-analysis of randomised controlled trials comparing antipsychotic monotherapy and polypharmacy highlighted that polypharmacy may be superior to monotherapy in certain clinical cases.³⁸

In addition to achieving adequate D₂ occupancy, antipsychotic polypharmacy also exploits other receptor-binding properties that could lead to improvement in other schizophrenia symptom clusters. For example, serotonergic, noradrenergic and histaminergic binding theoretically ameliorate depression, anxiety, insomnia, impulsivity and aggression. On the flip side, however, the patient is potentially exposed to adverse side-effects from multiple receptor binding or excessive binding via similar properties shared by antipsychotics (e.g. excessive histaminergic binding leading to daytime sedation or appetite stimulation and weight gain). Consequently, combining antipsychotics should be done rationally based on their binding profiles. One clear example is the need to avoid combining the partial D₂ agonism of aripiprazole with antipsychotics with full D₂ antagonism. The binding interference may lead to a worsening of symptoms due to aripiprazole's high affinity for the D₂ receptor, and the fact that even low doses such as 10 mg achieve 83% D₂ occupancy, and thus may displace full antagonists.⁶

High dosing of antipsychotics

Antipsychotic polypharmacy is not the only means of addressing the more complex and treatment-resistant cases of schizophrenia. High-dose monotherapy is a viable option as well. In fact, it has been argued that if the goal is to occupy a greater degree of D₂ receptors in order to address treatment-resistant positive and aggressive symptoms, high-dose monotherapy is the preferred option when compared with polypharmacy. High-dose monotherapy does, however, come at a greater financial expense and the risk of increased metabolic and other potential treatment-limiting side-effects.¹¹

It is impossible to know what dose of a particular antipsychotic is required to achieve the intended outcome. Therefore, the prudent action is to start low within the US Food and Drug Administration (FDA)- and British National Formulary (BNF)-approved guidelines for the particular medication. The medication can be gradually increased outside the FDA-approved dosing window until therapeutic response occurs or the patient develops intolerable side-effects. It is important that informed consent is obtained and treatment rationale is well documented when this occurs. Below we discuss the typical dosing ranges and special considerations for high dosing of the antipsychotics. A more detailed analysis can be found in Stahl & Morrissette's review of the topic.¹¹

Clozapine

Clozapine is typically only recommended after subsequent trials of other antipsychotics have failed. This is primarily owing to its side-effect profile. At typical dosing of 300–450 mg/day, clozapine binds to less than 50% of D₂ receptors, but as noted earlier, the antipsychotic benefits with this medication can be seen at as low as 20% occupancy.¹⁰ A meta-analysis by Davis & Chen revealed that patients on high levels of clozapine responded more frequently than those on low levels.³⁹ Clozapine can be dosed as high as 900 mg/day, but seizure risk does increase with higher plasma levels, so titration to this dose should be done slowly. Furthermore, due to the diverse binding profile of clozapine, improvement in multiple symptoms clusters is possible.

Quetiapine

Quetiapine has a relatively weak affinity for D₂ receptors and often requires high dosing to achieve intended outcomes. Only at the upper range of 400–800 mg/day are the antipsychotic properties of the medication seen. It is generally believed that a dose of 1200 mg/day is no more effective than the typical dosing range and carries greater incidence of metabolic effects; however, clinical practice has shown that 1800 mg/day may be useful in treating violent patients.^{2,5,39}

Olanzapine

Doses of olanzapine between 10 and 20 mg/day equate to 60–80% D₂ occupancy. Higher doses of 40–60 mg daily appear to be more effective, particularly with aggressive patients and in some forensic settings.^{2,32,40,41} A note of caution is that as plasma levels increase the risks of anticholinergic and metabolic effects also increase.^{5,10}

Risperidone/paliperidone

Risperidone reaches 70–80% of D₂ occupancy at doses between 2 and 6 mg/day. The risk of EPS is positively correlated with dose. Doses above 8 mg/day are generally not considered beneficial for most patients, but in some, the side-effects may not appear until higher dosages.⁵ As noted previously, even at 10 mg/day only 31% of patients required anti-Parkinsonian medication in the pivotal trials, again providing evidence that a subgroup may both require and tolerate higher dosages and plasma levels.¹⁶ Risperidone's active metabolite paliperidone has less chance of drug–drug interactions as it is not metabolised by the liver. Similar to risperidone, paliperidone carries increased risk of EPS as the dose increases.¹¹

Ziprasidone

Data support the use of high doses of ziprasidone, particularly in forensic settings at 360 mg/day.^{2–5,40,41} It can be difficult to achieve adequate plasma levels with ziprasidone in out-patient settings as food is required to increase absorption. It has been reported that ziprasidone has historically been under-dosed due to concern about increased agitation and QTc prolongation.

Aripiprazole

Aripiprazole has a different mechanism of action compared with the ‘first wave’ of SGAs. Contrary to its predecessors, high doses of aripiprazole may not result in increased efficacy in schizophrenia. This is due to its partial agonist properties and high affinity for D₂ receptors.¹¹ Doses of 40 mg/day are associated with 96.8% D₂ occupancy, so further increases will not have an impact on D₂ neurotransmission to any considerable extent.

Asenapine, iloperidone, and lurasidone

Asenapine, iloperidone, and lurasidone are newer atypical antipsychotics. Consequently, there is limited information that supports their use in high doses. Although doses of asenapine of 30–40 mg/day may be effective for some treatment-resistant cases, there are virtually no data supporting use at these higher doses, and the buccal absorption of asenapine declines significantly for each 5 mg increase in the dose. As with asenapine, there are limited to no data supporting the use of iloperidone at high doses. One treatment-limiting issue with iloperidone is orthostatic hypotension. Lurasidone is approved up to 160 mg/day for schizophrenia, but higher dosages have not been studied for efficacy, only for safety (e.g. thorough QT studies up to 600 mg). Similar to ziprasidone, lurasidone should be taken with food to increase absorption.¹¹

Summary

Schizophrenia is a relatively common psychiatric disorder but it is often difficult to treat. Although antipsychotic monotherapy at standard dosing levels is sufficient for the majority of patients, a subset will require ‘unconventional’ approaches such as antipsychotic polypharmacy and higher than normal dosing. If done cautiously and rationally, these approaches can provide much-needed benefit for those most in need of relief.

1.6.49 Should compulsory admission to hospital be part of suicide prevention strategies?

Abstract

The World Health Organization report *Preventing Suicide: A Global Imperative* provides governments with guidance for comprehensive suicide prevention strategies. However, it does not mention the role that compulsory admission to hospital of psychiatric patients should have in policies for suicide prevention. This was a missed opportunity for international discussion and guidance about a measure that, although widely used, is becoming increasingly controversial in light of the existing evidence and human rights norms.

Contents

- *Should compulsory admission to hospital be part of suicide prevention strategies?*
 - *Compulsory admission to hospital for suicide prevention*
 - *Compulsory admission to hospital: trade-offs and human rights*
 - *The need for guidance*

Legal and policy approaches to suicide have been changing significantly in the past decades. Notably, the decriminalisation of suicide attempts in many countries has been followed by an increasing recognition that the stigma around suicide must be grappled with and that adequate social and healthcare policies can reduce the rate of suicide in the population. In other words, the focus has shifted from criminal punishment and moral condemnation to awareness, support and prevention.¹

The 2014 World Health Organization (WHO) report *Preventing Suicide: A Global Imperative*¹ is an important step in this direction. It draws attention to the discrepancy between the magnitude of suicide as a health problem worldwide and the low priority it is given by national governments. The report also describes the risk and protective factors in suicide prevention based on state of the art research and offers guidance for comprehensive strategies for suicide prevention. The central message in the document is that suicides are preventable but this requires actions such as restricting access to the means of suicide, reducing excessive use of alcohol, collecting and collating good-quality data about suicide and suicide attempts, providing training for gatekeepers, improving the quality of mental healthcare services, and promoting responsible reporting of suicide by the media. The report is also clear that taboo, stigma, shame, guilt and discrimination surrounding suicide hamper effective suicide prevention policies as they discourage vulnerable people from seeking help.

However, despite its emphasis on the need for comprehensive strategies for suicide prevention, the compulsory admission to hospital of people at risk of suicide was not discussed in the WHO report. This should not come completely as a surprise given that compulsory admission to hospital was also ignored in the previous United Nations (UN) and WHO documents on which this report was built.²⁻⁴ Moreover, the literature on suicide prevention rarely lists compulsory admission to hospital among the measures for suicide prevention, and those who do normally do not distinguish between voluntary and compulsory admission.⁵⁻⁷

This gap in international guidelines and in the scholarly literature needs to be addressed. Compulsory admission to hospital is widely used as a measure for suicide prevention, but the trade-offs involved and the human rights implications make it a topic in which guidance and further discussion are urgently needed.

Compulsory admission to hospital for suicide prevention

Compulsory admission to psychiatric hospitals or psychiatric wards is allowed in many countries as a measure to prevent self-harm.⁸ In England and Wales, for instance, the Mental Health Act 1983 (MHA) provides the legal framework for the compulsory admission and treatment of patients with mental disorders of a nature or degree that warrants their detention in a hospital and who ought to be so detained in the interests of their own health or safety or with a view to the protection of other persons. Whether the patient has capacity to decide on their stay in hospital and has objected to it will not affect the legality of a detention under the MHA. A recent publication shows that there were over 63 000 detentions under the MHA in the period from 1 April 2015 to 31 March 2016.⁹ Considering the body of literature associating suicide with mental disorders^{6,10} (see, however, Hjelmeland *et al*¹¹) and that statistically people with mental disorders are at a higher risk to themselves than to others,¹² it is plausible to assume that prevention of self-harm is a common reason for compulsory admission to hospital.

Some would interpret this authorisation to detain as actually a duty to detain when there is a high and immediate risk of a person taking their own life. A failure to do so can be considered medical negligence and may also be a breach of human rights. In the case of *Rabone & Anor v Pennine Care NHS Foundation Trust* [2012],¹³ the Supreme Court unanimously held that the failure of the hospital staff to detain Melanie, a voluntary psychiatric patient who hanged herself from a tree after being allowed to spend the weekend with her family, was a breach of her right to life under Article 2 of the European Convention on Human Rights. According to the Court, given her history of depression and self-harm, including a previous suicide attempt, the hospital staff should have used their powers to detain Melanie under the MHA to protect her from the 'real and immediate risk of suicide' when she demanded to leave the hospital.

Even though this precedent applies to the UK only, it shows that a national strategy for suicide prevention may be incomplete without a policy for compulsory admission to hospital. In hindsight, it is clear that the deaths of people like Melanie could have been avoided were they admitted to hospital and put under close observation, treated, managed and prevented from having access to the means to take their own life.

Compulsory admission to hospital: trade-offs and human rights

When looking at individual cases of suicide and at the data from population-based studies there is evidence that compulsory admission to hospital saves lives.^{14,15} However, this does not answer the question of how, when or whether it should be used to prevent suicide. Compulsory admission to hospital involves trade-offs and has human rights implications that need to be considered in clinical, policy and legal decisions about its role in strategies for the prevention of suicide.

There is now compelling evidence that suicide, being a low-frequency event, is very difficult to predict. The clinical methods for predicting suicide among patients have a very poor predictive capacity.^{16–20} A recent meta-analysis revealed that, over an average follow-up of 5 years, almost half of all suicides are likely to occur in patients considered at low risk, and that 95% of high-risk patients will not die by suicide.²¹ This creates a trade-off between the need to be sensitive to the risk of suicide to reduce the chance of false negatives and the need to be specific to avoid false positives that may lead to unnecessary detentions. Assuming that it is impossible to predict whether a person is going to take their own life and that the best we can do is to estimate that 1 out of X people in a certain cohort will die by suicide, then a society that allows compulsory detention of people at risk of suicide has to admit that to save one person it will have to unnecessarily detain $(X - 1)$ people.

There are also concerns about whether compulsory detention may increase the risk of suicide in some cases. First, some people may not seek treatment because they are fearful of being forced to accept treatments not of their choice or of being detained for prolonged periods.²² This would go against the WHO recommendation that a national effort to prevent suicide should encourage people to seek help. Second, there is an association between suicide and psychiatric admission to hospital, as suicide risk peaks in the period immediately after admission to hospital and shortly after discharge.^{5,6,14,23,24} This association can be explained in part by the fact that individuals with higher risk of suicide are more likely to be admitted to hospital,²⁵ but some argue that admission to psychiatric in-patient care might actually increase the risk of suicide. The stigma, discrimination, impact on employability, trauma, isolation and the feeling of dehumanisation caused or augmented by compulsory admission to hospital may contribute to the extremely high risk of suicide in the first few days of admission and after discharge.^{17,22,26,27} Although further research is necessary,

this hypothesis does not seem farfetched given that people who are detained, disconnected from their social circle and experience trauma, abuse and emotional distress are at a higher risk of suicide.¹ Hence, it is possible that some of the (X1) people unnecessarily detained will in fact die by suicide as a result of compulsory admission.

The trade-offs and tragic choices in compulsory admission to hospital have clear human rights implications. Health systems and professionals who are under pressure to be sensitive to the risk of suicide to avoid breaching a patient's right to life will do so at the expense of specificity. This leads to an increase in unnecessary detentions, which interferes with the right to freedom of movement, autonomy, bodily integrity and private life of those detained. It may also affect the right to life of those whose risk of suicide increased as a result of their stay in hospital. Therefore, the rules and practices regarding the compulsory admission to hospital of people with mental disorders to prevent suicide are always choices between different rights and rights-holders.

There are also concerns about whether compulsory admission to hospital is inherently discriminatory against people with mental disorders as it denies them the right to decide about their own treatment. This concern is reflected in the discussions about whether compulsory admission to hospital is compatible with the UN Convention on the Rights of Persons with Disabilities (CRPD), in particular Article 14, which establishes that 'the existence of a disability shall in no case justify a deprivation of liberty'. The UN Committee on the Rights of Persons with Disabilities,²⁸ for instance, affirms in its guidelines on Article 14 of the CRPD that the 'legislation of several States parties, including mental health laws, still provide instances in which persons may be detained on the grounds of their actual or perceived impairment, provided there are other reasons for their detention, including that they are deemed dangerous to themselves or others. This practice is incompatible with Article 14 [...]'. Others, however, worry about how the prohibition of compulsory detention and treatment for people with mental disorders will affect the protection of other rights of people with disabilities, such as their rights to health and to life.²⁹

The need for guidance

In conclusion, four things can be said about compulsory admission to hospital as a measure for suicide prevention. First, it can save the lives of those who, without the care, treatment and management received in hospital, would have taken their own life. Second, owing to the poor suicide predictive capacity of the existing methods, false positives will occur and this results in unnecessary hospital admissions, which can be aggravated if legal accountability encourages defensive clinical practice. Third, there is the possibility that compulsory admission to hospital is partially responsible for the suicides of those who failed to seek help owing to the fear of involuntary detention or for whom the experience of being admitted to hospital contributed to the decision to take their own life. Fourth, it is still unclear how and if compulsory admission to hospital of people on the basis of their mental impairment and the risk of danger to themselves can be reconciled with the CRPD.

The trade-offs involved and the need for measures for the prevention of suicide to be compliant with human rights make the creation of guidelines concerning their use challenging, but necessary. The WHO is a forum in which an evidence-informed, international, multi-stakeholder discussion can shed light on the role (if any) that compulsory admission to hospital should have in a national policy for the prevention of suicide. It is unfortunate that the otherwise commendable 2014 report missed this opportunity. It may be uncomfortable for those advocating policies to prevent suicide to discuss compulsory admission to hospital as this is a measure in which the line that separates protection and harm can be very thin, and there is controversy about where it lies. However, as those working in the area of suicide prevention already know, avoiding a difficult issue is never the best way to deal with it.

1.6.50 Improving the quality of mental health services using patient outcome data: making the most of HoNOS

Abstract

Efforts to assess and improve the quality of mental health services are often hampered by a lack of information on patient outcomes. Most mental health services in England have been routinely collecting Health of the Nation Outcome Scales (HoNOS) data for some time. In this article we illustrate how clinical teams have used HoNOS data to identify areas where performance could be improved. HoNOS data have the potential to give clinical teams the information they need to assess the quality of care they deliver, as well as develop and test initiatives aimed at improving the services they provide.

A commitment to improving the quality of healthcare is central to the aims of the National Health Service (NHS). ¹ This commitment involves developing and evaluating new interventions and treatments, obtaining feedback from patients and learning from mistakes. ² It also involves monitoring and improving patient outcomes. Despite repeated calls for greater use of patient outcome measures in mental health, available evidence suggests that very few services use them to monitor change over time. ³ There are a number of important barriers which make it difficult to implement systems for monitoring patient outcomes, including access to reliable and valid measures, the need to protect patient confidentiality and the time and money needed to collect, analyse and report data. ^{4,5}

While many initiatives aimed at improving the quality of NHS services have been ‘top-down’, it is widely acknowledged that front-line clinicians have a key role in efforts to improve service quality.^{6,7} However, unless clinical teams have access to information about patient outcomes, they cannot assess their performance or identify areas where performance could be improved.

For the past 20 years the Health of the Nation Outcome Scales (HoNOS) have provided a means of assessing the health and social functioning of people who use mental health services.⁸ HoNOS is a clinician-rated outcome measure comprising 12 scales covering symptoms, functioning, social relationships and environmental issues. Each domain is rated by the treating clinician on the scale of 0 to 4: 0 means no problem, 1 means a problem that probably requires no intervention and 2, 3 and 4 correspond to ‘mild’, ‘moderate’ and ‘severe’ problems. They are rated by staff using all available information – not as a questionnaire or interview – based on the worst state in the reference period, usually 2 weeks. There is a glossary, and training in their use is generally recommended.⁹ Although it is possible to calculate a total HoNOS score for a patient, individual scores on each of the 12 scales provide a better guide to the problems they are experiencing and targets for future interventions and treatments. Originally developed to measure the health and social functioning of working-age adults with severe mental illness, the scales have been modified to assess mental health of older adults (HoNOS65+),¹⁰ children and adolescents (HoNOSCA),¹¹ people with intellectual disability (HoNOS-LD),¹² in secure settings (HoNOS-Secure)¹³ and with acute brain injury (HoNOS-ABI).¹⁴

Use of HoNOS in mental health services in England was patchy until work started on the development of a commissioning tariff based on a Mental Health Clustering Tool, which needed HoNOS scores to be completed on all patients who are in scope of the mental health tariff.¹⁵ While these plans are still in development, this initiative has led to widespread use of HoNOS throughout the country. In recent years clinicians have begun to consider how these data might be used to assess and improve the quality of care they provide. In the next section we present how clinical teams in three trusts have used HoNOS data to identify problems with the care they provide and plan ways to improve it.

HoNOS use – examples of application

Example 1: using HoNOS to examine reasons for admission

Reasons for admission to hospital or to crisis resolution/home treatment (CRHT) teams are poorly understood yet very important in terms of ensuring that available resources are used effectively. As the number of beds decreases, thresholds for admission are becoming increasingly important to assess at a service level.

A team in Southampton used routine HoNOS data to explore mental health problems (such as psychotic symptoms, suicidality and aggression) experienced by adults who were admitted to in-patient units and people referred to CRHT services. They compared the proportion of people who had problems requiring intervention (a score of 2 or more on different HoNOS items) among 3409 people admitted to hospital and 2991 referred to local crisis teams (*Table 1*). The most prevalent problems among people referred to either service were suicidality and agitation, with levels of agitation higher among those admitted to hospital. Nonetheless, clinicians were surprised to see that only around half of patients admitted to hospital and 39% taken on by crisis teams scored as requiring intervention for suicidality and/or agitation. Even when people with significant problems with psychosis or accommodation status were included, a significant minority did not appear to have major problems requiring intervention.

HoNOS scale differences between hospital and crisis team admissions

Scores > 2 on HoNOS items	Hospital <i>n</i> = 3409 %	Crisis team <i>n</i> = 2991 %
1: Agitation	29	16
2: Suicidality	22	27
3: Accommodation	6	5
4: Delusions and hallucinations	13	9
1 or 2	47	39
1 or 2, 3 or 4	66	53

When these findings were discussed within teams, clinicians raised the possibility that people may be being referred to in-patient or CRHT services because of a combination of different problems at less severe level or that staff were under-scoring these items. It also led to discussions about the level of severity at which people were being referred to these services. Discussions based on this information led to a review of in-patient services (numbers of beds in the area were higher than in other comparable catchment areas),¹⁶ and a review of thresholds for access to CHRT services.

Example 2: outcomes of patients treated by assessment and brief treatment teams

Community mental health teams in central London used routine data from HoNOS to examine outcomes of treatment. Changes in mean HoNOS scores were calculated for patients under the care of assessment and brief treatment teams between April 2013 and September 2014 by comparing the mean severity from initial review with that from a follow-up. Scores of 3 (moderate) or 4 (severe) were categorised as 'high' and scores of 0 (absent), 1 (minimal) or 2 (mild) were categorised as 'low', and proportions of people moving between low and high scores were plotted (*Fig. 1*). In *Fig. 1* differences in severity of each subscale of HoNOS are presented for people in clusters 1–5 (single non-psychotic episode), clusters 6–8 (enduring non-psychotic) and clusters 10–15 (psychosis). The data showed that a smaller proportion of people in clusters 6 to 8 had made progress during their time with teams; among people in clusters 6 to 8, fewer who had high scores at baseline had lower levels at follow-up, especially compared with people in clusters 10 to 15. When data were examined from four other sector services in the trust a similar pattern emerged, with a greater proportion of patients in clusters 6 to 8 failing to show evidence of improvement or problems becoming more severe between the two time points compared with people in clusters 10 to 15.

When these data were presented to front-line staff they commented that it can be difficult to help meet the needs of people in clusters 6–8 (predominately people with personality disorder) through the types of interventions available to staff working in assessment and brief treatment teams. Although staff working in these services are able to refer patients to a local specialist personality disorder service, many do not want the group-based psychological treatment offered by this service or are too chaotic and poorly motivated to engage in psychological treatment. Discussions prompted by a review of these data led to the development and piloting of a six-session brief intervention package for people with personality disorder offered by members of the local specialist team (details available from the authors on request). This package of treatment is based on National Institute for Health and Care Excellence (NICE) guidelines¹⁷ and focuses on psychoeducation and skills training. It is hoped that some people who initially reject the offer of longer-term psychological treatment can be engaged through this extended assessment and that others will benefit more from this approach than they do from the care they are currently receiving.

Example 3: comparing outcomes of older adults admitted to in-patient units

Staff working on an in-patient mental health unit for older adults with dementia and other organic conditions used routine HoNOS65+ data to examine outcomes of people admitted to their service. It was noted that over a 3-year period the mean percentage improvement in scores on the depression scale of the HoNOS65+ declined (*Fig. 2*). Outcomes can only be properly understood with reference to context and interventions. These data were therefore compared with those from a similar unit in the same trust with the same operational policy, lengths of stay, diagnostic and demographic characteristics, and initial severity scores. Data from this unit showed that mean percentage improvement on the depression scale over the same period was approximately 50%. The team did not have and still do not have direct data on interventions, but in 2001 there was a pilot study of the systematic recording of care plans, and these data were linked to outcomes data. It transpired that in the unit with the poorer outcomes, all patients with dementia were automatically given night-time benzodiazepine hypnotics. Furthermore, there was a strong association between being given night-time benzodiazepines and poor outcomes. During discussion with the teams it was agreed that routine use of benzodiazepines was a plausible explanation of poor outcomes and this policy was revoked. Over the course of the next year mental health outcomes of patients admitted to the unit improved (*Fig. 2*).

Discussion

The examples given above illustrate how front-line clinical teams have used routinely collected HoNOS data to examine and to try to improve the outcomes of the patients they treat. While changes to mental health services will continue to be made in response to new national policy directives, new research findings and new technologies, we believe that one of the most effective ways to improve service quality is ‘bottom-up’: through local teams using local data to drive change. However, front-line clinicians face a number of significant challenges when trying to assess and improve the quality of the care they provide. Chief among these are limited time and other resources needed to collect data on patient outcomes. We are aware of numerous occasions when clinical teams have made changes to the services they provide but have not had the resources to examine whether these changes led to improvements in patient care. In other instances, baseline audits are conducted that identify problems in a service that teams try to correct, but staff have not had time to assess whether these changes benefited patients. To fulfil the NHS promise to patients to continuously work to improve service quality, clinical teams need to be able to access data on patient outcomes. Yet the experience of participants in the UK Routine Clinical Outcomes Network (www.ukrcom.org) suggests that very few services provide outcomes data to their teams. Embarking on new efforts to collect patient- and staff-rated outcomes is expensive and time consuming. By contrast, routinely collected HoNOS data in England provide an important source of clinician-rated patient outcomes that do not require additional resources to be spent and can be used to assess and improve the quality of care that teams provide.

Challenges to widespread HoNOS use

While the vignettes above illustrate how HoNOS data have been used by front-line clinical teams, a number of obstacles need to be overcome if this approach is to become more widespread.

First, concerns have been raised about the quality of routine HoNOS data.¹⁸ Available evidence suggests that if staff are provided with appropriate support and training, HoNOS can be used to generate reliable information that can be used to compare different services and examine changes in patient outcomes over time.¹⁹ Second, IT systems in trusts need to be able to generate reports on outcome data in a form that clinical teams find useful. Third, data from HoNOS and other routine outcomes scales need to be interpreted cautiously. Random variation and subtle changes in practice and case-mix may have led to changes in patients outcomes over time. Separating real and spurious differences can be difficult.²⁰ Finally, teams need to be given time and space to examine their data, learn from them and use them to evaluate their efforts to improve service quality. If staff are supported to generate reliable data and systems are available to deliver data to front-line clinical teams, then these data have the potential to be used in clinical audit and in alternative models for improving service quality, such as Plan–Do–Study–Act cycles.²¹ The latter approach may have some advantages over traditional audits because it allows the impact of changes in practice to be examined more frequently and provides a more iterative approach to developing changes aimed at improving patient outcomes.^{22,23}

At present, most staff see collecting outcome data as an ‘invisible task’, in which time is spent collecting and entering data for no purpose.²⁴ If systems can be implemented that deliver feedback to staff on service-level patient outcomes, staff are more likely to value collecting these data. For instance, in South London and Maudsley NHS Foundation Trust and Central and North West London NHS Foundation Trust, clinicians have organised meetings for staff in which HoNOS data are presented and discussed. Feedback from staff attending these meetings has shown they value getting this information and their comments have been used to refine the way that data are collated and presented (most staff indicated a preference for the categorical change model presented in *Fig. 1* rather than changes in total HoNOS scores).

While HoNOS scores collected through the current mental health payment initiative¹⁵ provide a rich source of routine data on patient outcomes, the timing of assessments is unlikely to be optimal for evaluating the impact of treatments and services. Further work is needed to establish when outcome assessments are best undertaken in different settings to compare services and assess the impact of quality improvement initiatives.

HoNOS data are not the only form of evidence that mental health services collect. For instance, psychiatric in-patients are asked to complete the ‘friends and family test’ (a two-item short patient-rated experience measure).²⁵ However, there is very little evidence that these data are being fed back to clinicians to allow them to reflect on differences in levels of patient satisfaction over time or between different teams.²⁶ Such data also have the potential to stimulate bottom-up efforts to assess and improve service quality if steps are taken to use them in this way. One of the great strengths of HoNOS data is that they provide a summary of mental health, behavioural problems and social factors. Although this means that HoNOS can be used under circumstances where poor mental health or impaired cognition may limit the value of patient-rated data, there are drawbacks to relying solely on clinician-rated outcomes. The possibility that outcome data could be used to pay services based on patient outcomes could paradoxically reduce their value as a means to assess and improve service quality.²⁷ This is commonly known as Goodhart’s law after the British economist Charles Goodhart: ‘When a measure becomes a target, it ceases to be a good measure’.²⁸

Mental health trusts in England are currently collecting large amounts of outcome data using HoNOS. We believe that efforts by mental health services to use HoNOS data and other routinely collected patient outcomes have the potential to make better use of available resources and engage front-line clinicians in efforts to improve patient outcomes.

1.6.51 Personalisation and social care assessment – the Care Act 2014

understanding of its implications. We provide an overview of why it was developed, its underlying principles and international comparisons, as well as implications for assessments, interventions and outcomes. The impact on the lives of patients and carers is discussed, as well as dilemmas and challenges the Act presents. While it addresses other important aspects of social care, including safeguarding, Mental Health Act section 117 aftercare and duty of candour, we focus on personalisation because of the opportunities it provides to enhance management plans for people experiencing mental health problems.

Why was the Care Act 2014 developed?

The Care Act 2014 represents the latest evolution in current attitudes to care. It was asserted by Norman Lamb MP, Care and Support Minister in the UK coalition government, as ‘the most significant reform of care and support in more than 60 years’. ¹ Think Local Act Personal (TLAP, a partnership of more than 50 organisations, including the National Health Service (NHS), ‘committed to transforming health and care through personalisation and community-based support’ (www.thinklocalactpersonal.org.uk/About-us/)) sees it as representing a significant change in legislation, of importance to service users and carers in England and Wales because ‘for the first time it puts them in control of their care and support. It also makes clear what kind of care they should expect’ (www.thinklocalactpersonal.org.uk/Browse/careact2014/).

Social care law can be seen to have begun with the National Assistance Act in 1948 that contained provisions for the basis of the modern welfare state. Direct payments as a method of personalisation were introduced in 1996 by the Community Care Act. More recent updates, such as the Carers and Disabled Children Act 2000 and the Health and Social Care Act 2001, broadened and refreshed these approaches. Separately, safeguarding of adults from abuse was dealt with by the Department of Health in *No Secrets*. ² The Care Act 2014 succeeds earlier acts with a single statute.

The golden thread running through the Act is the promotion of individual well-being (*Box 1*): “‘The general duty of a local authority, in exercising a function under this Part in the case of an individual, is to promote that individual’s well-being.’ (Care Act 2014 section 1(1)) ‘As a service user who has in the past been a carer to a diverse group of individuals, I feel that had a lot of these changes been made in the past, many people’s lives would have transformed sooner rather than later. That being said, we are now moving forward to enable individual lives to be more fulfilled.’ (Deb Barnes)”

Box 1 Scope: purpose of the Care Act (adapted from the Care Act 2014)

- a. To reform the law relating to care and support for adults
- b. To reform the law relating to support for carers
- c. To make provision about safeguarding adults from abuse or neglect
- d. To make provision about care standards
- e. To establish and make provision about Health Education England
- f. To establish and make provision about the Health Research Authority
- g. To make provision about integrating care and support with health services

Box 2 Care Act specified outcomes

The specified outcomes as defined in the Act are: managing and maintaining nutrition maintaining personal hygiene managing toilet needs being appropriately clothed being able to make use of the adult’s home safely maintaining a habitable home environment developing and maintaining family or other personal relationships accessing and engaging in work, training, education or volunteering making use of necessary facilities or services in the local community including public transport and recreational facilities or services, and carrying out any caring responsibilities the adult has for a child.

What are the international comparisons?

In establishing the Care Act, a cap on spending for long-term social care was originally proposed to be introduced in April 2016. However, this has now been postponed until at least 2020. In 2014, The King’s Fund reviewed international comparisons for health and social care provision.³ It highlights that The Netherlands introduced a ‘universal’ (i.e. available to all) system of insurance for long-term care in 1968. In the 1990s it introduced caps in response to rising costs, but this led to long waiting lists and the caps were abolished. Latterly, they have raised the threshold to access social care and outlined aspects of care that are expected to be delivered by families. Sweden established the right to tax-funded legislation in 1982/1983, whereas countries including Germany, France, Japan and South Korea all have mandatory long-term care insurance schemes.

Assessment under the Care Act

Assessment of needs, both for service users and their carers, is a core aspect of the Care Act. The process is divided into three stages: identifying needs, assessing eligibility and care planning.⁴ Each of these should be viewed not only as a gateway to support but as an intervention in itself.

Stage 1: identifying needs

The Act places a statutory duty on local authorities to provide assessments for any adult, including carers, appearing to have a need for care or support, regardless of the local authority's view of the level of that need or the individual's financial resources (section 9–10). It is important to note that in some areas this responsibility may be delegated by the local authority to partner organisations, such as NHS foundation trusts, and that assessment may be carried out by a range of professionals, including healthcare professionals. This assessment should address the person's needs in relation to the specified outcomes as defined in the Care Act (*Box 2*). It aims to identify the impact of these needs, the person's desired outcomes, and whether the provision of care and support services will be effective in contributing to the achievement of these outcomes (section 9(4), 10(5)). For clarity, we have used the term 'specified outcome' as a technical definition to refer to those outcomes specified in the Care Act (*Box 2*) and 'personal outcome' to describe all possible outcomes individuals may see as important.

It is crucial that the individual, their carer and any other person the individual requests be fully involved in the assessment process. Consideration should also be given to the most appropriate kind of assessment. Options for supported self-assessment, telephone assessment, joint assessment with other agencies or a combined assessment of the needs of, for example, the individual and their carer, may be appropriate (Care Act section 6(3)). In addition, in cases where the individual has significant difficulty in representing themselves at assessment and has no suitable advocate, the local authority is required to provide an independent advocate regardless of the individual's capacity under the Mental Capacity Act 2005.⁵

Stage 2: assessing eligibility

At the eligibility stage, the Care Act replaces previous Fair Access to Care (FACS) guidance on eligibility criteria^{6,7} with a national eligibility threshold based on the causes, extent and impact of the individual's needs (~*Box 3*). It should however be noted that local authorities are able, where considered appropriate, to meet non-eligible needs and may choose to do so, for example, in order to prevent further deterioration.

Well-being, individual personal outcomes and eligibility

In order to judge eligibility, impacts and contexts of needs are relevant: individual needs must be considered against the specified outcomes to determine whether or not they can be met, and reasons for this should be understood. Some social needs are not addressed by the Care Act, for example housing and debt. A homeless person would not be eligible purely by virtue of their homelessness, but the reasons for homelessness may make them eligible. For example, becoming homeless solely through relationship breakdown would not be considered potentially eligible. However, homelessness through an inability to manage a tenancy due to the impact of severe mental illness (i.e. impaired 'ability to maintain a habitable home' as defined in the specified outcomes) may well be eligible.

Furthermore, the impact on well-being is a personalised assessment and an individual perception, so that two people with the same needs in relation to specific outcomes could end up with a different assessment of eligibility. For example, obsessive-compulsive disorder could manifest in repetitive behaviours which affect an individual's ability to maintain family relationships and employment. These two specified outcomes may be fundamental for one person and significantly affect their well-being. Another person may have very different priorities or personal outcomes that they want to achieve; their well-being is not significantly affected and they would not be eligible.

The word 'significant' is not defined in the legislation, rather it is a judgement made by the local authority after considering the person's needs and what is important to them. However, well-being is a broadly defined and holistically assessed concept, relating to areas such as: personal dignity; physical and mental health and emotional well-being; protection from abuse and neglect; control by the individual over day-to-day life; participation in work, education, training or recreation; social and economic well-being; domestic, family and personal relationships; suitability of living accommodation; and the individual's contribution to society.⁵

Box 3 The National Eligibility Threshold (Regulation 2(1)14)¹¹

An adult's needs meet the eligibility criteria if – the adult's needs arise from or are related to a physical or mental impairment or illness; as a result of the adult's needs the adult is unable to achieve two or more of the outcomes [...] and as a consequence there is, or is likely to be, a significant impact on the adult's well-being.

The key to assessment under the Care Act is understanding what personal outcome (personal aim, wish or goal) the individual is looking for and what their needs are, before considering how these needs can be met. Person-centred assessment focuses on the individual and the difficulty they have in achieving personal outcomes, balanced with their strengths and support network; it does not start with service provision. For example, the assessment does not begin with 'the person needs residential care', but rather may find that 'the person is unable to wash, dress and feed themselves. This is having an impact on their personal dignity and their ability to continue to live safely in their own home'.

The local authority must consider what strengths, resources and capabilities the person has themselves and within their support networks and wider community. This strengths-based approach to assessment and care planning can maximise opportunities for utilising assets found within communities and normative support networks, thereby reducing dependence on service provision by meeting people's needs in more innovative and creative ways.

Stage 3: care planning

In developing and delivering preventive approaches to care and support, local authorities should ensure that individuals are not seen as passive recipients of support services, but are actively encouraged and supported to participate and are able to design care and support based around achievement of their goals. All assessments and subsequent care and support plans should be person-centred and genuinely engage the person and people involved in their care throughout.

Support plans should consider the broader needs identified by the assessment as well as the personal outcomes associated with the specified outcomes the individual is looking to achieve to maintain or improve their well-being. The person's own capabilities, assets and strengths and the potential for improving their skills, as well as the role of any support from family, friends or others that could help them to achieve what they wish for, should be incorporated into the plan. A person's independence should be maximised across these networks before any statutory service provision is considered to meet the desired personal outcomes.

Any person who requires ongoing support and has eligible needs is entitled to have these needs met through a personal budget. The Care Act 2014 has given parity to carers, who are now entitled to have their own eligible needs met through a carer's personal budget. A personal budget is an amount of money allocated for a person's support; this can be managed with or on behalf of the individual by the local authority or a broker, or can be paid to the individual as a direct payment. Person-centred care and support planning means that a person can receive part or all of their personal budget as a direct payment. Direct payments aim to enable a person to exercise the maximum possible choice over how they are supported, who they are supported by and where they are supported. The person must understand how much money is likely to be required to meet their eligible needs and have clear and realistic expectations of what is available locally. People who self-fund are entitled to receive necessary information, advice and support with support planning.

The third national TLAP survey⁸ demonstrated that over three-quarters of personal budget holders reported a positive impact of personal budgets on their lives. People with mental health difficulties were more likely than other groups to report a positive impact on relationships with carers, family and friends. However, older people were less likely than other cohorts to report a positive impact on mental health.

Review

Plans may be revised as a scheduled review or in response to changing needs or circumstances. The review should be a positive opportunity to consider whether the plan is enabling the person to meet their needs and achieve their desired personal outcomes. At this point it can be considered whether the support provided is working (be this through a carer, the community, through a direct payment or a commissioned service through a personal budget), whether new personal outcomes need to be defined, or whether any changes need to be made to care and support to achieve improvement.

Responsibilities of professionals

The Care Act places a responsibility on the local authority to inform the individual of their eligibility determination and produce a written record of whether any of their needs meet the eligibility criteria, and the reasons for this decision. Where an individual does not have eligible needs, the local authority must also provide information on what support may be available in the wider community, or what preventive measures might be taken to prevent or delay the condition progressing. This will require professionals responsible for eligibility decision-making to clearly evidence the reasons for their decisions and present these in an accessible format for the person concerned.

Implications for service users and carers

The Care Act 2014 has changed the ability that a service user or carer has to influence assessment of their own needs and eligibility. Whereas the FACS criteria⁷ considered the needs of the individual, they did not consider their whole well-being and how this fits into their everyday lives, meaning that some service users may not have completely fitted into the specified categories. The criteria that the Care Act 2014 looks at focus on the individual in context, so that the impact on their well-being cannot now be overlooked or misjudged.

This holistic approach is mirrored by the TLAP 'I' statements, which make their markers for change much simpler to understand across a diverse range of individuals (*Box 4*). These statements complement the Care Act in allowing the individual service user to take control of everything that supports their specific needs and requirements. 'I' statements are presented in the form of first-person statements, for instance, 'I have the information and support I need in order to remain as independent as possible'.

'A service user or carer can automatically feel comfortable in all the statements as they are very clear and acknowledging. They allow you to take control of everything that supports your needs and requirements. The implications are quite dramatic; you feel worthwhile and not a burden to anyone and it allows you to take greater control of your own personal needs.' (Deb Barnes)

Box 4 Think Local, Act Personal 'I' statements⁹

- Information and advice: having the information I need, when I need it
- active and supportive communities: keeping friends, family and place
- flexible integrated care and support: my support my own way
- workforce: my support staff
- risk enablement: feeling in control and safe
- personal budgets and self-funding: my money.

Dilemmas and challenges

The Care Act 2014 has introduced some major statutory changes to the way social care is delivered nationally, and as such presents a number of dilemmas and challenges to service users, carers and service providers.

Assessment as intervention

Assessment under the Care Act should be an intervention in itself rather than merely a process by which individuals are granted or denied access to funded services. This presents challenges both for local authorities as a whole and for individual professionals in a number of areas, including the necessary provision of reliable and up-to-date information about local services, and management of the time and resources required to ensure that assessments can be completed in a full and holistic manner.

Provision of appropriate and proportionate assessment

Assessment under the Care Act 2014 requires local authorities to become more flexible in administering assessments and to develop assessment processes which allow for this both internally and in collaboration with other organisations.

Measurement of efficacy

Whereas the Care Act 2014 defines specified outcomes for service users and carers, the way in which these are met will be highly specific to each individual service user and may create challenges in the ways local authorities monitor and measure the efficacy of service delivery.

Provision of services

Local authorities are expected under the Care Act to promote and shape the local market so as to achieve diverse provision of care and support in their area. This carries with it budgetary implications with regards to commissioning, funding and fee-setting, which must be considered not only in terms of local authority budgets but also in relation to providers' sustainability.¹⁰

Carer support

The Care Act broadens previous definitions of the carer role and requires assessment of support needs for anyone who feels that they fulfil this role.⁶ The challenge for local authorities is to provide sufficient information to all potential carers on their rights to assessment and possible financial support, while managing the potentially increased demand for these assessments and provisions.

Conclusion

Time will tell whether the aspirations of the Care Act are achieved. The emphasis is clear that care should be holistic and empowering; promotion of well-being is at its core. It is hoped that it will develop services that are inclusive, work in a person-centred way, and achieve specific outcomes. The introduction of the Care Act makes this way of working a statutory duty that public services will be measured by. It will be through individual lives and stories that success will be realised.

1.6.52 Dr Robert George (Rob) Jones FRCPsych

: Formerly Honorary Professor of Old Age Psychiatry, University of Nottingham

- *Dr Robert George (Rob) Jones FRCPsych*
– : *Formerly Honorary Professor of Old Age Psychiatry, University of Nottingham*

For over 30 years Rob Jones, who died recently at the age of 69, was a pillar of old age psychiatry in Nottingham and beyond. Qualifying in Manchester in 1970, he trained there in psychiatry and was particularly impressed with David Jolley's work in old age psychiatry. Following research with David Goldberg, he moved in 1980 to Nottingham as senior lecturer in psychiatry in the department of Health Care of the Elderly that Tom Arie had newly set up. This comprised physicians, psychiatrists and other health professions – Rob worked opposite John Bendall, the senior lecturer in medicine, and was a key figure in the ambitious 1-month combined attachment in old age medicine and psychiatry for all medical students. The novel joint department attracted wide interest, visitors and attached workers coming from home and abroad. Courses in psycho-geriatrics sponsored by the British Council or the World Health Organization brought workers from more than 30 countries to Nottingham and Nottingham staff were often invited abroad. Rob also contributed to a British Council course in Warsaw.

Rob's research included studies of outcomes for care home residents and of community provision; he also participated in major national studies and published widely. He was involved in collaborations that have shaped the practice of old age psychiatry across the UK and internationally. These included the DOMINO-AD clinical trial,¹ which has shown that continuing anti-dementia drugs in people with moderate to severe Alzheimer's disease is worthwhile and does reduce the likelihood of entering a care home at least for a few months.

His most important research was around the care and services for older people with dementia, including, with Ian Rothera and others, a study of life expectancy after entering residential care.² More recently, he provided the psychiatry input into the Medical Crises in Older People programme led by John Gladman. This documented just how many very elderly, frail and vulnerable people are admitted to hospital.³ His later work included studies of care for people with dementia living at home and at the time of his death he was involved in the NIHR Programme Grant PrAISED: Promoting Activity, Independence and Stability in Early Dementia, led by Rowan Harwood.

Rob was a busy clinician and led a district service for older people which served some of the most socially deprived parts of Nottingham, whenever possible taking services to people's own homes. He retired from clinical work in 2013 but continued to be a trustee of the local Radford Care Group, reflecting his passion for the well-being of people living at home, particularly those with dementia. He continued also to work for the university, heading the teaching programme in Health Care of the Elderly until his full retirement in October 2015. Of course, this was not the last we saw of him! He carried on with his research interests, as well as work on public involvement in dementia research – he organised the monthly Centre for Dementia seminars at the Institute of Mental Health. His contributions were recognised by the university with an honorary professorship.

Rob Jones was born in Paignton, Devon, into a family of proud Welsh ancestry. His father edited the local newspaper and this doubtlessly contributed to his insatiable lifelong interest in current affairs. At home he was permanently tuned into BBC Radio 4 and his colleagues were often deeply impressed by his detailed knowledge of world news and politics, to say nothing of lower league football (Torquay United in particular). In Manchester he met Diane and they married in 1971.

Rob was a man of warm and generous personality. He was regarded with respect and affection by all who knew him. His enthusiasm and commitment to the cause of older people was inspiring. For the last 20 years of his career he led academic old age psychiatry in Nottingham, as well as the Trent Dementia Research Network from 2004 until the establishment of the Nottingham Centre for Dementia in 2014. A particular mission was to keep us psychiatrists in close alliance with our colleagues in geriatric medicine, notably through the combined medical student programme. He was especially noted for bundles of papers in carrier bags, festoons of keys and lanyards at his neck, and his characteristic hearty laugh.

Notwithstanding his interest in people, he was quite private. For example, nobody he worked with was aware that Rob had been living with multiple sclerosis for 15 years. Indeed, he completed numerous half marathons during this time. He was definitely not one to complain. After he suffered a myocardial infarction in 2015, we were able to welcome him back to work. It is no surprise, therefore, that his sudden death on 23 May 2016 from a cerebellar haemorrhage came as a blow to all.

He leaves his wife Diane, and his children Haydn, Rhian, David and Siân, along with nine grandchildren.

Contents

- *Mental Health in the Digital Age: Grave Dangers, Great Promise*

Technology has always been a double-edged sword: there are associated risks and benefits. As a practising psychiatrist I increasingly rely on technology at work, using next-generation electronic medical records and at times recommending appropriate smartphone-based applications as additional therapy for my patients.

In contrast to numerous other titles about technology and its impact on healthcare – which have emerged as a result of the massive technical advances in the past decade – *Mental Health in the Digital Age* does not focus only on the benefits

of the use of technology in mental healthcare. It offers a timely balanced perspective by also providing an in-depth analysis of the risks.

The risks highlighted in the book are not limited to addictive behaviours such as internet or gaming addiction, but also include cyberbullying and the increased risk of suicide due to pro-suicide websites and suicide pacts. Cyberbullying is perhaps one of the most common problems linked with the use of technology to date and it is not unusual for me and my team to see children and adolescents who refuse to go to school as a result of cyberbullying. Unlike conventional forms of bullying, cyberbullying implies the use of social networks and internet-based messaging services to harass an individual. This work examines not only the prevalence of the problem, but also the various prevention strategies available, such as having a specific academic curriculum to deal with the issue.

The authors review the existing literature comprehensively – referring also to current evidence – and look at the potential of technology across several areas of mental healthcare, including the provision of psychotherapy and the integration of patients' health records. They also discuss how recent advances – such as virtual reality – could in principle be a powerful tool in exposure therapy. As a team with an interest in e-health, my colleagues and I have been developing smartphone applications for various mental health disorders. The introduction of virtual reality technology means that we could perhaps tap on games and various other sensors and headset devices to create an interactive environment not just for psychotherapy but for other forms of interventions too.

This is a good guide for novices in e-health but equally a useful tool for the more experienced in this area. It would be helpful if a future edition included more detailed coverage of smartphone applications and their inherent risks and benefits – a topic of concern not only for clinicians, but patients at large.

1.6.54 MCQs in Psychiatry for Medical Students

Suzanne Dash¹

date

2017-6

Contents

- *MCQs in Psychiatry for Medical Students*

Love them or loathe them, most medical student written examinations now take the form of multiple choice questions (MCQs). Some medical educators dislike this assessment style, suggesting it encourages students to learn isolated facts in a superficial way. Yet, undeniably, MCQs provide an objective, time-efficient manner of evaluation.

MCQs in Psychiatry for Medical Students is a valuable resource for medical students undertaking their psychiatry rotations. It includes MCQs and extended matching items grouped into chapters concerned either with a type of disorder – for example, psychotic disorders and alcohol and substance misuse disorders – or another important aspect of psychiatry, such as physical health, pharmacological treatments, psychology and psychotherapy.

Each MCQ is accompanied by a paragraph or two explaining the correct answer. More information is provided than is strictly necessary to understand the answer, but this is illuminating rather than turgid. The 400-plus contemporary

references encourage the reader to consider issues in more depth than the superficial learning style many associate with MCQs, making the scope of this book potentially greater than is obvious from its title. In contrast, the three extended matching item questions in each chapter are not followed by explanations, making them far less informative.

Writing good MCQ distractor items is a challenge, and in a few places – especially questions on risk factors and protective factors – it is possible to guess the answer by eliminating answers simply based on whether they describe something positive or negative.

This is a must-have title for all medical students; it will pique the interest of many students and may even assist in recruiting future psychiatrists to the profession.

1.6.55 Falls in Scottish homicide: lessons for homicide reduction in mental health patients

John H. M. Crichton

Correspondence

John H. M. Crichton

(j.crichton@nhs.net)¹

date

2017-8

Abstract

The sustained fall in Scottish homicide rates follows crime reduction measures informed by the epidemiology of suicide. The violence reduction unit targeted young men carrying knives in public. The restriction of weapons immediately to hand appears to have caused an absolute fall in homicide just as suicide reduction was observed following changes to domestic gas supply. Further homicide reduction may be accomplished in the domestic setting with targeted changes in kitchen knife design in home safety planning for high-risk households. Most commonly homicides involving those in recent contact with mental health services in the UK have domestic characteristics and similar safety planning may be targeted at those with mental disorder and a history of violence.

Contents

- *Falls in Scottish homicide: lessons for homicide reduction in mental health patients*

The sustained fall in Scottish homicide rates to 10.65 per million in 2015–2016 marks a 60% fall in the homicide rate since the peak of 26.3 per million in 2005.^{1,2} The greatest fall in homicide involves encounters between young men in public places. The Violence Reduction Unit, formed in 2005, utilised a public health approach to target young men with educational programmes and stiff penalties aimed at achieving reduction in knife carrying outside the home.³ From 2005 to 2016 police in Scotland recorded a 69% fall in cases of offensive weapon carrying.⁴ From 2008 to 2015, Scottish hospitals saw a 63% fall in admissions and a 50% reduction in deaths arising from assaults with a sharp object.⁵

Limiting the availability of a lethal weapon immediately to hand outside the home has been associated with a dramatic decline in homicide and serious injury.

The targeting of knife carrying in Scotland is an example of situational crime reduction, a highly successful approach inspired by the fall in suicide following changes to domestic gas supply.⁶ The model, aimed at increasing the difficulty of accomplishing a criminal act, arose from observing the marked decline in the UK suicide rate associated with the change from coal gas to natural gas.⁷ A major means of suicide – placing one’s head in an unlit oven and breathing in the gas – abruptly disappeared. Not only was there a dramatic fall in carbon monoxide suicides but a fall in the number of suicides overall. It can be inferred then that there are a group of individuals who, while apparently committed to dying by suicide, can be deviated from a life-ending course of action by a seemingly trivial inconvenience.

Despite the fall in overall Scottish homicides, this has not been observed in homicides associated with those in recent contact with mental health services.⁸ The stereotype of homicides associated with mental disorder involving stranger victims and unusual weapons in public places is false. In a 10-year review of 870 UK homicides carried out by current or recent users of mental health services, the homicide victim was a spouse or ex-spouse in 21% of cases, another family member in 18% and other acquaintances 46%; 15% were stranger victims, as opposed to 24% stranger victims for all homicides.⁸ Similar findings were observed in a 15-year series of 271 homicides carried out by mental health patients in England, where 42% occurred in the shared home of the victim and perpetrator, 25% at the victim’s home and 4% in the perpetrator’s home.⁹ To test the hypothesis that ordinary objects were used in such homicides, this cohort was re-examined: 45% overall involved a knife and of those knives that could be identified 85% were kitchen knives.¹⁰ Homicides associated with mental disorder typically have domestic characteristics, involving family or acquaintances in a domestic setting, not the homicide type targeted in the Scottish campaign.

The evidence would suggest that limiting weapon carrying in public reduces homicides outside the domestic setting, but how can this be achieved within the home where kitchen knives are required? Long sharp-tipped knives have limited specific culinary utility and alternative designs are available.¹¹ One design has an ‘r’ shaped tip and has been demonstrated as being as effective as wearing an anti-stab vest in a thrust to the torso (details available from the author on request), although similar benefits to safety may be achieved with a rounded or square tips.

Perhaps murder mythology in fiction and in the news media, with its emphasis on the exceptional and planned murder, obscures the possible benefits to changes to knife design, which may reduce the injury of unplanned acts of impulsive violence within the home.¹² Yet there is media bias for reporting the unusual, stranger homicide involving those with mental disorder.¹³ This obscures the role of promoting home safety measures utilised in domestic violence reduction for those with mental disorder and a history of violence and weapon use. Such a public health approach could be criticised for restricting freedom and would not stop a planned act of violence. Conversely, this may provide a way of generalising the benefits observed in Scotland to a domestic situation. The role of simple barriers to immediate weapon use in homicide reduction may also indicate strategies for violence reduction in other contexts.

The author gratefully acknowledges colleagues at The Orchard Clinic, Edinburgh, for their constructive comments and support.

1.6.56 Evaluation of the 13-item Hypomania Checklist and a brief 3-item manic features questionnaire in primary care

date

2017-8

Abstract

Aims and method The mean delay for bipolar disorder diagnosis is 10 years. Identification of patients with previous hypomania is challenging, sometimes resulting in misdiagnosis. The aims of this study were: (a) to estimate the proportion of primary care patients with depression currently taking antidepressants who have undiagnosed bipolar disorder and (b) to compare a brief 3-item manic features questionnaire with the Hypomania Checklist (HCL-13). The sample comprised patients with a recorded diagnosis of depression, either on long-term antidepressant therapy or with previous multiple courses of antidepressants.

Results Of 149 participants assessed, 24 (16.1%) satisfied criteria for bipolar disorder. Areas under the curve (AUC) for the 3-item questionnaire and the HCL-13 were similar (0.79 and 0.72, respectively) but positive predictive values (PPV) were low.

Clinical implications Bipolar disorder may be underdiagnosed in primary care. A 3-item questionnaire could be used by general practitioners to screen for bipolar disorder in their patients with depression.

 - * *Analyses*
 - *Results*
 - * *ROC analyses*
 - *Discussion*
 - * *Strengths and limitations*
 - * *Clinical implications*

Bipolar disorder affects at least 1–2% of the population and is associated with considerable psychosocial impairment.^{1–4} Accurate diagnosis can be difficult because patients tend initially to present in primary care for help with depression rather than with manic features, and many primary care practitioners do not systematically assess for a history of bipolar disorder.^{5–7} Recently the National Institute for Health and Care Excellence (NICE) recommended that all patients in the UK presenting to primary care with depression should be assessed for a history of manic features, specifically ‘previous periods of overactivity or disinhibited behaviour’.⁸

Recent screening studies of bipolar disorder in UK primary care have identified that between 7 and 10% of individuals with depression may have undiagnosed bipolar disorder, usually bipolar disorder type II.^{9,10} It is also the case that individuals with difficult to treat depression and those with poor response to antidepressants are more likely to have unrecognised bipolar disorder.¹¹

//creativecommons.org/licenses/by/4.0/), which permits unrestricted re-use, distribution, and reproduction in any medium, provided the original work is properly cited.

The Authors own the copyrights to the individual articles.

In this context, we aimed to estimate unrecognised bipolar disorder within a sample of primary care patients with depression who were taking antidepressant medications, as well as to evaluate the potential clinical utility of two short screening questionnaires for bipolar disorder: the 13-item Hypomania Checklist (HCL-13)¹² and a brief 3-item manic features questionnaire. Our focus on these brief assessment instruments was stimulated by the need for questionnaires that could be used easily in primary care consultations, which are usually no longer than 10–15 min.

Method

Sample

Practice managers of 9 primary care practices in the west of Scotland identified from their databases 2633 patients who (a) had a recorded diagnosis of depression and (b) were either currently taking long-term antidepressants (more than 12 months) or had had 3 or more courses of antidepressants in the past 5 years. Then, 1860 potentially eligible patients were reviewed by their general practitioner (GP) for eligibility and 1833 written invitations were sent by post, with participant information sheets, on behalf of the research team. There were 204 people who responded to this invitation and 151 were interviewed, giving a response rate of 8.23%. The study was approved by the West of Scotland Research Ethics Committee (reference: 13/WS/0071 18th, approval letter dated April 2013).

Assessment measures

A research nurse completed the Structured Clinical Interview for DSM-IV (SCID-1)¹³ in person in order to obtain a gold-standard diagnosis. An assessment of practice notes was also conducted to corroborate findings from the SCID-1 assessment and to clarify medication regimens. Participants completed the HCL-13 and a brief 3-item bipolar screening questionnaire. This 3-item questionnaire (with a maximum score of 6) was based on the three core diagnostic features for bipolar disorder taken from DSM-5: elevated mood, severe irritability and overactivity.¹⁴ The questions and scoring were as follows: Have you ever had a period of time when you were feeling so good, 'high', excited or 'hyper' that other people thought you were not your normal self or you were so 'hyper' that you got into trouble? (Definitely no (score 0), perhaps yes (score 1), definitely yes (score 2).) What about a period of time when you were so irritable that you found yourself shouting at people or starting fights or arguments? (Definitely no (score 0), perhaps yes (score 1), definitely yes (score 2).) What about a period of time when you were physically much more active than usual, for example, when you had lots of different projects on the go at the same time? (Definitely no (score 0), perhaps yes (score 1), definitely yes (score 2).)

Analyses

Analyses included the Student's *t*-test, chi-squared test and chi-squared test for association, and were conducted using SPSS version 21 for Windows. To assess the likely clinical usefulness of the HCL-13 and 3-item questionnaires, in terms of differentiating between bipolar disorder and major depressive disorder (MDD), we calculated sensitivity, specificity, positive predictive value (PPV) and negative predictive value (NPV) using MedCalc and verified these manually. Positive and negative clinical utility measures were calculated using an online calculator constructed by the developer of the MedCalc test (www.psycho-oncology.info/cui.html).¹⁵

Results

Of those who had a full diagnostic assessment, two participants were excluded because their SCID results suggested a primary diagnosis of alcohol-related mood problems. In total, 24 participants from our final sample of $n = 149$ had a DMS-IV diagnosis of bipolar disorder (16.1%; 95% CI 10.8–23.2%) and the remainder had a diagnosis of MDD ($n = 125$, 83.9%).

There were no significant differences between the bipolar disorder group and the MDD group in terms of age, gender distribution and socioeconomic status (assessed using the Scottish Index of Multiple Deprivation, SIMD) (*Table 1*). However, as expected, the bipolar disorder group had higher mean scores on the HCL-13 (9.21 *v.* 6.61, $P = 0.001$) and on the 3-item questionnaire (4.79 *v.* 2.88, $P < 0.001$).

Characteristics of participants with major depressive disorder (MDD) and bipolar disorder

	MDD (<i>n</i> = 125)	Bipolar disorder (<i>n</i> = 24)	<i>P</i>
Age, years: mean (s.d.)	47.50 (10.50)	47.58 (8.79)	0.972 <i>a</i>
Females: <i>n</i> (%)	77 (62.6)	15 (62.5)	0.992 <i>b</i>
SIMD 1: <i>n</i> (%) <i>d</i> (most deprived quintile)	56 (45.5)	14 (58.3)	0.705 <i>c</i>
SIMD 2: <i>n</i> (%)	20 (16.3)	2 (8.3)	
SIMD 3: <i>n</i> (%)	15(12.2)	4(16.7)	
SIMD 4: <i>n</i> (%)	13 (10.6)	1 (4.2)	
SIMD 5: <i>n</i> (%) (most af- fluent quintile)	18 (14.6)	3 (12.5)	
HCL-13: mean (s.d.)	6.61 (3.36)	9.21 (2.77)	0.001 <i>a</i>
3-item questionnaire: mean (s.d.)	2.88 (1.84)	4.79 (1.56)	<0.001 <i>a</i>

HCL-13, Hypomania Checklist 13; SIMD, Scottish Index of Multiple Deprivation.

Student *t*-test.

Chi-squared test.

Chi-squared test for association.

No SIMD data for 1 participant with MDD.

ROC analyses

The receiver operating characteristics (ROC) curves in *Fig. 1* demonstrate that both the HCL-13 and the 3-item questionnaire performed well in terms of differentiating between MDD (*n* = 125) and bipolar disorder (*n* = 24). For the HCL-13, an area under the curve (AUC) of 0.72 (95% CI 0.61–0.84) demonstrates a ‘fair’ overall ability of the questionnaire to discriminate effectively between the two groups. Similarly, an AUC of 0.79 (95% CI 0.69–0.89) for the 3-item questionnaire also demonstrates a ‘fair’ overall ability. An AUC of over 0.80 is considered to demonstrate a ‘good’ overall ability to discriminate.¹⁶

Table 2 presents the sensitivity, specificity, PPV, NPV and likelihood ratio analyses. For the HCL-13, a threshold score of 8 points had a sensitivity of 75.0% and specificity of 55.28% but PPV was low at 24.66%. At a higher threshold of

9 points, the sensitivity was 70.83%, specificity was 63.41%, PPV was 27.42% and NPV was 91.76%. At the lower threshold of 7 points, the sensitivity was 79.17%, specificity was 52.03%, PPV was 24.36% and NPV was 92.75%. Therefore, a threshold of 4 points was chosen to give the best balance between different statistical parameters.

HCL-13 and 3-item questionnaire screening for bipolar disorder

Questionnaire	Threshold	Sensitivity (%) (95% CI)	Specificity (%) (95% CI)	PPV (95% CI)
HCL-13	13 points	4.17 (0.11–21.12)	99.19 (95.55–99.98)	50.00 (1.26–98.7)
12 points	12.50 (2.66–32.36)	95.12 (89.68–98.19)	33.33 (7.49–70.07)	84.78 (77.68–90.0)
11 points	45.83 (25.55–67.18)	87.80 (80.68–93.01)	42.31 (23.35–63.08)	89.26 (82.33–94.0)
10 points	60.50 (40.59–81.20)	78.05 (69.69–85.01)	35.71 (21.55–51.97)	91.43 (84.35–96.0)
9 points	70.83 (48.91–87.38)	63.41 (54.25–71.91)	27.42 (16.85–40.23)	91.76 (83.77–96.0)
8 points	75.00 (53.39–90.23)	55.28 (46.06–64.25)	24.66 (15.32–36.14)	91.89 (83.18–96.0)
7 points	79.17 (57.85–92.87)	52.03 (42.84–61.12)	24.36 (15.35–35.40)	92.75 (83.89–97.0)
6 points	83.33 (62.62–95.26)	36.59 (28.09–45.75)	20.41 (12.93–29.74)	91.84 (80.40–97.0)
5 points	91.67 (73.00–98.97)	24.39 (17.10–32.95)	19.13 (12.39–27.52)	93.75 (79.19–99.0)
4 points	95.83 (78.88–99.89)	16.26 (10.22–23.99)	18.25 (11.94–26.12)	95.75 (79.19–99.0)
3 points	100.00 (87.75–100.00)	15.45 (9.56–23.07)	18.75 (12.40–26.60)	100.00 (82.35–100.0)
2 points	100.00 (85.75–100.00)	15.45 (9.56–23.07)	18.75 (12.40–26.60)	100.00 (82.35–100.0)
1 point	100.00 (85.75–100.00)	11.11 (6.05–18.25)	18.75 (12.40–26.60)	100.00 (75.29–100.0)
3-item questionnaire	6 points	45.83 (25.55–67.18)	88.62 (81.64–93.64)	44.00 (24.40–65.0)
5 points	66.67 (44.68–84.37)	78.05 (69.69–85.01)	37.21 (22.98–53.27)	92.31 (85.40–96.0)
4 points	83.33 (62.62–95.26)	64.23 (55.09–72.67)	31.25 (20.24–44.06)	95.18 (88.12–98.0)
3 points	91.67 (73.00–98.97)	43.09 (34.20–52.32)	23.91 (15.63–33.94)	96.36 (87.47–99.0)
2 points	95.83 (78.88–99.89)	28.45 (20.69–37.29)	20.72 (13.61–29.45)	97.22 (85.47–99.0)
1 point	95.83 (78.88–99.89)	9.76 (5.14–16.42)	17.16 (11.20–24.63)	92.31 (63.97–99.0)

HCL-13, 13-item Hypomania Checklist; NPV, negative predictive value; PPV, positive predictive value.

Similarly, a threshold score of 4 on the 3-item questionnaire had a sensitivity of 83.33%, specificity of 64.23% and PPV of only 31.25%. At a higher threshold of 5 points, the sensitivity was 66.67%, specificity was 78.05%, PPV was 37.21% and NPV was 92.31%. At a lower threshold of 3 points, sensitivity was 91.67%, specificity was 43.09%, PPV was 23.91% and NPV was 93.36%. Therefore, a threshold of 4 points was chosen to give the best balance between these different parameters.

The positive clinical utility – the ability of the test to confirm cases of bipolar disorder – was poor for both tests. The

negative clinical utility a measure of screening and excluding bipolar disorder, was slightly better for the 3-item questionnaire than the HCL-13 at our threshold values: 0.611 (95% CI 0.541–0.682) compared with 0.582 (0.509–0.655). These thresholds were chosen to give the best balance between sensitivity, specificity, PPV, NPV and positive and negative clinical utility

Discussion

One of the goals of this study was to estimate how common DMS-IV bipolar disorders might be in a sample of primary care patients taking antidepressant medication, specifically those patients who were either taking antidepressant therapy for more than 12 months or who had had multiple courses of antidepressants over the preceding 5 years. We found that 16.1% of our sample had bipolar disorder. This rate is higher than in previous literature from the UK. In samples of primary care patients, Hughes *et al*¹⁰ found a prevalence of 7.3% whereas Smith *et al* found a prevalence of 9.6%. Both studies assessed patients with depressive disorder who had been prescribed antidepressant medication. It is possible that the addition in our study of participants who had previously been prescribed multiple courses of antidepressants led to a higher prevalence estimate for bipolar disorder, because unrecognised bipolar disorder is more common in patients with more severe and enduring depression.¹⁷

We also aimed to compare the HCL-13 and a brief 3-item questionnaire in terms of their ability to differentiate between patients with MDD and bipolar disorder. We found that the AUC for HCL-13 was 0.72, while for the 3-item questionnaire it was slightly higher, at 0.79. For both tests the ability to discriminate between MDD and bipolar disorder in terms of sensitivity and specificity was reasonable, but PPVs were low. This is a function of the low prevalence of bipolar disorder in primary care setting, but represents a potential limitation in terms of the usefulness of these instruments to GPs in everyday clinical practice.¹⁸ In a review of brief screening instruments for depressive disorder in a low-income country, Hanlon *et al*¹⁹ concluded that the low PPV at acceptable sensitivity levels may preclude their use in clinical settings.

Nevertheless, we would argue that there may be some use in primary care for these brief screening instruments alongside additional assessments, for example whether patients have a strong family history of mood disorder. The 3-item questionnaire in particular may be useful to GPs in terms of fulfilling the NICE requirement to assess all patients with depression for a history of manic features. The high NPV of 95% means that clinicians may find this useful for excluding a diagnosis of bipolar disorder in their patients with depression. The NICE guidance states that the ideal instrument should be brief, easy to administer and to score, and should be able to be interpreted without extensive and specialist training.⁸

Strengths and limitations

This was a reasonably large study that took a systematic approach to screening patients in primary care settings. We used definitions of bipolar disorder and MDD based on formal diagnostic classifications by using SCID assessment. The study included a range of people from different social backgrounds, with the majority living in some of the most deprived areas of Scotland. However, it may have been helpful to have more baseline demographic information on patients, such as ethnicity, family history of bipolar disorder and age at onset of depression, and the study may be subject to recall bias because it relied on the patient's recall of prior episodes of manic symptoms rather than a corroborative history. There may also be an issue of selection bias, because GPs were able to exclude certain participants if they felt that they were not suitable for this study. As a result of this, and the fact that only one method of recruitment was used in this study, there was a relatively small final sample given the number of invitations sent, which may have led to ascertainment bias. Moreover, the SCID interviewer was not masked to HCL-13 and 3-item scores, which may also have been a source of bias.

Another potential limitation is that the 3-item questionnaire had no requirement for a minimum duration of symptoms. It is possible that individuals with brief periods of affective instability, such as those with borderline personality disorder, would be inclined to respond positively to these questions. Similarly, we did not take a history of alcohol or drug use, and while we did exclude alcohol or substance-induced mood disorders, the use of psychoactive substances could have led to false positives with the 3-item questionnaire.

Clinical implications

A brief 3-item questionnaire may be clinically useful for GPs who wish to screen for manic features in patients with MDD. This could prompt more detailed assessment, such as an appointment with a relative or friend to obtain a collateral history before assessing the need for a referral to secondary care. Further studies are required in larger samples to assess the clinical usefulness of this test in screening, ideally without the issues of recruitment faced in this study. It may also be helpful to develop the 3-item questionnaire further, perhaps with the addition of other items such as the duration of symptoms. While the addition of items would lead to a more statistically sound test, it would also take longer to administer such a test, which may make it less clinically useful.

A proportion of primary care patients with MDD, perhaps as many as 1 in 5, may have undiagnosed bipolar disorder. For busy clinicians working in a time-restricted environment, we suggest that a brief 3-item questionnaire may be a useful screening tool for bipolar disorder and a first step towards a more comprehensive assessment.

1.6.57 Flexible assertive community treatment (FACT) model in specialist psychosis teams: an evaluation

Abstract

Aims and method The impact of flexible assertive community treatment (FACT) has been observed in people previously supported by assertive community treatment (ACT) teams, but its effect on those previously with a community mental health team (CMHT) has not been studied in the UK. An observational study was conducted of 380 people from 3 CMHTs and 95 people from an ACT team, all with a history of psychosis, following service reconfiguration to 3 FACT teams.

Results People previously with a CMHT required less time in hospital when the FACT model was introduced. A smaller reduction was observed in people coming from the ACT team. Both groups required less crisis resolution home treatment (CRHT) team input.

Clinical implications FACT may be a better model than standard CMHT care for people with a history of psychosis, as a result of reduced need for acute (CRHT and in-patient) services.

 - * *Conclusions*

Recent years have seen a widespread disinvestment from assertive community treatment (ACT), with many teams being merged into generic community mental health teams (CMHTs).^{1,2} Such changes have been criticised for moving away from evidence-based systems, instead adopting untested models of service delivery, with poorer quality care, described in a King's Fund report as 'a leap in the dark'.³ In some cases new services have adopted a flexible ACT (FACT) model, with people able to access intensive support delivered in the community using a team case-load and ACT principles, as and when they require it.^{4,5} In this model, care coordinators manage individual case-loads, but also work together to provide shared care for people at times of increased need, enabling seamless transition between high- and low-intensity care.

An observational study in the UK has not shown negative effects in people previously supported by ACT teams in terms of hospital admissions or need for crisis resolution home treatment team (CRHT) interventions.^{6,7} However, there have been no UK studies assessing whether there could be advantages for people previously supported by a CMHT but now receiving FACT. It might be expected that some people who have not previously had access to periods of more intensive support within the CMHT could benefit from the FACT approach, perhaps with a reduced need to have interventions from a CRHT or hospital admission.

Method

In South Warwickshire there had previously been a single, well-established ACT team, with outcome data over a 10-year period showing a reduced need for time in hospital.⁸ The area was also served by three generic CMHTs and a single early intervention team. The early intervention services were maintained, whereas each of the three CMHTs was divided into a team for people with a history of psychosis (recovery teams) and a team for people with other non-organic mental disorders. At the same time they became 'age-independent', with no upper age limit. The previous ACT team was disbanded and merged into the new recovery teams, which were configured to deliver services using the FACT model. A few months prior to the changes, the ACT team had absorbed a community rehabilitation team and therefore fidelity to the original ACT model had reduced. Characteristics of the ACT, CMHT and FACT teams are shown in *Table 1*.

Characteristics of the different teams

	CMHT	ACT	FACT
Case mix	People with psychotic or non-psychotic disorders	People with history of severe psychosis who have difficulty engaging with traditional services and often with comorbid problems	People with a history of psychosis
Age range, years	17–65 for new referrals, no upper age limit for existing users of the service	17–65 for new referrals, no upper age limit for existing users of the service	17 and upwards for new and existing users of the service
Care planning	Individual case management	Shared care	Individual case management with periods of shared care as needed
Interface with mental health professionals	Referrals made between professionals when needed	All professionals involved in delivery of care without referrals, on a needs-led basis	All professionals involved in delivery of care without referrals, on a needs-led basis
Care coordinator: patient ratio	30	12–15	25

ACT, assertive community treatment; CMHT, community mental health team; FACT, flexible assertive community treatment.

There was no change in acute hospital bed availability during the study period. However, a long-stay rehabilitation ward was closed at about the same time as the other changes took place, with most residents being discharged either to nursing homes or to intensive community placements with 24-hour live-in staff support. This group had been care-coordinated by the ACT team both prior to and following discharge.

The current study was a service evaluation of the new FACT-based recovery teams. It assessed their impact in enabling people to avoid time in hospital, to reduce the use of crisis home treatment support, and to examine how much face-to-face support people received from the new service. There were multiple changes associated with setting up the teams, all of which took place in June 2014. Many people experienced a change in care coordinator and/or consultant, and there were various teething problems with the transition. In order to avoid these becoming confounding variables, we chose to study a 13-month period starting 6 months after the creation of the new services: December 2014 until January 2016. We compared this with a 13-month period in the old services a year earlier (December 2012 until January 2014).

The trust uses a computerised notes system for all staff in the community, which constitutes the sole record of any contacts with clients. It can generate detailed reports on clinical contacts between specified time periods, broken down by team or staff member, and is routinely used for gathering trust performance data. Because people are constantly moving in and out of services, we decided to study only those people who were open to the new FACT service during the 13-month study period, and who had also been in one of the 3 CMHTs or the ACT team during the comparison 13-month period. Because of the closure of the rehabilitation ward, there was potential for a considerable impact on bed use data in the ACT arm of the study – the patients, having spent several years in hospital, were moving to nursing care or 24-hour live-in support. For this reason, we excluded from the bed use analysis those who were being discharged from hospital after several years into nursing or live-in community care.

Results

A total of 475 people who had also been with one of the previous legacy teams the year before were identified as being open to the new service. Of these, 95 had previously been with the ACT team and 380 with one of the CMHTs. Results were analysed separately for these two groups. Tests of significance between the old systems and the new FACT service were carried out using 2-tailed paired *t*-tests or, when data were skewed, using the Wilcoxon signed rank test. A Monte Carlo permutation test, as described by Good⁹ and derived from Fisher,¹⁰ was used when there was no standard statistical method available, such as to compare partially paired data. This type of testing gives a *P*-value directly (much like Fisher's exact test) without an intermediary test statistic such as a *t*-value. To keep the false detection rate (i.e. the overall type 1 error) low at 0.05 on account of multiple testing, we used the Benjamini-Hochberg¹¹ correction, which gave a significance level alpha of 0.0288. This means that *P*-values of less than 0.0288 are significant. Where a significant difference was observed in one group but not in the other, *post hoc* power calculations were carried out in order to check for any potential type 2 errors. Demographic and clinical characteristics of people from the two legacy teams are shown in *Table 2*.

Demographic and clinical characteristics of the cohorts

Previous team	ACT (<i>n</i> = 95)	CMHT (<i>n</i> = 380)
Gender, male: %	66.0	54.2
Age, years: mean	45.3	47.7
Time in services, years: mean	13.7	11.0
ICD-10 diagnosis, %		
Schizophrenia	78.3	53.4
Schizoaffective disorder	16.3	4.7
Bipolar affective disorder	4.3	28.2
Other	1.1	13.8

ACT, assertive community treatment; CMHT, community mental health team.

Face-to-face contacts with the FACT teams

For people previously with the ACT team, the number of face-to-face contacts with a member of the new FACT team reduced from 1.16 to 0.69 per week, with a corresponding reduction in mean duration of contacts from 65 to 38 minutes per person. These differences were statistically significant and are of similar magnitude to the changes observed in the other UK study of FACT.^{6,7} The number of contacts by support workers was not significantly different (0.25 compared with 0.29), but the proportion increased from 22 to 43%. In other words, the reduction of face-to-face contacts in the new FACT system for people previously in the ACT team was a result of less involvement of qualified staff. The number of community-based contacts reduced significantly in the new service, but the proportion was greater, indicating that, overall, more contacts had been lost in clinic settings compared with those in the community. For people previously with a CMHT there was very little difference in number and duration of contacts when the service adopted the FACT model. However, there was greater use of support workers and more contacts were in community settings, consistent with the principles of the FACT model (*Table 3*).

Contacts with FACT team compared with previous service (ACT or CMHT)

Previous team	ACT (<i>n</i> = 95)	CMHT (<i>n</i> = 380)				
Face-to-face contacts per week: mean	1.16	0.69	<0.0001 _a	0.47	0.45	0.6018 _a
Duration, minutes: mean	64.80	38.13	<0.0001 _a	26.38	25.33	0.5544 _a

People with any admission: <i>n</i>	15	11	0.3458 _b	71	52	0.0388 _b

ACT, assertive community treatment; CMHT, community mental health team; FACT, flexible assertive community treatment.

2-tailed paired *t*-test.

Monte Carlo permutation test.

2-tailed Wilcoxon.

$P > 0.0288$ not significant (after Benjamini–Hochberg correction).

Contact with the CRHT and hospital use

The number of face-to-face contacts with the CRHT was compared before and after the changes, and significant reductions were seen in both groups. Similarly, the number of people who required any face-to-face support from the CRHT was significantly lower following the changes.

For people who had previously been with the ACT team there was a 19% reduction in number of days spent in hospital, which failed to reach statistical significance. However, the power calculated *post hoc* was only 4%, which indicates that the numbers were insufficient to conclude there was no difference following the change of model. There was also a reduction in mean number of admissions in this group but numbers were too low for a meaningful comparison to be made. In the CMHT group, reductions in bed use were much greater, with a 36% reduction following the introduction of the FACT model, which reached statistical significance. There was also a non-significant reduction in admissions in this group.

Discussion

People previously with a CMHT

There have been no other UK studies exploring the effect of the FACT model on people who had previously been with a CMHT. We observed that these people experienced less than half the number of face-to-face interventions with the CRHT than when they were with a CMHT, which was statistically significant. This is consistent with the FACT philosophy of enabling people to seamlessly move to a high-intensity team approach at times of increased need.¹² Hence, it is possible that during periods of crisis, people were able to receive intensive community support within the FACT team, reducing the need for transfer to the CRHT. Similarly, the reductions in bed use would be consistent with the ability of the FACT model to support people at times of crisis with less need for admission. There were no changes in background bed availability in the services that would provide an alternative explanation for these reductions.

People previously with the ACT team

The other UK evaluation of FACT considered 112 people who had previously been with an ACT service, comparing their hospital and CRHT use before and after the change,^{6,7} but without an appraisal of the impact of people going to FACT from a CMHT. Our findings for people who had previously been supported by the ACT team were similar, with no evidence of adverse consequences in terms of increased need for admission or increased crisis home treatment team contact in the first year. This was despite a considerable reduction in face-to-face support from mental health services. In fact, bed use was reduced, but not significantly, although this has to be interpreted with caution and may not be clinically meaningful as the number of people admitted during the study period was very low.

A possible explanation for this is that a FACT approach could be a more efficient model than ACT because people only receive high-intensity team-based interventions at times of need, freeing up resources for those who most need them. However, our previous follow-up study of the ACT population in South Warwickshire⁸ showed that most people, once they had been with the service for 5 years, reverted to a relatively low level of bed use. The average time with the ACT team had been over 6 years, and by the time the services changed most of these people were relatively stable. Hence, it might be expected that they would cope well with a move to a less intensive service. Any conclusion that there was no evidence of harm when moving from ACT to FACT would therefore be limited to the context of people who have already received a period of several years of intensive ACT interventions.

Limitations

Because there were a number of changes to services, including moving to an ‘age-independent’ model, caution needs to be exercised in interpreting the findings as being solely attributable to the FACT model. One of the limitations of the observational design is the possibility of regression to the mean or background variations which could contribute to reduced hospital use or less contact with the CRHT. Change point analysis can mitigate against this,^{13–15} particularly if combined with start points staggered in time in order to reduce the effect of wider system changes which might influence results. However, because the time period under study was relatively short and the changes in team structure occurred on the same date it was not possible to use this technique. The most robust method for addressing confounding factors would be a randomised controlled trial, but this was beyond the scope of our pragmatic evaluation. The pragmatic method was limited to routinely collected contact data and did not capture more personally meaningful information about satisfaction, social functioning and engagement with services, which are known benefits of ACT.¹⁶

ACT teams have had varying levels of success in terms of achieving fidelity to the model.¹⁷ Without the use of an objective measure, such as the Dartmouth Assertive Community Treatment Scale (DACTS),¹⁸ it is not possible to know with certainty the degree to which the South Warwickshire team was practising according to the ACT principles. Although previous DACTS measures taken several years earlier had shown high fidelity, this had been eroded with less use of shared case-loads and lower staff to patient ratios. Hence, the observations about the outcome for people who had been with the ACT team cannot be extrapolated with certainty to other ACT teams with higher fidelity. This argument also applies to the Firn studies^{6,7} of dismantling ACT teams, which failed to measure ACT fidelity. Although a FACT fidelity scale is available (from The Netherlands),¹² this has never been validated in a UK setting. As Dutch FACT teams also undertake the role of a 24-hour crisis home treatment service, it would not be meaningful to use this scale with a service in the UK, where this function is provided by separate teams.

Conclusions

This is the first study in the UK which has examined the impact of adopting the FACT model on people previously supported by a CMHT within a generic community psychosis service. Although limited by the observational design, the results are consistent with the hypothesis that FACT may be of benefit to this group, who previously did not have access to ACT. People who had been with the CMHT were able to receive increased support delivered with a team case-load at times of increased need, a key component of the FACT approach, thereby reducing their need for the help of the CRHT. We would argue that there is still a case for maintaining ACT teams, which have been much more rigorously assessed than FACT, and that the benefits to patients justify the investment in these services. However, where mental health providers are planning to disband ACT services, there would be value in configuring new teams according to the FACT model, which appears to be a safe alternative in the short term for people who have been with an ACT team for several years.

1.6.58 Burnout and psychiatric morbidity among doctors in the UK: a systematic literature review of prevalence and associated factors

date

2017-8

Abstract

Aims and method To systematically review the prevalence and associated factors of burnout and stress-related psychiatric disorders among UK doctors. An extensive search was conducted of PubMed, EBSCOhost and British medical journals for studies published over a 20-year span measuring the prevalence of psychiatric morbidity (using the General Health Questionnaire) and burnout (using the Maslach Burnout Inventory).

Results Prevalence of psychiatric morbidity ranged from 17 to 52%. Burnout scores for emotional exhaustion ranged from 31 to 54.3%, depersonalisation 17.4 to 44.5% and low personal accomplishment 6 to 39.6%. General practitioners and consultants had the highest scores. Factors significantly associated with increase in the prevalence of burnout and psychiatric morbidity include low job satisfaction, overload, increased hours worked and neuroticism.

Clinical implications The results indicate a worryingly high rate of burnout and psychiatric morbidity among UK doctors, which could have a huge negative impact on healthcare provision in general. Factors at personal and organisational levels contribute to burnout and psychiatric morbidity, and so efforts made to counter these problems should target both levels.

Doctors have a legal duty broader than that of any other health professional and therefore a responsibility to contribute to the effective running of the organisation in which they work, and to its future direction.¹ In an environment where their health and well-being is not prioritised doctors sometimes become ill, manifesting features of burnout and/or stress-related psychiatric disorders. Such psychiatric morbidity, or ‘caseness’, is detected using self-reported instruments such as the General Health Questionnaire (GHQ).² Doctors also experience ‘burnout’, which is defined as a syndrome of exhaustion, cynicism and low professional efficacy.³ Maslach *et al* described burnout as a prolonged response to chronic emotional and interpersonal stressors on the job, and stated: ‘What started out as important, meaningful, and challenging work becomes unpleasant, unfulfilling, and meaningless. Energy turns into exhaustion, involvement turns into cynicism, and efficacy turns into ineffectiveness’.

Increased prevalence of psychiatric morbidity and burnout has been established in studies from different parts of the

world. A study of Italian physicians found an estimated prevalence of psychiatric morbidity to be 25%, and prevalence of burnout on the emotional exhaustion scale of the Maslach Burnout Inventory (MBI) to be 38.7%.⁵ Other studies have reviewed the factors associated with the development and maintenance of psychiatric illness and burnout among doctors. A survey of Australian doctors found that having medico-legal issues, not taking a holiday in the previous year and working long hours were all significantly associated with psychiatric morbidity.⁶ Self-criticism as a medical student was significantly correlated with psychological stress as a doctor in a cohort followed over 10 years by Firth-Cozens.⁷

Burnout among doctors can lead to self-reported suboptimal patient care,⁸ and to major medical errors.⁹ Psychiatric morbidity increases the likelihood of retirement thoughts and retirement preference.¹⁰ Behavioural responses to burnout established in the literature also include alcohol and drug misuse, physical withdrawal from co-workers, increased absenteeism, arriving for work late and leaving early, and employee turnover.¹¹ An extreme reaction to stress can be suicide, even though the pathway to this is complex and multifactorial. A UK survey of suicides between 1979 and 1983 ranked the medical profession as 10th in the list of high-risk professions.¹²

Mental ill health can be found within every workplace in every country. In the UK the total cost to employers of mental health problems among their staff is estimated at nearly £26 billion each year: £8.4 billion from sickness absences and £15.1 billion from reduced productivity at work.¹³ The National Institute for Health and Care Excellence (NICE) found that promoting the mental well-being of employees can yield economic benefits for the business or organisation, in terms of increased commitment and job satisfaction, staff retention, improved productivity and performance, and reduced staff absenteeism.¹⁴ For the National Health Service (NHS) to reap the benefits described by NICE, priority should be given to employee mental health. However, the constant structural changes to the NHS in England have created instability and lack of job security within the public health workforce.¹⁵ The Health and Social Care Act of 2012 has placed doctors at the centre of clinical commissioning groups in charge of shaping services and made them responsible for £65 billion of the £95 billion NHS commissioning budget.¹⁶ This imposes on doctors, especially general practitioners (GPs), a responsibility unlike any before,¹⁷ one which their training has not prepared them for. The ability to cope with the challenges of working in the NHS and the possibility of stress and burnout were highlighted in the annual meeting of the British Medical Association in 2013,¹⁸ and are the focus of this review.

Numerous research papers document burnout and stress-related psychiatric disorders in doctors worldwide, but none has presented the results in the form of a systematic review showing the prevalence and associated factors among UK doctors. The overall aim of this review was to redress this by assessing the prevalence of burnout and psychiatric morbidity among UK doctors working in different specialties, and to explore the associated identified factors. The objectives were to review the prevalence of the syndrome of burnout and psychiatric morbidity, to explore the nature of the relationship between burnout and psychiatric morbidity, and to identify other factors associated with the development and/or perpetuation of those conditions.

Method

Search strategies

The words ‘burnout’ and ‘doctors’ were put into the search field of the EBSCOhost website specifying the following databases: Academic Search Complete, CINAHL Plus, PsycINFO and PsycARTICLES. Limiters activated were: English language, human, apply related words, and a time limit of January 1993 to December 2013. A total of 562 articles resulted from this, reduced to 489 automatically after duplicates were removed; 28 articles were selected for further analysis, and out of these 9 remained based on the study inclusion and exclusion criteria. Using the same parameters but with the words ‘psychiatric morbidity’ AND ‘doctors’, a total of 97 articles were generated, reduced to 77 after the removal of duplicates, and from these only 1 was selected as new and appropriate. Again using the same parameters but with the words ‘stress’ AND ‘doctors’ NOT ‘nurses’, 3560 articles came up, reduced to 2259 after duplicates were removed; 23 new articles were reviewed in greater detail, and from these 5 new and appropriate articles were selected.

An advanced search on PubMed with the words ‘doctors’ OR ‘physicians’ AND ‘stress’, with a time limit of 1 January 1980 to 15 December 2013 and other limits (human, English language, clinical trial, journal article, reviews, lectures) generated 5973 articles. After careful analysis of the abstracts 28 new articles were identified for more detailed review, and from these 10 were selected as new and appropriate.

Two searches within the group of British medical journals with the phrases ‘burnout and doctors’ and ‘doctors and stress’ with the time limit of January 1993 to December 2013 yielded two new and appropriate papers.

A review of the reference lists of already-identified papers yielded three relevant papers.

Altogether, this extensive search yielded 30 relevant papers which were included in the units of analysis for this review (*Fig. 1*).

Fig. 3: Flowchart of the study selection process.

Inclusion criteria

Certain criteria had to be met before a study was included in the units of analysis: it had to answer any of the research questions for the measurement of the prevalence of psychiatric morbidity the study had to have used any version of the GHQ, and for the prevalence of burnout syndrome only the MBI was considered population group – only medical doctors in the UK irrespective of which organisation they work in minimum sample size of 50 published between January 1993 and December 2013 published in the English language.

The questionnaires

The GHQ is a well-validated and widely used screening tool for the detection of minor psychiatric disorders (psychiatric morbidity) in the general population.¹⁹ The GHQ-12 is self-administered and only takes about 5 min to complete. It enquires about the experience of psychosocial and somatic symptoms in recent weeks. Each of the 12 items is measured on a 4-point Likert scale. Studies validating the GHQ-12 against standardised psychiatric interviews indicate that a cut-off score of 4 or above indicates a high probability that the individual suffers from a clinically significant level of distress (‘caseness’ or psychiatric morbidity).

The MBI is a 22-item self-report questionnaire, which is well recognised and widely used to measure burnout in relation to occupational stress.²⁰ It has three subscales: personal accomplishment (measured by 8 items), depersonalisation (measured by 9 items) and emotional exhaustion (measured by 5 items). Responses are rated for each item according to frequency on a 7-point scale from ‘never’ to ‘every day’. The total score for each subscale is categorised ‘low’, ‘average’ or ‘high’ according to predetermined cut-off scores, based on normative data from a sample of American health professionals. A high degree of burnout is indicated by high scores on the emotional exhaustion and depersonalisation subscales and low scores on the personal accomplishment subscale.

Data extraction

A simple paper data extraction tool was created in Microsoft Word, and the tables from this have been used to portray the results in the results section. Data were extracted by the author over the months of November and December 2013.

Results

A total of 30 papers considered relevant and appropriate based on the study inclusion and exclusion criteria were included in this review. *Table 1* summarises these papers.

Findings on prevalence

Seven studies^{21,22,24,25,27,30,50} had quantifiable data on the prevalence of both psychiatric morbidity and burnout (an in-depth analysis of studies reviewed in this paper is included in an online data supplement to this article). Altogether 22 studies reported on prevalence of psychiatric morbidity, and the range was 17–52% (average 31%). GPs and consultants had the highest scores. Fourteen studies had burnout scores, with nine reporting scores as percentages and five as mean scores; one study²⁸ had both percentage and mean burnout scores. For emotional exhaustion the scores ranged from 31 to 54.3% and mean scores ranged from 2.90 to 31.26; for depersonalisation the scores ranged from 17.4 to 44.5% (1.95–15.68) and for low personal accomplishment the range was 6–39.6% (4.36–34.21). GPs, consultants and pre-registration house officers had the highest levels of burnout in the studies.

McManus *et al*,⁴⁶ in a UK-wide study carried out in 2009, had the largest sample size at 2845 doctors and reported prevalence of psychiatric morbidity at 19.2%. The other two UK-wide studies with samples of over 1000 cutting across specialties and grades^{23,43} reported psychiatric morbidity prevalence rates of 27.8% and 21.3%, respectively. Taylor *et al*⁵⁰ reviewed 1308 consultants from different specialties and found the prevalence of psychiatric morbidity to be 32%.

One longitudinal study³⁰ found no significant increase in the prevalence of psychiatric morbidity over 3 years in a non-specific group of doctors. Another longitudinal study⁵⁰ found a significant increase in psychiatric morbidity and emotional exhaustion among consultants over 8 years.

The only European Union (EU) study looking at the prevalence of burnout in GPs from 12 EU countries³⁹ found lower average scores on all burnout scales compared with those of English GPs.

Findings on associated factors

Job satisfaction was found to be protective against the effect of stress on emotional exhaustion. The number of hours worked, job stress and overload were associated with increased psychiatric morbidity in eight studies. Two studies^{22,38} found that women had significantly higher psychiatric morbidity than men, but three studies^{27,34,45} did not find any association with gender. The personality trait of neuroticism was significantly associated with increase in psychiatric morbidity in three studies,^{35,43,47} while conscientiousness was a protective factor. Psychiatric morbidity was also positively associated with taking work home and with the effect of stress on family life.

Job satisfaction was negatively correlated with burnout in three studies.^{21,22,25} Age was an interesting factor; increased depersonalisation was found in younger doctors in five studies,^{21,22,27,29,31} whereas emotional exhaustion increased with

age in two studies.^{22,41} Being single was associated with increased burnout scores, and neuroticism increased burnout significantly in two studies.^{43,47} Increased job stress and workload increased burnout in three studies, with significantly lower emotional exhaustion scores in part-time GPs.

Findings on the direct relationship between burnout and psychiatric morbidity

Three studies^{25,30,46} found significant positive correlations between psychiatric morbidity as measured by the GHQ, and burnout syndrome. Using the process of casual modelling, McManus *et al*³⁰ found that when scores were considered in 1997 and later in 2000, emotional exhaustion increased psychiatric morbidity, and *vice versa*. Personal accomplishment increased emotional exhaustion directly, and increased psychiatric morbidity directly but also indirectly through increasing emotional exhaustion. When other mental health problems were considered, anxiety and depression were found to increase psychiatric morbidity in three studies,^{35,37,38} and depression increased depersonalisation.⁴¹

Discussion

The findings indicate that the prevalence of psychiatric morbidity among UK doctors is quite high, ranging from 17 to 52%. This compares unfavourably with the results from a longitudinal survey of people living in private households within the UK, which found an 18-month period prevalence of common mental disorders to be 21%.⁵¹ Only 4 of the 22 studies that reported on psychiatric morbidity found prevalence of less than 21%,^{26,30,32,46} which is slightly better than 27% found in a study of palliative care physicians in Western Australia.⁵² An earlier study of junior house officers in the UK found psychiatric morbidity in 50% of doctors,⁵³ but this was in a period when the working pattern of junior doctors was relatively unregulated. More recent studies of junior doctors contained in this review found the prevalence of psychiatric morbidity to be around 19%.^{26,32} Concern over increasing prevalence of common psychiatric illnesses was borne out by the results from the study which found a 5% increase in morbidity among a cohort of consultants over an 8-year period.⁵⁰

This review also found a high prevalence of burnout among UK doctors measured using the MBI. It lends further support to the growing body of evidence which has found the syndrome of burnout to be prevalent all over the world among health professionals. In a sample of Australian doctors, 24% suffered burnout;⁵² in a New Zealand sample of medical consultants one in five did;⁵⁴ and in a cross-section of Japanese doctors 19% were affected.⁵⁵ This review found even higher rates of burnout, with the prevalence of emotional exhaustion ranging from 31 to 54.3%, which would suggest UK doctors are comparatively more prone to burnout. GPs generally had higher scores for burnout,²⁹ particularly in the study of European family doctors,³⁹ which found that the only countries in which GPs had higher burnout scores than England were Turkey, Italy, Bulgaria and Greece. Emotional exhaustion among a cohort of consultants was shown to have increased over an 8-year period,⁵⁰ with a prevalence of 41% in 2002.

This review has been able to pool together different studies which report on factors associated with the development and perpetuation of psychiatric morbidity and burnout. Neuroticism was positively and significantly correlated with psychological distress and burnout in three studies.^{35,43,47} Neuroticism refers to a lack of psychological adjustment and instability leading to a tendency to be stress-prone, anxious, depressed and insecure, and it has been shown to negatively predict extrinsic career success.⁵⁶ McManus *et al*,⁴³ in a 12-year longitudinal study on a cohort of students who started studying medicine in 1990, found that doctors who are more stressed and emotionally exhausted showed higher levels of neuroticism all through their careers. Neuroticism was also positively associated with perceived high workload. The researchers concluded that neuroticism was not only a correlate but a cause of work-related stress and burnout. Similar findings were noted by Clarke & Singh⁵⁷ in a study looking at the pessimistic explanatory style of processing information, which is a manifestation of neuroticism. In that study neuroticism was shown to positively predict psychological distress in doctors, and the authors recommended that susceptible doctors should be offered cognitive-behavioural therapy (CBT) to alter their explanatory style.

In an editorial titled 'Why are doctors so unhappy?' Richard Smith stated that the most obvious cause of doctors' unhappiness was that they feel overworked and under-supported.⁵⁸ Job stress, feeling overloaded and the number of hours worked were positively linked to psychiatric 'caseness' and burnout in many of the studies in the present review, and this cut across specialties and grades. A General Medical Council (GMQ survey⁵⁹ of doctors in training found that 22% felt their working pattern leaves them short of sleep at work, and 59% said they regularly worked beyond

their rostered hours. Increasing job stress without a commensurate increase in job satisfaction was associated with the presence of psychiatric morbidity, and job satisfaction was also positively correlated with illness in six of the reviewed studies^{21,22,25,34–36}. Another significant finding was the correlation between psychiatric disorders and burnout, with the two feeding off each other, leading to worsening outcomes.

The public health importance of these findings cannot be overemphasised. GPs are at the frontline of healthcare delivery in the UK, and around 90% of all NHS contacts take place in primary care, with nearly 300 million GP consultations a year.⁶⁰ The estimated total number of GP consultations in England rose from 217.3 million in 1995 to 300.4 million in 2008, with a trebling of telephone consultations, and with the highest consultation rates among the growing population of elderly individuals.⁶¹ Increased live births of over 110 000 over the past 10 years,⁶² and an ageing population⁶³ have contributed to the pressure felt by services in general. However, in spite of the increased demand on primary care services, the proportion of the NHS budget that is spent on general practice has slumped to record levels, and GPs report that this has compromised the quality of care they can provide.⁶⁴ Under these circumstances, the added expectation from the UK Department of Health that GP surgeries should open for longer hours and should expand patient choice will undoubtedly lead to even more psychological distress and burnout among GPs.

A government-driven emphasis in the NHS on performance management and targets increases job demands and stress among managers,⁶⁵ and increases psychiatric morbidity among doctors. The current climate of austerity in the UK, and the expectation that doctors should continue to provide high-quality care to patients within an NHS intending to make £20 billion worth of savings,⁶⁶ further expose doctors to burnout and stress. Psychiatrists are already having to deal with the expected increase in demand for mental health services stemming from the economic downturn,⁶⁷ and the increase in suicide rates⁶⁸ among the working-age population. Psychiatrists are particularly vulnerable to burnout, and patient suicide is a factor significantly associated with stress and burnout in this group.⁶⁹

Burnout among doctors can affect the entire public health workforce because as a syndrome it is considered ‘contagious’.⁴ With the push for doctors to take up leadership positions at every level within the NHS a burnt-out doctor can negatively affect the entire healthcare delivery system. Unhealthy coping strategies in response to burnout and stress were identified in this review: these include retiring early, taking work home, taking it out on family, mixing less with friends, and avoidance, all of which work against the development of a healthy work-life balance.

Limitations

Some key limitations are worth highlighting. First, all the studies were cross-sectional surveys using questionnaires sent to the participants online or by post. Response rates varied, with some as low as 17%, and only in half of the studies was effort made to increase the response rate by sending reminders or repeat questionnaires. Non-response bias could have affected the results. Second, although the MBI was used in all the studies examining burnout, different versions of the MBI were utilised. With the GHQ some studies used the 28-item version but most used the 12-item version. The cut-off for ‘caseness’ using the GHQ also differed between studies and ranged between 3 and 5. However, these differences may not have significantly affected the overall findings given that a study to validate the two versions of the GHQ found no difference between them, and also established that the different cut-off for ‘caseness’ did not affect the questionnaire’s validity.²

The cross-sectional method used for the surveys makes it difficult to draw a firm conclusion on the outcomes from a cause and effect perspective. Also, the number of potential confounders for the presence of burnout and common psychiatric disorders is vast and cannot be controlled for in surveys alone.

The fact that this literature review ends in 2013 may be considered a limitation, but the hope is that this paper will trigger more research in this area, and the author’s intention is to update the literature review by 2023.

Recommendations

Doctors are ultimately responsible for the quality of care they provide at any time, and they need to be aware of their own vulnerability to burnout and psychiatric illness, and of their impact on patient care. Traditionally, doctors take pride in working a lot of hours,⁷⁰ and are 3 to 4 times less likely to take days off sick compared with other health professionals;⁷¹ this combination is a recipe for burnout. A whole list of support networks is available on the GMC website,⁷² and doctors should be encouraged to utilise these. However, there is a 'culture of fear' among doctors regarding the GMC, and 96 doctors, a lot of whom had mental health problems, have died by suicide since 2004 while being investigated by the GMC.⁷³ A lot more work is therefore needed to make the most vulnerable doctors feel supported.

At an organisational level, approaches designed to reduce the workload of doctors should be prioritised. Changes to doctors' contract of service should reflect an understanding of the impact of work-related factors on the health and well-being of doctors, and any such contract should contain the necessary protections to reduce the experience of psychiatric illness and burnout. The benefits of a healthy workforce on the quality of care provided in the NHS cannot be overstated.

1.6.59 The impact of transforming care on the care and safety of patients with intellectual disabilities and forensic needs

John L. Taylor Iain McKinnon Ian Thorpe Bruce T. Gillmer

Abstract

NHS England recently published a national plan to develop community services for people with intellectual disabilities and autism who display challenging behaviour by using resources from the closure of a large number of hospital beds. An ambitious timescale has been set to implement this plan. The bed closure programme is moving ahead rapidly, but there has been little progress in developing community services to support it. This paper discusses the impact of the gap between policy and practice on the care and safety of patients with intellectual disabilities and forensic needs who form a distinct subgroup of the target population and are being disproportionately affected by this government policy.

The policy context

Building the Right Support, a national plan to develop community services and close hospital beds for people with intellectual disabilities and autism who ‘display behaviour that challenges’ (p. 4), was published last October by NHS England and its local authority partners. ¹ The genesis of this plan was the Winterbourne View scandal in 2011, which involved the systematic abuse of people with intellectual disabilities in an independent sector hospital unit run by Castlebeck Care in Bristol, England. ² This led to a concordat that committed the Department of Health to a rapid reduction in the number of people with intellectual disabilities and challenging behaviour in hospital beds by mid-2014. ³ Under pressure from politicians and stakeholder groups, who claimed that the government had failed to deliver on its concordat promises and that the situation had worsened, ⁴ the chief executive of the National Health Service (NHS) committed to a 2-year intellectual disability hospital closure programme during a parliamentary select committee hearing on services for people with intellectual disabilities and challenging behaviour in early 2015. ⁵

The ensuing national plan includes the closure of 45–65% of local clinical commissioning group (CCG)-commissioned and 25–40% of NHS England national specialist-commissioned in-patient beds by 2018. This is a ‘starting point’ and commissioners are encouraged to be ‘ambitious in thinking about how much further they can go’ (p. 6; unless stated otherwise, all quotations in this commentary are from *Building the Right Support* document ¹). The rationale for these numbers and timescale is unclear beyond what NHS commissioners and local authorities have told the plan’s authors ‘they believe is possible’, which was then ‘sense-checked’ against geographical variations in current in-patient service usage (p. 27). The money saved from these bed closures is to be reinvested in the development of community services (p. 6). The national plan is clear that this transition will involve significant costs. It is stated that commissioners ‘will need to invest in new community support *before* closing inpatient provision’ (p. 7, italics added). Also required is the ‘temporary double running of services as inpatient facilities continue to be funded whilst new community services are established’ (p. 44). Local Transforming Care partnerships were tasked with drawing up implementation plans to support a new model of care and to start delivering against these plans by 1 April 2016.

Lack of investment in community services

Unfortunately, little progress appears to have been made in agreeing, let alone implementing, new community service models to support the bed closure plans as envisaged in the national plan. The current authors work clinically with patients with intellectual and developmental disabilities who display offending and offending-type behaviours in in-patient and community services across six CCG areas in the north-east of England. As a group we have been closely involved in initiatives to increase hospital discharge rates and reduce readmissions, bed numbers and lengths of stay as well as to support and strengthen community services for people with intellectual disabilities who are at risk of offending. These innovations pre-date the Transforming Care programme and have already led to the closure of two in-patient units and a number of satellite beds in our services (40 beds in total). Despite our engagement and commitment to this transformation process we are concerned about the impact of the national plan, and the manner in which it is being implemented locally on patient care, patient safety and the safety of others.

The North East and Cumbria is one of six ‘fast-track areas’ in the national plan, set up with £2.06 million support from the NHS England Transforming Care programme to ‘help fund transitional costs and speed up implementation’ (p. 12). Fast-track areas aim to reduce in-patient bed usage by around 50% within 3 years, thereby ‘freeing up tens of millions of pounds which will be invested in community-based support to prevent hospital admissions’ (p. 13). The North East and Cumbria service model, which aims to deliver a 50% reduction in in-patient admissions, is currently in draft form and the ‘new community model’ embedded within the overall service model is not due to be considered by the North East and Cumbria Transforming Care Board until September 2016 at the earliest. Once the model is agreed,

implementation plans will need to be developed, and resources including people and funds will need to be identified to enable it to be initiated. Judging by the pace of progress to date, this is likely to take considerable time. In the meantime, plans for in-patient bed closures are progressing rapidly, with 31 out of 112 beds (35%) across our medium- and low-secure and locked rehabilitation services currently empty as part of the closure programme.

The effects of Transforming Care

The impact on patient care and safety of the drive to close in-patient beds without first having developed or strengthened community services is already beginning to show locally. The population served by these in-patient services, in contrast to the intended target population, is relatively high functioning intellectually (that is, mild/borderline in intellectual disability terms),⁶ shows high levels of psychiatric comorbidity⁷ and personality disorder characteristics,⁸ and generally does not display 'behaviour that challenges', but outwardly directed high-impact offending behaviour that has resulted in criminal convictions and/or detention under the Mental Health Act 1983 on the basis of 'abnormally aggressive' and/or 'seriously irresponsible' behaviour. Chief among the behaviours that bring these patients into these services are serious violence and aggression, sex offences, damage to property and firesetting.⁹ The most recent national census data reflect this offending behaviour profile, in that 33% of patients with intellectual disabilities detained under the Mental Health Act in England are subject to Part III criminal sections, and 21% of that group are subject to Ministry of Justice restrictions, meaning that they cannot be discharged without the approval of the Secretary of State or a mental health tribunal.¹⁰ Just 17% of in-patients with intellectual disabilities in the census were informal – that is, not detained under the Act.

The imperative to empty and then close in-patient beds has resulted in pressure being applied on clinical teams through commissioner-led 'care and treatment reviews'¹¹ to provide discharge dates for some forensic patients who continue to present levels of risk that local service providers and community teams are not adequately resourced to manage, or to consider transfers from NHS to independent hospital beds. Some evidence for the movement of patients around the in-patient system – possibly to create the illusion of progress – comes from a recent update from the NHS England Director of Transformation – Learning Disabilities,¹² who reported that in April 2016, 20 of the net 100 recorded discharges were in fact transfers to other hospitals, and the destination of a further 20 discharged patients was unknown.

There is also concern that owing to the pressure to discharge as quickly as possible to meet the national plan targets, patients' rehabilitation is being hurried and/or truncated, resulting in some people being discharged before they are ready to take on the challenges of living in the wider community, or without the receiving community services being properly prepared to manage the risks these patients continue to present. The high level of clinical complexity and associated forensic risk in this population can require a significant period of assessment, formulation and specialist treatment to help patients develop thinking styles and attitudes, emotional control strategies and lifestyles less compatible with offending behaviour. A carefully considered and planned period of pre-discharge preparation is an important component of the treatment pathway and is essential to facilitating a successful transition from hospital to community care.

Another consequence of the current rapid bed closure policy is that people with intellectual disabilities and forensic needs who require urgent hospital treatment are being admitted to generic psychiatric services. This includes patients who have been previously detained in hospital under the Mental Health Act 1983 and discharged on community treatment orders, and who have been subsequently formally recalled to hospital owing to escalating risks of harm to themselves or others. Admission to acute psychiatry units can result in these patients being targeted and exploited by more able patients. In addition, they are unable to access appropriate assessment and treatment as the staff teams in these services have little or no experience of working with this population and lack the specialist skills required.¹³ This will result in longer periods of in-patient admission for these patients as access to suitable interventions aimed at reducing forensic risks is delayed.

One aim of the Transforming Care programme is to prevent people with intellectual disabilities and challenging behaviours from undergoing unnecessary admissions to intellectual disability and mental health in-patient services. Whether an admission is necessary or not is inevitably a matter of judgement. With the requirement for commissioner agreement to admission, there is a real risk of the judgement of clinicians being circumvented. Efforts to prevent admission to hospital by increasing supervision and support to people in community settings to manage emerging risks have paradoxically resulted in situations amounting to *de facto* deprivation of liberty in some cases, where a short informal

hospital admission to allow the risks to be assessed and required amendments made to care plans would have been a less restrictive and more clinically effective option.

Discussion and conclusions

People with intellectual disabilities who require treatment in hospital for behavioural, psychiatric and forensic problems should have access to the best evidence-based interventions available, delivered by caring staff with positive attitudes and person-centred values, in good-quality, safe environments. It is clear that a disproportionate number of people with intellectual disabilities are detained in hospital under the Mental Health Act¹⁴ and, once detained, they have on average longer lengths of stay than detained patients who do not have intellectual disability.¹⁵ The *Building the Right Support* national plan aims to address these inequities, albeit based on uncertain evidence and questionable assumptions.

There is no credible evidence or analysis presented to support the proposed bed reduction numbers. Between 1988 and 2015 the number of intellectual disability beds in the NHS reduced dramatically, from approximately 33 000 to about 2500.¹ It is debatable whether this 90%-plus reduction over the past 30 years has been caused by centrally driven government policy initiatives, for example *Valuing People*,¹⁶ or the impact of human services theories, such as social role valorisation,¹⁷ on the deinstitutionalisation and community care movements in the 1980s and 90s.¹⁸ Either way, looking at the most recent census of in-patient services for people with intellectual disabilities in England,¹⁰ 83% were legally detained under the Mental Health Act 1983, with all of the scrutiny and protections this affords via mental health tribunals, hospital managers' hearings and Care Quality Commission inspections. It could be argued therefore that the majority of the remaining intellectual disability in-patient beds represent equipoise in the system and, as such, the current huge diversion of resources into forcing the closure of these remaining beds is unlikely to be successful in the long term.

The national plan starts from the supposition that all people with intellectual disabilities 'should have a home within their community' (p. 4). Seemingly underpinning this position is a belief that families and the community are always better for people with intellectual disabilities and that hospital services do not provide safety and sanctuary for some people. For many of our patients with forensic needs, their histories indicate that families and the community can be part of the problem rather than the solution. Putting to one side the fact that communities are generally not keen to embrace people who might have violently or sexually assaulted people in their midst, or set fire to their buildings, people with disabilities frequently experience abuse, aggression and violence in and by the community.¹⁹ There are many examples of people like Brent Martin, who was brutally murdered in 2007 by his more able 'friends' in Sunderland 3 months after being discharged from hospital.²⁰

A further assumption underpinning the national plan is that hospital admissions should be as short as possible. There is an apparent lack of understanding that the population managed and treated by in-patient forensic intellectual disability services is distinct from the population envisaged within the Transforming Care programme. Patients with significant forensic histories have frequently experienced high levels of abuse, neglect and deprivation. They require time to develop insight into their difficulties in relating to others, acquire skills in regulating their emotions and acknowledge their future support needs. The application of a bed closure policy and as yet unclear community service model that is designed for a very different population carries significant risks of harm for patients with intellectual disabilities and forensic needs, as well as for others. The implementation of that policy without the required and promised investment in and development of community services is especially concerning. Some of the unintended consequences of this approach might include more vulnerable offenders with intellectual disabilities being sent to prison rather than diverted to hospital for appropriate treatment as recommended in the Bradley Report²¹ While imprisoned, such offenders will likely be targeted by other prisoners because of their disabilities and will remain at risk of re-offending, as they will be unable to access prison offending behaviour programmes²² Finally, it is perhaps ironic that this policy will possibly lead to an increase in the use of independent sector hospital beds for people with intellectual disabilities – exactly where this all started.

1.6.60 Prevent: what is pre-criminal space?

2017-8

Abstract

Prevent is a UK-wide programme within the government's anti-terrorism strategy aimed at stopping individuals from supporting or taking part in terrorist activities. NHS England's Prevent Training and Competencies Framework requires health professionals to understand the concept of pre-criminal space. This article examines pre-criminal space, a new term which refers to a period of time during which a person is referred to a specific Prevent-related safeguarding panel, Channel. It is unclear what the concept of pre-criminal space adds to the Prevent programme. The term should be either clarified or removed from the Framework.

The Prevent Training and Competencies Framework¹ begins thus: “Prevent is part of the Government's counter-terrorism strategy CONTEST and aims to stop people becoming terrorists or supporting terrorism; as such it is described as the only long term solution to the threat we face from terrorism. Prevent focuses on all forms of terrorism and operates in a pre-criminal space, providing support and redirection to vulnerable individuals at risk of being groomed in to terrorist activity before any crimes are committed. Radicalisation is comparable to other forms of exploitation; it is therefore a safeguarding issue staff working in the health sector must be aware of. [...] Staff must be able to recognise signs of radicalisation and be confident in referring individuals who can then receive support in the pre-criminal space.” (p. 5) The Framework is cascaded down the National Health Service (NHS) hierarchies in England to ensure that all front-line staff in the NHS receive mandatory training in the Prevent process. NHS staff refer patients considered vulnerable to radicalisation to local Prevent leads and onward to Prevent case managers and the Channel panel. The Channel acts as a multi-agency panel along the lines of other safeguarding panels in England.

This Training and Competency Framework follows from the *Prevent Duty Guidance*,² the *Channel Duty Guidance*³ and the *Channel: Vulnerability Assessment Framework*⁴ produced by the government following *CONTEST: The United Kingdom's Strategy for Countering Terrorism*⁵ and the Counter-Terrorism and Security Act 2015. The Framework does not name these documents but mentions two other documents which focus on multi-agency working. The first, *Safeguarding Children and Young People*,⁶ details the roles and competencies for healthcare staff when working with other professionals to safeguard children and young people. The second, *Building Partnerships, Staying Safe*,⁷ stresses the importance of effective interprofessional working.

The focus of the Framework is on training. Among the competencies listed within is to understand the concept of pre-criminal space. This article examines this term using publicly accessible government documents and internet searches performed on Google and Google Scholar. It is a textual analysis, read in the context of other government documents,⁸ which presumes that what is read may not necessarily be what the authors initially intended. Meanings applied to words, particularly new compound words, gain significance over time and use.⁹ One of the presumptions of this method is that textual analysis may not relate directly to what is happening in practice.

Pre-criminal space in the NHS England Framework

'Pre-criminal space' appears four times in the Framework document, including twice in the introduction: 'Prevent focuses on all forms of terrorism and operates in a pre-criminal space' (p. 5) '... individuals [...] can then receive support in the pre-criminal space' (p. 5) '... aware[ness that] [...] the health sector contribution operates in pre-criminal space' (p. 8) 'Understand [...] the concept of pre-criminal space' (p. 10). The meaning of 'pre-criminal space' can be deduced from these quotes. 'Prevent focuses on all forms of terrorism and operates in a pre-criminal space' suggests that pre-criminal space may relate to specific physical spaces and times where professionals 'operate' or act within the aims of the Prevent programme. The statement that 'individuals [...] can then receive support in the pre-criminal space' suggests that the professional activity involved is 'support'. What constitutes 'support' is detailed in the *Channel Duty Guidance*.³ The fact that 'the health sector contribution operates in pre-criminal space' implies that other health sector activities may not operate in the pre-criminal space. In what way NHS activity in this 'space' is different from that in other space is not stated anywhere. The need for health professionals to understand 'the concept of pre-criminal space' suggests that there is an important difference between what pre-criminal space is and what it is not. Read in the context of Prevent² and *Channel Duty Guidance*,³ pre-criminal space is likely to start on acceptance of a referral of a person within the Channel panel, or perhaps on referral or discussion of the possibility of referral by NHS staff to Channel personnel. Thus, pre-criminal space has temporal and spatial aspects. As the time and space is decided by negotiation with and between professionals, the term also has inter-professional dimensions. This is supported by Framework naming documents that focus on effective multidisciplinary work rather than the Prevent and Channel Duty guidelines.^{6,7}

The Framework document views the Prevent programme as part of the wider safeguarding agenda. However, there is one important difference compared with other safeguarding panels: the coordinator of the Channel process, the Channel Police Practitioner (CPP), is a police officer or is employed by the police (ref. 3, para. 30). Thus, unlike other safeguarding procedures, the police have a central coordinating function.

Coining of 'pre-criminal space'

The term pre-criminal space is new. It was introduced by this Framework and cascaded to all trusts by NHS England. The term does not occur in non-NHS Prevent documents or in CONTEST. References to pre-criminal space since the term was introduced are largely found in trust documentation and NHS PowerPoint presentations, together with some journalist reports and blogs. For instance, the *Telegraph* comments on the police use of the term and possible repercussions on state-Muslim relations.¹⁰

All NHS trusts in England are mandated to enact the Framework document and produce policy or guidance documents. None of these documents define pre-criminal space any further. Many use pre-criminal space with quotation marks, a few prefacing the term with 'so-called'. The usual statement is a reiteration of 'Prevent operates in the pre-criminal space'. Occasionally the hyphen is replaced by a space between 'pre' and 'criminal' but the words are never placed directly together. The most detailed definition we have found comes from a glossary in a Prevent document from

Mersey Care NHS Trust, beginning with a precautionary note: ‘These definitions relate to PREVENT and are not always authoritative in any wider context.’ ‘Pre-Criminal Activity/Space’ is explained by focusing on ‘multi-agency working to ensure that individuals are diverted away before any crime is committed’.¹¹ This definition merges ‘space’ with multi-agency activity.

Denotation and connotation

So far we have argued that pre-criminal space refers to the time when a person is engaged by the Channel panel and related professionals. It denotes the time, space and interprofessional activity involved in planning, coordinating support and possibly monitoring in the NHS England Prevent programme. What is unclear is whether the Channel process and panel meetings are in any way different from other multi-agency activities. This may be deduced by examining possible connotations of the term based on participants’ understanding of language use in its social context.

Pre-criminal space consists of three terms: ‘pre’ meaning before, ‘criminal’ as a person who has committed a crime or repeated crimes, and ‘space’ as a continuous physical area. ‘Pre’ appears to modify the second term, ‘criminal’, rather than space. Hyphens are not usually used after prefixes such as ‘pre’, unless the resulting meaning becomes ambiguous, for example ‘pre-order’ rather than ‘preorder’. Thus, the use of the hyphen both gives a separation between pre-crime and crime and creates the link. The term implies that the ‘space’ is pre-criminal, not the individual. While the use of the term ‘space’ suggests a physical space, such as a meeting room, there are no references to where the vulnerable person is to be supported. ‘Space’ in this context is used as a relational concept, common in expressions such as ‘I need space to think’, meaning ‘I need a place for myself, away from certain social relationships’.

The derivation of pre-criminal space

The etymology of the term is significant to the discussion. ‘Pre-crime’ and ‘space’, as separate words, suggest they are potentially independent concepts. The term ‘precrime’ was said to be coined by science fiction writer Philip K. Dick in his short story *Minority Report*.¹² The drama is based on the concept that crime has not occurred yet but will occur in future unless measures are taken. The belief that crime can be prevented by identification and intervention has a long history. In the 19th century, Lombroso’s theory of criminal atavism famously purported to identify future criminals by their abnormal physical appearance. In recent years, criminologists use the term pre-crime to criticise the move to criminalise people prior to the committing of crime.¹³ More recently, the term ‘pre-criminal space’ has been used in the US security industry in relation to Islamic fundamentalist terrorism.¹⁴ We find no evidence that the concept of ‘space’ in pre-criminal space derives from academic theorising about space. Depending on context, however, space connotes elements of time as well as physical or abstract forms of space. Space in pre-criminal space can thus gain different metaphoric associations depending on the immediate social context. Pre-criminal space may describe the physical space where ‘support’ is planned, ‘operated’ or monitored. It may also relate to the time that the person is subject to the Channel panel process, or to differences in the social rules of interprofessional interaction, as compared with different safeguarding panel discussions. Finally, it may refer to differing social identities of the person referred to the Channel panel and the professionals involved.

Rhetoric

The Framework provides an abbreviated and reasoned argument in support of the Prevent programme and the involvement of health professionals. Like all arguments, it persuades through the use of the metaphoric qualities which words gain in use. There are two sets of metaphors within the Framework, one pertinent to NHS professionals and the other to the police. The health metaphors are borrowed from structural engineering, with vulnerability and support suggesting the diathesis-stress model. The person is weakened from external assault or internal deficiency; structural support is provided from outside so the individual can withstand potential assaults or threats. Even the WRAP acronym (Workshops to Raise Awareness of Prevent) suggests physical bodily protection against external threat. The criminal justice terms (i.e. radicalisation, extremism, CONTEST, counter-terrorism, strategy) suggest a heightened spatial metaphor, polarisation and direction of movement. The creation of the term pre-criminal space may be an attempt to bridge the health and police use of metaphor: the health metaphor aiming for stability and predictability, while the criminal justice

metaphor focuses on adaptability. The lack of effective definition of pre-criminal space allows for evolving inter-agency norms during the Channel process to vary with context.

If new concepts emerge by visual analogy,¹⁵ pre-criminal space can be seen as an extension of crime prevention. It can be visualised as a system of continuous and contained passages. Prior to the vent (derived from the Latin root, as in *prevent*), professionals direct radicals, people who have an attractive or repulsive charge or energy, past the vent and into the channel. As the radicals pass along the vent their charge or energy becomes less strong and the radical no longer moves towards the extreme.

If the term pre-criminal space mobilises healthcare professionals and Channel partners towards a crime prevention role of health intervention, pre-criminal space has the potential to act as a form of ‘excitable speech’ to alert listeners to the threat of terrorism.¹⁶ The rhetorical use of the term pre-criminal space during the Channel process could be perceived as an attempt to persuade professionals to disclose information or make decisions they would otherwise not make in other safeguarding forums and in comparable circumstances.

Opinion

The Training and Competency Framework is an action plan, laying out who does what, when and with whom. For the implementation of Prevent, terms need to be defined to such a degree that the participants can understand the concepts involved. Indeed, the Framework itself asks NHS staff to understand the concept of pre-criminal space (p. 10). Pre-criminal space clearly denotes a period of time in the Prevent process without adding further meaning and keeping open the opportunity for the term’s possible rhetorical use in Channel meetings.

One synonym for pre-criminal space is crime prevention. This raises the possibility of changing the wording of the Framework to replace this obscure and newly coined term with ‘crime prevention’. Alternatively, discussion and clarification of the concept of pre-criminal space would allow it to define the participants’ relationships as the crime prevention activity proceeds. Further multidisciplinary research linking NHS documents to practice may enable the Prevent guidance and framework to be linked with practice. When the time comes for the Prevent framework to be updated (although no such date is given in the document), we recommend that the term should be clarified or removed.

We thank the Newton International Fellowship, supported by the Royal Society, the British Academy, and the Academy of Medical Sciences.

Abstract

Neuroleptic malignant syndrome (NMS) is a rare but potentially fatal adverse event associated with the use of antipsychotics. Although atypical antipsychotics were initially considered to carry no risk of NMS, reports have accumulated over time implicating them in NMS causation. Almost all atypical antipsychotics have been reported to be associated with NMS. The clinical profile of NMS caused by certain atypical antipsychotics such as clozapine has been reported to be considerably different from the NMS produced by typical antipsychotics, with diaphoresis encountered more commonly, and rigidity and tremor encountered less frequently. This article briefly discusses the evidence relating to the occurrence, presentation and management of NMS induced by atypical antipsychotics.

Neuroleptic malignant syndrome (NMS) refers to an idiosyncratic severe adverse reaction associated with the use of antipsychotics. It is a rare and unpredictable side-effect that has been associated with both first- and second-generation antipsychotics.^{1,2} It occurs in about 0.02–3% of individuals who are prescribed antipsychotics.³ NMS is generally characterised by rigidity fever, autonomic dysregulation, tremor, elevated creatine phosphokinase (CPK) levels and leucocytosis (*Box 1*).⁴ NMS is a potentially fatal adverse event. It can lead to permanent neurological impairment in survivors in the form of parkinsonian symptoms and cognitive deficits, which could be primarily ascribed to the raised core body temperature and ischaemia following rhabdomyolysis.^{5–7}

Atypical (second-generation) antipsychotics were initially considered to have negligible risk of inducing NMS due to their distinctive pharmacodynamic characteristics.⁸ In fact, side-effect profile has been one of the important distinguishing features between typical (first-generation) and atypical antipsychotics. However, considerable research evidence has accumulated to suggest that atypical antipsychotics are also associated with NMS.^{9,10} Clozapine was one of the earliest atypical antipsychotics implicated in the causation of NMS.¹¹ Subsequently, almost all of the atypical

antipsychotics have been associated with the occurrence of NMS. The clinical features of NMS induced by atypical antipsychotics have been reported to be somewhat different from those induced by typical antipsychotics.¹⁰

Atypical antipsychotics are among the most commonly prescribed antipsychotics.^{12,13} They are utilised for the treatment of a range of psychiatric disorders including schizophrenia, mania, depression with psychotic symptoms and personality disorders, and for behavioural symptoms in dementia and intellectual disability.^{14,15} Hence, understanding the clinical presentation and occurrence of NMS associated with atypical antipsychotics is of clinical relevance. This article discusses the evidence relating to the occurrence of NMS with atypical antipsychotics and various aspects of management for this condition. The authors reckon that the definition of ‘atypical’ antipsychotics itself may not have clear margins,¹⁶ yet the term ‘atypical’ remains in clinical usage to refer to those medications that have comparably smaller chances of causing extrapyramidal symptoms. We do not aim to present a systematic review of the topic, but rather a pragmatic review of the literature on NMS with atypical antipsychotics.

Reports of atypical antipsychotics causing NMS

Risperidone

Risperidone has been associated with probably the largest number of cases of atypical antipsychotic-induced NMS.^{9,17} It has been noted more frequently in the younger age group who had been antipsychotic naive. A severe clinical picture of typical NMS has been encountered, marked by rigidity, extrapyramidal symptoms, fever and highly elevated CPK levels. Tachycardia was more common than diaphoresis and autonomic dysregulation occurred frequently.⁹

Clozapine

Cases of clozapine-induced NMS, reported since the 1980s, typically occurred with rapid dose increases. Also, many patients who developed clozapine-induced NMS had a history of NMS with other antipsychotics. Tachycardia, tachypnoea, diaphoresis and autonomic lability were encountered frequently, possibly due to clozapine acting on adrenergic and muscarinic receptors.¹⁸ Rigidity and extrapyramidal symptoms were rare, possibly due to the lower affinity of clozapine to the D₂ receptor. The increases in CPK were lower and delayed when compared with other antipsychotics. The occurrence of fever and autonomic instability in patients receiving clozapine in the absence of rigidity may necessitate ruling out the diagnosis of clozapine-related agranulocytosis before a diagnosis of NMS.¹⁹ The clinical severity of clozapine-induced NMS has been described to be lower than with other antipsychotics, and hence such cases have infrequently required intensive care unit admissions. The infrequent occurrence of rigidity and extrapyramidal symptoms in patients with clozapine-induced NMS require a high degree of suspicion for this diagnosis. However, certain researchers have suggested that clozapine-induced NMS should not be considered as a diagnosis in the absence of typical features of NMS.²⁰

Box 1 Symptoms and signs commonly encountered in neuroleptic malignant syndrome

- Fever
- Rigidity
- Elevated creatine phosphokinase (CPK) levels
- Tachycardia
- Tachypnoea
- Altered mental state
- Fluctuating blood pressure
- Diaphoresis
- Leukocytosis

Olanzapine

Although olanzapine has been reported to present with the typical features of NMS, extrapyramidal symptoms and fever were absent in a small proportion of patients. Autonomic imbalances and diaphoresis are frequent, and are often the first signs to appear in patients with olanzapine-induced NMS. Nausea was infrequent, probably due to the antiemetic purported properties of olanzapine,²¹ but neurological impairments such as hemiplegia, ataxia and seizures have been reported.⁹ Several cases have been reported in patients receiving other medications apart from antipsychotics, for example mood stabilisers and antidepressants, and the clinical picture of NMS has been more severe in such patients.⁹

Amisulpride

Several cases of amisulpride-induced NMS have been described in the literature,^{22,23} many reported in elderly males. The clinical profile primarily involves an altered mental state, frequent rigidity and high levels of CPK, whereas high fever, tremor and other autonomic symptoms have been reported less frequently. The lower propensity to cause autonomic symptoms is probably due to low affinity in amisulpride for muscarinic, adrenergic, serotonergic and histamine receptors than in other antipsychotics.²⁴

Quetiapine

Quetiapine-induced NMS has been primarily reported in the elderly, although it has also been described in children.²⁵ Clinically, it presents with extrapyramidal symptoms and prominent autonomic symptoms such as tachycardia, blood pressure fluctuations, tachypnoea and diaphoresis. These prominent autonomic symptoms may be consequent to norepinephrine reuptake inhibition, histaminergic antagonism and serotonin toxicity associated with the use of quetiapine.²³ The outcome of quetiapine-induced NMS has been relatively poor, probably due to the older age of patients in whom it has been reported.⁹

Aripiprazole

Several case reports and case series have accumulated on the occurrence of NMS in patients receiving aripiprazole.^{26,27} Rigidity and altered mental state seem to be present frequently in such patients, while fever, diaphoresis and tachypnoea are less frequent. NMS has been reported to occur more commonly with fast upward titration of dosages of aripiprazole. The severity and duration of NMS seem lower than in other antipsychotic medications, probably due to the partial dopamine agonist activity of aripiprazole. Aripiprazole has also been implicated in combination antipsychotic regimens, when used alongside other atypical antipsychotics such as clozapine.²⁷

Ziprasidone

Few cases of ziprasidone-induced NMS have been described.^{28,29} The onset of NMS in these patients has been generally abrupt, with most displaying typical features such as alterations of mental state, fever, diaphoresis, tachycardia, blood pressure alterations, leukocytosis, tremor, and other extrapyramidal symptoms with high CPK. No fatality has been reported with ziprasidone to date, and recovery is usually achieved in about 10 days.

Paliperidone

Paliperidone has a similar pharmacodynamic profile to risperidone, but it has a lower affinity for dopamine receptors and higher serotonin antagonist activity. Paliperidone-induced NMS has been described mainly in patients who have been previously treated with other atypical antipsychotics and have had a recent dose increase or cross-titrations.^{30,31} Paliperidone-induced NMS presents with a typical clinical profile with mental state alteration, rigidity, diaphoresis, hyperpyrexia, tremor and other extrapyramidal symptoms, and the outcome is favourable, with resolution achieved in all cases.

Zotepine

Several cases of zotepine-induced NMS have been described in the literature.^{22,32} Rapid dose escalation was reported in one case, although NMS has also developed with the usual titration pattern. Zotepine-associated NMS presents with alterations of mental state, rigidity, diaphoresis, fever, tachycardia and leukocytosis, with less frequent occurrence of tremor, tachypnoea and alterations in blood pressure.

Other atypical antipsychotics and summary

At present, there is a single case report of iloperidone being considered as a cause of NMS.³³ The patient, who had schizophrenia, developed mutism, diaphoresis, diffuse lead pipe rigidity and tachycardia without fever or marked increase in CPK levels. The outcome was favourable, but the patient also required anticoagulation therapy for the management of comorbid pulmonary embolism.

Blonanserin was reported as a cause of NMS in a 30-year-old female with intellectual impairment.³⁴ The patient presented with fever, tachycardia, rigidity, extrapyramidal symptoms and leukocytosis after the initiation of blonanserin. Symptomatic improvement was seen after discontinuation.

Although different atypical antipsychotics have different NMS clinical symptom profiles, rigidity, tremor and fever are encountered less frequently with atypical antipsychotics, whereas diaphoresis is quite common. Clozapine is particularly associated with atypical presentations of NMS with infrequent CPK level elevations. Risperidone, on the other hand, produces a clinical picture more similar to the NMS induced by typical antipsychotics. Some of the atypical antipsychotics have also been associated with serious features such as myoglobinuria and acute renal failure.^{35,36}

Risk factors for atypical antipsychotic-induced NMS

A few significant risk factors for atypical antipsychotic-induced NMS have been identified. They have been reported in one study as male gender, confusion, dehydration and delirium.²⁵ Another study reported Black and minority ethnic background, antipsychotic polypharmacy, use of aripiprazole, and increasing dosing patterns.³⁷ More recently, it has been suggested that rapid dose escalation of the antipsychotic may be a risk factor for NMS.² The demographic profile of patients who developed NMS with atypical antipsychotics does not seem to differ substantially from that of patients with NMS induced by typical antipsychotics.

Management

Diagnostic uncertainty

The clinical picture and features of NMS with atypical antipsychotics seem to be different from those of typical antipsychotics. This had led to uncertainty over the diagnosis of NMS in patients on atypical antipsychotics who manifest only few of the NMS symptoms.³⁸ Among the core symptoms of NMS, fever is often encountered less frequently in patients with atypical antipsychotic-induced NMS.³⁸ The issue is further complicated by the various operational definitions of NMS.³⁸ The DSM-IV-TR defines NMS as the presence of severe muscle rigidity and elevated temperature after antipsychotic initiation along with two or more of: diaphoresis, dysphagia, tremor, incontinence, changes in level of consciousness, mutism, tachycardia, elevated or labile blood pressure, leukocytosis, or laboratory evidence of muscle injury (elevated CPK level). Various other criteria for NMS have been postulated, each with varying emphasis on the individual symptoms and signs.³⁹ Another set of criteria defines NMS in patients with either three major symptoms (hyperthermia, rigidity, elevated CPK level) or two major and four minor symptoms (diaphoresis, tachycardia, tachypnoea, abnormal blood pressure, leukocytosis, altered consciousness).⁴⁰ Yet another diagnostic system defines NMS through the presence of extrapyramidal symptoms and fever (37°C) alongside three minor symptoms within a 48-hour period.⁴¹ This may potentially mean that a case fulfilling the diagnosis of NMS according to one set of criteria may not do so with another set. The DSM-5 has taken a pragmatic approach of not explicitly stating the number of criteria required for the diagnosis of NMS.

It has been proposed that with the growing awareness of NMS, those in the early course of its development may benefit from early identification and immediate treatment. This may lead to an abortive course of NMS development, with an incomplete picture and only few of the criteria being met. Hence, some authors have proposed a dimensional concept of NMS, which takes into consideration the minor and subthreshold forms of NMS.^{38,42} This is likely to further our knowledge about NMS pathophysiology, clinical profile subtypes and appropriate management strategies.

Furthermore, various other medical and neurological conditions may present with a clinical picture similar to NMS (briefly mentioned in *Box 2*). Patient condition may require expedient decisions so that a rational line of management can be instituted. Hence, the clinician may need to take a brief and focused history for being reasonably sure about the diagnosis. Neuroimaging and electroencephalogram may be helpful for ruling out neurological pathologies mimicking NMS. For example, in patients with psychosis, catatonia may be considered as a differential diagnosis, especially when the patient is mute and exhibits staring. It may not be possible to exhaustively rule out all differential diagnoses, and at times management may need to be started on an empirical basis.

Treatment strategies for NMS

The management of NMS caused by atypical antipsychotics would not be substantially different from the management of NMS induced by typical antipsychotics (*Box 3*). NMS is a medical emergency and requires immediate attention for clinical management. Clinical diagnosis should be supplemented by laboratory tests, particularly CPK levels and total leukocyte counts. Once the diagnosis is suspected, the offending antipsychotic agent must be immediately stopped. Regular monitoring of the vitals should be carried out. The patient should be moved to the intensive care unit based on the severity of their medical condition. Intensive care would typically focus on monitoring of cardiorespiratory and renal status. Serial monitoring of serum electrolytes should be performed and corrected as required. In extreme hyperthermia, physical cooling measures may be instituted.

Several pharmacological options are available for the treatment of NMS.^{43,44} Dopaminergic agents such as amantadine and bromocriptine have been demonstrated to decrease the duration of and mortality associated with NMS. Amantadine 200 mg to 400 mg per day in divided doses is administered either through a nasogastric tube or orally. Bromocriptine is started at the dose of 2.5 mg three times a day and can be titrated upwards to 45 mg per day. Benzodiazepines, particularly lorazepam, can be given when underlying catatonia is suspected and where agitation is encountered in the patient. Lorazepam challenge can be done with 1 to 2 mg lorazepam administered parenterally, and may be continued in cases which show some response. Dantrolene is a muscle relaxant that can be applied in cases presenting with severe rigidity and hyperthermia. It is initiated at doses of 1–2.5 mg/kg body weight and can be repeated 6 hourly if improvement is seen. It can be administered orally after improvement with the parenteral preparation.

Box 2 Differential diagnosis of neuroleptic malignant syndrome

- Amphetamine toxicity
- Anticholinergic delirium
- Benign extrapyramidal side-effects
- Brain abscess
- Catatonia
- Heat stroke
- Malignant catatonia
- Malignant hyperthermia
- Meningitis or encephalitis
- Mid-brain structural lesions
- Non-convulsive status epilepticus
- Sepsis
- Serotonin syndrome
- Thyrotoxicosis

The altered mental state encountered during NMS also needs attention. If sedation is required, benzodiazepines may be a preferred choice. The medical management of the patient takes precedence over the underlying psychiatric disorder. As the patient's condition improves, discussion about further treatment options may be initiated.

Re-challenge with antipsychotics after NMS

One of the important considerations for a clinician is to whether to start another antipsychotic after a patient develops NMS. If the antipsychotic had been started for the control of psychotic symptoms, then the risk of psychosis without the cover of antipsychotics is high. The clinician may have to weigh the pros and cons of re-starting antipsychotic medication: the advantage of making the patient more manageable against the risk of inducing NMS.

Box 3 Treatment of neuroleptic malignant syndrome

- Consider shifting to intensive care unit
- Regular monitoring of vitals
- Monitoring of electrolytes and correction if required
- Management of medical comorbidity
- Physical cooling measures if required
- Dopaminergic medications: amantadine and bromocriptine
- Muscle relaxant: dantrolene
- Benzodiazepines: for management of agitation, when clinical suspicion of catatonia is present

Several reports of post-NMS antipsychotic re-challenge have been published.^{45–48} Indications for a re-challenge need to be clearly documented and other options of management (including electroconvulsive therapy) should be explored. Taking informed consent from the patient and/or family members/carers becomes necessary in such circumstances. Re-challenge should be done with an atypical antipsychotic with low propensity to cause NMS and dose titration should be gradual. Careful monitoring should be instituted, watching the evolution of symptoms of NMS. The re-challenge strategies thus adopted are in no way different from those post-NMS due to typical antipsychotics.

Conclusions

As psychiatrists, we are likely to encounter NMS induced by atypical antipsychotics during clinical practice. Although it is an uncommon adverse event of antipsychotic use, the potential fatality requires the clinician to take cognisance of this, and institute treatment immediately. The presentation of NMS induced by atypical antipsychotics, especially clozapine, may be quite different from NMS induced by typical antipsychotics – rigidity and tremor are encountered less frequently, while diaphoresis is probably encountered more frequently. Hence, a high degree of clinical suspicion may be required. Overall, the management of NMS induced by atypical antipsychotics is not broadly different to the management of that induced by typical antipsychotics. Additionally, an episode of resolved NMS does not preclude the subsequent initiation of antipsychotics, although due caution needs to be exercised while re-challenging antipsychotics in patients with a history of NMS induced by atypical antipsychotics.

1.6.62 Drug information update. Lithium and chronic kidney disease: debates and dilemmas

Sumeet Gupta Udayan Khastgir

Correspondence

2017-8

Abstract

Lithium is an established treatment for bipolar disorder and an augmenting agent for treatment-resistant depression. Despite awareness of renal adverse effects, including chronic kidney disease, for the past five decades, there has been a lack of research evidence. This has led to debates around the existence and magnitude of the risk. This article discusses the current evidence base regarding the link between lithium and chronic kidney disease, monitoring of renal functions and its clinical implications.

– Conclusions

Lithium is one of the oldest psychotropic medications. It remains the gold standard treatment for bipolar disorder and an augmenting agent for treating depression. Over the past few decades, additional benefits of lithium have also come to light, most importantly its role in preventing suicide and Alzheimer's disease.^{1,2} As it is often used as a maintenance treatment for lifelong disorders, concerns have been raised about its potential long-term organ toxicity, mainly the effect on glomerular function leading to chronic kidney disease (CKD).^{3–5}

Debate 1: does lithium cause CKD?

The association between CKD and lithium has been known for a long time, and monitoring renal function in patients receiving lithium therapy has been the norm for many decades. Despite this, there has been little research into the renal adverse effects of lithium so far. A link between lithium therapy and CKD has received increasing recognition, and there are several explanations for this. First, glomerular function decreases gradually as a normal part of the ageing process; increased life expectancy has led to increasing numbers of lithium patients being diagnosed with CKD. Second, there has been a resurgence of interest in lithium and its safe use, owing to its proven effectiveness in bipolar disorder in comparison with other mood stabiliser drugs and its anti-suicide effect. Last, more effective monitoring of renal function and the use of more sensitive measures to diagnose CKD, such as the estimated glomerular filtration rate (eGFR) rather than serum urea and creatinine levels, have led to the early identification of affected patients.

Despite significant progress over the past two decades, doubts still remain about the existence and magnitude of the risk.^{3–5} Unlike its tubular adverse effects, which more commonly present with polyuria and polydipsia, the glomerular adverse effects of lithium therapy appear after long-term use and might not normalise or improve after its discontinuation. It has therefore been difficult to attribute causality for this adverse effect.

The debate about lithium nephrotoxicity started in 1977, with reported abnormalities in renal biopsies from a small group of patients treated with lithium.⁶ Initial cross-sectional, case-control and small cohort studies with short-term follow-ups reported contradictory findings on the toxicity risk.^{7–10} In 1994, Bendz *et al* published a study of 142 patients who had been taking lithium for more than 15 years. The authors measured the glomerular filtration rate (GFR) by chromium-51-labelled ethylene diamine tetra-acetic acid (⁵¹Cr]EDTA) clearance and found that in 21% of patients the GFR was lower than in the demographic-matched population control group.¹¹ Two meta-analyses of these diverse studies failed to produce conclusive evidence for or against lithium nephrotoxicity. Although they showed that patients on lithium therapy had worse renal function than controls (as measured by serum creatinine levels or the eGFR), they reported that the clinical significance was questionable. Both meta-analyses highlighted poor quality data and significant heterogeneity among studies.^{12,13}

Recent epidemiological studies utilising large databases have consistently shown that CKD (defined as an eGFR of < 60 ml/min/1.73 m²) is common among lithium patients but that lithium therapy increases the risk of CKD. In addition, renal failure in patients with end-stage renal disease (ESRD) is not as rare as previously thought.^{14–17} In a retrospective cohort study using the General Practice Research Database, Close *et al* reported that patients taking lithium for bipolar disorder had a twofold increased risk of developing renal failure and a two-and-a-half-fold increased risk of developing CKD of any stage compared with lithium-naïve patients.¹⁴

The relationship between lithium therapy and renal failure or ESRD has been investigated in many other studies that mainly use data from databases of patients undergoing renal replacement therapy (dialysis or renal transplant). A Swedish study found that 0.81% of renal replacement therapy patients had kidney disease attributable to lithium-induced nephropathy. Moreover, the risk of ESRD in lithium-treated patients was nearly sixfold greater than in the general population.¹⁷ Another recent retrospective cohort study, of renal replacement therapy patients in Australia, reported that the incidence rate of ESRD due to lithium therapy had increased significantly from 0.14 cases per million population per year (95% CI 0.06–0.22) in 1992–1996 to 0.78 cases per million population per year (95% CI 0.67–0.90) in 2007–2011. This report emphasised that lithium-induced nephropathy is not a rare cause of ESRD, and is becoming more common.¹⁸ However, the debate is far from over and contradictory findings continue to be published. For example, in a review of patients with ESRD in Sweden, Aiff *et al* found 32 cases of ESRD in patients who had started taking lithium before 1980 but none in those who had started taking lithium after 1980. Hence, the authors suggested that the opposite was true: renal failure might not be a problem with the current practice of maintaining lower serum

lithium levels along with better monitoring of renal function.¹⁹ In a recent population-based retrospective cohort study in Denmark, Kessing *et al* also failed to identify any patients with lithium-induced ESRD. However, their findings indicated that bipolar disorder is independently associated with CKD.²⁰ Therefore, uncertainties about the magnitude of the CKD risk are yet to be resolved.

It is clear that not all patients taking lithium experience glomerular adverse effects. Most likely, only a select group of patients develop CKD and only a small proportion of these progress to ESRD.²¹ Moreover, the association between lithium therapy and CKD is unlikely to be entirely explained by coincidence or confounding variables (such as age, other psychotropic drugs or comorbid medical/psychiatric illnesses). Discrepancies among studies were largely due to methodological differences such as varied parameters to assess renal function and definitions of renal impairment, short-term follow-up, a lack of patients on long-term lithium therapy, combining high-risk and low-risk groups, choice of control group (healthy *v.* psychiatric patients), and an inability to control the confounding variables. Definitive data on the magnitude of the risk are still lacking. Moreover, in the absence of any pathognomonic histological or biochemical changes, lithium-associated CKD remains a diagnosis of exclusion.

Debate 2: is there any relationship between the tubular and glomerular adverse effects of lithium?

It was previously assumed that CKD is preceded by tubular adverse effects of lithium. However, differences in the prevalence of tubular and glomerular adverse effects and a lack of correlation between reduced glomerular function and tubular abnormalities on renal biopsy (in the form of tubular dilation and microcysts) argue against this assumption.^{22,23} Despite this, the presence of tubular adverse effects is suggested to increase the risk of CKD, hence the suggestion that treating or preventing tubular adverse effects might help to prevent deterioration of glomerular function.²¹

Debate 3: is it possible to identify patients at high risk of developing CKD/ESRD and to predict the prognosis of these adverse effects?

As only a small proportion of patients on lithium therapy experience CKD, early identification of these high-risk patients might help to prevent and manage this adverse effect. Over the years, researchers have tried to identify both susceptibility and treatment-related factors such as associations with ageing, comorbid physical/psychiatric health problems, cumulative lithium dose or treatment duration, dosing frequency, and number of toxicity episodes.

Acute lithium toxicity is known to cause acute renal failure, and many patients suffer renal impairment even after recovering from an acute episode. There is consistent evidence that acute nephrotoxicity episodes can lead to CKD.^{6,9,24} Recently, Clos *et al* suggested that lithium-associated CKD is primarily mediated by acute lithium toxicity, and that avoiding lithium toxicity can prevent renal impairment.²⁵ Studies suggest a relationship between impaired renal function and either persistent high serum lithium levels (>0.6mmol/L *v.* <0.6mmol/L) or a single serum lithium measure of > 1.0 mmol/L. As these were not prospective studies, it is difficult to establish a causal relationship, especially as reduced renal function can also increase serum lithium levels.^{26,27} On the other hand, a recent randomised placebo controlled trial of low-dose lithium therapy (serum lithium levels of 0.25–0.50 mmol/L) in elderly patients with mild cognitive impairment did not show a significant difference in eGFR over a 4-year follow-up period.²⁸ The study suggests that lower therapeutic levels of lithium might not impair renal function.²⁸ In contrast, other studies have failed to show a relationship between CKD risk and lithium dose or serum lithium levels.^{17,24} It is well established that higher serum lithium levels provide better protection against another affective episode (especially a manic episode). Therefore, the debate about what serum lithium level represents a balance between safety and effectiveness is likely to continue until more definitive data become available.

Once-daily dose is thought to be associated with less renal impairment than multiple daily doses.²¹ Although a few studies do not support this, none have so far reported disadvantages for once-daily dosing.²⁹ Therefore, although a definitive answer is lacking, it makes sense to adopt a once-daily dosing strategy. Comorbid physical health conditions such as diabetes or hypertension can independently cause CKD, but CKD is also commonly seen in lithium-treated patients, even in the absence of a comorbid physical illness. Therefore, comorbidity is unlikely to entirely explain the association between lithium and CKD.

So far, evidence about CKD risk factors is limited and somewhat contradictory. However, it indicates that lower therapeutic lithium doses might have a reduced detrimental effect on renal function and that acute lithium toxicity should

be avoided to prevent renal dysfunction. Furthermore, once-daily dosing might be safer than multiple daily doses.

Debate 4: how can we effectively monitor glomerular adverse effects?

Monitoring renal function in patients on lithium therapy has been the norm for many years, but there are significant discrepancies among the different guidelines on the parameters that should be used and the frequency of monitoring.^{30–32} The UK National Institute for Health and Care Excellence (NICE) recommends 6-monthly monitoring; the British Association for Psychopharmacology recommends annual monitoring; and the American Psychiatric Association recommends monitoring every 2–3 months for the first 6 months, followed by 6-monthly to annual measurements.^{30–32} However, they do not give specific guidance about the parameters for measuring renal function and continue to recommend measuring serum urea and creatinine levels, although recent guidelines have started to recommend measuring the eGFR. In other medical areas, measuring serum urea and creatinine levels is no longer a preferred option for monitoring renal function: standard practice is to monitor the eGFR. Many equations can be used to calculate the eGFR from serum creatinine concentration, with differing accuracies. Recent NICE guidelines on managing CKD suggest using the CKD Epidemiology Collaboration (CKD-EPI) equation. They also suggest using the CKD-EPI equation based on cystatin C levels if accurate GFR estimates are necessary.³³ Psychiatry guidelines do not recommend any particular method for calculating the eGFR.

The importance of measuring proteinuria to monitor renal function in CKD patients is now firmly established. Proteinuria is an independent predictor of CKD progression, cardiovascular disorders and all-cause mortality.³³ However, a role for estimating and monitoring proteinuria in lithium-related renal impairment is yet to be established. The evidence so far is sparse and contradictory: some reports suggest that proteinuria is linked to lithium-associated CKD and indicates a poor prognosis, while others suggest that lithium-associated CKD is not associated with proteinuria and that in the presence of proteinuria one should rule out other causes.^{5,10,21} However, recent publications have highlighted the importance of monitoring proteinuria in patients with lithium-associated CKD.^{21,34}

Unfortunately, psychiatric guidelines have not kept up with advances in nephrology, and we need guidelines for evidence-based monitoring of renal function. Recent publications suggest that renal function should be monitored regularly via the eGFR and that the degree of proteinuria should be measured in patients with a declining eGFR or an eGFR of <60 ml/min/1.73 m.^{2,21,34} However, these recommendations are developed for CKD associated with other aetiological factors, and more specific evidence-based monitoring guidelines need to be developed to screen and monitor lithium-associated CKD.

Dilemma 1: should lithium be stopped if a patient develops CKD?

The most common dilemma clinicians face is what to do if a patient on lithium therapy develops CKD. In this scenario, the clinician must decide whether to continue or discontinue lithium. Advice in the literature is contradictory, ranging from discontinuing lithium as soon as renal function starts to deteriorate (as evidenced by two consecutive tests) to continuing lithium even in the presence of CKD.^{18,35} The decision to discontinue lithium is based on the assumption that lithium is a causative factor for CKD and that its discontinuation would improve renal function or at least slow down deterioration. However, neither of these assumptions is completely supported by current evidence.^{4,5,36} Moreover, we still do not know whether lithium-associated CKD is reversible or irreversible. It has been suggested that this adverse effect might be reversible at the initial stages, only becoming irreversible after a certain threshold is reached.^{4,21} Presne *et al* suggested that the threshold might be somewhere between a GFR of 25 and 40 ml/min/1.73 m².²² Thus, the advantages of discontinuing lithium are uncertain.^{4,5,35,36} On the other hand, there is enough evidence to suggest that lithium discontinuation is associated with high risk of relapse for patients with mood disorders, especially those with bipolar disorder. Moreover, the illness might become treatment refractory.²¹ One of the advantages of lithium is its anti-suicide effect: the risk of suicide is known to increase after lithium discontinuation.³⁷ The decision to continue or discontinue lithium treatment should thus only be taken after careful assessment of the benefits and risks, and because of uncertainties surrounding these, it is essential that the decision-making process should include patients and all of the professionals involved, including nephrologists. Our experience agrees with a documented report that many psychiatric patients prefer to maintain their mental stability against the unknown risk of further deterioration in renal function.³⁸ In clinical practice, it is not unusual to request that a nephrologist makes this treatment decision. However, it is important that psychiatrists should not abdicate responsibility, because nephrologists might not be fully aware of

the risks associated with the psychiatric illness.^{5,21,34,35} Another option would be to continue lithium treatment while closely monitoring renal function. Many authors have suggested trying to keep the lithium level at the lower end of the therapeutic range, although there is not much evidence that this prevents further deterioration in renal function. However, as CKD patients are particularly prone to lithium toxicity, this strategy appears prudent.

Dilemma 2: should we consider lithium therapy for patients already diagnosed with CKD?

There is not much research evidence to support or dispute this decision. Lithium treatment may lead to further deterioration in renal function, which could be clinically important because the renal reserve is already low in patients with CKD. A study of elderly patients suggested that individuals with pre-existing CKD were more susceptible to a lithium-associated decline in renal function³⁶ On the other hand, we should not deprive such patients of an effective therapy because of unproven adverse consequences. In 2012, Werneke *et al* designed a mathematical model based on the existing, but limited, evidence to analyse the risks and benefits of continuing or discontinuing lithium therapy for CKD patients. They concluded that most patients should continue lithium treatment even if long-term renal adverse effects develop. They also recommended prescribing lithium to CKD patients because treatment benefits outweighed the risks.³⁵ However, at present there is not enough evidence to support any decision.

Conclusions

Limited knowledge of its renal (especially glomerular) adverse effects has led clinicians to either avoid or prematurely discontinue lithium therapy because of the perceived risk of a negative renal outcome. Over the past decade, a few large database studies have confirmed the existence of lithium-associated CKD, but uncertainty remains about the magnitude and determinants of the risks. Lithium therapy is here to stay and we should learn to optimise its efficacy and safety. There is a need for large-scale prospective studies focused on the early identification of high-risk patients and for developing evidence-based guidelines to monitor renal function in patients treated with lithium.

1.6.63 Shared decision-making in medication management: development of a training intervention

Ute Stead Nicola Morant Shulamit Ramon

shared decision-making in medication management in mental health as part of the Shared Involvement in Medication Management Education (ShIMME) project. Three stakeholder groups (service users, care coordinators and psychiatrists) received training in shared decision-making, and their feedback was evaluated. The programme was mostly well received, with all groups rating interaction with peers as the best aspect of the training. This small-scale pilot shows that it is feasible to deliver training in shared decision-making to several key stakeholders. Larger studies will be required to assess the effectiveness of such training.

Shared decision-making is a collaborative process in which clinicians and patients make treatment decisions in partnership. Both partners bring valuable contributions to this process: patients share their experiences, values and preferences, and clinicians support patients in clarifying these, as well as providing clinical expertise and evidence-based information about treatment options. Jointly, they aim to reach an agreement on the best way to proceed.¹⁻³

Shared decision-making is considered particularly relevant for preference-sensitive decisions, where there are several reasonable treatment options and evidence does not support a clear best choice. Different options require the balancing of possible benefits against potentially significant adverse or as yet unknown effects.³⁻⁵ Most medication decisions in mental health fall into this category, which makes psychiatric medication management an important area for shared decision-making.⁶

There are good reasons for encouraging adoption of shared decision-making in mental health. Many patients wish for greater participation in treatment decisions.⁷ In chronic conditions, where long-term healthcare decisions are required, studies have shown that shared decision-making improves satisfaction, adherence and well-being.⁸ Shared decision-making is at the core of recovery principles which promote autonomy and self-management skills, as well as being considered essential for delivering patient-centred care.⁹ National and international government initiatives,^{1,10-13} such as the UK Health and Social Care Act 2012 and the US Patient Protection and Affordable Care Act 2010, endorse shared decision-making, as do professional bodies¹⁴⁻¹⁶ and practice guidelines.¹⁷⁻²¹ Shared decision-making is an expected element of all NHS care (Health and Social Care Act 2012, s. 23, 26). Although there is evidence of its benefits, and many patients want greater involvement,⁷ the adoption of shared decision-making into routine clinical practice continues to be slow,^{22,23} especially in mental health.²⁴

A range of interventions has been developed to promote implementation of shared decision-making, predominantly in physical health.²⁵⁻²⁸ Although this is an evolving area, relatively few interventions focus specifically on treatment decisions in mental health.^{6,29-33} Evidence is sparse regarding the effectiveness of such interventions in general,^{23,25} and in mental health settings in particular,³³ although some promising results have been reported. These include a study of in-patients with schizophrenia or schizoaffective disorder who received five sessions of shared decision-making training;²⁹ a multifaceted programme based on shared decision-making concepts for primary care physicians treating patients with depression;³⁰ a peer-run Decision Support Centre in the waiting area of a psychiatric medication clinic;³¹ and online resources supporting shared decision-making.³² The limited evidence available points towards interventions being more effective when involving healthcare professionals and patients together, rather than only targeting one group.²³

The Shared Involvement in Medication Management Education (ShIMME) project was set up to promote shared decision-making of service users (the term ‘service users’ was used in the ShIMME project and has been retained here) in medication decisions by delivering a specially developed training programme to three key stakeholder groups: service users, care coordinators and psychiatrists. (In the context of the ShIMME project ‘care coordinator’ refers to psychiatric nurses, social workers, occupational therapists, psychologists, support workers, peer workers and students training in these disciplines.) To our knowledge this is the first UK-based project to deliver and evaluate such an intervention that targets multiple stakeholders simultaneously.

The project was a partnership between Cambridgeshire and Peterborough NHS Foundation Trust (CPFT) and Anglia Ruskin University. Reflecting the strong collaborative ethos, service users were active team members jointly with academic researchers, mental health practitioners and other professionals working within CPFT.

This paper describes the stages of the ShIMME project: consultations about shared decision-making, development and implementation of a pilot intervention, and evaluation of feedback. It is one of several articles relating to the project.

34–36

Method

Consultation phase

The initial phase of the project involved a literature review and consultation with local stakeholders about the process of shared decision-making. Data were collected via focus groups with practitioners and users of adult mental health services in CPFT. Four focus groups were conducted with service users ($n = 27$), two with psychiatrists ($n = 4$), one with community psychiatric nurses (CPNs, $n = 10$), and one with care coordinators other than CPNs ($n = 8$). Four individual telephone interviews were also conducted with psychiatrists. Discussion was generated in response to open questions about current practice in medication management, how decisions should ideally be made, perceived barriers to and facilitators of shared decision-making, and how shared decision-making training should be conducted. Consultation groups lasted around 90 min and were audio recorded. The anonymised transcripts were analysed using thematic analysis,³⁷ conducted with NVivo software (www.qsrinternational.com). This involved a detailed exploration of transcript texts by two team members who worked in collaboration to iteratively develop themes.

The following themes about shared decision-making in medication management, which are presented in more detail elsewhere,³⁴ emerged from this analysis and fed into the development of the training programmes.

1. Ongoing respectful, trusting, open and honest relationships are paramount – service users’ concerns and experiences need to be heard and taken seriously.
2. Differences of power in the consultation can be complex and a barrier to shared decision-making – clinicians can underestimate the effect this has.
3. Access to reliable, user-friendly information is essential, including information about reducing or coming off medication and adverse effects of medication.
4. All available treatment options should be considered, including non-pharmacological treatments.
5. The process of shared decision-making needs to be flexible, taking into account preferences and situations which may change over time. Acute stages of illness or crisis situations were identified as times when shared decision-making would be likely to be more problematic.
6. Broader stakeholders (beyond service user and prescribe! ¹) have important roles in the shared decision-making process (e.g. other professionals, carers).
7. There is currently significant variation in medication management and the extent to which this involves shared decision-making.

Training intervention: design

A multidisciplinary working group including service users, academic researchers, psychiatrists, a mental health nurse and a pharmacist met regularly to develop the training intervention. The results of the consultations, literature review and examples of existing practice fed into the development.

Training was designed to be delivered to service users, care coordinators and psychiatrists in parallel but separate groups. The aim was to optimise the impact of the intervention by delivering it simultaneously to key stakeholders who are actively involved in medication management, while addressing the specific training needs and concerns of each group. Each group was facilitated by a service user trainer, and either a psychiatrist (for service user and psychiatrist groups) or a mental health nurse (for care coordinator groups), allowing participants to learn from two relevant perspectives.

The programme employed a range of interactive learning methods. These included specially commissioned video material showing different clinical scenarios, small group exercises, general group discussions, use of testimonials and role plays. The resource materials and hand-outs covered a diverse range of views and approaches, to raise awareness and stimulate discussion. All participants had access to the public section of the project website (www.shimme.arcusglobal.com) as well as a secure discussion forum for their group.

The training programmes for the three stakeholder groups covered the same core content: background to the project key components of shared decision-making in the clinical encounter and rationale for promoting shared decision-making barriers to and facilitators of shared decision-making awareness of the effects of power imbalances in psychiatric consultations developing collaborative relationships importance of clarifying personal preferences, values and experiences in shared decision-making the concept of a ‘meeting of two experts’ in the clinical encounter, with personal experience and clinical expertise complementing each other³⁸ accessing and appraising information about medication, including examples of decision aids raising awareness of adjuncts or alternatives to medication addressing issues around coming off or reducing medication trialling of versions of three paper-based tools developed for supporting and recording the shared decision-making process information about useful websites.

In addition to the core content, the service user groups focused on: practising setting personal goals and identifying preferences making use of a personal well-being plan and self-help resources looking beyond medication to enhance well-being, drawing on Deegan’s work on ‘personal medicine’³⁹ introduction to assertiveness how to access information about medication, including a talk by a National Health Service (NHS) trust mental health pharmacist, who was available for further discussion afterwards supported ‘hands-on’ experience exploring relevant websites.

Besides the core content, the care coordinator training focused on adopting the role of a ‘shared decision-making coach’, supporting service users to play a more active part in the shared decision-making process³⁵ The programme for psychiatrists focused on competencies and resources that support embedding shared decision-making into routine clinical practice while acknowledging real-life challenges.

Training intervention: delivery

All training group participants were recruited from CPFT community mental health services: service users from the rehabilitation and recovery pathways; and professionals from these services and from assertive outreach teams. Service users were invited to participate by their care coordinators and psychiatrists and care coordinators were approached by team managers. In total, 47 service users, 12 psychiatrists and 35 care coordinators took part in the training.

Training was held in three different locations to reduce travelling for participants. Service users were reimbursed for travelling costs and received a fee (£40) for completing an evaluation before and after the programme.

The training was delivered in small group settings (2–12 participants), with each cohort completing their course of training together. An atmosphere of trust, acceptance and respect was encouraged. Participants had the opportunity for informal interaction before and after sessions as well as during breaks. Facilitators and project team members could be contacted between sessions for additional support.

Service user training groups were structured into four 2h sessions, meeting fortnightly After the training, two follow-up sessions were offered for ongoing support. Care coordinators met three times, at monthly intervals, for 1.5 h.

Psychiatrists had two 2 h sessions, one month apart, with an online self-study component. For organisational reasons one multidisciplinary team of clinicians received their training together in a single day.

Evaluation

The experience and impact of the training intervention was evaluated by collecting quantitative and qualitative data anonymously from participants at different stages of the project.

After providing baseline data, participants and facilitators completed a short questionnaire after each session, and participants completed a longer one immediately after the final training session. The questionnaires explored what the participants had hoped to learn from the programme, their views on its content and impact, and feedback on particular sessions, practical aspects, teaching methods and support materials.

Analysis of quantitative and qualitative data examining the impact of the intervention at a 12-month follow-up, as well as an economic analysis, will be reported on separately.

Results

Although care coordinators and psychiatrists were mostly trained in separate groups, their demographic and feedback data are reported as one group of clinicians. Demographic and attendance data for service users and clinicians are shown in *Table 1* and *Table 2*.

Attendance	37 (79%) attended at least 3 sessions of 4	20 of 21 (95%) attended at least 2 sessions of 3 14 attended team training day	6 of 10 (60%) attended both training sessions 2 attended team training day

The mean length of contact with mental health services for service users was 17 years. The most common reported diagnoses were schizophrenia, schizoaffective disorder or psychosis (*n* = 28, 60%), followed by depression (*n* = 12, 26%), bipolar affective disorder (*n* = 9, 19%), personality disorder (*n* = 5, 11%), anxiety (*n* = 4, 9%) and post-traumatic stress disorder (*n* = 4, 9%). Some participants reported multiple diagnoses. The majority of service users received state benefits (*n* = 43, 92%), with *n* = 39 (83%) on a disability living allowance.

Immediate post-programme feedback was given by 61 (65%) participants: 33 (70%) service users and 28 (60%) clinicians, including 22 (63%) care coordinators and 6 (50%) psychiatrists. Before starting the programme, service users mostly hoped to learn about ways to cope with their symptoms not solely focused on medication, to understand their medication better and to negotiate decisions. Clinicians were particularly interested in improving their practice, learning about the model and process of shared decision-making, availability of support materials, and sharing experiences with colleagues.

Expectations of the programme were largely met in both groups, with the majority of participants expressing a positive view about its content. In all groups, the opportunity for discussion and exchange of views with peers was highlighted as the best aspect of the programme. In addition, service users valued the clarity of the information conveyed, access to resources and the prospect of greater collaboration in consultations. Clinicians also appreciated access to resources and the information given, as well as the opportunity to reflect on their own practice, particularly in the case of psychiatrists.

There was little negative feedback. Just over half of service users (*n* = 17, 52%) and the majority of clinicians (*n* = 20, 71%) did not identify any aspects of the programme as being 'least satisfactory'. Some service users mentioned dissatisfaction with practical aspects or teaching methods, and a few referred to difficulties reading all the paperwork/understanding everything. A small number of psychiatrists expressed concerns about a perceived bias against their profession. Most participants felt the training was pitched at the right level. Use of the project website was variable, with about half of service users visiting it outside sessions. Most psychiatrists visited the website, but only a few

care coordinators did. The online forum was not used by any of the groups.

Most clinicians rated the training programme as relevant to their clinical practice, but fewer expected that what they had learned would shape their future practice. Over half of service users expected or were at least hopeful that the programme would affect future practice.

A summary of the post-programme feedback is given in *Table 3*.

Summary of feedback

	Service users (<i>n</i> = 33)	Clinicians (<i>n</i> = 28)
Most important things participants hoped to learn <i>a</i>	Lifestyle changes/coping with symptoms/alternatives to medication Understanding medication Management/SDM/negotiating decisions Sharing experiences Understanding side-effects of medication Assertiveness/confidence with professionals Info about project/research Reducing/coming off medication	Improving practice Learning about SDM model and process Support materials/tools for SDM Sharing ideas and practice Information about medication, including side-effects and coming off Learning about the project Gaining confidence in discussions with service users Understanding service user perspective
Views on content of the programme	Positive views 28 (85%): interesting, helpful, informative, empowering, encouraging, learned a lot Other comments 4 (12%): SDM needs to be implemented from consultant psychiatrist downwards/did not learn that much concrete	Positive views 21 (75%) 18 (82%) care coordinators, 3 (50%) psychiatrists: very good, good, interesting, informative, well-balanced Other comments 4 (14%): repetitive, some prejudice against psychiatrists
Best aspects of programme <i>a</i>	Meeting others, exchanging views and experiences, supportive environment Information conveyed, new ideas and access to resources Learning to be involved in my medication management, feeling confident my views will be listened to	Interaction with others, chance to discuss implementation of SDM Direction regarding resources/tools to support SDM, information Concept of SDM Gaining confidence in promoting SDM/putting SDM into practice Reflecting on own practice Getting service user perspective
Least satisfactory aspects <i>a</i>	Practical aspects, teaching methods Not understanding everything, not able to read all paperwork Parts boring, same	Practical aspects, teaching methods Perceived bias against psychiatrists Did not improve personal knowledge of medication Content
Training pitch at right level	32 (97%)	20 (71%): 17 (77%) care coordinators, 3 (50%) psychiatrists
Use of project website	17 (52%)	11 (39%): 6 (27%) care coordinators, 5 (83%) psychiatrists
Relevance of training programme and impact on future practice	Expecting impact: 12 (36%) Hopeful of impact: 7 (21%) Doubtful/unsure: 5 (15%) Relevant for others: 2 (6%)	Relevant: 23 (82%) Impact on own practice in future: yes 16 (57%), no 1 (4%), hopeful/probably 2 (7%)

SDM, shared decision-making.

Listed in order of frequency.

Discussion

The ShIMME project was a small-scale exploratory project with an emphasis on service users co-leading in all aspects, while aiming to ensure the views of all key stakeholders were integrated into the development and delivery of the training intervention.

The training programme was well received overall, demonstrating the feasibility of providing group-based training in shared decision-making to service users and practitioners in NHS community settings. In this case, service user participants were drawn from the rehabilitation and recovery pathways which serve people with chronic and often severe mental health problems. Demographic data from participants indicated high levels of chronicity and disability. The positive feedback, good attendance and engagement from this group suggest that taking part in shared decision-making training is possible and worthwhile for people experiencing a range of mental health challenges.

Feedback indicated that service user participants were interested in being actively involved in managing their mental health, including gaining a better understanding of medication and exploring a range of other strategies to foster well-being. Clinicians showed an interest in improving their practice by learning about shared decision-making.

Members of all the stakeholder groups gave positive feedback about the group-based training, allowing for the exchange of ideas and experiences with peers. This was also reflected in facilitator comments about the supportive atmosphere and participants' enjoyment of meeting with each other in the service user groups. Interaction with peers seemed to be an important aspect of the whole programme.

There may also be advantages in service users and clinicians attending joint training groups, allowing participants from different backgrounds to work together on an equal basis and to gain a better understanding of others' perspectives without the pressures and structures of the clinical encounter. The involvement of carers and important others might bring further benefits.

The feedback about the content, approach and pitch of the teaching within the group of psychiatrists was not quite as positive as in the other groups. The reasons for this are likely to be multifaceted and would warrant further exploration, with possible adjustments of the programme. Away to enhance acceptability and engagement would be to encourage more psychiatrists to become involved in shared decision-making training and development of tools.²⁸ Use of the project website was limited, in particular by care coordinators and service users. Technical difficulties with the website might have contributed to this, but comments during sessions indicated that some participants, particularly service users, had low IT confidence and limited internet access outside the training sessions. Future training programmes will need to provide non-digital resources, as well as supporting access and use of IT resources.

The project team developed three paper-based tools to support the process of shared decision-making, which were trialled in training groups and repeatedly revised. Although useful, these would need to be integrated into the existing electronic records system to be truly effective in promoting, supporting and documenting the process of shared decision-making without significantly affecting consultation time. At present this remains a challenge, but there have been some promising recent developments.⁴⁰

Both groups of clinicians considered the training relevant to their clinical practice, although they appeared uncertain whether the programme would influence their future practice. This might be due to concerns about additional barriers to implementation or aspects of the training itself. Despite their positive feedback about the programme, service users were also cautious about its impact. This might reflect the perception that they have little influence in making significant changes to their healthcare delivery or doubts about positive initiatives being translated into clinical practice.

While this pilot programme had the limitations of a modest number of participants, not all of whom provided feedback, the consultation data from local stakeholders, the development of the training programme and the feedback from participants were all encouraging. Drawing on experiences from this project, CPFT has been working towards implementing shared decision-making across the trust by embedding shared decision-making into its procedures, raising awareness and offering training to practitioners across the trust (www.promise.global/sdm.html). The associated Recovery College (www.cpft.nhs.uk/about-us/recovery-college-east.htm), which is open to service users, family, friends and staff,

also included training in shared decision-making. The pilot project benefitted from a supportive environment within the trust, and the success of implementation in other organisations would depend on their own local conditions.

The complexity and difficulty of implementing shared decision-making in a mental health setting should not be underestimated.^{36,41} For it to truly become a routine part of clinical practice, changes in attitudes and behaviours are necessary among all parties involved, as well as the wider society.^{36,42} Psychiatrists are well placed to take on a leadership role in promoting shared decision-making within health services and should also be pivotal in explaining the benefits of increased patient autonomy and responsibility to the general community.

We thank all ShIMME project team members, service users and practitioners, as well as Dr Fiona Blake, Sheena Mooney, Mary Jane O'Sullivan and others for critically reviewing the manuscript. We are grateful to Prof. Matthew Large for his contributions as part of the *BJPsych Bulletin* Author Mentoring Scheme.

1.6.64 Trainee experiences of intellectual disability psychiatry and an innovative leaderless support group: a qualitative study

2017-8

Abstract

Aims and method There is very little research into the challenges of training in intellectual disability psychiatry or into interventions which may address these challenges. Using focus groups, we explored the experiences of intellectual disability psychiatry trainees, and evaluated a leaderless trainee support group developed in Bristol.

Results Five distinct themes were identified via framework analysis: that trainees felt unprepared for the difference from previous posts; the need for support; the value of the group; that trainees were concerned about judgement in supervision; that the group structure was valued.

Clinical implications Our findings highlight the support needs specific to intellectual disability psychiatry trainees. Leaderless peer support groups may be a valued resource to address such issues, and may be a useful model to be considered by other training schemes.

Intellectual disability psychiatry (also known as learning disability psychiatry particularly in UK healthcare services) is a specialty in the UK involving the assessment and management of mental health problems in individuals with intellectual disability and other developmental disabilities. Trainees in intellectual disability psychiatry face specific challenges, including the need to acquire enhanced communication skills, understand a range of genetic, neuropsychiatric and neurodevelopmental conditions, and utilise knowledge of complex psychopharmacology.¹ They may also have to confront substantial existential and societal issues associated with caring for vulnerable individuals who face exclusion and disadvantage in many aspects of their lives.²

Although there is little published literature, one study exploring the experiences of intellectual disability psychiatry trainees described strong feelings of isolation, alienation, lack of skills and impotence, not unlike the feelings experienced by the patient groups the trainees worked with.² Prompted by these findings, trainees on the Bristol intellectual disability psychiatry training scheme developed an innovative, leaderless trainee support group (*Box 1*) after taking advice from a consultant psychotherapist. The group aimed to provide a forum for reflective peer support for core and advanced intellectual disability psychiatry trainees (doctors specialising in psychiatry, previously termed senior house officers and specialist registrars). It has continued since 2005, with individual membership varying from 6 months (core trainees) to 3 years (advanced trainees).

Here we report the findings of a qualitative study exploring the experiences of trainees in intellectual disability psychiatry who participated in this support group. The aims were to explore doctors' experiences of training in intellectual disability psychiatry, in particular the positive and negative aspects of working in this specialty, and the role of support and supervision; and to evaluate the model of a leaderless peer support group from the perspective of its participants.

Box 1 Trainee support group

- **Who:** All core and advanced trainees in intellectual disability psychiatry placements are invited. Typical attendance is 3–6 participants, dependent on need, leave or competing priorities. The group does not have a facilitator or leader, and was set up with an egalitarian structure.
- **When:** Fortnightly before the academic programme.
- **Where:** On the site of the academic meeting, central in the area between the different placements.
- **How long:** 90 min.
- **Structure:** 10 min of chat as people arrive, 70 min of focused support group. No fixed agenda, time used between trainees depending on needs that day.
- **Boundaries:** start and end time, confidentiality, respect.

Method

We approached this project using a qualitative design, as we were interested in exploring a variety of individuals' interpretations of their experiences.³ Although one-on-one interviews were an alternative, focus groups provided a time-efficient way to gather data, allowed discussion of the issues raised, and enabled researchers to gain a sense of whether the individuals identified with each other's experiences.⁴

Procedure

Two focus groups were held, one for each cohort, each lasting 90 min. Focus groups were facilitated by two of the researchers (J.N. and J.K. for the first cohort, and J.K. and D.R. for the second), who used a topic guide and encouraged free-floating discussion. The facilitators sought clarification when needed, and prompted the participants to move on to new areas when they started to repeat previously discussed issues, or after periods of prolonged silence. They also encouraged participants to share examples from their own work wherever possible. Recordings were transcribed, including spoken words, speech fillers and dysfluencies, by a medical secretary.⁵

The topic guide comprised four sections: experiences of working with people with intellectual disability; the role of support and supervision in training in intellectual disability psychiatry; reflections on the value and usefulness of the trainee support groups; specific consideration of the leaderless, egalitarian model of the trainee support group. The list was generated from data gathered via a previous semi-quantitative survey investigating perceptions of the trainee support group held by trainees and trainers in 2007.

Participants

All doctors who had been members of the trainee support group during the preceding year were invited to participate in each of the study's two focus groups. This process was performed twice, 4 years apart, sampling two non-overlapping cohorts. This was to allow exploration of whether experiences were cohort specific. Each focus group comprised five participants. The first included three core and two advanced trainees and the second two core and three advanced trainees. Each group was mixed gender and had trainees from different community learning disability teams (CLDTs) in the scheme. The ages of the participants were between 25 and 40 years.

Participation was voluntary, without incentive and occurred during work time. All participants consented to their comments being recorded and transcribed for analysis, with individual identities removed.

Ethical considerations

The regional training programme director reviewed the proposal, considered relevant ethical issues and gave approval for the study.

Analysis

Framework analysis was the most appropriate analytic method, given its relative simplicity and ease of use, and served the intended aims of seeking themes rather than generating explanations or new theories or concepts. A process similar to the framework analysis described in detail in Rabiee was followed.⁵

Stage 1

Two authors (J.K. and D.R. in the first and R.S. and H.T. in the second focus group) independently immersed themselves in the focus group transcript as a whole. The transcript was manually coded on paper, thus developing a 'thematic framework'.

Stage 2

Following this, quotes were highlighted, pasted into a separate document and arranged by broad themes.

Stage 3

The interpretation stage of the analysis was done jointly between each pair of authors and involved refining and condensing the themed quotations using suggested criteria of: attention to frequency; emotion/intensity; specificity (attention to actual personal experience over hypotheticals); and extensiveness. Internal consistency (reduced attention to views subsequently contradicted or changed) could not be reviewed as suggested by Rabiee,⁵ as individuals could not be consistently tracked throughout the transcript.

Stage 4

The final stage involved a review of the analysed and interpreted data to see whether they had resulted in significantly overlapping themes suggestive of an overarching or superordinate theme. Themes were named by a process of abstraction as described by Fade.⁶ A requirement for reflexivity was acknowledged from the outset. Thus, researchers' influence was viewed as a necessity for making sense of the richness of the data generated by group participants rather than as bias to be eliminated.⁷

Results

Results of thematic analysis

Five distinct themes evident in both focus groups were identified. Owing to the anonymisation of participants during transcription, it was not possible to attribute quotes to specific participants. However, the quoted contributions incorporated a broad range of views arising in themes evident in both focus groups. Furthermore, it was evident in the transcript that they did not represent any one dominant voice.

Theme 1: unprepared for difference

Both groups perceived placements in intellectual disability psychiatry as being quite different to other psychiatry posts. This was viewed as having both positive and negative facets. Positive aspects included having more time allocated to conduct detailed assessments, and the potential to work jointly with colleagues from other professional groups. These were seen as enabling the doctor to assess the patient in a holistic manner and the overall experience was described as 'rewarding' by several trainees: "You don't just see the person in one dimension; you are seeing a holistic view. Working with people with disabilities ... can be very rewarding." A variety of negative issues were discussed, including problems associated with reliance on suboptimal collateral histories and doctors questioning their own abilities to provide adequate care to this patient group, particularly with respect to specialist skills such as epilepsy management: 'Suddenly you are asked to treat something you've probably not had a great deal of training for [epilepsy]... suddenly you are expected to already know about it.' Some trainees appeared to be aware of such differences prior to starting posts, which was sometimes a source of apprehension. However, for others it was more of a surprise: 'I think it is very

different to what one gets in general psychiatry and I think that is not clear at the outset and sometimes can come as a surprise.’

A sense of isolation while working in these posts was part of the discourse in both groups. The change from being in large mental health teams to smaller CLDTs, where the other professionals have limited psychiatry training, was noted. The low number of medical colleagues in the CLDTs also generated feelings of isolation, as did the geographical spread of posts: “The posts can be quite isolating ... there might be you and another doctor within the team. We are quite isolated, we are far and few. There is that huge geographical spread which means that you don’t tend to see people informally.”

Theme 2: need for support

The trainees described the need for help and support in coping with aspects of their work. For example, there were accounts of doctors struggling with the emotions evoked by working with a patient group with disabilities: “I think it is quite difficult to work with people with [intellectual disabilities]; especially people who are severely ... physically and mentally disabled, it can make [you] feel quite low if you see those people who are completely dependent on carers. If you work with someone who has so much pain and trouble, if you work with them and you don’t get any support, I think I would personally get depressed, just thinking about it. If you don’t actually discuss your feelings with someone else who understands where you are coming from, I think that can pile on and on and can actually start affecting you in your personal life too.” Some trainees also described being overwhelmed by the additive effect of numerous emotionally challenging encounters: ‘In a week you collect things in your head. If there were deaths you would have a formal debrief, but these things are not deaths. They are things that keep on happening, small things.’

Many of the participants also expressed feelings of impotence to ‘fix’ the underlying conditions of their patients with intellectual disability: ‘I’ve always been taught to diagnose a disorder and treat it... I felt powerless.’

The trainees described the trainee support group and consultant supervision as addressing different support needs: “I think they are quite separate things... they do quite different things. I think... supervision is about supporting your work and this [trainee support group] is a place that supports you.”

The trainee support group was also highlighted by several trainees as a useful place to talk about difficulties related to training and difficulties experienced within CLDTs.

Being a doctor who is newly working in learning disability and the emotions that generates and the challenges of training, I think you get more out of discussing that with a group of people who are going through the same thing.

Theme 3: value of the group

The trainees described finding the group a source of: “Genuine support and encouragement and reassurance. We talk, and when you talk it comes out, and you are able to share, and it is not so ... painful anymore.” Some participants also recalled specific clinical and nonclinical issues where the group had been helpful to them: ‘I was struggling ... the support was phenomenal.’ Trainees also stated that the group had a positive impact on their clinical work: ‘I think it does help us to become better clinicians in terms of how to deal with our emotions ... we do learn from each other a lot.’

Positive aspects to the structure of the group included: permission to discuss anything, the group being confidential, and the opportunity to be with peers who are experiencing similar challenges: “The openness and the fact that you feel a bit equal ... you can pretty much bring anything there. I can speak and no one will judge me.” Sessions that had been of most value were reported to be those that were best attended, and setting ground rules was considered helpful to the group. If the group discussion was solely focused on an informal chat or issues such as rota swaps, it then lost its supportive benefits: ‘Incredibly valuable [sessions] have been the ones where people, lots of people, have come and come on time, and other times they definitely have felt like a missed opportunity.’

Theme 4: judgement in supervision

Participants described finding it easier to talk about their feelings with peers in the group than in consultant supervision. In particular, worries were expressed regarding looking incompetent during supervision, as the consultant would need to sign off the trainee at the end of the placement.

I don't want to say something [in consultant supervision] that will make me look bad, that will go on my file.

I would probably be worried in supervision that I don't want to say that I felt unsure about myself.

I find the trainee support group is more about me and about how I am coping, whereas clinical supervision is everything about the client and getting my assessments and appraisal.

Part of the issue might be your unhappiness with your interaction with other members of the team or with your consultant, which ... you would find difficult to discuss in supervision.

However, consultant supervision sessions were deemed more appropriate for some other issues, which trainees said they would not discuss in a group setting: 'Certain personal and professional issues that you may want to discuss in a supervision environment I wouldn't do in a Balint group or here.'

Theme 5: group structure

The egalitarian model was described as enabling core and advanced trainees to express their opinions knowing trainees were viewed as of equal value to the group: 'My views were valued and ... I could also give advice to my senior colleagues, which is not always respected everywhere, so this was a major strength.'

It also allowed all members to talk about what they felt was important to them rather than to a facilitator. However, some noted a downside that a less confident member might not highlight their desire to bring a new topic to a session, and the group could be dominated by particular individuals: "There is a freedom in the group that comes from the fact that it's unstructured and doesn't particularly have an agenda. I think a chairman would be useful [...] in asking if particular quiet members would [...] like to say anything because there are some people who have attended and I haven't heard speak in 6 months." The lack of a leader was thought to promote a more lax view on attendance and punctuality, and some trainees and consultants were reported as giving the group a lower priority than other aspects of the trainees' work. Group members arriving late or leaving early was disruptive and disturbing: 'We value the group, we see it as valuable or we wouldn't come at all, but we don't value it as highly as other things in our timetable so it tends to be the first thing that gets bumped.'

Discussion

This study adds substantially to the very limited literature detailing the peculiarities and challenges of training in intellectual disability psychiatry.^{1,2} One strong theme that emerged from our results was how trainees considered training in intellectual disability to be different from other psychiatric posts and the degree to which they were prepared for this. The reasons cited were related to both the specifics of the work and the structure of teams. It is well known that psychiatric disorders in intellectual disability may be more complex to diagnose, particularly owing to difficulties in effective communication. A further contrast with many other areas of psychiatry is the degree to which healing or restoration to full function or participation is possible. In intellectual disability psychiatry, the primary disability is often the intellectual impairment or associated developmental disorder, thus treatment of any mental illness may restore the patient's previous level of functioning and quality of life, but no further. Despite epilepsy management being a common role for the intellectual disability psychiatrist,⁸ our findings suggest that many trainees felt apprehensive about their skills and confidence in this area.

Feelings of isolation were also highlighted. CLDTs in the area of the study are geographically spread out and based away from their mainstream psychiatric colleagues. Separation from peers has been noted as off-putting to foundation doctors,⁹ but few studies explore feelings of isolation among psychiatry trainees² It has been noted previously that

individuals who work with people with disabilities can feel stigmatised and isolated.^{10–12} Stigma by association is the process by which relatives, support staff, friends and associates feel stigmatised owing to their contact with a stigmatised group.^{13,14} This may also affect trainees working in this area and contribute to their feelings of isolation. We think that one reason the group was valued could be its ability both to reduce the feeling of isolation by bringing trainees together, and to mitigate some of the stigma felt by enabling the trainees to share difficult experiences. One could speculate that the group may have not just attenuated some potential negatives of the subspecialty training, but also contributed to the enjoyment and reward of it. If this were to be true, it would be interesting to study whether training schemes in areas with specialty-specific support or educational groups do better in relation to trainee retention or satisfaction than those without such structures.

It should be noted that despite the challenges, there was also a strong and pervasive feeling of positivity about training and working in intellectual disability psychiatry. Such experiences were startlingly absent in previous work,² but are important to note to reassure future recruits in the specialty. In particular, the trainees mentioned the term ‘rewarding’, a varied and complex concept.¹⁵ The view that community-based intellectual disability psychiatry would be rewarding was predicted some 30 years ago,¹⁶ although this is the first study as far as we are aware that affirms this view. Intellectual disability requires a particularly holistic approach, often not dissimilar to the approach of general practitioners (GPs). While there is an absence of published surveys or qualitative studies on what psychiatrists find rewarding, interpersonal relationships between doctor and patient have been found to be particularly satisfying for GPs.¹⁷ However, we are unaware of similar studies among psychiatrists.¹⁸

Both focus groups discussed how consultant supervision and the support group were different, but mutually supportive and compatible. When surveyed, UK trainees report they are mostly happy with supervision and find it useful.¹⁹ The Royal College of Psychiatrists recommends that supervision should enable ‘the development and assessment of clinical and personal skills under direct one-to-one supervision by an expert’ and should be ‘focused on discussion of individual training matters’.²⁰ The hierarchical nature of consultant supervision is both valued by trainees²¹ and necessary for valid competency assessments, but this can be a potential barrier to seeking support in some areas, particularly revealing vulnerabilities to a supervisor who is also an assessor. Personal upset and secondary grief relating to patients is considered by some supervisors and supervisees to be a boundary breach in supervision.²² The trainee support group is set up without hierarchy and this may have contributed to reducing boundaries around discussing vulnerabilities. Honest discussion about how trainees were ‘coping’ was easier in the trainee support group than supervision, despite the College suggesting consultant supervision should include this.²⁰ This study adds to previous work suggesting some mismatch between intent and what trainees feel comfortable discussing.²³ This space for honesty is a value of the group but it would be a concern if the availability of the trainee support group and its support acted as a colluder or barrier to honesty in consultant supervision.

Group peer support may be more beneficial than alternatives such as paired peer support. Several of the benefits described in both focus groups suggested similarities to Yalom’s therapeutic factors: universality, altruism, guidance, imparting of information, cohesion, and existential factors.²⁴ That senior trainees stayed in the group for up to 3 years may reinforce some of these factors, and their relative maturity and existing trust following a longer involvement in the group may provide additional support.²⁵ It also provides senior opinions, which have been found to be supportive when shared in other contexts.²⁶ A common concern when leaderless groups are used for supervision is a loss of focus on the task and drifting into support and advice-giving.^{27,28} As the model presented here is primarily for support, and advice is part of that, the lack of leader is not a concern in this context, although the results did suggest that some participants would have liked a facilitator role in encouraging quieter members to contribute.

As this is an analysis of a single group and the findings have not been replicated elsewhere, it is difficult to generalise the utility of such groups to other areas. However, we think similar models of egalitarian peer support that require limited resources for setting up may have the potential to benefit trainees in other, smaller or more challenging, specialties.

Strengths and limitations

The qualitative design and use of focus groups is appropriate to investigate attitudes and experiences of trainees. The training rotation is relatively small, with 7–9 core and advanced trainees available to attend the trainee support group in each 6-month period. ‘Group think and the articulation of group norms may have introduced a positive bias. However, the anonymity of participants in the transcript is likely to have mitigated self-censorship and there was evidence of a diversity of opinion, particularly illustrated by both praise and criticism of the trainee support group and highlighting a range of experiences in training. The anonymisation happened at transcription rather than at analysis stage. This precluded the ability of the authors analysing the data from tracking individuals’ comments or reviewing whether they were linked to particular posts or trainers. Generalisability is a concern in qualitative studies, and was also a concern in this particular training scheme. First, at the time of the focus groups, the Bristol scheme was performing above average on trainee satisfaction in GMC surveys.²⁹ Second, many of the CLDTs may be unusually isolating for trainees compared with elsewhere in the country by virtue of their geographic spread and relatively rural setting. Finally, in several CLDTs within the scheme, most team members, except psychiatrists, are employed by a different organisation and may have few psychiatric skills.

In conclusion, we have highlighted some of the challenges and rewards of training in intellectual disability psychiatry. Our evaluation of an egalitarian, trainee-led peer support group suggests that the model could be useful for other intellectual disability psychiatry training schemes. Whether this could be a support structure suitable for other specialties remains to be studied.

We thank Dr Andrew Clark, consultant psychotherapist, for help with setting up the group; Dr Kristina Bennert for recording equipment; Gill Wetherall for transcription of the tapes; Dr Helen Sharrard, training programme director, and all consultant trainers for supporting the groups; and importantly, all trainees who enthusiastically participated in them over the years.

1.6.65 Scottish independence: the view of psychiatry from Edinburgh

woman whose research work had wrenched the pendulum radically in the direction of biological psychiatry, with her landmark *Lancet* paper ¹ showing anatomical differences on CT scans between the brains of those with and without schizophrenia. I feared that she ate psychotherapists for breakfast, although she had sounded kind and friendly on the telephone. My anxiety was misplaced, since the person who emerged was a woman of fierce intelligence, with rigorous, idealistic, uncompromising and wholly admirable moral standards; compassionate and committed to patients and science, without any personal vanity, unless you include intellectual certainty.

Professor Johnstone is not a postmodern relativist: her life has indeed been a life scientific. For her this is seamless: the scientific truth is what leads to effective and therefore optimal treatment. She has never given interviews before, owing to a self-deprecating Scottish horror of self-publicity, but agreed to speak now as a retired professor.

Eve Cordelia Johnstone, ‘Scottish neuroscientist’, is the eighth generation of Glaswegian Presbyterian doctors, but the first woman doctor in her family. She laughed gently at my southern ignorance in asking about Catholicism in Glasgow: of course the Catholics were often of Irish origin, poor, poorly educated and discriminated against. No chance of eight generations of doctors then. (In fact, her father was a dentist because his serious deafness made medicine impossible.)

She remembered vividly the poverty and overcrowding in Glasgow, the worst in the UK at the time. One of her first patients on medical take was an exhausted woman presenting with open tuberculosis, a urinary tract infection and a haemoglobin of 8, who arrived late at night, after three jobs that day: scrubbing steps, cleaning offices, then washing dishes. ‘Had she ever been to the hospital before?’ I ask. ‘Yes, to be sterilised after having 13 children.’ The woman was 35 and looked 20 years older. Infant mortality was 28/1000 in Glasgow at this time, compared with about 6/1000 now.

Born in 1944, the young Eve was sent to an academic private Presbyterian girls’ school and was an obvious high flyer. This remained the case: she qualified in medicine in Glasgow in 1967. As a woman medical student, she was one of a 20% maximum quota. Most of her female contemporaries ended up doing a bit of part-time practice rather than working ‘in a serious capacity’, as she put it.

As a clinical researcher who looked after patients with scrupulous care, she is proud of having been supported by the Medical Research Council (MRC) continuously for 33 years, which is almost unprecedented. She did research at Northwick Park in Harrow from 1974 until 1989, and was Professor and Head of Department of Psychiatry at the University of Edinburgh from 1989 until 2010. She has a reputation in Edinburgh for supporting younger psychiatrists, although she has no time for slacking (or striking, as a doctor): ‘I worked 12 hours a day, it was what I expected’.

The struggle for schizophrenia

In 2016 it may be hard to remember the climate in which the 1976 *Lancet* paper landed. ¹ Debate on the origin and meaning of mental illness was in the international public domain. The flamboyant R. D. Laing, a fellow Scot, was describing psychosis as a sane response to an insane society, chiming perfectly with the other social and sexual revolutions in progress. ² Thomas Szasz published *The Myth of Mental Illness* in the same year, depicting psychiatrists (and all other doctors) as agents of social control. ³ In 1975 Miloš Forman’s *One Flew over the Cuckoo’s Nest* portrayed the excesses of medicalisation, incarceration and psychosurgery. ⁴ A famous study emerged in the USA in 1973, showing how journalists going to the emergency room complaining of ‘hearing’ three words in their heads attracted the diagnosis of schizophrenia. ⁵ This massively discredited conventional psychiatric diagnosis. In the UK, David Cooper published *The Death of the Family* (1971), describing the family as the crucible of mental illness, and coined the term ‘anti-psychiatry’. ⁶ The now discredited and mother-blaming notion of the ‘schizophrenogenic mother’ was widely held.

So just imagine the hostile reaction that a paper showing anatomical changes in schizophrenia would receive. As Professor Johnstone remembers: ‘There was all this anti-psychiatry stuff [...] People were saying schizophrenia didn’t exist [...] I had to prove my opponents wrong.’ As she reminisces today, it is not difficult to detect her contrarian relish for the battle: Professor Johnstone had no time for these theories. ‘There were 200 000 people in hospital with schizophrenia [...] what did they think they were there for?’ she asks incredulously. It was also the time that John Wing had written about the phenomenon of institutionalisation, ^{7,8} although she points out ‘he never claimed that the institutions were the cause of the illness’.

In her own mind, Professor Johnstone was crystal clear: “‘I felt it had to be that this was a disease, but I couldn’t prove it [...] and then the non-invasive method of CT scanning came in. I was lucky. Before that people had to do pneumoencephalography (injecting air into the ventricles and X-raying them, resulting in terrible headaches and worse), so there were no controls because of the dangers of the technique. The papers were all in Japanese or German.’” This is a chilling moment: we are talking the Third Reich. ‘It sounds awful to admit’, she says ‘but the best papers [in support of the notion of schizophrenia as a disease originated in] the Third Reich. The Nazis wanted proof that schizophrenia was an inherited degenerative condition.’ When the 1976 study was published, even other neuroscientists objected, suggesting that the anatomical change could be secondary to drug treatment or encephalitis. ‘But I knew something was wrong with these people [...] When I was 21, I saw a 21-year-old woman, terribly distressed by paranoid delusions, who had been working in a bank 3 weeks earlier. It was ridiculous to say this was due to imperfect interpersonal reactions at home [...] just stupid.’

With iron determination, she then went on to refute all the challenges to the original paper with a study of 600 people with schizophrenia in Shenley hospital.⁹ They were followed up until death, and their brains at autopsy showed larger ventricles and smaller brains. However, there was no gliosis, suggesting that the pathology may be neurodevelopmental. Professor Johnstone, for all her modesty, cannot suppress an element of glee in having pipped to the post her American research competitors. Daniel Weinberger, backed by the enormous funds of the National Institute for Mental Health, confirmed her findings 2.5 years later.¹⁰ Not shirking controversy, she then ran a placebo-controlled trial of electroconvulsive therapy (ECT), which demonstrated ECT to be effective, albeit only for about 8 weeks, particularly in those depressed patients who experienced delusions and had intellectual disability.

Her next project, the Edinburgh High Risk Study,¹¹ was a prospective study of 16- to 22-year-olds, carefully comparing the incidence of developing schizophrenia in a cohort of people whose relatives had schizophrenia, the controls having no family history. Twenty-one of the high-risk group who then developed schizophrenia in fact had some anatomical differences in the brain when they were still well. The changes include smaller amygdala and hippocampus and hyperfolded gyration. Of course, this finding raises a host of ethical issues in relation to premorbid diagnosis and its implications.

I asked Professor Johnstone what she thought of the recovery model, and she was sceptical: “‘Seems to me a bit of a semantic issue [...] if it’s a dreadful illness, very hard for families, specially if you knew the people before they became ill [...] and people don’t want to say how bad it’s going to be. I don’t think the [Royal College of Psychiatrists] has emphasised psychopharmacology enough. We need much more individually tailored treatments, taking account of distinct side-effect profiles, not general algorithms. Unfortunately, it’s not true that the drugs we have now are vastly better, although it is better to have a wider range.’” She sees non-pharmacological treatment as ‘a bit better than nothing, if [the patient] will engage’, but her scrupulous honesty demands that we acknowledge that ‘a terrible thing has happened to them.’ Talking to her it was clear that she personally provided intensive clinical care to her patients and their families, and we could easily agree that continuity of care is crucial and dangerously eroded in many overstretched contemporary psychiatric services. She is unconvinced of the benefits of the newer antipsychotics: ‘It’s true the side-effects are different, but they hammer weight on to you, which is very distressing for young people.’ As for clozapine, the benefits have been ‘greatly exaggerated’.

Her academic success has been recognised. She received a CBE in 2002 for services to medicine, and a Lifetime Achievement Award of the European Psychiatric Association in 2009. She also had many senior roles in the MRC, including the chairing of the highly publicised inquiry into the disastrous linking of the MMR (measles, mumps and rubella) vaccine and autism. With the distressed parents of autistic children leading a class action against the government on the basis of the Wakefield paper,¹² she was truly in the eye of the storm. ‘I had to carry the parents with me.’ The disgraced Wakefield ‘got what he deserved’, she says.

In retirement Professor Johnstone has remained actively interested in the link between schizophrenia and cognitive impairment. She reminds me that there is a 3% point prevalence of schizophrenia in people with mild intellectual disability, three times higher than in the general population. The focus of understanding is in the area of overlap of schizotypal cognitions, molecular genetics and anomalies of brain structure, where ‘we are seeing a final common pathway that leads to schizophrenia.’ The large data-sets she has in this area fit well with the work of the Patrick Dick Wild Centre, a charitable trust in Edinburgh set up for research into autism, fragile X syndrome and intellectual disability. Politically savvy and persuasive, she raised the funds for the centre, named after a person with severe autism.

Future hopes

In terms of the future, she told me about some hopeful developments in Edinburgh, which have potential for a personalised preventive psychiatry. Starting with a simple skin biopsy fibroblast, stem cells and then neurones can be grown, giving an opportunity to ‘develop drug treatments which basically work on an individual patient’s brain which has been developed in a dish’, as Professor Stephen Lawrie, her successor at the University of Edinburgh, put it. Roll on the day.

1.6.66 Handbook on Obsessive-Compulsive and Related Disorders

Lynne M. Drummond¹

date

2017-8

Contents

- *Handbook on Obsessive-Compulsive and Related Disorders*

This multi-author book examines the disorders categorised in DSM-5 as obsessive-compulsive and related disorders (OCaRDs) and also covers two other related disorders: illness anxiety and obsessive-compulsive personality disorders. The text is written by experts in the field, many of whom were instrumental in developing the concept of OCaRDs in DSM-5. Unlike many multi-author publications, this is brief and to the point. Each of the chapters is arranged in a structured format which includes a general introduction; diagnostic criteria and symptomatology; epidemiology; comorbidity; course and prognosis; psychosocial impairment; developmental considerations; gender-related issues; cultural aspects of phenomenology; assessment and differential diagnosis; aetiology and pathophysiology; treatment (somatic as well as cognitive and behavioural) and a summary of key points at the end. Most chapters also contain illustrative case vignettes which demonstrate the disorders and their potential severity.

This excellent title should be on the bookshelf of every psychiatrist, whether working with adults or children. Mental health workers, managers and commissioners often overlook common conditions such as obsessive-compulsive disorder and body dysmorphic disorder, regarding them as less severe and important than conditions such as schizophrenia. This work describes the hugely detrimental effects these conditions can have on the individual’s mortality, morbidity and social functioning. It also considers newly defined disorders, such as hoarding and skin-picking disorders. These conditions are poorly understood and have generally not been researched extensively. They do, however, appear to be widespread and often have extreme consequences on the individual’s mental and physical well-being. For example, hoarding disorder, which was previously often classified as obsessive-compulsive disorder or else obsessive-compulsive personality disorder, may affect up to 6% of the adult population. Excessive hoarding can lead to death due to fire risk or the falling of large numbers of possessions resulting in an avalanche. It also frequently coexists with self-neglect and – owing to the extreme shame – social isolation. Nevertheless, few community mental health teams in the UK offer comprehensive treatment for hoarding disorders. Some enlightened councils have developed hoarding protocols incorporating housing agencies, social services, and mental and physical health services but overall these are patchy and rare.

Hopefully, heightened awareness will lead to systematic research and a better understanding of the disorders and their treatment, as well as the development of effective services. This handbook would be a perfect introduction to these areas for a busy practitioner seeking brief but authoritative information.

1.6.67 Shrink Wrapped: Tales from Psychiatrists

Gary Cooney¹

date

2017-8

Contents

- *Shrink Wrapped: Tales from Psychiatrists*

There is something that feels a little otherworldly about *Shrink Wrapped*. As readers, we are invited to find our way into the psychiatrist's mind, to take our bearings from this anonymous collection of short anecdotes and reflections, written by psychiatrists, as a point of departure into understanding what it might mean to be a modern-day 'shrink'. We find warm, affectionate and humorous musings that are abruptly punctured by sharper observations, memories painful to revisit, self-doubt, recrimination and a sense of ever-questioned legitimacy. It is an honest, undiluted look into the experiences of eight psychiatrists, the whispered, confessional moments that blurred the boundaries of their personal and professional lives.

There is a strength of variety to the collection and, at its best, it draws us into questioning ourselves: what kind of a psychiatrist have I become and how did I get here? Does the voice I'm reading remind me of my own thoughts or my own journey? There are, however, one or two weaker moments alongside: in its editorial efforts to be snapshot-succinct, it can sometimes feel frustratingly whimsical and underdeveloped, like a string of highly promising film trailers. There are also passages that veer a little close to what might be found in the reflective practice section of an online portfolio.

Shrink Wrapped is as intimate and conversational as a cup of tea with a close colleague. It considers our own professional self-consciousness, 'the navel-gazing and self-doubt' that besiege our specialty, and takes a frank, unabashed look at the inevitable cross-pollination of our work and life experiences. The collection provides the reader with moments of piercing honesty, such as this summation from one particularly candid contributor, reflecting on what she, as a psychiatrist, might represent: 'I am very clearly a middle class professional White woman who is sitting here telling [the patient] what is happening.'

But who was this woman? Indeed, who were any of these interviewees? Their names are listed in the acknowledgements but not alongside any of their own contributions, an editorial device which purports to leave us free to explore the book in our own way. I found this troubling, untethering, as if I were experiencing these voices in an alternative space. It felt more in service to the interviewees, in defining the boundaries of the reader-writer relationship. It reminded me a little of the dynamic in clinic: you might be able to learn something about a psychiatrist, but not on your own terms. A lot will also be held back.

1.6.68 Service user perspectives on coercion and restraint in mental health

Diana Rose Emma Perry Sarah Rae Naomi Good

date

2017-8-01

Abstract

Coercion remains a central aspect of many people's mental healthcare. It can include the use of legislation to restrict freedoms, the use of physical restraint, the restriction of freedom of movement and/or association, and the forced or covert administration of medication. There is good evidence that the use of such measures can traumatise service users. This article reports the findings of a survey of service users regarding their experiences of coercion and restraint and embeds this in the wider international and institutional environment.

Contents

- *Service user perspectives on coercion and restraint in mental health*
 - *The CRPD*
 - *Global South*
 - *Industrialised West*
 - *Conclusion: minimising coercion and restraint*

Most jurisdictions in the industrialised West promulgate mental health legislation which permits infringement of liberty and treatment against the will of the person detained. Increasingly, coercion in the community is also allowed. Partly at the behest of the World Health Organization, other countries are developing similar legislation. This ability to compel and coerce is unique in medicine and, from within psychiatry, has been called discriminatory (Dawson & Szmukler, 2006) and criticised for the focus on risk.

Dealing first with the United Nations' 2006 Convention on the Rights of Persons with Disabilities (CRPD) and its implications for coercion and compulsion globally, this article summarises what is known about service users' responses to coercion and compulsion, which includes chemical, physical and mechanical restraint. Responding to the paucity of studies focusing specifically on physical restraint (which is commonly followed by chemical restraint), this article reports on recent experiences of people subject to this practice in the UK while situating this in more general concerns.

The CRPD

The CRPD appears to be top of the agenda for service user movements everywhere except the UK. The European Network for (ex) Users and Survivors of Psychiatry (ENUSP) has provided a point-by-point explanation of how European human rights legislation is in breach of the CRPD and the World Network (WNUSP) was involved in drawing up the Convention itself. It is important as it is the first time that people 'with psychosocial disabilities' have been recognised as equal in law to other citizens in terms of rights.

But the Convention is controversial, particularly since the publication of the General Comment on Article 12, which states that all persons with disabilities must be deemed to have legal capacity all of the time. This intensifies the commitment in Article 14 to abolish compulsory detention and treatment by doing away with the last criterion on which it could be justified. The General Comment has drawn the ire of leading Western psychiatrists (Freeman *et al*, 2015). The debate is also not settled within service user circles, as shown by the different positions of Tina Minkowitz and Anne Plumb (see Spandler *et al*, 2015).

Global South

The CRPD language of ‘persons with psychosocial disabilities’ has also had important implications in the Global South. There is a move from the terms ‘user/survivor’ to ‘persons with psychosocial disabilities’. For example, the Pan African Network of Users and Survivors of Psychiatry is now the Pan African Network of Persons with Psychosocial Disabilities. A similar move has been counselled in India (Davar, 2013). This is not simply a change in language but a political position that states ‘we don’t have psychiatry and don’t want it’.

An Indonesian government programme, Aceh Free Pasung, intends to protect the human rights of people with severe mental illness by eliminating the practice of *pasung* from the province. *Pasung* means restraint by shackles, rope, wooden stocks and cages, and can cause death. Since the alternative was the building of a mental health hospital, the initiative has enabled access to free hospital treatment (Minas *et al*, 2011). Its replacement with neuroleptics, restraint and hospital confinement is nevertheless problematic.

Industrialised West

Decisions about coercion often hinge on the concept of risk. Recent evidence suggests that risk assessments exclude service users from the discussion and render invisible the fact that the assessments are more or less fictions in actuarial terms (Coffey *et al*, 2017).

How risk of harm within mental health settings is perceived and managed has received attention. However, harm in the context of restraint is mostly not recognised. Nonetheless, restraint-related deaths have been reported throughout the Western world, including in the UK, where 38 deaths have been recorded since 1988, 15 of people from Black and Minority Ethnic (BME) communities (Aiken *et al*, 2011). A qualitative study of in-patients showed that nurses and patients had very different accounts of both the determinants of and appropriate responses to violence and aggression (Rose *et al*, 2015).

Reviewing evidence of the effects of restraint, Cusack *et al* (2016) concluded that ‘restraint can be a form of abuse, its inappropriate use often being a consequence of fear, neglect and lack of using de-escalation techniques’.

A small pilot study by the National Survivor User Network (NSUN), as yet unpublished, surveyed 65 people about their experiences of restraint and recruited respondents mainly through the weekly e-bulletin. The findings align with Strout’s (2010) integrative review of the international qualitative literature on patient perspectives on the use of restraint. Strout identifies four categories: negative psychological impact, re-traumatisation, perceptions of unethical practices, and the broken spirit. Of the respondents surveyed in the NSUN study, 43% ($n = 28$) stated that their most recent experience of restraint had felt like an act of aggression ‘a great deal’, 12% ($n = 8$) ‘a lot’ and 15% ($n = 10$) ‘somewhat’. Although the number was small, all respondents from BME communities ($n = 5$) stated that their experience had felt like an act of aggression ‘a great deal’ or ‘a lot’. Respondents frequently cited the unnecessary use of physical force and the number of staff members who were involved in each incident of restraint. The most frequent reason for restraint given by respondents was the refusal to take medication, and physical restraint was routinely followed by a rapid tranquillising injection. This was often experienced as shaming and humiliating:

When I become agitated it is very obviously extreme fear and terror. On each occasion it is ALWAYS male staff pinning me down – always face down so [I] can’t breathe or move and who pull my underwear off/down to inject. They know the abuse history – it has been a police case. They never have talked to me afterwards. It is like being raped again.

One clear theme was the link between instances of physical restraint and tranquillisation with re-traumatisation. Consistent with studies of women’s experience of restraint representing an event that re-enacts the experience of trauma and sexual abuse, Gallop *et al* (1999) found that restraint and associated feelings of humiliation, punishment and powerlessness engendered traumatic emotional reactions such as fear, anxiety and rage.

Half of the respondents stated that experiencing physical restraint had affected their engagement with services ‘a great deal’. The majority reported a loss of trust in staff, and increased fear, suspicion and wariness. Others reported that they avoided services because of their experiences.

The Promise study (Wilson *et al.*, 2015), which informs the development of a proactive care framework to reduce the need for physical intervention, involved interviews with both staff and patients. The most dominant theme to emerge centred on staff–patient communication and relationships, with 11 patients and 19 staff members providing suggestions:

if you wish to reduce the number of restraints a high level of communication is needed whatever the issues of a particular patient, whatever their predisposition to violence or hatred of psychiatric staff, or factions within the resident group, or dislikes of a particular patient. In an ideal world there must be more verbal communication ... the culture is to encourage what Winston Churchill used to say was a 'jaw jaw rather than war war', to counsel and support a person onto a different state of thinking. (Wilson *et al.*, 2015)

Conclusion: minimising coercion and restraint

In the NSUN study, 94% ($n = 50$) of respondents reported that restraint could have been managed very differently, emphasising that if staff had taken the time to listen and to speak to them addressing fears, frustrations and concerns, the situation could have been avoided. Respondents said that staff needed better training and that service users should be involved in this.

No differences were found in the experiences of restraint occurring within the past 10 years compared with the past 2 years. Of the NSUN respondents, 40% ($n = 23$) reported incidents of restraint that occurred within the past 2 years, suggesting no recent improvement in experiences of restraint. These findings signal that the 2-year UK government programme 'Positive and Safe', launched in 2014 with the goal of reducing the need for physical restraint (Department of Health, 2014), has had no impact to date and that a fundamental culture change is needed. This directive was followed by an investigation involving the facedown restraint of a woman eight and a half months pregnant in July 2016 (*Mental Health Today*, 2016).

There are various arguments for reducing coercion and restraint and many different approaches that service users say they find more beneficial. Since 2007 the Mental Health Act in England has made it mandatory for advocacy to be practised by professionals alone, although the service user voice is not completely absent (Newbigging *et al.*, 2015). It will be important to regain and strengthen the user voice within peer and self-advocacy, as has happened in Africa (Kleintjes *et al.*, 2013).

Joint crisis plans or advance directives are counselled by many as a means of reducing incidents of restraint and of listening to the needs of service users (Papageorgiou *et al.*, 2002; Amering *et al.*, 2005). Approaches that include peer facilitators and improvements to the frequency and quality of communications are crucial. Some existing institutional systems make good communication a practical impossibility.

From the perspective of service users, coercion and restraint are mostly harmful and must stop being legitimised. There is an urgent need to challenge and address these practices as they represent gross human rights violations according to the stipulations of the CRPD. UK compliance with the legislation is due to be monitored in the next 2 years.

Conflict of interest. No authors have any conflicts of interest to declare.

1.6.69 Patient safety and quality of care in mental health: a world of its own?

Danielle D’Lima Mike J. Crawford Ara Darzi Stephanie Archer

Correspondence

Danielle D’Lima (d.d’lima@ucl.ac.uk)¹

date

2017-10

Abstract

Quality and safety in healthcare, as an academic discipline, has made significant progress over recent decades, and there is now an active and established community of researchers and practitioners. However, work has predominantly focused on physical health, despite broader controversy regarding the attention paid to, and significance attributed to, mental health. Work from both communities is required in order to ensure that quality and safety is actively embedded within mental health research and practice and that the academic discipline of quality and safety accurately represents the scientific knowledge that has been accumulated within the mental health community.

Contents

- *Patient safety and quality of care in mental health: a world of its own?*

With repeated examples of failure across the healthcare system,^{1,2} there has long been a need to understand how we can better uphold and improve on the quality and safety of care that is being provided to our patients. There is a gap between the policy and guidelines generated from research evidence and the practice of medical, nursing and allied health professionals. This gap is at risk of increasing, owing to an under-appreciation of heterogeneity in local context³⁻⁵ and the ever-growing demands on the healthcare system, with fewer resources provided to manage them. As a result, quality and safety in healthcare, a discipline which aims to integrate scientific understanding with applied practice, has made significant progress over recent decades and is now regarded as an active and established community of researchers and practitioners alongside the fields of improvement and implementation science.⁶⁻⁸

Such growth has been reflected in the establishment of discipline-specific journals. For example, the BMJ launched *BMJ Quality and Safety* in 1992, and in 2006 a journal devoted purely to implementation science was introduced – *Implementation Science*. The evolution of the discipline has also included the development and refinement of a number of methodological tools, such as Plan, Do, Study, Act (PDSA) cycles and Driver Diagrams, which draw on the manufacturing industry to support individuals in applying continuous quality improvement (CQI) principles in healthcare practice.⁹

Despite the growing international interest in quality and safety in healthcare, its application to a mental health context has not been explored.¹⁰ It cannot be assumed that findings based on physical health in acute care hospitals can be automatically applied to mental health. This is because of the different challenges presented by patients and settings in this specialised area of care, including a greater emphasis on community-based care, greater use of Mental Health Act legislation and increased risk of self-harm.¹⁰ Mental health in general has been viewed as a neglected area and one in which patients may be less likely to have a voice when it comes to their care and safety.¹¹ It has also been suggested that

the stigma surrounding mental health issues has the potential in itself to contribute to staff neglecting patient safety and quality of care.¹⁰ In order to deliver high-quality care to patients, it is essential that a firmer understanding of patient safety and quality of care in mental health is not only developed, but also disseminated appropriately to ensure that it has the greatest impact.

Key literature searches of high-profile quality and safety journals reveal that there is a lack of published literature under the umbrella term of mental health. For example, a high-level search conducted in *BMJ Quality and Safety* in July 2016 based on the search term 'mental health' appearing in the title or abstract returns just 56 hits across all archives. When restricted to 'mental health' appearing in the title only (and therefore indicating that it is the primary focus of the article), the search returns just 17 results. This is disappointing, especially when compared with similar searches on key search terms for other medical specialties, for example paediatrics (94 hits for title and abstract) and surgery (237 hits for title and abstract). These findings are also reflected in other notable quality and safety journals such as *Implementation Science* (30 hits for 'mental health' in a title-only search) and the *International Journal for Quality in Health Care* (15 hits for 'mental health' in a title-only search). We recognise that there are inherent challenges in these comparisons, including selection of terminology and disciplines; however, these searches are intended to be illustrative rather than exhaustive.

Even the small number of studies that are returned from these searches do not consistently focus on mental health as the primary setting of interest. Instead, mental health tends to form one component of a system-level study often associated with high-level quality improvement and quality of care structures in the healthcare system.¹²⁻¹⁴ In other instances, mental health is positioned as just one example or context alongside physical health settings and is therefore not the sole focus of the article or its key messages.¹⁵⁻¹⁷ Generally, the work being published in these quality and safety journals does not focus on aspects of safe care that may be of specific importance to a mental health setting or explore how established quality and safety metrics apply and translate to this unique context. However, searches do identify a systematic review on medication errors in mental health¹⁸ and some work around continuity of care and communication between in-patient and out-patient mental health settings, for example.¹⁹

Contrary to these findings, searches run across the broader medical and social science literature reveal that much has been published on the topic of quality and safety in mental health in other, more specialty-specific areas (e.g. psychiatric nursing journals). For example, academic teams in mental health led by Louis Appleby, Len Bowers and Joy Duxbury contributed a significant amount of work. Therefore, it seems that the issue is not necessarily a lack of work on quality and safety within a mental health context, but instead a lack of its representation as part of the stand-alone quality and safety discipline.

The specialty-specific literature succeeds at providing a significant amount of research into patient safety incidents that are more precisely related to a mental health setting. These include violence and aggression, patient victimisation, suicide and self-harm, seclusion and restraint, and absconding and missing patients.¹⁰ Other key areas that apply more broadly across all settings are falls and other patient accidents, adverse medication events and adverse diagnostic events such as misdiagnosis. This literature is not without its faults, however, as there is a tendency for it to focus on areas of safety that may be of greatest concern to the public rather than areas of quality that may contribute most to patient experience and clinical outcome effectiveness. It may also not be fully reflective of the vast developments that have been made in understanding quality and safety in healthcare more broadly.

There is a clear disparity between the two bodies of literature (i.e. work around mental health within the established quality and safety discipline and work around quality and safety of care within the broader and less defined mental health discipline). In recent years there has been a call for 'parity of esteem' between physical and mental health (i.e. recognition of mental health as an equally important discipline within medicine).^{20,21} The data that we have presented certainly suggest that there is no parity in the attention being paid to quality and safety, and this is an area that requires attention. The structure of the National Health Service (NHS) is guilty of fostering this separation, to some extent, through commissioning different organisations to provide physical and mental healthcare.²² However, Academic Health Science Networks are aiming to help break down historical barriers between acute care and mental health trusts.

Furthermore, the two bodies of literature appear to exist in silos and do not explicitly refer to or build on one another as a matter of course. Therefore, the core integration of the quality and safety discipline with the mental health setting is currently lacking and not fully reflective of the scientific understanding that has been incrementally built up via the specialty-specific journals. The opportunity has also been missed for the two bodies of work to effectively communicate, learn from each other's limitations and strengthen one another. For example, a more thorough integration could ensure

that quality and safety is explored across the board within the mental health setting in a way that is appropriately sensitive to the local context without being restrictive. This approach is likely to have the greatest direct benefit to mental health patients when such research translates into clinical practice.

It is important to discuss and reflect on the potential reasons for this disparity in order to understand how it might be rectified in the future. It is possible that academics focusing specifically on quality and safety as a research area (i.e. not wedded to any particular specialty) are not conducting a sufficient amount of research in a mental health context. Assuming that academics of this type are more likely to submit to quality and safety rather than specialty-specific journals, it is possible that the issue centres on a lack of work being completed in these settings by patient safety and quality improvement researchers.

A recent independent report into the quality of in-patient mental health services highlighted the need for further training and use of quality improvement in mental health services.²³ The Royal College of Psychiatrists also recognise this issue and have set up a working group to steer progress. The Institute for Healthcare Improvement (IHI) is working with a number of mental health trusts in the UK to build capacity and capability to implement quality improvement programming at scale. It is important to recognise the challenges in applying improvement science in different healthcare delivery models, targeting different health conditions that follow very different courses. For example, the challenge of adapting quality improvement methodology for long-term conditions (which is often the case in a mental health setting) as opposed to interventional healthcare where it is simpler to measure impact and change pre- and post-implementation.

We must also consider what drives authors to publish in specialty-specific rather than quality and safety journals. It may be the case that mental health professionals and academics are more motivated to do so. For example, they may have concerns about ensuring that their work has the greatest impact or be unaware of the alternative journals that are appropriate. If this is the case, then raising awareness across the scientific community will be vital for ensuring that authors submit their work to the most suitable outlet in terms of target audience and opportunities for translation. On a separate note, it is possible that work is already being submitted to quality and safety journals but is not being accepted. There may be factors around quality of work and acceptance processes that need to be considered. This could be due to differences in academic approach and levels of rigour across the disciplines.

These dilemmas have a number of potential implications for both research and practice, and recommendations for the future are required in order to increase and support integration between the two bodies of work. Both the quality and safety and mental health disciplines should be concerned by the clear disparities between their bodies of work. Existing in silos automatically forms a barrier to effective quality improvement and safer patient care. Mental health should form a core part of the quality and safety agenda and influence the ways in which it grows and develops as a discipline over time. The disparity may also prevent the academic expansion of the discipline as a science owing to a lack of incremental growth that is fully reflective of all relevant research on this complex topic area. It is also likely that the mental health community will miss out on full access to the knowledge that has been accumulated within the quality and safety discipline, which will therefore prevent optimal patient care.

Quality and safety journals should explicitly invite submissions from the mental health community in order to demonstrate their openness to work based in this setting. Simultaneously, mental health professionals and academics should be made aware of the different disciplines with which they could be integrating their work, and should not be penalised for publishing their work in quality and safety rather than specialty-specific journals. The long-term goal should be to normalise that quality and safety journals are a viable option for mental health professionals' academic work. This would involve incorporating and building on the present understanding of quality and safety that has already been developed more broadly, rather than scoping out a separate area of quality and safety that applies solely to the mental health setting. Patient safety and quality of care in mental health should not be existing in a world of its own but instead be a fully integrated component of the broader scientific discipline. It is the responsibility of members of both communities to ensure that this happens.

1.6.70 A Devil's dictionary for mental health

Abstract

Clinical psychiatry, for all its emphasis on scientific rigour, is mediated mainly by words rather than by numbers. As with other professional areas, it has developed its own set of jargon words and phrases. Many of these are not the technical terms traditionally seen as jargon, but standard English words and phrases used in an idiosyncratic way. They therefore go unnoticed as jargon, while enfeebling our communications. I have used the template of Ambrose Bierce's *The Devil's Dictionary* to highlight some examples, with the aim of helping us all to talk, write and, perhaps, think more clearly.

Contents

- *A Devil's dictionary for mental health*
 - *What is jargon?*
 - *My Devil's Dictionary*
 - *Casting out demons*

A review of health literacy suggests that patients often do not understand what doctors are trying to tell them – and, rather obviously, tells us that we should be more straightforward.¹ But it is not just us. The US boss of Pfizer has exasperated a British parliamentary committee with his obscure business jargon.² Farrington has highlighted the chasm between clinical and managerial language.³ Brian Lask pilloried the 'infestation' of family therapy publications with jargon, pomposity and impenetrability.⁴ And, although they were mainly addressing technical obfuscation, a pair of psychologists have trenchantly characterised much of the research communication in their field as 'bullshit'.⁵ They recommend translating 'others' procedures and outcomes in(to) ordinary language' to separate out any discernible content from the chaff of jargon.

But I am not here going to consider how we talk to patients or managers – or even researchers and academics. I have been thinking about how we talk to each other. It can be said that technical jargon does not matter inside a profession because each participant understands the words involved. It only becomes a problem when a professional tries to communicate with outsiders.⁶ But I think we may have a problem in day-to-day communication between those of us involved in mental health services. Over the past few years I have noticed the appearance of words and phrases which, because of their novelty and lack of definition, create real problems with communication. Many of these can be seen as 'weasel' words or phrases. They carry a covert meaning or overtones of meaning – or, sometimes, no meaning at all. They can be defined as 'something that someone says either to avoid answering a question clearly or to make someone believe something that is not true' (<http://dictionary.cambridge.org/dictionary/english/weasel-words>). Some are more technical, but all can be seen as forms of jargon owing to their characteristic use in medicine and psychiatry.

What is jargon?

But what is jargon? The current version of the online Oxford Dictionary defines it as ‘Special words or expressions used by a profession or group that are difficult for others to understand’. It also tells us that it been with us for nearly 400 years, being derived from Late Middle English, originally in the sense of ‘twittering, chattering’, later ‘gibberish’ (www.oxforddictionaries.com/definition/english/jargon). Earlier dictionaries are more robust: ‘Barbarous or debased language: gibberish: speech full of technical terms etc’.⁷ Synonyms include slang, cant, idiom, argot, patter and gobbledegook (www.thesaurus.com/browse/jargon). Nobody much likes jargon, even though we all seem driven to use it.

At first hearing, such language may not sound at all technical. The words or phrases are drawn from day-to-day English, but, as we use them, their meaning starts to dissolve. They become the aforementioned weasel words because they are either novel or of broad, inclusive meaning. Those inside a profession find that they can use such language in an idiosyncratic way to preserve professional authority and power.⁸ If you cannot understand a discussion, you cannot participate. The young may feel that they have to use this language to be an authentic part of professional life. The old, consciously or unconsciously, realise that it can be used to conceal, confuse, stonewall and neuter objections or criticism. Moreover, jargon is mostly categorical and conceptual, not concrete and specific. It can present an intimidating facade behind which, if one takes the trouble to look, there is little of substance. Although unsavoury, is it not a victimless crime? Not according to the House of Commons Public Administration Select Committee. They felt that ‘the use of inaccurate, confusing or misleading official language which results in tangible harm, such as preventing individuals from receiving benefits or public services, should be regarded as maladministration’ (p. 16).⁶ Perhaps, then, we should take this issue more seriously.

One might, in an uncharitable moment, single out managers as the main offenders. However, I have heard colleagues from our sister professions talking impenetrably, as well as my fellow psychiatrists and, regrettably, myself. We are all guilty. So, I decided to round up some words and phrases that seem, to me, to be misused in this way. Some of these are specific to psychiatry and mental health, some are used across medicine. Some remain a local coinage, others have attained a more universal currency. We hear some in the front line, in wards and community teams, and others in committee rooms and consultation papers. Ambrose Bierce was a 19th-century journalist who was similarly intrigued by the ways in which language can be misused. I have used the template of his *The Devil’s Dictionary*⁹ to produce my own, somewhat scattershot, rogue’s gallery.

My Devil’s Dictionary

Acting out: an analytical term provoked by extravagant behaviour. Example: ‘the patient acted out by shouting in the lounge’. We are thereby relieved from the burden of considering the matter further.

Adherence (to medication, advice, etc.): a delusion, held by all doctors, most strongly by enthusiastic pharmacologists. For us, a mainstay of treatment. For our patients, an irritation best neglected. They are reluctant to reveal their disinterest, not wishing to distress their psychiatrist.

Acuity: a snappy euphemism which removes to arms-length the stress and risk of our under-resourced and risky services. Essential to reduce the anxiety felt in higher echelons of management.

Behavioural: a term used by those of us with no behavioural training, to describe behaviour of which we disapprove (*see* ‘Acting out’). Commonly combined with ‘just’ – ‘It’s just behavioural’. Usually paired with the helpful conclusion: ‘he/she is not for our service’.

Best evidence: the cracked and misty lens with which the one-eyed man navigates the country of the blind.

Care pathway: a sequence of ideal interventions (*see* ‘Best evidence’) for a model patient. Lengthy and complicated, so best illustrated on a sheet of A3 paper. The dogged patient may be said to trudge, march or run the gauntlet on such a trek.

Challenge: the presentation of the impossible and implausible as a bold plan. Example: the NHS Challenge – save £20 billion in the next 3 years while improving quality. You can then, subsequent to the inevitable failure of the plan, pillory those involved as being old-fashioned, inflexible, not trying hard enough ... according to taste.

Clinician: a drone, a harmless drudge who sees patients. They can apparently perform audit, supervision and research simultaneously (*see* ‘Job description’). Their ability to be in two places at once (*see* ‘Job description’) suggests that they would have been burned as witches in less scrupulously rational times.

Consultation: the practice of gathering views about a proposed change in a service. To complain that such views are subsequently ignored would be both harsh and naive (*see* ‘Listening event’ and ‘Efficiency saving’).

Cover: an illusion of doubles. It suggests that an overworked colleague will also do your work in your absence. Essential to maintain the appearance of an adequately staffed service.

Cut: the Voldemort word that must never, ever, be uttered (*see* ‘Efficiency saving’). Sometimes linked with ‘Transformation’.

Distress: a catch-all for every experience from mild anxiety to raging psychosis. As one gently minimises the more extreme and intractable varieties of experience, one can slyly insinuate that psychiatry is just a way to medicalise normal experience.

Efficiency saving: as the wolf to Red Riding Hood’s grandmother. Cloaked in two benign words with which none can take issue, it stalks our services – and suddenly they disappear. *See also* ‘Challenge’ and ‘Cut’.

Evidence: the single academic paper that supports one’s proposed course of action.

Holistic: a synonym for comprehensive, originating from the word ‘whole’. But where did the ‘W’ go? The spelling generates a spurious overtone of spirituality. Clearly not intentional; evidence of unconscious processes at work.

Hypothesis: a simple idea that leaves port to the sound of marching bands, but then founders on the rocks of bureaucracy or upon the craggy island of sober reflection.

Integration: the unicorn of service provision. Often spoken of but rarely seen. Some say they have seen it in Birmingham. Others say it is a mirage, glimpsed by the desperate.

Innovation: a novelty that attracts money.

Inappropriate (behaviour): rational behaviour of which we disapprove. Studiously neutral, it is commonly used in close proximity to an emphatic font. Example: ‘patients must *not* use our accident and emergency department inappropriately’.

Job description: a work of fantasy that masquerades as a workaday agenda. As nectar to the bee, it attracts naive applicants to your service while obscuring the inquisitive gaze of our College. Any subsequent disaffection can be met with the phrase ‘caveat emptor’.

Just: an excellent way to deny complexity. One can avoid the trouble of biopsychosocial formulation without admitting to idleness, ignorance or indifference. Example: ‘It’s just... behavioural/social/drug-induced...’.

Liaison: the assurance that someone will, at some time, communicate something to someone. Example: ‘Community mental health team to liaise with primary care’. A common parasite of care plans and strategy documents. The phrase ‘liaison psychiatry’ can be honourably exempted.

Listening event: a talking shop.

Metric: a swaggering and self-confident synonym for ‘number’, ‘figure’ or ‘statistic’. It ballasts with false weight the inadequate and corrupted data that leak out of our struggling services.

Medical model: a synonym for the crudely biological. Essential if one has a sketchy acquaintance with medicine but a sincere desire to damn psychiatry. Best bolstered by a quote from an antique textbook which few have ever read – or even heard of.

Mission statement: a haiku of the obvious. A way for those remote from the front line to sincerely avow the commitments of an organisation. Only misfits and malcontents could assert that such statements are banal and platitudinous.

New ways of working: the promise that clinical drones (see above) can become queen bees. The admirable and novel element is that psychiatrists should, as far as possible, steer well clear of patients.

Ongoing: a way to communicate to the naive reader an impression of dogged and ceaseless activity.

Paradigm shift: a bit of a change. It proclaims how different (and how much better) your pet idea (*see* ‘Hypothesis’) is from everything that has gone before. Such shifts promise seismic change but most, mysteriously, register zero on the Richter scale of life.

Prioritisation: cutting one service to provide another. One service dies and another is born. Disney’s circle of life.

Quality indicator: an easily measurable irrelevance.

Quality improvement: an unarguable good. It marvellously exempts management from any responsibility for the lack of armaments or ammunition and ‘empowers’ frontline platoons to sort out the subsequent carnage.

Research: the selection of an unrepresentative group of people, the provision of an unsustainable intervention and the careful selection of a rating cut-off point to show your intervention to its best advantage.

Recovery: a two-edged sword. To Tweedledum, an essential reorientation of services to patient priorities. To Tweedledee, a pretext for culling rehabilitation services.

Reconfiguration: another attempt to rearrange the chairs on the deck of the Titanic (*see* ‘Transformation’).

Significance (statistical) (*see also* ‘Research’): a simple number that lends colossal weight to negligible differences.

Signposting: a respectable way to rebuff those seeking help from our service. We direct the patient towards another step on their therapeutic pilgrimage (*see* ‘Care pathway’), braced by the pious assurance that another will meet their need. Much loved by hard-pressed commissioners for whom distance from our services is by far the best medicine.

Target: a worthy aim, applauded by all. The resources marshalled to meet it hyperperfuse privileged parts of the organisation but induce gangrene and necrosis elsewhere.

Triage: a battlefield technique to sift the doomed from the salvageable. Applied to civilians in peacetime when the money runs out.

Transformation: an ‘abracadabra’ word, the promise to turn an ugly duckling into a swan. This powerful spell can reduce resistance to modish technology or to shedding staff. Memories mysteriously fail when the new swan proves to be just another maladroit fowl.

Vision(s): in a patient, evidence of brain dysfunction. In ourselves, evidence of foresight, imagination and understanding.

Work-life balance (*see* ‘Job description’): an excellent way to communicate an uncomfortable truth. Example: ‘We know you need to work X+1 sessions to do the job, but we will only pay you for X sessions’. Dissimulation is charmingly paired with an expression of concern for one’s welfare.

Casting out demons

The American edition of the online Oxford Dictionary, somewhat uncharitably, states that weasel words are ‘intentionally ambiguous or misleading’.⁷ I am less judgemental and would suggest that they have a less deceitful function. They help us to feel more at ease with difficult truths we have both to confront ourselves and to present to others. However, although we may feel more comfortable, we will not be communicating as well as we could – and not thinking as clearly as we should. I would not go as far as the Local Government Association which was widely reported to have published, for its members, a list of banned words and phrases.¹⁰ After all, context is everything and, in spite of my accusations, some of these words may be used quite helpfully from time to time. But an awareness of them can serve us as the canary once served the coal miner: as a sign that something may not be quite right, and that we need to keep our wits about us. To the charge that I am a cynic, I confess that I do not have the stomach for it. I still shrink from the uncomfortable and cling to desperate and unreasonable hopes. I have been unable to yet become that paragon described inimitably by Bierce⁹ (p. 34) as ‘A blackguard whose faulty vision sees things as they are, not as they ought to be’.

This list is not comprehensive and is certainly not static. New weasel words will emerge as others wither and perish. Each of us can identify our own offenders. To pay attention to how we talk (and write) is not self-indulgent. It can help us to think more clearly, to communicate more meaningfully and to engage with reality rather than self-serving fantasy.

1.6.71 Personality disorder services in England: findings from a national survey

Abstract

Aims and method We aimed to evaluate the availability and nature of services for people affected by personality disorder in England by conducting a survey of English National Health Service (NHS) mental health trusts and independent organisations.

Results In England, 84% of organisations reported having at least one dedicated personality disorder service. This represents a fivefold increase compared with a 2002 survey. However, only 55% of organisations reported that patients had equal access across localities to these dedicated services. Dedicated services commonly had good levels of service use and carer involvement, and engagement in education, research and training. However, a wider multidisciplinary team and a greater number of biopsychosocial interventions were available through generic services.

Clinical implications There has been a substantial increase in service provision for people affected by personality disorder, but continued variability in the availability of services is apparent and it remains unclear whether quality of care has improved.

Personality disorder is a serious mental health condition affecting up to 52% of psychiatric out-patients and 70% of in-patients and forensic patients.¹⁻⁴ Given the significant public health implications associated with the disorder – including extensive use of healthcare resources, high rates of suicide and reduced life expectancy – effective treatment is a priority.⁵⁻⁸

In 2003, the National Institute for Mental Health England (NIMHE) published *Personality Disorder: No Longer a Diagnosis of Exclusion*, challenging the healthcare community to address shortcomings in the treatment of people with personality disorders.⁹ Citing a survey of English mental health trusts conducted in 2002, the paper brought to attention the variability in practice and highlighted institutionalised stigmatisation which explicitly barred patients with personality disorder from mainstream services. At that time, only 17% of trusts had a dedicated personality disorder service, 40% provided some level of service, 28% had no identified service, and 25% did not respond.⁹

The 2003 NIMHE publication⁹ set out broad principles for how personality disorder services should be developed, stipulating that they should be multidisciplinary, follow a hub-and-spoke model, accept the management of risk, use the care programme approach (CPA),¹⁰ offer specialist biopsychosocial interventions, deliver training and consultation, and support the development of patient networks. Similarly, the 2009 guidance on borderline personality disorder from the National Institute for Health and Care Excellence (NICE) specified that mental health trusts should develop specialist multidisciplinary teams and/or services for people with personality disorders.^{11,12} In 2011, a preliminary investigation at a regional level found that specialist service capacity for those with personality disorder was inadequate.¹³ There have been no systematic attempts at a national scale aimed at understanding how the evidence for the management of personality disorder is being applied or whether service availability has become more uniform.

In 2014, the National Personality Disorder Service Review Group was formed to evaluate the extent to which variable service availability affects those with personality disorder. The group used the vision of *Personality Disorder: No Longer a Diagnosis of Exclusion* as its benchmark. Through this lens, we sought to map the availability and nature of dedicated personality disorder services, and to compare these to the care for clients with personality disorder available through generic services. The group drew on a wide range of evidence to define the concept of a ‘dedicated personality disorder service’. This included the Delphi study of the 11 pilot personality disorder projects within the National Personality Disorder Programme.¹⁴ We considered a dedicated service as one which is explicitly designed to manage the care of individuals affected by personality disorder, as opposed to a generic service which might be considered a typical community mental health service. *Table 1* displays the characteristics hypothesised by the group to distinguish dedicated from generic services.

Summary of service characteristics

Dedicated personality disorder services	Generic services
Personality disorder inclusion	No diagnostic inclusion/exclusion criteria
Variable service availability	Ubiquitous
Personality disorder-specific interventions	Offer range of biopsychosocial interventions
Specialist team	Mainstream multidisciplinary team
Local, regional and national catchment	Local catchment
Variable tiers (T1 to T6)	Locally focused tiers (T2 to T3)
Target complexity	Range of complexity
Treatment, consultation and training	Treatment orientation
Variable framework (includes CPA)	Operate under CPA framework

CPA, care programme approach.

Aims

The primary aim of this study was to describe a number of organisations which provided care for those affected by personality disorder and whether this care was delivered through dedicated personality disorder services, generic services or both.

The secondary aim was to evaluate the provision of services for personality disorder along key quality indicators outlined by NICE and NIMHE,^{9,11,12} and explore any differences between dedicated and generic services. The quality indicators evaluated were: Is there a multidisciplinary team available? Is care managed under the CPA process? Are patients offered specific interventions for personality disorder within a biopsychosocial approach? Are services involved in education, training and research? What level of patient and carer involvement do services employ? What exclusion criteria, if any, are applied by services?

Method

Survey design

We conducted a cross-sectional survey of mental health organisations in England using a questionnaire designed for this study. Data were collected between January and June 2015 using an online survey tool (www.surveymonkey.com).

Sample

The sample included any English mental health National Health Service (NHS) trust or independent provider of mental healthcare to adults or young people. In 2015 there were 57 relevant English mental health NHS trusts and 10 independent service providers, all of whom were approached to participate in the survey.

Procedure

Letters were sent to the medical directors of each NHS mental health trust and the CEOs of the independent providers informing them of the survey and requesting the name of the individual who they considered to have the requisite knowledge to complete the survey. Once details of these individuals were obtained, letters were sent inviting them to take part. Non-responders were followed up at least twice where necessary, offering further information or support to complete the survey questionnaire.

Survey questionnaire

Following an analysis of available literature, the electronic survey was structured to address the primary and secondary aims of the project. Participants were asked to briefly describe their organisation (e.g. NHS or independent provider, geographical remit) and their own professional role. They were then given a brief definition of a dedicated personality disorder service and of a generic service and asked to indicate whether their organisation had services of each type and detailed questions about its characteristics. We requested details of a maximum of five dedicated personality disorder services per organisation.

Questions relating to service characteristics included service leadership, team make-up, service access, inclusion and exclusion criteria, care management framework, intervention availability, patient and carer involvement, and training, education and research activity. The survey took up to 45 minutes to complete and could be conducted electronically or with telephone support.

Data analysis

Data were downloaded from Survey Monkey and entered initially into Excel for checking and data cleaning, and transferred to STATA (version 11) for statistical analysis. To address the primary aim of the survey, the characteristics of services were summarised descriptively in order to build a picture of service availability and characteristics. The availability of biopsychosocial interventions was assessed by generating a score ranging from 0 to 100 based on the number of available interventions of each type, weighted to give equal consideration to each of the three domains. The availability of personality disorder-specific interventions was assessed by determining whether services offered psychological therapies developed specifically for personality disorder.¹⁵ The level of perceived patient and carer involvement was similarly analysed and scored from 0 to 100 based on the number of involvement activities for each service, with paid involvement double weighted.

To address the secondary aims of the survey, logistic and linear regression was used to evaluate the effect of service type (dedicated or generic) on professional diversity, exclusion criteria, CPA usage, biopsychosocial provision, patient and carer involvement, and training, education and research activity. Multilevel models, with a random effect for organisation, were used to adjust for the potential higher similarity between services within the same organisation than between services from different organisations. Robust standard errors were used for linear variables that did not conform to a normal distribution. Where significant differences between dedicated and generic services were found, multivariate models were used to adjust for the influence of potentially confounding service characteristics.

Results

Respondents

Of the 57 relevant English mental health NHS trusts, 52 responded (response rate 91%) and of the 10 independent service providers approached 4 responded (response rate 40%).

Primary study aim: availability of services for people with personality disorder

Of the 56 organisations that responded to the survey, 47 (84%) reported having at least one dedicated personality disorder service and 43 (77%) reported having both generic and dedicated services. The remaining 4 organisations (7%) stated that they did not have any generic services and that all services were specialist; all offered dedicated personality disorder services. Nine organisations (16%) did not have any dedicated personality disorder services, and all of these stated that their generic services catered to personality disorder. Patients were reported to have equal access to dedicated personality disorder services in 31 (55%) of the organisations surveyed.

The number of dedicated personality disorder services per organisation ranged from 1 to 5 (mean 1.7, s.d. = 1.1). Across the 52 English mental health NHS trusts, 71 dedicated personality disorder services and 48 generic services were described, a mean of 1.37 dedicated service per organisation (range 0–5). The four independent service providers described ten dedicated personality disorder services; a mean of 2.50 dedicated service per organisation (range 1–5). *Figure 1* compares the findings with the survey of 2002. To aid comparison, the independent sector organisations have been removed from the 2015 results so that only English NHS mental health trusts are referred to. Tables 2, 3, 4, 5 and 6 summarise the characteristics of the dedicated and generic services across all domains surveyed.

Secondary study aims: quality indicators of available services

1. Is there a multidisciplinary team available?

Across services, teams varied widely in their multi-disciplinary composition (*Table 2*). Within services, team make-up was significantly less diverse in dedicated than in generic services, with the latter utilising almost twice as many different types of professional on average (dedicated personality disorder services mean 5.7, s.d. = 3.0; generic services mean 10.5, s.d. = 5.1 ($= 4.85$, 95% CI 6.37 to 3.32, $P < 0.01$)). Dedicated services remained less professionally diverse than generic services after adjusting for the range of biopsychosocial interventions available, the provision of personality disorder-specific interventions, and the profession of the service lead ($= 3.14$, 95% CI 4.46 to 1.82, $P < 0.01$). This suggests that the less diverse workforce in dedicated services was not simply due to providing a more focused range of interventions.

2. Is care managed under the CPA process?

Almost all services used the CPA as their management framework. There was no difference between dedicated and generic services in CPA usage (odds ratio (OR) = 0.22, 95% CI 0.04 to 1.47, $P = 0.12$).

3. Are patients offered specific interventions for personality disorder within a biopsychosocial approach?

Across services, there was a fairly wide availability of a number of different biological, psychological and social interventions. *Table 3* includes the mean biopsychosocial ratings stratified by service type. Generic services had significantly higher biopsychosocial ratings than dedicated ones, indicating a greater availability and diversity of interventions ($= 3.02$, 95% CI 2.32 to 3.73, $P < 0.01$). However, services led by medics offered a greater range of interventions than those led by other professionals ($= 1.09$, 95% CI 0.97 to 2.84, $P < 0.01$), as did services with a more diverse professional make-up ($= 0.38$, 95% CI 0.32 to 0.45, $P < 0.01$). Biopsychosocial intervention provision did not differ between dedicated and generic services after adjusting for these factors ($= 0.69$, 95% CI 0.29 to 1.68, $P = 0.17$). Contrary to hypothesis, the availability of interventions developed specifically for personality disorder (such as dialectical behaviour therapy (DBT), mentalisation-based therapy (MBT), schema-focused therapy (SFT) and systems training for emotional predictability and problem solving (STEPPS)) did not differ significantly between dedicated and generic services (OR = 0.91, 95% CI 0.37 to 2.21, $P = 0.83$).

4. Are services involved in education, training and research?

Most services were involved in at least one of these activities (*Table 4*). The rates of participation in these activities for dedicated services were approximately twice those of generic services, and dedicated services were significantly more likely than generic services to be involved in all three of these activities (i.e. education, training and research) (OR = 6.18, 95% CI 2.29 to 16.69, $P < 0.01$). This difference remained significant after adjusting for the profession of the service lead and for the professional diversity of the team (OR = 31.67, 95% CI 4.26 to 235.5, $P < 0.01$).

5. What level of patient and carer involvement do services employ?

Table 5 contains the mean patient and carer ratings stratified by service type. Very few services had no patient or carer involvement, and the odds of having any involvement activity did not differ between dedicated and generic services (OR = 1.17, 95% CI 0.42 to 3.22, $P = 0.77$). However, dedicated services had significantly higher patient and carer involvement ratings than generic ones, indicating involvement in a greater number of service development, care planning, service delivery, training and leadership activities (= 6.29, 95% CI 3.03 to 9.55, $P < 0.01$). This difference remained significant after adjusting for the profession of the service lead and for the professional diversity of the team (= 9.76, 95% CI 3.90 to 15.62, $P < 0.01$).

6. What exclusion criteria, if any, are applied by services?

No services excluded individuals on the basis of a diagnosis of personality disorder. Across both dedicated and generic services, the most common exclusion criterion was uncontrolled substance misuse, followed by active risk to others (*Table 6*). Almost half of services (43%) had no exclusion criteria. Dedicated services were significantly more likely than generic ones to have exclusion criteria (OR = 10.95, 95% CI 3.31 to 36.19, $P < 0.01$). This difference remained significant after adjusting for the profession of the service lead and for the professional diversity of the team (OR = 5.02, 95% CI 1.24 to 20.35, $P = 0.02$).

Discussion

This national survey was the first of its kind and captured data provided by 56 relevant mental health organisations in England. With a response rate of 91% for English mental health NHS trusts, and a sample of independent service providers, we can be confident the survey is representative of personality disorder provision in England.

The majority of organisations described both dedicated personality disorder services (84%) and generic services (91%), and in organisations with no dedicated services all provision for personality disorder was through a generic service. This quantifies the progress made in this area since 2002 and points to a fivefold increase in organisations providing dedicated personality disorder services.⁹

This represents substantial progress in a decade in which the economic landscape has been challenging. Yet, while on this measure we can see substantial progress at an organisational level, the survey indicates a worrying level of variability at a local level, with only 55% ($n = 31$) of organisations indicating equal access to the dedicated services they provide.

The 2003 NIMHE publication formally introduced the concept of dedicated personality disorder service as distinguished from generic service, and this distinction has been further developed in the current paper.⁹ We had *a priori* assumptions about the nature of dedicated and generic services (*Table 1*), and this survey allows a more detailed conceptual analysis. The survey methodology steered respondents to consider the concept of dedicated *v.* generic services. Analysis of the descriptive and statistical differences between the 81 dedicated and 51 generic services allows us to draw some conclusions about these two types of service provision. For instance, we found that generic services draw from a wide range of professional disciplines, which is in line with their broader remit. Seemingly, dedicated services draw from a more restricted range of professional disciplines; this supports the notion that they are specialist, niche services.

Contrary to our *a priori* hypothesis, dedicated services were no more likely to provide personality disorder-specific interventions when compared with generic services. Furthermore, generic services provide a significantly wider range of biopsychosocial interventions than dedicated ones, although there was some suggestion that this was influenced by their employment of a significantly more diverse workforce and by their higher rates of medical professional leadership. The accessibility of these interventions and the quality of their delivery are unknown; however, NICE guidance stipulates that specialist interventions are best delivered by specialist services.¹¹

The delivery of developmental activities is a clear priority for dedicated services, with almost all involved in training, and significantly more dedicated than generic services involved, indicating that they deliver both training and education and research. This is in keeping with both the 2003 NIMHE publication and NICE guidance.^{9,11,12} Patient and carer involvement is also prioritised by dedicated services, with patients and carers involved in significantly more service development, management and delivery activities than those in generic services. Dedicated services appear to show greater selectivity in patient choice than generic ones, as significantly more operate with exclusion criteria. Given that impulsivity is a diagnostic criterion for borderline and dissocial personality disorder, it is noteworthy that active risk to others (23%) and substance misuse (53%) were so widely quoted as exclusion criteria for dedicated personality disorder services.

Limitations

The response rate for the independent providers should be treated with caution as it is subject to selection bias. Responses were self-reported and there may have been variation in the interpretation of what constituted a dedicated personality disorder service.

In the comparisons made with generic services, the respondents were asked to provide an overview of all of the generic services within their organisation. Although this was pragmatically necessary, given the large numbers of generic services within any organisation, this approach requires the reader to consider the comparisons with appropriate caution. In particular, the findings which relate to the personality disorder-specific interventions and range of staff within the multidisciplinary team will be skewed by this methodology.

While this survey is able to give a good organisational-level description of service availability, mapping the local provision is achieved to a limited degree. Perhaps the most important consideration is that the indicators used in this survey to consider the quality can only provide a broad brush-stroke indication, owing to necessary methodological trade-offs for pragmatic purposes.

Understanding the consistency with which individual patients and carers can expect adherence to best practice and the timeliness of the interventions offered is beyond the scope of this survey. We believe this body of work begins to elucidate the questions which need to be considered, but it is a long way from achieving that. Indeed, the largest limitation of this work is that at best it provides a broad overview of provision. To properly understand what is actually delivered to those in need will require a more systematic and sustained effort to describe quality standards and ensure, perhaps through accreditation, that best practice is being followed.

Further developments

This paper charts the most systematic attempt to date at mapping the provision of care across England for those affected by personality disorder. What is clear is that the past decade or so has seen considerable progress in providing a service for this range of disorders. Despite this progress, data presented here provide evidence that there remains continued exclusion, variability of practice and inconsistencies in the availability of services.

The current NICE guidance, in step with the evidence base, supports the provision of a range of cost-effective interventions and the establishment of specialist services from which to deliver them. The initial offering presented here lends weight to the call for the establishment of authoritative commissioning guidance and service standards to ensure that patients and carers have access to the care that they need.

The National Personality Disorder Service Review Group work stream was seeded by a small project funding initiative through the Royal College of Psychiatrists' Faculty of General Adult Psychiatry in 2014 and West London Mental

Health Trust Research and Development. A multidisciplinary group was formed with representations from psychiatry, psychology, psychotherapy and expertise through lived experience of personality disorder. At various stages through the project the affiliates included: the Faculty of General Adult Psychiatry, West London Mental Health Trust Research and Development, Informed Thinking, The Medway Engagement Group and Network (MEGAN) and the Imperial College Centre for Mental Health. The project was granted approval as a service evaluation through the audit department of West London Mental Health Trust.

1.6.72 Perceptions and knowledge of antipsychotics among mental health professionals and patients

Abstract

Aims and method To assess the patients' most influential concerns regarding long-acting injectable antipsychotics (LAIs) and mental health professionals' preconceptions about these concerns. For both groups, to assess the level of knowledge about LAIs. This cross-sectional study used semi-structured interviews of patients with schizophrenia or schizoaffective disorder ($n = 164$), nurses ($n = 43$) and physicians ($n = 20$).

Results The mental health professionals overestimated many of the patients' fears of LAIs, and the expressed fears exceeded the actual experiences of patients already on LAIs. Acceptance to switch to LAIs was associated with shorter time from diagnosis. Nurses and patients disclosed limited knowledge of antipsychotics.

Clinical implications Physicians and nurses should aim to identify the individual patient's concerns about LAIs in the discussion about choice of antipsychotic treatment early in the course of illness.

Adherence to antipsychotic treatment is a major challenge and an important predictor of the outcome in patients with schizophrenia and schizoaffective disorder.¹ The risks of relapse and admission to hospital increase immediately after discontinuation, even with small treatment gaps.^{2–5} With oral antipsychotics, such gaps often go undetected until relapse – an issue that can be overcome by use of long-acting injectable antipsychotics (LAIs).⁵ There is growing evidence that, compared with oral treatment, LAIs reduce the risk of discontinuation, relapse and hospital admission.⁶ Furthermore, owing to superior pharmacokinetics, the use of LAIs is considered to increase the likelihood of finding the lowest effective dose, which subsequently reduces the risk of side-effects.^{7,8}

Despite the identified advantages, LAIs are not used as widely as might be expected. The prescription frequency varies greatly between countries,⁹ indicating that factors other than the patient's attitude influence the utilisation rate. While patients' attitudes towards LAIs become more positive with increased knowledge and experience of the treatment,¹⁰ clinicians often overestimate patients' resistance against LAIs, anticipating that they will be concerned about the injection procedure.^{10–12} This impedes so-called shared decision-making, an approach with the potential to increase adherence.¹³ Patients are frequently excluded from the discussion about the choice of antipsychotic formulation,¹⁴ and one reason may be resistance arising from mental health professionals' preconceptions.

We aimed to investigate the specific concerns that affect patients' perceptions of LAIs, and to what extent mental health professionals' preconceptions agree with these perceptions. Furthermore, we aimed to identify knowledge gaps about antipsychotic formulations among both patients and mental health professionals.

Method

Design

We conducted a cross-sectional study of mental health professionals' and patients' perceptions and knowledge regarding antipsychotic treatment in a psychiatry catchment area in Stockholm, Sweden, operated by PRIMA Adult Psychiatry. Data were collected in semi-structured interviews performed by a research nurse (L.C.) at the participant's home clinic between January and October 2015. The participants were enrolled upon giving written informed consent. The study was approved by the regional ethical review board in Stockholm (ref. 2015/47-31).

Participants and setting

We studied three categories of participants: (a) patients on LAIs; (b) patients on oral treatment; (c) mental health professionals, including physicians and nurses.

We identified all patients with schizophrenia or schizoaffective disorder. Patients with no medical treatment or with previous but discontinued LAIs, as well as patients who had been on LAIs >5 years were excluded. Other exclusion criteria were language barriers (i.e. need of interpreter in consultations), cognitive impairment and severe autism spectrum disorders. We collected information on patients' age, gender, years with diagnosis, marital status, number of children, highest achieved academic degree and occupation. The patients on oral medication were block randomised on diagnosis (schizophrenia/schizoaffective disorder), gender and age to two separate arms. The first group was included in this study to represent those on oral medication, while the second group did not participate and will act as controls in a future intervention study.

All physicians and nurses working in the psychosis sector of PRIMA were asked to participate. We recorded age, gender and extent of experience within the psychiatric field.

Questionnaires

We conducted semi-structured interviews based on different questionnaires specific to each participant category and designed for the present study. Participants graded their potential concerns with a mark on a continuous 100 mm scale ranging from 0 ('Does not affect at all') to 100 ('Decisive to decline LAIs'). Potential concerns included in the questionnaire were pain at administration, possible observation time of 3h, embarrassment at administration, restricted autonomy, feeling of being controlled, being obliged to show up at the clinic regularly, lack of ability to decide when medication is administered, and stigmatisation. The questions were designed to address the participant appropriately, for example, mental health professionals: 'To what extent do you think fear of pain affects the patients' perception?'; patients on oral medication: 'To what extent does fear of pain affect your perception?'; and patients on LAIs: 'To what extent does pain affect your perception?'. The investigated concerns were predefined based on a literature review and clinical experience.^{10,15,16}

Questions about knowledge of the differences between LAIs and oral treatment regarding achieved plasma concentration, side-effects and risk of readmission to hospital were identical for all participants and included pre-specified nominal options. In questions regarding clinical approach among mental health professionals, participants were asked to state items freely. Physicians stated their most common reasons for prescribing LAIs, and their strategies to encourage patients to consider LAIs. Furthermore, they were asked to speculate what the patients' key reasons for accepting LAIs are. These answers were assessed using thematic analysis after the study was complete.

Nurses were asked whether they tried to influence patients' and physicians' choice of formulation (yes/no). Patients on oral medication were asked whether they had previously been offered LAIs and whether they knew of the features of being on LAIs. Finally, at the end of the interview, all patients were asked about their perspective on switching formulation (positive/negative).

Statistical analysis

Anonymised data were analysed using Prism 5.03 for Windows. Sample comparisons were made using Fisher's exact test for categorical variables (gender, positive/negative towards switching to LAI). The Mann-Whitney [*U*-test or Wilcoxon matched-pairs test was used for continuous variables (age, illness duration, mental health professionals' experience and questionnaire responses on a 100 mm scale), where appropriate.

Results

Inclusion and exclusion of study participants

We identified 875 patients in the catchment area with a diagnosis of either schizophrenia or schizoaffective disorder; 341 patients were currently being treated with LAIs (39%). Of the 875 patients, 302 met our inclusion criteria. Finally, 101 patients on oral treatment and 63 on LAIs participated in the study. The reasons for not participating are presented in *Fig. 1*. All 21 physicians and 46 nurses working in the psychosis sector of PRIMA were asked to participate; 1 physician and 3 nurses declined owing to lack of time.

Participant characteristics

There were no statistical differences regarding characteristics between patients on LAIs and patients on oral medication, except that patients on oral medication were more likely to have achieved a higher academic degree (*Table 1*). The median age of the 20 physicians was 47 years (range 34–69) and 45% were women. The median number of completed years in the psychiatric field was 6.5 years (range 0–20). The 43 nurses had a median age of 51 years (range 27–67) and 81% were women. The median length of experience in the psychiatric field was 12 years (range 0–36), and 51% were specialists in psychiatric care.

Characteristics of interviewed patients

Characteristics	Patients on oral treatment (<i>n</i> = 101)	Patients on LAIs (<i>n</i> = 63)	<i>P</i>
Females, <i>n</i> (%)	46 (46)	26 (41)	n.s.
Age, years: median (range)	50 (21–84)	51 (24–74)	n.s.
Diagnosis, <i>n</i> (%)			
Schizophrenia	71 (70)	41 (65)	n.s.
Schizoaffective disorder	30 (30)	22 (35)	n.s.
Duration of illness, years: median (range)	21 (1–55)	18 (1–45)	n.s.
Highest education, <i>n</i> (%)			
Elementary school	21 (21)	24 (38)	0.020
High school	49 (49)	31 (49)	n.s.

Underage children living at home, <i>n</i> (%)	8 (8)	3 (5)	n.s.

LAIs, long-acting injectable antipsychotics; n.s., not significant.

Perceptions of LAI antipsychotics

Comparing patients on oral antipsychotics *v.* patients on LAIs, fears exceeded the actual experiences for all factors examined (Table 2, online Fig. DS1), but fear was only statistically significant for the concerns of being tied to the clinic (62 *v.* 28, $P = 0.018$) and loss of decision-making regarding when to take the medicine (45 *v.* 8, $P = 0.001$). Overall, patients' results tended to be polarised to either end of the 100 mm scale whereas the mental health professionals' results were more centred in their distribution.

Estimated and actual fears as well as experienced factors affecting the decision to decline long-acting injectable antipsychotics (LAIs)

Factors	Mental health professionals ($n = 63$)	Patients on oral treatment ($n = 101$)	P	Patients on LAIs ($n = 63$)	* P * a
Pain at the injection site	50.5 (11–95)	28 (0–100)	0.001	12 (0–100)	0.21
Being regularly tied to a clinic	49 (5–98)	62 (0–100)	0.24	28 (0–99)	0.018
Observation time at the clinic after one certain type of LAI	64 (4–98)	89 (0–100)	<0.0001	67 (3–98)	0.23
Embarrassment of having an injection	41 (1–93)	12 (0–98)	<0.0001	17 (0–100)	0.11
Reduction in autonomy	62 (5–93)	30 (0–98)	0.0025	10 (0–100)	0.18
Loss of ability to decide when to take the medication	56 (4–95)	45 (0–100)	0.13	8 (0–98)	0.001
Feeling of being controlled	56 (3–94)	25 (0–100)	0.013	13 (0–100)	0.58
Perceptions of stigma of being on LAI	51 (4–88)	17 (0–100)	0.0004	11 (0–100)	0.63

The questions were presented orally and adapted based on the participant category, *i.e.* mental health professionals, patients on oral treatment and patients on LAIs.

Patients on oral treatment *v.* patients on LAIs.

Only the 7 patients on long-acting injectable olanzapine who had experienced a 3 h observation time were included.

Patients on LAIs were asked to recall their fears before switching from oral treatment. They graded their recalled fears higher than the actual experiences regarding all factors except for observation time (online Table DS1). The differences were small, but reached statistical significance for pain (24 *v.* 12, $P < 0.0001$), embarrassment (9 *v.* 7, $P = 0.0006$), reduction in autonomy (13 *v.* 10, $P = 0.0027$) and loss of ability to decide when to take the medicine (14 *v.* 8, $P = 0.019$). Finally, there were no statistically significant differences between the graded fears of patients on oral treatment *v.* recalled fears in patients on LAIs (data not shown).

Mental health professionals overestimated the concerns of orally treated patients regarding feared pain (51 *v.* 28, $P = 0.001$), embarrassment (41 *v.* 12, $P < 0.0001$), reduction in autonomy (62 *v.* 30, $P = 0.0025$), feeling of being controlled (56 *v.* 25, $P = 0.013$), and stigma (51 *v.* 17, $P = 0.0004$; Table 2, online Fig. DS1). Conversely, they underestimated the patients' concerns regarding the 3h observation time required after injection of LAI olanzapine (64 *v.* 89, $P < 0.0001$).

Knowledge of oral and LAI antipsychotics

All physicians (100%) claimed that LAIs are associated with a more stable plasma concentration than oral treatment (Table 3). For nurses, patients on oral treatment and patients on LAIs, the corresponding proportions were 56%, 16% and 22%, respectively.

Mental health professionals' and patients' knowledge about oral v. long-acting injectable antipsychotics (LAIs) regarding plasma concentration, side-effects and frequency of readmission to hospital

Topic	Physicians (n = 20)	Nurses (n = 43)	Patients on oral treatment (n = 101)	Patients on LAIs (n = 63)
Plasma concentration, n (%)				
Lower/more stable with LAIs	20 (100)	24 (56)	16 (16)	14 (22)
Equal	0 (0)	11 (26)	23 (23)	20 (32)
Lower/more stable with oral	0 (0)	4 (9)	41 (41)	20 (32)
Don't know	0 (0)	4 (9)	21 (21)	9 (14)
Side-effects, n (%)				
Less with LAIs	15 (75)	12 (28)	18 (18)	27 (43)
Equal	3 (15)	17 (40)	25 (25)	19 (30)
Less with oral	1 (5)	11 (26)	45 (45)	11 (17)
Don't know	1 (5)	3 (7)	13 (13)	6 (10)
Risk of rehospitalisation, n (%)				
Less with LAIs	19 (95)	37 (86)	21 (21)	23 (36)
Equal	0 (0)	3 (7)	40 (40)	20 (32)
Less with oral	1 (5)	2 (5)	15 (15)	5 (8)
Don't know	0 (0)	1 (2)	25 (25)	15 (24)

Eligible answers were presented as pre-specified nominal options.

Of physicians, 90% stated that LAIs are superior or equal to oral treatment concerning side-effects. For nurses, patients on oral treatment and patients on LAIs, the corresponding proportions were 68%, 43% and 73%, respectively.

All physicians but one (95%) and 86% of nurses claimed that LAIs reduce the risk of readmission to hospital, while 21% of patients with oral treatment and 36% of patients on LAIs claimed LAIs to be superior in this matter.

Clinical approach to LAIs among mental health professionals

Poor adherence, limited insight and multiple relapses were the most common reasons for prescribing LAIs, mentioned by 80% of physicians. However, one-fourth considered LAIs an option even early in the disease course. Their strategies to encourage patients to consider LAIs were to inform them about the advantages of the formulation (65%) and about the risks and consequences of treatment discontinuation (40%). Exploring patients' fears was a strategy mentioned by 20% of physicians.

Half of physicians believed that not having to remember to take pills was the key reason for patients to accept LAIs. Other factors mentioned were good insight (40%) and that LAIs are associated with lower frequency of relapse (20%).

Of nurses, 31 (72%) replied that they actively tried to influence the patients' attitude towards one or the other formulation, and 29 (67%) actively tried to influence the physician's decision.

Patients' perspective on switching

Almost half of the patients on oral treatment (41%) declared that they had little or no knowledge of LAIs. At the end of the interview, they were asked whether they would switch to LAIs if offered by their treating physician. While 78 (77%) said no and three (3%) could not decide, 20 (20%) declared that they would agree to switch if offered such an option. The patients willing to switch had fewer years since diagnosis than those who were reluctant (12 v. 24, $P = 0.0013$; online Fig. DS2). Furthermore, the proportion of women was higher in the positive group (75% v. 44%, odds ratio (OR) = 3.9, $P = 0.023$). They considered pain (7 v. 40, $P = 0.020$), being tied to the clinic (26 v. 70, $P = 0.017$), reduction in autonomy (9 v. 30, $P = 0.034$) and stigma (6 v. 27, $P = 0.035$) to be less important issues than did the patients who were reluctant to switch to LAIs.

A total of 21 (33%) patients on LAIs would switch to oral treatment if they were offered it, 1 (1.6%) could not decide and 41 (65%) preferred to continue with LAIs. There were no statistically significant differences between patients who were positive v. patients who were negative about switching formulation with regard to age, number of years with diagnosis or gender. Those who opted to stay on LAIs were less concerned with the lack of autonomy (7 v. 40, $P = 0.015$) and the feeling of being controlled (9 v. 50, $P = 0.0011$). They also gave more correct answers regarding differences in side-effects between oral formulations and LAIs (85% v. 52%, OR = 5.3, $P = 0.012$).

Discussion

In this study, we found that patients' concerns with LAIs were minor except when considering observation time and being tied to the clinic, and that there was a mismatch in the assessment of specific concerns between the patients and the mental health professionals. We identified important knowledge gaps among patients and nurses. As many as one-fifth of the patients on oral medications were willing to switch to LAIs; these potential switchers were more recently diagnosed than those who were reluctant.

The patients on oral treatment were most concerned about observation time post-injection and about being tied to the clinic when asked about LAIs. This indicates that they valued their time and that practical issues surpassed in significance emotional ones such as stigma, a feeling of being controlled and embarrassment. All fears expressed by patients on oral treatment exceeded the actual experiences of patients on LAIs. This could be a result of selection bias, in that patients on LAIs were less concerned even before accepting LAI treatment. However, since patients on LAIs were speaking from experience, this difference may also reflect that these issues had a lower impact than expected once the patients had been started on LAIs. That the recalled concerns pre-LAIs were similar to the levels of concern among those still on oral treatment also supports this hypothesis.

Mental health professionals tended to answer questions by placing the indicator centrally on the 100 mm scale, which may reflect uncertainty as they were just estimating the patients' experiences. The patients' answers, on the other hand, were polarised, indicating that their opinions were more set. Patients also graded some factors distinctly low and others distinctly high. In light of this, physicians should be encouraged to learn more about the individual patient's concerns. Only 20% of physicians reported that they used this strategy when discussing treatment regimens.

According to previous studies, physicians' knowledge regarding antipsychotic formulations varies.^{16,17} Physicians in the current study showed very good knowledge. However, a significant proportion of the interviewed nurses had knowledge gaps concerning some of the advantages of LAIs. This could have a negative impact on the patient's attitude towards LAIs, especially as the majority of nurses claimed that they actively tried to influence both doctors and patients in the discussion on treatment choices. Patients already on LAIs had significantly better knowledge about the reduced side-effects with LAIs than patients on oral treatment. This most likely reflects their own experiences. It could also be an effect of information provided by mental health professionals – information many patients on oral treatment reported as lacking. This is of concern, as we know that patients' attitudes towards LAIs are likely to become more positive with increased knowledge and experience of the treatment.¹⁰ The physicians' observed reluctance to bring up the topic may be due to their anticipation that the patients are unlikely to accept the offered LAI. However, keeping the patients uninformed makes shared decision-making impossible.¹⁵

The majority of the patients on LAIs chose to keep this formulation and as many as 20% of the patients on oral treatment were willing to use LAIs. This is in line with a previous study in which 16% were positive towards a formulation

switch.¹⁴ This also supports the hypothesis that the use of LAIs could be limited by factors other than rejection by the patients.¹² Some physicians claimed that they offered LAIs early in the disease course, but their most common reasons for prescribing LAIs were poor adherence to oral medication and recurring relapses. Previous studies also report non-adherence^{16,17} and multiple relapses¹⁷ as key criteria for prescribing LAIs. This may be unfortunate as longer illness duration was associated with being reluctant to switch. Instead, this motivates a discussion of LAIs early on in the course of illness, especially as there is cumulative evidence that the use of LAIs as early as after the first admission to hospital decreases the risk of treatment discontinuation, relapse and readmission.^{4,5,18}

Limitations

Our study has several limitations. Not all patients in the targeted study population were included, and some patients could not be reached or were not present to complete the questionnaire. Some were only scheduled for visits once per calendar year, while the study was limited to 10 months. It is possible that patients were either too ill to present themselves or were stable enough to postpone yearly visits. The patients on LAIs were asked to declare their perceptions prior to starting on LAIs, which introduced recall bias. However, we excluded all patients on LAIs 5 years, reducing the effect of this bias. Finally, patients on LAIs are indisputably a selection of patients who have once accepted that formulation. However, the lack of significant differences between the graded fears of patients on oral treatment compared with recalled fears in patients with LAIs may indicate that this selection bias is of minor concern. A strength of this study was that all interviews were performed by the same person (L.C.), securing consistency across interviews.

Clinical implications

In conclusion, physicians should aim to set aside their own preconceptions and instead make time to identify the individual's specific fears regarding LAIs, preferably early in the course of the illness. In addition, there is room for improvement regarding patients' knowledge of antipsychotic formulations. Adequate education would be of value to strengthen nurses' knowledge about LAIs. Finally, there is room for improvement regarding patients' knowledge of antipsychotic formulations.

1.6.73 Mental capacity legislation in the UK: systematic review of the experiences of adults lacking capacity and their carers

date

2017-10

Abstract

Aims and method Capacity legislation in the UK allows substitute decision-making for adults lacking capacity. Research has explored the experiences of such adults and their carers in relation to the Adults with Incapacity (Scotland) Act 2000, and the Mental Capacity Act 2005 in England and Wales. A systematic review of the relevant research was performed using a framework method.

The Authors own the copyrights to the individual articles.

Results The legislation provided mechanisms for substitute decision-making which were seen as useful, but there were negative experiences. Decision-making did not always seem to follow the legislative principles. Awareness of the legislation was limited. Most research was qualitative and some was of low methodological quality. Data were too heterogeneous to allow comparisons between English and Scottish law.

Clinical implications Capacity legislation was generally viewed positively. However, some experiences were perceived negatively, and the potential benefits of the legislation were not always utilised.

In law, mental capacity is the ability to make decisions, and it relies on a number of attributes such as comprehension and reasoning.¹ Capacity legislation exists to allow legally valid decisions to be made about finances, welfare or medical treatment where the individual lacks mental capacity. In Scotland this legislation exists as the Adults with Incapacity (Scotland) Act 2000 (AWIA) and in England and Wales as the Mental Capacity Act 2005 (MCA). Northern Ireland has recently adopted the Mental Capacity Act (Northern Ireland) 2016.

Prior to the introduction of legislation, English capacity law was criticised by the Law Commission as being unsystematic and out of step with disability rights.² The Scottish Law Commission described Scottish capacity law as fragmented and archaic.³ The AWIA and the MCA were introduced to reform capacity law, and are similar in many respects. They set out principles which aim to promote the rights of adults who lack capacity, and create mechanisms to allow substitute decision-making, a process whereby another individual has the legal power to make decisions on the disabled adult's behalf. The MCA has a specific 'best interests' process, which allows some decisions to be made without court proceedings, whereas there is no equivalent process in the AWIA. The Northern Irish legislation mirrors the MCA in many regards. The terminology varies between jurisdictions, for example, guardianship in the AWIA is similar to deputyship in the MCA.

A number of studies have explored the experiences of adults lacking capacity and their carers in relation to the legislation, and this systematic review draws together findings from this area of research.

Method

This review systematically appraised the research evidence exploring how adults lacking capacity and their carers experienced capacity legislation. It followed the Centre for Reviews and Dissemination guideline.⁴ The process is summarised in *Fig. 1*. All experiences related to the AWIA and the MCA were considered of interest, from everyday decision-making to perceptions of court proceedings and their outcomes. There was no research relating to the Northern Irish legislation, because the review was undertaken prior to its adoption. In this review, ‘carers’ included family and professional carers who made substitute decisions in a day-to-day caring role.

Fig. 4: Flow chart of study selection process.

The primary research question was ‘What are the experiences and perceptions of adults lacking capacity, their carers and the general public in relation to capacity legislation in the UK?’ The secondary research question was whether such experiences varied between jurisdictions.

The published literature consisted of both quantitative and qualitative research. Studies were included if they were published after the year 2000 (the year of introduction of the AWIA) and consisted of quantitative or qualitative research about the experiences or perceptions of adults lacking capacity, their carers or members of the general public in relation to the MCA or AWIA. There was no restriction placed on diagnosis. Exclusion criteria included studies where the individuals were minors, studies of capacity to participate in research, and studies carried out prior to the implementation of whichever Act was relevant. Papers such as accounts of service development activities, assessments of educational interventions and legal commentaries were also excluded. Research publications from sources other than peer-reviewed journals were included, because it seemed likely that there would be a paucity of evidence in the peer-reviewed literature. Although this strategy increased the likelihood of low-quality evidence entering the review, this was addressed by consideration of quality in the synthesis of the results.

A literature search was performed during June 2015. The databases were Medline, PsycINFO, EMBASE, Web of Science, ESRC, Social Care Online, BAILII, HeinOnline and LexisLibrary. The search terms were the keywords ‘Mental Capacity Act’, ‘Adults with Incapacity Act’, and ‘Adults with Incapacity Scotland Act’. Each abstract was screened. Duplicate papers and papers originating outside the UK were not included. Additional papers were sought from reference lists, conference proceedings and contact with authors. The abstracts of the papers were compared with the exclusion criteria. The complete paper was read if it was unclear from the abstract whether the paper should be included. The remaining papers were read once to exclude irrelevant papers from the final sample.

Quality assessment was carried out using the Multi-Methods Appraisal Tool (MMAT),⁵ which was selected because it offered the ability to assess the quality of all the various types of studies in the sample. It consisted of screening questions followed by questions for quantitative, qualitative and mixed-methods studies. No studies were excluded from the final sample because of low quality.

This review followed guidance that items should be regarded as data for secondary research only if they were described as results or findings in the primary research.⁶ A data extraction form was developed during a reading of the final sample papers. The data extraction form consisted of headings taken from the results sections of the final sample papers. Results from each study were then extracted if they were relevant to any heading on the data extraction form. Analysis used a framework method⁷ with a matrix consisting of each study along the x-axis and each heading from the data extraction form along the y-axis.

Results

There were 11 papers in the final sample, containing 12 distinct studies. The type and quality of studies are summarised in *Table 1*. Most of the studies used qualitative or mixed methods. There was variation in the quality of studies; only 4 of the 12 studies were rated as having the highest methodological quality and had been published in peer-reviewed journals. The other eight studies presented their results clearly but failed to report important information.

Type and quality of studies in the final sample

Study	Act	Type	Peer-reviewed journal?	MMAT score
Badger (2009) ⁸	MCA	Multiple qualitative methods	No	3/4
Badger & Parnell (2009) ⁹	MCA	Multiple qualitative methods	No	2/4
Jevon (2014) ¹⁰	AWIA	Quantitative survey	No	2/4
Jingree (2015) ¹¹	MCA	Qualitative interviews	Yes	4/4
Killeen & Myers (2004) Ch. 4 ¹²	AWIA	Mixed-methods – quantitative survey and qualitative interviews	No	2/4
Killeen & Myers (2004) Ch. 5 ¹³	AWIA	Qualitative interviews	No	2/4
Manthorpe <i>et al</i> (2012) ¹⁴	MCA	Qualitative interviews	Yes	4/4
Mental Welfare Commission (2011) ¹⁵	AWIA	Qualitative interviews	No	2/4
Myron <i>et al</i> (2008) ¹⁶	MCA	Mixed-methods – questionnaires and qualitative interviews	No	1/4
Samsi & Manthorpe (2011) ¹⁷	MCA	Qualitative interviews	Yes	4/4
Samsi & Manthorpe (2013) ¹⁸	MCA	Qualitative interviews	Yes	4/4
Williams <i>et al</i> (2012) ¹⁹	MCA	Mixed-methods – quantitative survey and qualitative interviews	No	2/4

AWIA, Adults with Incapacity (Scotland) Act 2000; MCA, Mental Capacity Act 2005; MMAT, Multi-Methods Appraisal Tool.

Research aims and participants are summarised in *Table 2*. Although there were data related to experiences in courts in Scotland, there were no data related to the Court of Protection in England and Wales. The data about the AWIA related mainly to guardianship, and the data about the MCA related mainly to decision-making practices. Therefore, no direct comparison between specific elements of the AWIA and MCA could be made.

Aims and participants in studies in the final sample

Study	Act	Research aim	Population context	Participants
Badger (2009) ⁸	MCA	Explore decision-making	Intellectual disability	27 participants: 2 staff and 1 family member for each of 9 disabled adults in 3 settings (none of the 9 disabled adults directly involved)
Badger & Parnell (2009) ⁹	MCA	Explore decision-making	Not described	24 participants: 6 disabled adults with 2 staff and 1 family member for each
Jevon (2014) ¹⁰	AWIA	Assess experiences of guardians	Not described	193 welfare guardians (27% response rate)
Jingree (2015) ¹¹	MCA	Explore decision-making	Intellectual disability	15 support workers from a single service
Killeen & Myers (2004) Ch. 4 ¹²	AWIA	Explore power of attorney and intromission with funds	General public	3 individuals who had made a power of attorney and 5 individuals who had applied for intromission with funds (8% response rate)
Killeen & Myers (2004) Ch. 5 ¹³	AWIA	Understand the operation of guardianship	Mixed	58 professionals, carers, and adults with incapacity involved in 13 guardianship cases – exact composition not reported
Manthorpe <i>et al</i> (2012) ¹⁴	MCA	Assess links between personal and professional experiences of dementia	Dementia	123 professionals (70 of whom had experience as carers)
Mental Welfare Commission (2011) ¹⁵	AWIA	Assess experiences of guardians and supervisors	Not described	58 welfare guardians (family or carer)
Myron <i>et al</i> (2008) ¹⁶	MCA	Assess staff, family and patient knowledge of capacity	Mixed	73 staff, 20 disabled adults, and 6 carers
Samsi & Manthorpe (2011) ¹⁷	MCA	Understand how older people planned for their future	General public	37 self-identified ‘well’ people aged over 50 years
Samsi & Manthorpe (2013) ¹⁸	MCA	Explore decision-making	Dementia	12 dementia dyads (person with dementia plus their carer)
Williams <i>et al</i> (2012) ¹⁹	MCA	Explore decision-making	Mixed	385 participants, mostly professionals – 5 interviews from the perspective of carers

AWIA, Adults with Incapacity (Scotland) Act 2000; MCA, Mental Capacity Act 2005.

None of the four studies from Scotland had been published in peer-reviewed journals and none received the highest rating of methodological quality. Two of these studies were separate pieces of research in a single publication.^{12,13}

The findings are summarised in *Table 3*. For reasons of parsimony, the 15 items from the data extraction form were collapsed into four headings in the results, but all data were retained.

Summary of findings

Theme	Finding
Positive experiences	Having a legal basis for decision-making was recognised as useful Benefits such as increased safety and quality of life were sometimes described The ability to use the mechanisms of the Acts to plan for the future was seen as beneficial, although only a minority did this The legislation was sometimes perceived as empowering
Negative experiences	Court and other legal processes were seen as challenging and cumbersome, and costs may be off-putting Some participants had extremely negative experiences The legislation was sometimes perceived as disempowering
Decision making	Decisions were sometimes but not always made with the disabled adult's participation Carers sometimes struggled to make decisions in the best interests of the adult lacking capacity There could be conflicts of interest between the adult lacking capacity and the decision maker
Other issues	There were variable findings related to support and supervision There was a lack of understanding of the legislation on the part of the general public and carers A need for carers to be assertive was described The most common reason for applying for powers was because of a wish for a formal role in decision-making There were no findings about carers' abilities to assess capacity There were no findings about deprivation of liberty Data were mainly derived from carers

Positive experiences

One study from Scotland reported that family carers saw guardianship as positive because it offered them the ability to manage their relative's welfare and finances. Improved safety and quality of life were described in several cases. Half of the six adults with incapacity interviewed in this study described improvements in their quality of life.¹³ In a telephone survey, most guardians stated that guardianship was useful, but a minority reported that it made little difference, or found it a negative experience.¹⁵ In a postal survey of guardians, most of the participants described welfare guardianship as being useful, but the response rate (26.7%) in this study was low and the result may not represent the experience of carers.¹⁰ Those who had made a power of attorney or who had made a successful application for intromission with funds saw the process as a positive experience. However, there were only a total of eight participants in this mixed-methods study.¹²

Some older members of the general public in England saw potential benefits from making a power of attorney, but most described a disinclination to plan for the future. Any plans that were made were usually of a financial nature. Individuals living alone with no family described difficulty in appointing someone to look after their affairs.¹⁷ The finding of participants failing to make powers of attorney or advance decisions, despite believing in their utility, was repeated in a group of professionals who had personal experience as carers.¹⁴ Only a minority of elderly people made a power of attorney in another study by the same researchers.¹⁸

Negative experiences

One study involved 58 professionals, carers and adults with incapacity who had been involved in court proceedings for 13 guardianship cases in Scotland. The process was described as perplexing and inhibiting for carers, and confusing and stressful for adults who lacked capacity. The process made some carers feel ‘isolated and under pressure’ and was described in negative terms such as ‘a nightmare’ and ‘an enormous waste of time’.¹³ By contrast, the instruments of the AWIA which did not require court proceedings were viewed generally positively.¹²

However, negative experiences were not just restricted to experiences in court. A minority of participants in the telephone survey of guardians found being a guardian to be a negative experience in general.¹⁵ One study of the MCA included five cases of best interests decision-making from the point of view of family carers, and the experience in each case was described as disempowering and distressing for the carers. No further details were given because the carers were not directly interviewed, but this finding contrasted markedly with the largely positive views of the MCA expressed by professional respondents in the same study.¹⁹

As well as the cases of carers appearing disempowered, some adults who lacked capacity were observed to resent the powers that others held over them.¹³ However, some carers in Scotland who had gone through processes to be formally appointed with decision-making powers saw themselves as empowered.^{12,13} In this review, the legislation was perceived as empowering’ for some and disempowering for others.

Decision-making

A qualitative study of support workers found decision-making to be inconsistent with the MCA; there was no assumption of capacity, and decisions were rarely oriented towards best interests.¹¹ Other support workers described struggling to balance their duties under the MCA with duty of care and safeguarding obligations, and stated that limited resources restricted their ability to support decision-making in practice.⁹ Another group felt that organisational policies, the influences of others such as family and professionals, and their duty of care restricted their ability to engage the adults in best interests decision-making.⁸

Some decision-making was clearly compliant with the general principles of the legislation. All 12 carers for individuals with dementia described the importance of best interests decision-making. They stated that they attempted to maintain the autonomy of the adult who lacked capacity and took a decision-specific approach to each question. They described the use of strategies to enhance the disabled adult’s participation in decision-making, and used their knowledge of the person’s previous wishes. However, even these carers described conflicts of interest between their needs and those of the adult with incapacity, and admitted struggling to decide what constituted best interests.¹⁸ The situation was similar in Scotland, with carers reporting difficulties assessing the most beneficial course of action and understanding the views of the adult with incapacity.¹³

Overall, it appeared to be the case that immediate carers (whether family carers or support workers) sometimes found difficulty in making decisions which adhered to the principles of the legislation, and that there could be conflicts between the wishes of the adult lacking capacity and the priorities of the decision maker. Although the degree of engagement with the principles varied between studies, this finding was consistent in all the studies which examined this theme, including in two of the four highest-quality studies.^{11,18}

Other findings

Practical support

Older members of the public in England were generally unaware of potential resources to support making powers of attorney or advance decisions, and some suggested that this might be helpful.¹⁷ Carers described a lack of practical support for decision-making for the adult lacking capacity, and some would have liked more.¹⁸ In one study, carers could identify potential sources of support, but these were generic supports such as friends, relatives, general practitioners and social services.¹⁶ In Scotland, around 75% of guardians were satisfied with the level of supervision and support they had from their local authorities.¹⁵ Guardians in another study perceived that they received insufficient support but were subject to excessive scrutiny.¹³ The perception of excessive scrutiny was shared by holders of intromission with funds.¹²

Lack of knowledge of the legislation

There was a lack of awareness on the part of the general public about the legislation. None of the respondents in a study of older members of the public in England were aware of the MCA, or that it could potentially support their choices for the future, but a few understood the nature of a power of attorney.¹⁷ Only 3 of 12 ‘dementia dyads’ (consisting of a person with dementia and their carer) had heard of a power of attorney, and only a single pair had utilised one.¹⁸ This lack of understanding of the legislation was apparent even where carers had been trained or where they held specific powers. Support workers thought that they needed more training in using the MCA^{8,16} and were observed to be unclear about some of their duties under the MCA.⁹ Guardians in Scotland were ignorant of their responsibilities to document the use of powers, and were unaware that they could delegate them.¹⁵ Some respondents felt that improved sources of information were necessary.¹³ Organisations caring for disabled adults had policies about risk which needed to be revised to comply with the principles of the legislation, and education about the MCA was suggested not just for professionals, but for adults lacking capacity and family carers as well.⁸

Assertiveness of carers

Those professionals with personal experience of being family carers described a necessity for carers to be ‘assertive’ in using the MCA to compel health and social services to act in the best interests of the adult who lacked capacity.¹⁴ The need for guardians to be ‘assertive and articulate’ was also described in Scotland.¹³

Application for financial/welfare powers

Data about the reasons for making applications for formal financial or welfare powers were only found in studies from Scotland. In a survey of guardians, the most common reason described for applying for guardianship was a wish for a formal role in the care of the adult with incapacity.¹⁵ Carers applied for intromission with funds because they believed that they had no other means of managing the person's finances.¹²

Absent or limited data

There were no findings in relation to carers' abilities to assess capacity. No data in the sample related to experiences of formal legal proceedings under English law in the Court of Protection. There was no information about experiences of Deprivation of Liberty Safeguards. Although many adults lacking capacity participated in the studies in this review (*Table 1*), the experiences of carers dominated the findings (*Table 2*).

Discussion

Methods and limitations

This review offers a systematic appraisal of the empirical research literature exploring how adults lacking capacity and their carers experience capacity legislation in the UK. Both quantitative and qualitative data were sought in the process of this review, but most of the studies in the final sample used qualitative or mixed methods. The lack of quantitative studies presented difficulty in data synthesis, because methods for the systematic review of qualitative research are not well established.^{4,6} However, there were benefits from utilising qualitative data to answer this review's research questions. Qualitative methods were appropriate to answer the primary researchers' questions because they are concerned with experiences and perceptions,⁴ are not reliant on random sampling²⁰ and can draw conclusions from small sample sizes.²¹ However, this systematic review cannot make claims of generalisability because it is based mainly on qualitative data, and the prevalence of the experiences described in this review cannot be determined.

There are other limitations which mean that the findings of this review must be treated with caution. This review relied on a single researcher and therefore sampling of papers and quality assessment were carried out without independent checks to ensure consistency. Two-thirds of the studies had not been published in peer-reviewed journals and some were of low quality. Most of the data from England and Wales related to decision-making, and none related to aspects of English capacity law such as experiences in court. Some of the data from Scotland were more than 10 years old, and may not reflect current practices. Data were heterogeneous and the secondary research question could not be answered because direct comparisons between specific components of English and Scottish law were not possible. However, the data were not so heterogeneous as to prevent the use of framework analysis.

Findings

What does this systematic review say about the AWIA and the MCA from the perspectives of the people who are subject to these laws? This review found that the legislation provided family carers with the ability to manage decisions for adults lacking capacity on a legally valid basis, and the mechanisms to allow this were generally seen as satisfactory. There were reports of improved safety and quality of life in some cases, including from some adults who lacked capacity. The ability to make plans for future incapacity was seen as useful. These positive consequences of the AWIA and MCA suggest that the legislation has achieved its goals, at least judging by the standards set by the law reformers of the 1990s.^{2,3} However, although a detailed discussion of human rights is beyond the scope of this paper, it must be acknowledged that the paradigm of disability rights has changed since the drafting of these laws; for example, there is pressure from the United Nations' Committee on the Rights of Persons with Disabilities to replace existing capacity laws with alternative approaches which do not utilise substitute decision-making and which would allow legal capacity regardless of the level of mental impairment.²² These proposals are based on an interpretation of Article 12 of the UN Convention on the Rights of Person with Disabilities²³ which has excited controversy²⁴ and been criticised

as undermining rather than promoting the rights of people with mental illnesses.²⁵ However, if that interpretation of Article 12 is accepted as authoritative, then key areas of UK capacity legislation are incompatible with international law.²⁶

In this review, some positive consequences of the AWIA and the MCA were mitigated by other findings. Perhaps not unexpectedly, adults lacking capacity sometimes resented the powers held over them. There were experiences of both empowerment and disempowerment. Potential benefits such as advance planning were not always realised; for example, planning for the future was seen as potentially beneficial, but despite this few people made powers of attorney or advance decisions. This is an area of concern given the relative simplicity of such instruments compared with the cost and complexity of the legal proceedings which can become necessary when someone loses capacity. Awareness of the legislation seems to be lacking, and public education might increase the utilisation of advance planning. However, not everyone will have the desire or ability to nominate a suitable power of attorney.

Education about the legislation may also be beneficial. As well as a lack of knowledge about the legislation on the part of the general public, support workers and family carers who held specific powers were sometimes unaware of their responsibilities. Decision-making was not always fully compliant with the legislative principles. Although some of the studies with these findings were conducted shortly after the introduction of the legislation when knowledge might be expected to be limited,^{8,9,16} other studies continued to demonstrate this finding several years later.^{11,15}

Legislation could be experienced as either empowering or disempowering by carers. Although some adults lacking capacity described positive outcomes, others described concepts similar to disempowerment. The AWIA and the MCA have been lauded as progressive and empowering instruments.^{27,28} It is true that both are grounded in principles such as enablement, least restriction, and the participation of the adult who lacks capacity in decision-making. Nevertheless, these principles are only empowering in the sense that they return disabled people to the legal status of any other citizen, and do not give them any additional rights to allow them to overcome their impairments. Series²⁹ has observed that most of the mechanisms of the MCA have the effect of transferring power away from disabled adults, and for this reason disputes the claim that the MCA is empowering. The AWIA may be viewed as disempowering for the same reason.

In this review, negative experiences of the legislation related mainly to court proceedings, although data were lacking about the Court of Protection in England and Wales. The transfer of significant decision-making powers between individuals is always likely to require formal proceedings, which will often be perceived as challenging and costly by the applicants. What other options are there? Moving to a tribunal system could potentially decrease costs and reduce distress because the proceedings take place outside the courts. However, tribunals might prove more expensive because of the addition of an extra judicial tier,²⁷ and may not necessarily be experienced more positively than court proceedings.

The initial legislation did not deal with the provision of due legal process for adults without capacity who require restrictive care regimes but lack the ability to challenge their *de facto* detention (so-called 'Bournewood patients').³⁰ This gap in the law still exists in Scotland.³¹ In England and Wales, provisions to deal with this issue were made in the form of the Deprivation of Liberty Safeguards, but these were criticised by the House of Lords, which recommended the process be replaced.²⁷ Both the AWIA and the MCA are undergoing reform to deal with this issue. This review found no data about deprivation of liberty, and it is unfortunate that there are no perspectives from patients or their carers to inform the changes to this area of law.

Finally, the participation of disabled adults in research about capacity legislation needs to be improved. Most of the findings in this review were drawn from carers, despite many adults who lacked capacity having been recruited into the studies. It is disappointing if researchers have made efforts to include such participants, only for those voices to be lost, and future research should take care to avoid this.

This study formed part of an MSc in Mental Health and Law from Queen Mary University of London. Dr Erminia Colucci, Dr Ruth Fletcher and Dr Yasmin Khatib commented on the design of this study and drafts of the manuscript. Dr Lucy Series suggested additional papers for this review.

1.6.74 Does the cognitive therapy of depression rest on a mistake?

Abstract

Cognitive therapy for depression is common practice in today's National Health Service, yet it does not work well. Aaron Beck developed it after becoming disillusioned with the psychoanalytic theory and therapy he espoused and practised. But Beck's understanding of psychoanalysis appears to have been seriously flawed. Understood rightly, the psychoanalytic approach offers a cogent theory and therapy for depression which, unlike the cognitive approach, takes us to its emotional-motivational roots. A clinically successful therapy can afford to eschew theory and rest on its pragmatic laurels. This is not the case for cognitive therapy. The time is right to re-examine the psychoanalytic theory and treatment of depression.

- *Does the cognitive therapy of depression rest on a mistake?*
 - *Psychopathological theory*
 - *Therapeutic practice*
 - *Implications*

Cognitive-behavioural therapy (CBT) is, alongside antidepressant medication and counselling, today's mainstay treatment for depression in the UK. Such treatments tend to work better than nothing at all,¹ yet in general fare little better than placebo,^{2,3} suffer relatively high relapse rates, and often struggle to provide a complete remission.^{4,5}

CBT treatments for anxiety disorders, by comparison, appear more successful.⁶ They work by helping the patient articulate, then transcend, their underlying inchoate fears, the transformative learning happening directly within action and experience. This bottom-up experiential focus contrasts with the cognitive treatment of depression, where the patient is more typically trained in an arduous top-down task of managing unhealthy habits of mind through attentional and behavioural training and rational self-management.⁷

One reason for the rather low remission and high relapse rates for CBT-treated depression may be that the treatment does not reach to the emotional roots of the problem. That CBT principally theorises and treats the maintaining, rather than identifies underlying, causes of depression was acknowledged by Aaron Beck, the American psychiatrist who developed the cognitive aspect of this pragmatic depression treatment in the 1950s.⁷

The psychoanalytic psychology Beck displaced had a theory of the root cause of depression: avoidance of intolerable emotion blocks healthy emotional functioning, depletes uncontrived self-possession, and lowers self-esteem.⁸ But his clinical experience (as a psychoanalytic psychotherapist) and scientific research (on depression, anger and dreaming) led Beck to discount the significance of such unconscious emotion. Ever the pragmatist, he focused instead on treating the conscious assumptions and ruminations of the patient which, he proposed, were maintaining their depressive state.

This article argues that the versions of psychoanalytic theory and therapy Beck espoused, practised and then rejected were recondite and implausible. The claim is that Beck mistakenly threw out the psychoanalytic baby of a significant psychological understanding and treatment of depression with the bathwater of a rather idiosyncratic understanding of psychoanalytic theory and practice. The thesis offered is theoretical rather than scientific: it considers the fundamental conceptual matter of how that theory is itself to be understood, rather than the secondary empirical matter of evidence for or against hypotheses derived from particular interpretations of it. But given the availability of far more plausible versions of psychoanalytic theory and practice that outline and treat depression at its emotional roots, and given the relatively poor success of CBT for depression, the time is now right to put the psychoanalytic theory back on the table and test hypotheses and therapies derived from it.

Psychopathological theory

An important theme in psychoanalytic psychopathology has depression resulting from the avoidance of feelings of loss. When the acute sadness of letting go of a beloved or an aspiration is too painful, the patient may avoid it by shutting down and instead become flat and morose. This, however, prevents adaptation to loss, since sadness is simply the most fundamental form that our recognition of loss takes. Another especially significant theme has depression resulting from the unconscious avoidance of anger towards those to whom we are attached. Rather than risk the feared relational fallout from expressing anger, the patient unconsciously depletes herself, trading that sense of self-worth that would be provided by an angrily assertive sense of injustice for the stability of her relationship. A third theme has depression resulting from the unconscious avoidance of fear. Rather than face the vicissitudes of uncontrollable fate in one's love and work, the patient instead constructs and lives in a dismal and diminished version of himself, his situation and his future. Even if life thereby becomes grim, at least now it will not take him by surprise.

Such ideas form but three strands of a more complex psychoanalytic conceptualisation of depression,⁸⁻¹⁰ but are fairly widespread in both popular and clinical culture for good reason. For clinically what we discover, again and again in straightforward cases, is a depressed person who avoids sadness, fear and in particular anger by going flat, downgrading her sense of her own value, shutting down self-assertion, not allowing herself to get even reasonable hopes up, falsely characterising herself as perpetrator rather than victim of relational injustices, characterising herself as deserving of treatment which reasonable others would consider unjust, denying the significance of her unmet emotional needs, and envisaging a world in which the exercise of agency appears foolhardy. In more complex cases, however, we find masochistic self-abasement added to an anger-avoiding dynamic: unconscious hatred towards another breaks through the attempts at self-suppression and gives rise to intolerable guilt, and this in turn inspires self-punishment where the anger towards the other is 'retroflected' (taken out on oneself), leading to further and darker melancholic misery.⁹

It was by way of a reaction against such psychoanalytic theory that a young, psychoanalytically minded American psychiatrist and dream researcher developed the theory and practice of cognitive therapy. Following a helpful personal experience of psychoanalysis, Aaron Beck treated several depressed patients using psychoanalytical methods, applied (albeit unsuccessfully) for membership of the American Institute of Psychoanalysis, and published a few papers on psychoanalytic psychotherapy and on the themes of his depressed patients' dreams.^{11,12} Reading these today we learn in particular of his scientific interest in the increased prevalence of thwarted, deprived, excluded, rejected, injured and ashamed themes in his patients' dreams, and of his clinical interpretation of these along psychoanalytic lines.

Already in these early papers, however, we find a curious feature which presages his later rejection of psychoanalysis: although most of the themes Beck describes (e.g. 'I was in a restaurant but the waiters would not serve me'; 'Everyone was invited to the party but me'; 'My fiancée married someone else') appear interpretable in terms of the simple hypothesis of motivated self-depletion, surprisingly he interprets them all in terms of the more complex dynamic of self-hatred: the depressed patient's misery is always seen as deliberately rather than incidentally self-inflicted, reflecting his 'need to suffer'.¹³ Dreams such as not getting food that is requested, or being rejected – which in themselves appear at most to indicate a need to safely anticipate setbacks or protect cherished others from one's resentment by portraying

life as hopeless and oneself as worthless – are instead counterintuitively read as ‘the representation of self-punitive tendencies ... the depressed person feels guilt about his ego-alien drives and punishes himself for them.’¹¹

The question naturally arises as to why Beck was so drawn to the masochism hypothesis. And this is particularly significant because it was when his later experimental and clinical investigations – including his patients’ appropriately negative reactions to interpretations overly organised by this hypothesis – rightly led him to doubt whether he really was meeting everywhere with self-hatred, that he threw out the entirety of the baby of the general psychoanalytic theory of depression along with the specific counterintuitive bathwater of an over-reaching application of the masochism hypothesis. Which is to say that the entire project of explaining why a patient may be unconsciously motivated to think and feel and act in depressive ways was abandoned; in Beck’s hands their condition now collapsed into a habitual rut of self-maintaining negative thought, feeling and behaviour.

One answer to why Beck was so compelled by the masochism hypothesis that it overrode his recognition of the frequent sufficiency of the simpler theory of motivated self-depletion is apparent in the early papers themselves. Beck somehow entirely forgets about the psychoanalytic ideas of depression as due either to thwarted mourning or to avoided fear, becoming solely preoccupied by the idea of it as due to suppressed anger. Such depression as did not appear to evince anger (since, one imagines, it was really due to suppressed sadness or fear) could then only be brought into line with the suppressed anger hypothesis by positing that such a patient was masochistically contriving to make herself depressed.

Another answer only becomes apparent in Beck’s later writings; it concerns the nature of dreaming. (Grasping this takes a little patience, but it is worth the effort.) In these later writings he tells us that what he was actually trying to do in his early research was to set the clinical psychoanalytic theory of depression as a function of suppressed anger on a firmer scientific basis by providing quantitative psychological evidence of unconscious anger in the dreams of his depressed patients.^{14,15} Although he did not report it at the time, what he later tells us he found is what has also been established since:¹⁶ that as a group people with depression have fewer themes of anger in their dreams than people who do not have depression. This puzzled him, as somehow he had understood the Freudian idea of dreams being the ‘royal road to the unconscious’¹⁷ to mean that feelings unacceptable to the waking patient ought to show up straightforwardly in their dreams.¹⁴ The finding of fewer angry themes in the dreams of patients with depression therefore appeared to contradict the psychoanalytic hypothesis of depression as resulting from suppressed anger. This troubled Beck, but – at least until he found independent evidence of the implausibility of this interpretation – he realised he could save the psychoanalytic theory by interpreting the very dreaming of such miserabilist dreams as masochistically motivated (‘he makes himself dream such miserable dreams because he hates himself’).

What is deeply unclear in all of this is why Beck thought that Freud’s theory posited that unconscious emotions ought to be directly manifest and countable in dreams. After all, Freud’s theory was that dreams serve to protect sleep by helping prevent the dreamer’s anxious recognition of emotions they find unacceptable, such as anger towards loved ones. In that theory dream construction involves the disguise – through displacement, condensation, reversal, negation and projection – of such impulses and emotions as threaten a comfortable sense of self–other relations. (Freud’s ‘royal road’ refers not to a direct, undisguised revelation of the unconscious, but rather to dreams offering particularly rich sites for interpreting the products of defences against intolerable feelings and motivations – by contrast with the myriad, emotionally irrelevant concerns of waking life.) In retrospect it seems at least possible that Beck’s enthusiasm to formulate and test a psychoanalytic hypothesis using the quantitative methods of empirical psychology ended up getting the better of his grasp of the psychoanalytic theory itself.

To sum up so far: a central plank of cognitive therapy’s origin myth has it that it developed out of an apparent scientific disconfirmation of the clinical psychoanalytic theory of depression as a motivationally explicable state.¹⁴ But in retrospect what seems more likely to have happened is that an inappropriate quantitative methodology deployed to provide support for an unlikely theory of depressive dreaming actually found against it; that an implausibly general theory of depressive masochism was developed to save the floundering analytic theory; and that when this overly general masochism theory was dropped for good reason, the whole idea of symptoms as motivated by the avoidance of intolerable feelings – i.e. the whole idea of a depth psychology – was jettisoned for no good reason at all.

Therapeutic practice

As described above, the development of cognitive therapy's psychopathological theory rests on its unwarranted rejection of the psychoanalytic notion of depression as unconsciously motivated. The development of cognitive therapy's psychotherapeutic technique, however, depends on its rejection of the centrality for psychotherapeutic practice of what psychoanalysis terms the 'transference relationship'.⁷ A curious aspect, then, of Beck's development of cognitive therapy is that it was actually inspired by his encounter with, and dawning realisation of the clinical significance of, what are clearly recognisable as his patients' transferences to him.

First, a note on 'transference'. A defining preoccupation of psychoanalysis is with how immersion in relationships which inspire concern and attachment – such as those with psychotherapists, partners, parents, employers, etc. – so readily elicits unrealistic fearful and idealising expectations concerning others' views of us. These relentlessly maintained, emotionally charged expectations are seen by psychoanalysis as being at the root of much psychopathology, and their manifestations inside and outside of therapy are known as negative and positive transferences. They can be easy to attend from, as it were, but powerfully difficult to attend to – i.e. they are often unconscious – and their patterns are typically transferred from one significant other to another over time.^{18,19} The task of psychoanalytic therapy is the patient's emancipation from distorting transference patterns, a task prosecuted by first facilitating the flourishing and then the subsequent experiential emancipation from the transferences between patient and psychotherapist, an experience that can then generalise to the transferences in the rest of the patient's life. Much of a psychoanalytical psychotherapist's training has to do with developing his ability to make room for and be emotionally touched, yet not inexorably swept along, by the patient's transference so he can think about, experience, describe, and help liberate the patient from her unconscious depressogenic emotional habits.

To return to cognitive therapy. As Beck¹⁵ tells the story, he had a patient who would lie on the couch each session and regale him with lurid tales of her sexual exploits, while he sat back and offered somewhat by-the-book psychoanalytic interpretations regarding the content of whatever it had occurred to her to say. At the end of one session, however, Beck asked his patient how she was feeling; she replied 'anxious'. Beck first suggested to her, in an interpretation focusing only on intra-psychic issues, that conflicts about sex were making her anxious. She cautiously responded, however, to the effect that her real worry was interpersonal: her worry was that he was bored by her. Beck then began to see 'that there's a whole stream of pre-conscious thinking that goes on that the patient doesn't normally communicate to the analyst'¹⁵ – especially pessimistic, biased, black-and-white, over-general irrational expectations concerning what the therapist thinks and feels about the patient. Beck came to call these transference expectations the patient's 'negative automatic thoughts' (NATs) and, drawing on the 'rational therapy' of Albert Ellis,²⁰ went on to develop a significant range of procedures to help the patient attend to and challenge their NATs.

There are several curious things about this and related narratives Beck offers.²¹ The first is that Beck the novice psychoanalyst started out (as one does) by naively listening to and interpreting the explicit content of what the patient freely said, rather than listening in with an analytic ear to what she was not saying, to the unconscious dimension of the transference (i.e. listening to how he featured latently in her mind), or listening in to his own countertransference (i.e. to the feelings provoked in him by, in particular, the performative rather than declarative aspect of her discourse). Thus, despite the patient's manifest lack of inhibition in talking about sex, Beck still interprets her anxiety as due to sexual conflict.

The second is that when Beck shows a real interest in his patient, asking her how she feels, she is able to acknowledge her transference to him, and they can understand it together to beneficial effect. We go on to hear that these worries (which, despite, or perhaps because of, being so very omnipresent in her mind she never discussed before) are actually common for her in other settings too. As the therapeutic relationship is strengthened (by Beck's concerned question about her actual feelings), the emotionally alive experience of the transference (her worries about Beck being bored by her) also begins to be acknowledged and worked through, and interpretative speculation about intra-psychic conflict is foregone.

The most striking thing about Beck's narrative, however, is that this therapy-potentiating emotional experience of the transference is set aside almost as soon as it is encountered. Anyone who has been in psychotherapy will know how replete it is with holding back acknowledgement, both to oneself and to the therapist, of one's thoughts and impulses for fear of encountering one's own or the therapist's disapproval, despite such fears speaking right to the heart of such emotional difficulties as brought one to therapy in the first place. Notwithstanding the simplicity of the 'fundamental

rule' of psychoanalysis – to 'free associate', i.e. say whatever is actually on your mind (which is not the same as saying whatever you feel like saying!) – the fact is that no one can truly follow it,^{21,22} since we naturally associate away from rather than towards conflictual emotional preoccupations.²³ This is why the therapist's job is often to listen not so much to the content of what is said as to performative matters of style, timing and omission. Beck, however, construes NATs as merely incidentally hard for the patient to articulate and challenge – due to a lack of training in attending to and reporting on them²¹ – rather than because of their emotional valence. This, I submit, is intuitively implausible. More consonant with everyday clinical and personal experience is the notion that his patient did not elaborate her actual worries because she feared they might not be disconfirmed – and chose instead to distract herself and please him with endless talk about sex, presumably since, as we all know, Freudians do have rather a reputation for being interested in such matters!

Cognitive therapists are often accused of ignoring the importance of the therapeutic relationship, but as Beck's daughter Judith Beck explains, this is false – cognitive therapy 'requires a good therapeutic relationship. Therapists do many things to build a strong alliance. For example, they work collaboratively with clients ... ask for feedback... and conduct themselves as genuine, warm, empathic, interested, caring human beings.'²⁴ However, as psychoanalytical psychotherapist Jonathan Shedler responds, 'This is the kind of relationship I would expect from my hair stylist or real estate broker. From a psychotherapist, I expect something else. [Beck appears] to have no concept that the therapy relationship provides a special window into the patient's inner world, or a relationship laboratory and sanctuary in which lifelong patterns can be recognized and understood, and new ones created.'²⁵ Shedler's optimism regarding his hair stylist and estate agent perhaps warrants some cognitive restructuring, but his point about the therapeutic relationship stands.

A relationship which is not merely instrumentally useful (as intended by cognitive therapy), but itself intended as the unique locus of change (as in psychoanalytic therapy), is one which both activates the patient's latent transference fears (that the therapist is untrustworthy, angry etc.) and simultaneously provides enough of a working alliance to enable such prototypical fears to be experienced, understood and worked through in real time. With a merely collaborative and empathic focus the opportunity is lost for the real-time eliciting and challenging of the patient's underlying emotional preoccupations. The result is somewhat like trying to conduct exposure therapy for a phobia without physically encountering the fearful stimulus, or like a chat between two adults about the difficulties of a child left waiting in the next room.

A popular canard has it that psychoanalytic psychotherapy is unhelpfully preoccupied with the past, whereas CBT is practically focused on the present. This ignores the way both therapies tend to formulate current disturbance in terms of childhood-acquired pathogenic beliefs. More importantly, it ignores the fact that, at the level of technique, CBT tends to focus on matters arising in the patient's past week, whereas a transference-focused psychotherapist hones in on uncomfortable transference feelings alive right now between patient and therapist. Rather than providing merely intellectual insight to further an ongoing project of dreary self-management, itself supplementing an already exhausting project of defensively managing intolerable feelings, psychoanalytic psychotherapy instead offers an intrinsically mutative emotional exchange which already constitutes a growth in self-possession and a change of heart, obviating the need for such self-management.

Implications

Work in the transference is designed to facilitate a patient's living exposure to their real underlying fears about how they would be seen if they were to allow themselves their own true feelings. The opportunity is thereby provided for a true change of heart – i.e. for emancipation from depressive cognition through an experiential recovery, acceptance and integration of hitherto unconscious emotional experience. Ideally, this would reduce the need to manage the dismal distal products of this emotional evasion with therapeutic techniques of behavioural activation, cognitive challenge or mindfulness. The result of such an effective therapy for depression would be akin to that sometimes achieved by CBT for anxiety conditions: a transformative learning, from the experiential ground up, that reinstates true self-possession.

The time is past for studies comparing outcomes of self-professed cognitive therapy/CBT and psychoanalytic practitioners. The apparent success of particular therapies in such trials is better predicted and explained not by therapeutic model²⁶ but by the theoretical orientation of the lead experimenter,²⁷ the personal qualities of the therapists,²⁸ or by theory drawn from quite different models.²⁹ Beck himself expressed the wish that cognitive therapy as a school die out,³⁰

the apt thought here being that what matters is not the treatment model but rather the particular treatment qualities which are individually worthy of study.

CBT treatments for depression often suffer high drop-out rates.³¹ One possible explanation for this is a lack of attention to transference. Sometimes this may be because negative transference undermines the therapeutic collaboration, although ideally CBT therapists are trained in recognising and managing this.⁷ At other times it may be because psychotherapeutic relationships that are merely collaborative, rather than offering experiential work in the transference, do not hit the therapeutic spot. Recently, however, there has been a resurgence in the general theory of,⁸ clinical practice and treatment manual for,³² and outcome studies supporting a transference-involving psychoanalytic approach to depression. With regard to outcome, outstanding results in helping patients with treatment-resistant depression which is not readily resolved by CBT have been obtained by particular practitioners of psychoanalytic psychotherapy³³ and somewhat optimistic results have been obtained with similar patients in the multi-practitioner Tavistock Adult Depression Study.³⁴

The present article has not been concerned to argue for a psychoanalytic approach to depression on the basis of empirical evidence. Instead, it noted that Beck's development of a cognitive approach to depression was predicated on his rejection of a psychoanalytic understanding of depression in particular, of the dynamic unconscious in general, and of psychoanalytic psychotherapeutic methods – and that his rationale for all this was flawed. What he developed in its stead does not stand or fall on this basis, and there are several benefits (especially clinical pragmatism and a strong research tradition) to the therapy he developed. But, given both the flawed rationale for rejecting a psychoanalytic approach which, rightly understood, possesses considerable clinical plausibility, and given the relatively poor results obtained by CBT for depression in much clinical practice, the time is surely right to revisit the psychoanalytic model.

1.6.75 The cognitive therapy of depression rests on substantial theoretical, empirical and clinical foundations: a reply to Dr Gipps

2017-10

Abstract

Dr Gipps claims that the cognitive therapy for depression rests on a mistake. But his anachronistic analysis of Beck's early research from the perspective of current psychoanalytic theory misses the point. The value of the research was not that it disproved psychoanalytic theory, but that it generated a model of depression that has revolutionised psychotherapy research. Psychoanalysts are belatedly adopting research methods that Beck pioneered half a century ago. The cognitive model of depression has explanatory power for both maintenance and vulnerability and has substantial research underpinning it. Cognitive therapy for depression has a larger body of evidence for its efficacy and relapse prevention effect than any other psychotherapy. Transference-focused approaches to depression have yet to establish themselves in the same way.

- *The cognitive therapy of depression rests on substantial theoretical, empirical and clinical foundations: a reply to Dr Gipps*
 - *Psychopathological theory*
 - *Therapeutic practice*
 - *Conclusions*

Dr Gipps's polemic against Beck's cognitive therapy for depression rests on two assumptions. First, that cognitive therapy 'doesn't work very well' for the condition, and second, that the cognitive model is invalid because it is based on a flawed understanding of psychoanalysis. The first statement is misleading – cognitive-behavioural therapy (CBT) has the most comprehensive evidence base of all the psychological therapies. The second statement is largely irrelevant – the cognitive model of depression rests on a substantial body of research that is independent of the experiences that led to its original formulation. This reply will review the evidence for the effectiveness of psychological treatments for depression, highlighting the selectiveness of Dr Gipps's interpretation of the literature. It will then examine the cognitive model, demonstrating that it is far richer than he suggests, and has developed and changed in the light of extensive research. Finally, Gipps's caricature of CBT practice will be challenged: contemporary CBT does have something to say about experiential avoidance and interpersonal processes. It has the flexibility to address these as and when necessary without making them the sole vehicle for change. Gipps seems to believe that by denigrating Beck's psychoanalytic credentials and claiming his theory is based on a misunderstanding he can somehow erase nearly 60 years of research supporting the cognitive model. This is merely opinion, not reasoned scientific discourse.

Dr Gipps argues that current treatments for depression 'fare little better than placebo' so we should turn to psychoanalysis. He claims poor results for medication, counselling and CBT, but neglects to mention that trials of psychodynamic psychotherapy have not demonstrated it does better than CBT (the reverse may actually be the case).¹ If we take a non-partisan approach, the conclusion is that a number of treatments work for depression. For instance, a recent meta-analysis of randomised controlled trials (RCTs) reported effect sizes for CBT, counselling and short-term psychodynamic psychotherapy at 0.67, 0.57 and 0.69, respectively.² Dr Gipps, however, disingenuously selects a small uncontrolled trial of intensive short-term dynamic psychotherapy ($n = 10$) as his argument for the potential superiority of the psychodynamic approach.³ All these psychological treatments are as effective as antidepressants, but the superiority of all treatments over placebo may, as he suggests, be less than was once assumed.⁴ There is indeed a powerful placebo effect in mild depression, but this seems to lessen as severity of depression increases.⁵⁻⁹ It is also important to note that although placebo may do well in the short term, patients are more likely to relapse.¹⁰ Cognitive therapy still has the largest evidence base of all the psychotherapies for depression; not only is it effective in the acute phase, but it also reduces relapse.^{11,12} Its effects are not restricted to RCTs: in naturalistic settings 40% of patients recover and 64% show reliable improvement.¹³ The empirical data give us no reason to abandon CBT for depression.

Psychopathological theory

The implication of Dr Gipps's rather condescending analysis is that cognitive therapy would not have been created if Aaron Beck had been a better psychoanalyst (we are pointedly told that Beck failed entry to the American Institute of Psychoanalysis). According to Gipps, Beck got the wrong end of the stick, and his misunderstanding of theory led him to devise a set of experiments that set psychopathology off on the wrong track for the next half century. The problem here is that Beck's early work is scrutinised from the perspective of current psychoanalytic theory rather than seen in its historical context. It appears the 'mistake' Beck made was to be unaware of British psychoanalysis when he carried out his ground-breaking research in the late 1950s. Gipps's main reference is Trevor Lubbe's 2011 book written from the perspective of the British object relations school, which Beck is unlikely to have encountered in his analytic training in the USA – a training inclined towards instinctual and ego theories. Should we then abandon all Freud's work because his theories, originally framed in biological terms, were based on a misunderstanding of modern neurology?¹⁴ Gipps describes clearly what he sees as the current consensus of psychoanalytic thinking on depression which has unconscious avoidance of emotion at its centre: avoidance of feelings of loss, avoidance of anger towards those to whom we are

attached, and avoidance of fear. Rather than face these feelings the patient retreats into depression, preferring to live 'in a dismal and diminished version of himself, his situation and his future.' Beck's investigations tested one aspect of the anger-avoidance theory of depression: the masochism hypothesis. Anger towards another is repressed because it is unacceptable, but it breaks through and is then turned on the self. This internalised hostility leads to self-punishment, manifested in the self-criticism and self-abasement found in depression. Gipps wonders why Beck was drawn to the masochism hypothesis to the exclusion of others. The simple answer is that the introjected anger hypothesis was the prevailing theory of depression in American psychoanalysis at the time. Even in 1988 David Milrod could still write that 'the essential elements in a depression are the self-directed aggression and the mood state to which it leads'.¹⁵ In this context Beck's investigation of internalised hostility is very reasonable, and his research design perfectly acceptable for its time. But the significance of this research is not that it disproved psychoanalytic theory, but that it stimulated a powerful new theory. Whether one accepts the cognitive model or not, it has made an enormous contribution to the development of empirically based research in depression. Beck showed that it was possible to construct a theory that was refutable, and his steadfast focus on testing his theories has led to changes and modifications on the basis of research evidence. This is in contrast to psychoanalysis, which tends to change on the basis of new theoretical or clinical trends, but rarely in response to new research evidence. The first outcome study of cognitive therapy for depression, for instance, demonstrated that psychological therapy could be as effective as pharmacotherapy and showed that therapy could be operationalised and manualised.¹⁶ Even psychoanalysts now admit the value of treatment manuals!¹⁷ Any studies demonstrating the efficacy of psychoanalytic psychotherapy therefore owe a considerable methodological debt to Beck's pioneering work in outcome research.

So what is this mistaken cognitive model of depression? According to Beck, pervasive negative thinking is at the centre of depression: negative views of the self, the world and the future. These thoughts result from an information processing bias that selectively attends to negative events, negatively interprets situations, and encodes them as negative memories. These processes result from the activation of underlying cognitive structures or schemas, in the form of dysfunctional beliefs.^{18–20}

There is considerable evidence for this cross-sectional model: for a shift in information processing, for the reciprocal interaction between low mood and negative thinking, and for the presence of dysfunctional beliefs in depression.^{21,22} Beck also formulated a developmental model to explain vulnerability to depression. Negative events in childhood, for example loss of a parent, lead to negative beliefs which become activated when specific events impinge on these schemas. Beck revised this theory in the light of findings that severe life events are not always necessary to precipitate depression. An accumulation of milder stressful events can contribute, and with each successive episode the severity of event needed to trigger depression becomes lower (the kindling effect).²³ A further refinement of the model came with the discovery that when a depressed mood was evoked people prone to depression exhibited negative cognitive biases (cognitive reactivity).²⁴ These new findings were integrated into the theory using the concept of the depressive mode – a network of cognitive affective, motivational, behavioural and physiological schemas activated in depression. The mode is 'a complex neural network, including multiple relevant brain regions that are activated or deactivated during depression' (p. 971).¹⁹ With repeated depressive episodes the network of beliefs becomes stronger and relatively autonomous, so that minor stressors trigger the depressive mode. The cognitive model provides a comprehensive account of both vulnerability to and maintenance of depressive episodes. It does focus on unconscious processes, i.e. schemas and information processing biases, but these are unconscious because they are automatic, not because they are repressed. Regardless of its origins, the cognitive model stands on its own merits as an account of significant phenomena in depression.

Therapeutic practice

Dr Gipps's main criticism of CBT practice seems to be that it is not psychoanalysis. The collaborative, problem-solving relationship which is at the heart of good CBT is ridiculed as superficial because it apparently misses the opportunity to work with the transference. CBT, unlike psychoanalysis, is a problem-focused therapy, and one of its strengths lies in the way the problem is placed on the table and the therapist and patient work together to solve it. In depression this allows for a partnership in solving realistic problems and the identification of blocks to problem-solving arising from the patient's negative thought processes. For instance, negative predictions about being rejected may lead a patient to be socially avoidant, further reinforcing their depression. The therapist helps the patient test their beliefs by attending a social event and noting the outcome. This 'collaborative empiricism', together with the structure and focus

of therapy, engages the healthy adult functioning mode and minimises regressive transference so that the patient can learn strategies to help them out of their depression.²⁵ When negative interpretations of the therapist's behaviour arise these can be worked on together, for instance by noting how the patient's fear that the therapist may be cross with them is an example of a pattern of depressive misinterpretation that occurs outside the session with others. As the developmental conceptualisation is deepened over the course of therapy, the underlying assumptions that drive this reaction might be identified (e.g. 'If I make a mistake I'll be rejected'), their origins in parental criticism discussed, and the schemas modified. This is work with the transference but in the service of learning how to manage negative reactions activated when the person is depressed. With patients with personality disturbance the focus on the interpersonal relationship becomes more important and changing interpersonal schemas becomes one of the key goals of therapy. This is what Gipps calls the 'real-time eliciting and challenging of the patient's underlying emotional preoccupations.' However, CBT has the flexibility to work with the therapeutic process when necessary, but is not shackled to it as the only vehicle for change.

A second, more interesting, point made by Gipps concerns the role of experiential avoidance in depression. This is central to CBT for anxiety, where much of therapy focuses on identifying negative predictions and setting up behavioural experiments to test the fear. This is indeed often done in real time, through experiments in the session such as panic induction. This is of course very effective without any reference to transference. Recent developments in 'third-wave' CBT explicitly address emotional avoidance, and there is room for more attention to this within the standard cognitive model of depression. In mindfulness-based cognitive therapy, for instance, mindfulness meditation is taught as a skill to help patients practise moving from the ruminative depressive mode into a mode where they are present for whatever they are experiencing, approaching difficult feelings rather than moving away from them.²⁶ Although this concept of avoidance of emotions is similar to that in the psychoanalytic model, the significant differences are that it is not conceptualised as a motivated avoidance arising from a dynamic unconscious, and that it is perfectly possible to work with it outside the transference.

Dr Gipps's final criticism of CBT practice regards its project of 'dreary self-management'. Psychoanalytic psychotherapy, by contrast, 'offers an intrinsically mutative emotional exchange which . . . constitutes a growth in self-possession and a change of heart, obviating the need for such self-management.' This is wonderful news. Many of us would love to engage in a therapy that magically transforms us so that we do not have to pay attention to our habitual patterns that so frustratingly trip us up, but this is not what good psychodynamic psychotherapy is actually about. It involves noticing reactions outside the session as well as within, and considerable repetitive work on the self. Depression is a relapsing condition and it is patronising and misleading to imply that learning ways to manage it is unnecessary. Patients who successfully negotiate the vicissitudes of recurrent depression learn to identify risk factors that make them vulnerable, recognise how structuring their week helps to maintain positive mood, and how they can easily fall into negative thought patterns. Cognitive therapy gives them tools for doing this, but also changes underlying beliefs, to reduce vulnerability to depression.

Conclusions

Cognitive therapy is a tried and tested therapy for depression. It has a proven relapse prevention effect, but is not a panacea and is not the only effective treatment for depression. Most of these therapies do not work with the transference, and there is nothing to suggest that a transference-focused therapy will be hugely more effective or reduce dropout rates. The results from the two reported trials of psychoanalytic therapy are promising, but much more research is needed before they can be compared with the accumulated evidence for the effectiveness of CBT. Dr Gipps's article is based on a mistaken reading of the research into CBT as a therapy, and an anachronistic approach which judges Beck's evaluation of psychoanalytic theory in 1959 by the standards of 2016. What Beck developed stands not on this, but on almost 60 years of research. This has not only generated a robust theoretical model of depression, but has given psychoanalysts methodologies they now use to evaluate their own theories and therapies. The cognitive model of depression is likely to be around for another 60 years, but it will evolve and change on the basis of empirical research rather than theoretical whimsy.

1.6.76 Suicide patterns on the London Underground railway system, 2000–2010

Abstract

Aims and Method Suicidal acts on underground railway networks are an area of public health concern. Our aim was to review recent epidemiological patterns of suicidal acts on the London Underground to inform future preventive interventions. Data from 2000 to 2010 were obtained from the British Transport Police via a Freedom of Information request.

Results The mean annual rate of suicidal acts from 2000 to 2010 was 5.8 per 100 million passenger journey stages. Of those who died by suicide, 77.3% were of White Northern European ethnicity. A fifth had a history of mental illness.

Clinical implications The widening gap between the number of recorded suicide attempts and completed suicides is encouraging. Further research is required regarding the role of drug and alcohol use, psychiatric history and area of residence. Installation of platform screen doors should be considered in future railway network expansion.

The London Underground was built in 1863 and was the world's first underground railway system.¹ Today it comprises 11 train lines serving a total of 270 stations across 402 km.¹ In 2015/16 it saw the completion of 1.34 billion journeys across its network.¹ Suicide on underground railway systems is a major cause for public health concern. Railway suicide can have a traumatic impact on both train drivers² and witnesses, and can lead to significant train delays, with substantial economic consequences.³

Between 1940–49 and 1980–89 the mean number of suicidal acts per year on the London Underground rose from 36.1 to 94.1.⁴ Previous studies have suggested an association between the rising number of suicidal acts across the national railway and increasing volumes of passengers across railway networks;^{5,6} however, this finding has been inconsistent across studies.⁷ Use of preventive measures to stop suicidal acts on railways has been the focus of several studies, for example, concentrating on changes to the immediate environment, media reporting and interagency collaborations.⁸

Our aim was to review recent epidemiological patterns of suicidal acts on the London Underground to better inform future preventive interventions.

Method

Data covering deaths by suicide between 2004 and 2010 and 'person under train' incidents between 2000 and 2010 were obtained by one of the authors (M.R.) on 7 October 2011 through a Freedom of Information request to the British Transport Police. Data covering completed suicides between 2000 and 2003 could not be provided owing to changes in coding. No further information in relation to this was provided by the British Transport Police.

The data provided by the British Transport Police included demographic information (age, gender, ethnicity) of suicide victims between 2004 and 2010. Age was categorised as: <15 years, 15–44 years, 45–74 years and > 75 years. The authors also received figures pertaining to all suicide attempts (which included incidents where individuals were prevented from jumping in front of a train or accessing the tracks) and all 'person under train' incidents (intentional and accidental) between 2000 and 2010.

Information regarding the total number of journeys completed on the London Underground was obtained from the publicly accessible Transport for London (TfL) 2011 *Travel in London* report.⁹ Passenger journeys were recorded as 'journey stages', where a journey stage represents a segment of a trip made on a particular mode of transport. For example, a journey made up of two stages could include a walking stage to the Underground station followed by a second stage on the Underground network.¹⁰

Results

Between 2000 and 2010 there were 644 recorded suicide attempts on the London Underground. The mean annual rate of suicide attempts during this period was 5.8 per 100 million journey stages (95% CI 5.0–6.5). Between 2004 and 2010 there were 132 deaths by suicide. The mean annual rate of individuals who died by suicide during this period was 1.8 per 100 million journey stages (95% CI 1.4–2.2). In addition, there were 38 deaths in which the coroner recorded an open verdict and 9 deaths in which the inquest had not yet taken place or in which the British Transport Police did not have access to the outcome of the verdict. The total number of 'person under train' incidents between 2000 and 2010, which included both intentional and accidental acts, was 433. The mean annual rate of 'person under train' incidents during this period was 3.9 per 100 million journey stages (95% CI 3.6–4.2).

Figure 1 shows an increase in the number of suicide attempts from 2004 to 2009, which is more marked than the increase in the number of incidents of death by suicide. The number of 'person under train' incidents, however, remained relatively constant. Our data revealed a small increase in the number of suicide attempts and 'person under train' incidents during May–August, with a peak in June, as illustrated in *Fig. 2*.

Fig. 5: Suicide attempts v. deaths by suicide, 2000–2010.

Tables 1 and 2 display the age and ethnicity distribution for males and females in incidents of deaths by suicide 2004–2010. Age at death was not available for two male individuals, and ethnicity data were not available for one

male individual. Of the deaths by suicide, two-thirds ($n = 88$) were male and a third ($n = 44$) were female. The average age at death was 40.7 years in males and 45.5 years in females.

Of the 132 individuals who completed suicide on the London Underground, 110 (83.3%) were resident in London at the time of the event. Information was unavailable for one individual. A history of mental illness was confirmed in 20.5% of individuals ($n = 27$).

The Northern Line had the greatest number of recorded suicide attempts ($n = 145$) between 2000 and 2010, followed by the Central Line ($n = 99$) and Piccadilly Line ($n = 92$). The lowest numbers of suicide attempts during that period were recorded on the Jubilee Line ($n = 27$) and Bakerloo Line ($n = 33$).

King's Cross St Pancras station saw the highest number of suicide attempts between 2000 and 2010 ($n = 18$), followed by Mile End ($n = 17$), Victoria ($n = 16$), Camden Town ($n = 15$), Archway ($n = 13$), Liverpool Street ($n = 13$), Oxford Circus ($n = 12$), Green Park ($n = 12$) and Earl's Court ($n = 11$). Suicide attempts led to delays in underground railway services; between 2000 and 2010 the Northern Line and Piccadilly Line experienced the greatest total delays (8484 min and 5521 min, respectively). The Jubilee Line recorded total delays of 2396 min and the Bakerloo Line 1911 min over the same period (*Fig. 3*).

Discussion

Suicide patterns over time

There was a marked increase in the number of suicide attempts across the London Underground from 2004 onwards, although this trend was beginning to reverse in 2009. Although there was also a rise in deaths by suicide during that period, this was of a lesser degree. In their 2016 paper looking at suicide trends across the entire England and Wales railway system, Taylor *et al* found that male suicide rates had increased from 6 to 8.4 per million from 2000 to 2013, with the greatest increase observed between 2010 and 2013, from 6.4 to 8.4 per million.¹¹ By contrast, female suicide rates remained relatively constant. Although previous studies looking at suicide attempts on underground railway systems have suggested a case fatality rate of 43 to 55%^{4,12,13} (compared with 90% on overground railways¹⁴), this does not fully

explain the extent of the difference observed. Increased reporting of suicide attempts by London Underground staff may be a factor, as well as the introduction of preventive interventions allowing for the early identification of persons at risk.

TfL has worked towards suicide prevention since the 1990s.¹⁵ This has included strategically placed Samaritans campaign posters and telephones within stations. More recently there has been further collaborative work with the Samaritans to train staff in identifying persons at risk, and giving them the confidence to intervene.¹⁶ Additional interventions have included platform-edge barriers on the Jubilee Line and gates to prevent passengers from entering tunnels at existing stations, as well as use of video surveillance and markings/warning signs to prevent individuals from approaching the platform edge.¹⁵ Presence of staff on platforms during rush-hour periods may also be helpful. The increase in the number of suicide attempts and deaths by suicide in 2008 and 2009 may in part be explained by the financial crisis of 2008.¹⁷

The number of journey stages made on the London Underground increased from 0.976 million in 2004 to 1.065 million in 2009.⁹ There have been several studies exploring a potential link between higher numbers of passenger journeys and the incidence of suicide, with variable findings. Sonneck *et al* found no such association on the Viennese subway,⁷ whereas in Stockholm, Sweden, and The Netherlands, authors noted a positive association.^{5,6} Although Waterloo station is the busiest in terms of passenger flow,¹⁸ it does not feature in the top 20 stations for suicide attempts on the London Underground in 2000–2010.

Our data did not reveal any marked variation in suicide attempts across the year, although there was a small increase in events during May to August, with a peak in June. Findings in other studies have been variable. Although Dinkel *et al* found no association between seasons of the year and suicide events,¹⁹ others have noted a small increase in suicide events during the summer months⁴ or during the months of April and September.²⁰ Even though summer months are associated with higher numbers of tourists in London, it is unclear whether this has had an effect on the number of suicide attempts during those months. Although a majority of those who died by suicide on the London Underground were mostly resident in the city, the time of year of their death was not available, nor was the proportion of London residents represented among those individuals who attempted suicide.

Demographics

The stark overrepresentation of men in the 15- to 44-year age group (61.4%, $n = 57$) among those who died by suicide was in keeping with national figures (England), where the proportion of males is approximately two-thirds.²¹ The overall gender distribution of suicide victims on the London Underground was very similar to that recorded nationally during the same period (2004–2010), with 66.9% of cases being male and 33.1% female. By contrast, the proportion of females aged over 75 years was almost double that of males (6.8% and 3.5% respectively), although the numbers were very small and therefore need to be interpreted with caution.

This is the first study looking at the ethnic distribution of suicide victims on the London Underground. The predominance of individuals of White Northern European background (>75%) is significant in a place like London where people of White ethnic background make up less than 60% of the total population,²² in particular since 83.3% of individuals who died by suicide on the London Underground were resident in the city. Moreover, use of the London Underground is evenly distributed across different ethnicities.²³ There are currently no data available on the ethnicity of individuals who die by suicide nationally, hence we do not know whether individuals of White Northern European ethnicity are also overrepresented relative to other ethnic groups. Similarly, we do not know whether individuals of White Northern European ethnicity are overrepresented in suicide incidents occurring across the rest of the national railway network or involving violent suicide methods.

In our sample a fifth of individuals had a history of mental illness. Unfortunately, no further data were available regarding their diagnosis, level of psychiatric care at the time of suicide or whether they were current or recent in-patients of a psychiatric unit. Proximity of stations or railway suicide ‘hot spots’ to psychiatric hospitals has been highlighted as a risk factor for suicide in several studies,^{4,5,12,24,25} although the result was not found to be significant across the Stockholm railway system.⁵ In their 1987 study of 100 individuals who had attempted suicide on the London Underground, Cocks found that 13 were current psychiatric in-patients, and 2 had been discharged within 48 h of the event.²⁶ Fifteen individuals had expressed suicidal ideation in the 24 h preceding the event. Although proximity to a

psychiatric hospital was not taken into account in this paper, the presence of a history of mental illness in a fifth of those who died by suicide highlights the need for staff working in psychiatric hospitals to be aware of the proximity of any nearby Underground stations in their assessment of risk in patients.

Additional risk factors

In Stockholm, authors found that the stations with the highest suicide rates were associated with higher levels of surrounding drug-related crime.²⁷ Previous studies have shown that consumption of alcohol or drugs was a characteristic of about 10 to 20% of individuals who had attempted or died by suicide on an underground railway system.^{12,28,29} In the UK National Confidential Inquiry into Suicide and Homicide by People with Mental Illness, the authors noted that 54% of those who died by suicide and had been in contact with mental health services over the past year had a history of alcohol and/or drug misuse.³⁰ Intoxication with drugs or alcohol can increase the risk of impulsive and risk-taking behaviour and may have been a contributing factor in the incidents observed on the London Underground, including ‘person under train’ incidents of accidental cause. Unfortunately, the British Transport Police do not currently collect this information. Consumption of alcohol on the London Underground is forbidden; however, consideration must be given as to how to manage the risk of suicidal behaviour or accidental injury in intoxicated individuals.

Use of preventive measures

Several recent studies looking at suicide attempts on underground and overground railway systems have focused on the use of preventive measures. Diminishing ease of access to the track through barrier methods is suggested as an effective intervention, although Cox *et al* noted a lack of studies demonstrating this.³¹ In Seoul, the presence of platform screen doors (PSDs) reduced suicides on the underground network by 89%.³² PSDs are continuous panels that separate the platform from the train, only opening when the train is in the station. Half-length PSDs (1.6 m) were less effective than full-length PSDs; however, full-length PSDs were 120–150% more expensive to install.³² The effectiveness of PSDs was also noted in Hong Kong.³³ Portions of the Jubilee Line include the presence of PSDs, which may be a contributory factor to the lower number of suicide attempts observed on this line relative to the rest of the network. The presence of PSDs would also reduce the risk of accidental falls on to the railway tracks, thus reducing the number of ‘person under train’ incidents. Although the cost of installing these doors makes their presence across the railway network unlikely in the near future, their potential for significantly reducing the number of injuries or deaths on the tracks should be considered when planning future network renovation or expansion.

Other proposed interventions include increasing the presence of drainage pits, as mortality at London Underground stations that have a drainage pit was 44% *v.* 76% at those stations without, in incidents of individuals falling or jumping in front of trains.³⁴ These drainage pits were originally constructed to drain water between the tracks in deep-tunnel stations. Installation of blue lights at platforms was put forward as an effective measure by Matsubayashi *et al* in 2013³⁵ but this benefit was minimised by Ichikawa *et al* the following year.³⁶ Another suggested measure is reducing the average speed of trains entering the station at peak times.²⁹ In Vienna, changing the way in which media reported suicides on the underground by making it less dramatic was followed by a reduction in suicide.⁷

Strengths and limitations

This is the most recent study looking at patterns of suicide on the London Underground since 1994. It is also the first study looking at ethnicity within incidents of death by suicide on the Underground, and the findings raise new and important dimensions when seeking to introduce preventive measures.

There were several limitations to the study: no data were available for deaths by suicide between 2000 and 2003 owing to changes in coding, and death by suicide could not be confirmed in 47 cases owing to the recording of an open verdict or the outcome of the inquest not being available. Because of the relatively rare occurrence of deaths by suicide on the London Underground the numbers used in the study were small, leading to possible sample size bias. The limited breadth of information collected by the British Transport Police meant that certain risk factors (e.g. use of drugs/alcohol

or whether individuals were psychiatric in-patients at the time of the event) could not be adequately explored in our sample. The study is further limited by the absence of data beyond 2010.

Conclusions

Suicide on the London Underground railway system continues to be an important public health issue. The widening gap between the number of recorded suicide attempts and deaths by suicide is encouraging and may reflect the introduction of preventive measures. Use of PSDs has been proven to be effective for both suicidal acts and accidental ‘person under train’ incidents and needs to be considered when planning railway renovation or construction projects. The overrepresentation of people of White Northern European ethnicity among those who attempted suicide requires further exploration, as does the proportion of non-residents involved in suicide attempts on the London Underground across the year to better target preventive interventions. Finally, the collection of data on alcohol and drug use, as well as a more detailed psychiatric history, would help to inform further research and implementation of preventive measures for suicidal acts on the London Underground.

We thank Dr Neel Halder for his invaluable guidance and support as a mentor under the *BJPsych Bulletin* author mentoring scheme.

1.6.77 Psychiatric neurosurgery in the 21st century: overview and the growth of deep brain stimulation

Kenneth Barrett

Correspondence

Kenneth Barrett

date

2017-10

Abstract

Ambulatory deep brain stimulation (DBS) became possible in the late 1980s and was initially used to treat people with movement disorders. Trials of DBS in people with treatment-resistant psychiatric disorder began in the late 1990s, initially focusing on obsessive–compulsive disorder, major depressive disorder and Tourette syndrome. Despite methodological issues, including small participant numbers and lack of consensus over brain targets, DBS is now being trialled in a wide range of psychiatric conditions. There has also been more modest increase in ablative procedures. This paper reviews these developments in the light of contemporary brain science, considers future directions and discusses why the approach has not been adopted more widely within psychiatry.

In 2014 the Mayo Clinic posted an online video in which a musician plays the violin while a neurosurgeon operates on his brain. Electrodes are being directed to an area of his thalamus with the aim of suppressing an essential tremor by electrical stimulation. Playing the violin during surgery was the best way to test whether the electrodes were in the right place. They were, and the operation was a success.¹

Deep brain stimulation (DBS) was first used to treat severe tremor in people with Parkinson's disease in 1987 and was subsequently found effective in severe dystonia.² Since then, tens of thousands of people have undergone the procedure for movement disorders and the technique has largely replaced earlier lesion-based methods. The most recent application, to 'benign' essential tremor, perhaps highlights its relatively low side-effect profile and patient acceptance. In 1999 a Belgian team used DBS in three people with treatment-resistant obsessive-compulsive disorder (OCD), with favourable results. There have since been DBS trials in a wide range of psychiatric conditions, and a more modest increase in ablative procedures.³ 2014 saw the publication of *Psychosurgery: New Techniques for Brain Disorders* by French neurosurgeon Marc Lévêque, the first 'state of the art' textbook to use that term in 40 years.⁴ It was a translation from the French; Anglophone practitioners in the field prefer a word with less toxic associations: neuromodulation.⁵

Whatever you call it, the use of DBS – and to a lesser extent lesion-based psychiatric neurosurgery – is on the rise, and this paper will review these developments. The aim is to inform rather than tilt opinion in a particular direction, but given the polarising nature of the subject it seems relevant to state the perspective from which it is written. The author is a retired neuropsychiatrist who formerly worked in a comprehensive service for working-age adults, within which the most frequent neurological diagnosis was acquired brain injury. While in training, he obtained a doctorate in electroencephalogram-based psychophysiology. A history project on psychiatric neurosurgery in the mid-20th century led to several outcomes, including an essay that prompted the Editor to commission this review.⁶

Background

Renewed interest in psychiatric neurosurgery has occurred against a background of major revisions in the way we think about the brain. At the beginning of the 20th century, anatomist Santiago y Cajal wrote: "Once brain development has ended the fount of growth and regeneration of axons and dendrites dries up irrevocably. In adult centres the nerve paths are something fixed, ended and immutable."⁷ That 'immutable' view of neurons held sway within brain science for much of the past century, although there were dissenting voices, particularly between the World Wars.⁸ The brain's capacity to structurally adapt and even regenerate was eventually demonstrated at the end of the century, by magnetic resonance imaging (MRI), functional MRI (fMRI) and other techniques. In addition, simplistic notions of functional localisation are being replaced by task-related and 'default' systems and networks.⁹ The past 25 years have also witnessed a transformation in our understanding of glial cells. Once viewed simply as the brain's scaffolding and housekeepers, they are now known to guide brain development, shape response to injury, modulate synaptic transmission, and operate an independent chemically based communication system.¹⁰ How all this produces mind remains a topic rich in speculation, with recent theories encompassing 'embodied' cognition and quantum biology.^{11,12} The implication of all this for psychiatry remains to be determined.

In the 1930s neurologist Egas Moniz speculated that in the brains of some people with chronic mental illness, 'the cellular bodies remain altogether normal ... but their multiple liaisons, very variable in normal people ... have arrangements that are more or less fixed'.¹³ He believed the most likely location for such an aberration was the pathway

between the prefrontal cortex and the thalamus. In 1935/6 he tested his theory by directing a surgeon to produce small lesions in that area, in 20 patients with mental illness – the first ‘prefrontal leucotomy’ series. Moniz’s targeted and theory-based approach was soon eclipsed by Freeman & Watts’ more destructive and indiscriminate procedure.¹⁴ The extensive damage that it produced often rendered behaviourally disturbed hospital patients with psychosis docile and, in some cases, dischargeable. The potential economic benefits of that were not lost on the architects of the UK’s National Health Service (NHS): in its first 5 years, there were more than 7000 leucotomies.¹⁵

Chlorpromazine rendered such destructive procedures in people with psychosis unnecessary and over the following 20 years psychosurgery teams – focusing on a narrower range of disorders – sought maximum benefit from minimum damage. Nonetheless, public distrust and dissenting voices increased, particularly in the USA, a trend fuelled by experiments on behaviourally disturbed children and aggressive prisoners.¹⁶ Beginning in 1974 a US Congressional Committee held hearings on psychosurgery, with a view to a possible ban. In the end, they recommended better regulation and, in any event, the number of operations fell dramatically over the next 30 years.¹⁴

Ambulatory DBS became possible in the 1980s because of technical developments (MRI, microprocessors, batteries, etc.) but also because the brain structures and pathways that produce movement had been mapped. Although the structures underlying emotion and behaviour, and the paths between them, have also been mapped, exactly how they produce the complexities of emotional life is much less clear. For that reason, a wide variety of brain areas have been targeted in this new wave of psychiatric neurosurgery. Despite the many theories as to how and why DBS and ablative procedures improve some psychiatric conditions, we do not actually know.

Technicalities: electrodes and procedures

All but two of the procedures in current use involve insertion of electrodes into the brain. The exceptions are vagus nerve stimulation (VNS) and gamma knife capsulotomy. Such surgery usually involves attaching a stereotactic cage to the head as a means of directing electrodes to brain locations mapped by MRI. VNS involves isolating the left vagus nerve in the carotid sheath in the neck and looping two electrodes around it. Electrodes in both cases are wired to a programmable stimulator placed subcutaneously in the upper chest wall (*Fig. 1*).¹⁷

Fig. 6: Illustration of an implanted deep brain stimulation system.

Each electrode includes an anode and a cathode. When an electrical current is applied the brain tissue between them joins the circuit. Three to five volts are usually applied in DBS at pulse frequencies above 100/s. At such frequencies brain tissue immediately surrounding the electrodes is deactivated/depolarised. However, just outside that area, volume conduction leads to electrical stimulation of axons, propagated upstream to cell bodies and downstream to synapses, interrupting local brain function while also producing effects more remotely. At frequencies below 100 – 15 pulses/s, for example, in VNS – stimulation is also produced in the tissue immediately surrounding the electrodes. Electrodes have been used experimentally to stimulate brain tissue in humans since the late 1940s.¹⁸ They have also been used to produce lesions, through thermocoagulation. In anterior cingulotomy, for example, a 10 mm exposed portion of the electrode is heated to 85°C for 60 s.

In gamma knife surgery, multiple narrow beams of gamma radiation intersect at a pre-mapped point in the brain, hence the skull is not opened.¹⁷

Brain targets and treatment rationales

Box 1 summarises the brain targets used in most psychiatric neurosurgery over the past 20 years, and the conditions treated in each case. The targets for current lesion surgery are those that have been found to produce the most benefit with the fewest adverse effects. The targets used for psychiatric DBS were chosen in four ways.

1. The first trial, in 1999, targeted the anterior limb of the internal capsule because lesion surgery to that area has been found in some cases to reduce the symptoms of severe OCD.³ The anterior cingulate and subcaudate areas, and the combination of the two, were chosen for similar reasons, in relation to major depressive disorder (MDD).
2. The subthalamic nucleus (STN) is the favoured target in Parkinson's disease. Following DBS, some patients with comorbid OCD experienced a reduction in the severity of those symptoms, hence its selection for trials in OCD.
3. fMRI has revealed increased metabolic activity in the subgenual cortex and habenula in some patients with MDD. Hence, those areas were targeted based on the hypothesis that such hyperactivity may be causal, rather than simply a manifestation of depression.
4. Tourette syndrome sits on the boundary between movement and compulsive disorder, which has contributed to the wide range of brain targets available, including the thalamus, STN, globus pallidum, nucleus accumbens and internal capsule.

Box 1 Brain targets used in psychiatric neurosurgery

Stimulation procedures

Deep brain

- Anterior limb internal capsule (obsessive-compulsive disorder (OCD), depression, anorexia nervosa)
- Nucleus accumbens (OCD, depression, anorexia nervosa, addictions)
- Subgenual cortex (depression)
- Globus pallidus (Tourette syndrome)
- Habenula (depression)
- Posterior hypothalamus (aggressive behaviour)
- Thalamus centromedian nucleus (Tourette syndrome)
- Subthalamic nucleus (OCD)
- Inferior thalamic peduncle (depression)
- Nucleus basalis (Alzheimer's disease)
- Fornix (Alzheimer's disease)
- Basolateral amygdala (post-traumatic stress disorder)

Cortical surface (epidural)

- Dorsolateral frontal (depression)
- Orbitofrontal (depression)

Vagus nerve (depression)**Ablative procedures****Thermocoagulation**

- Anterior capsulotomy (OCD, depression)
- Cingulotomy (OCD, depression, addiction)
- Limbic leucotomy (OCD)
- Subcaudate tractotomy (depression, OCD)
- Nucleus accumbens (addiction)

Radiosurgery ('gamma knife')

- Capsulotomy (OCD)

VNS was first used in the 1990s to treat some forms of refractory epilepsy. Improvement in the mood of some individuals was noticed, an effect that was independent of seizure response. Trials in treatment-resistant depression yielded positive outcomes, but a later study including a 'sham' surgery group suggested a significant placebo effect.¹⁹

Several authors have sought to explain the beneficial effects of stimulation-based procedures and lesion surgery on depressed mood and anxiety by reference to two cortico-striato-thalamocortical (CSTQ 'loops'.²⁰ Similar loops were previously identified in relation to movement, prior to the introduction of DBS, including inhibitory (GABA-based) and excitatory (glutamate-based) pathways.²¹ The CSTC loops, by contrast, involve a wider range of neurotransmitters, with complex interactions that are yet to be defined. Such 'circuits' may, however, explain the variety of targets that seem to produce at least some benefit in psychiatric DBS studies. It seems reasonable to speculate that tapping into and stimulating the loop at many points could influence and modify the whole network.

Protocols, conditions and outcomes

Lesion-based, ablative surgery continues to be available, including at two centres in the UK, but in most countries it is confined to a very small number of cases each year.^{22,23} The exceptions are Russia and China where it is now frequently used in the treatment of addiction.^{24,25} Radiosurgery has made lesion surgery possible without opening the skull and one report confirmed efficacy in OCD comparable to older techniques.²⁶ At the Editor's direction, the remainder of this review will focus on DBS.

The investigators who first applied DBS to the treatment of psychiatric disorders were aware of the legacy of past psychosurgical excesses and the ethical issues it raised. With that in mind a collaborative group drew up a list of research guidelines, published in 2002.²⁷ They include independent evaluation of potential participants according to strict diagnostic, severity and duration criteria; the need to ensure that individuals are able to give informed consent at the outset and for as long as the treatment continues; and ensuring DBS is never used for 'political, law enforcement or social purposes'.²⁷ Most investigators also use established severity ratings and response criteria based on them (such as a 35% or more reduction on the Yale-Brown Obsessive Compulsive Scale²⁸).

In the early years the focus of DBS studies was on people with treatment-resistant OCD, Tourette syndrome and MDD. The textbook cited at the beginning of this paper tabulates all such studies up to 2013 for each of these diagnoses, including patient numbers, brain targets, follow-up times and reported outcomes.²⁹ In summary: OCD: 11 studies involving 9 targets in a total of 86 patients followed up from 3 to 31 months; positive outcomes in 33–100% Tourette syndrome: 10 studies involving 7 targets in 40 patients followed up from 3 to 36 months; positive outcomes in 23–82% MDD: 6 studies involving 5 targets in 55 patients followed up from 12 to 36 months; positive outcomes in 30–75%.

The longer the duration of the follow-up overall, the better outcomes tended to be, but no one target appeared markedly superior. Whereas in movement disorder, and to an extent in Tourette syndrome, improvement occurred soon after stimulation commenced, in OCD and MDD improvement took many weeks to begin, symptoms diminishing further as time progressed. This perhaps indicates that rather than simply turning off ‘malfunctioning’ neurons, stimulation causes gradual beneficial change in the networks and systems it taps into. One exception to this delayed response was a study in which seven people with MDD received DBS to the medial forebrain bundle. The pulse frequency was lower than usual (see ‘Technicalities’ section) and at 1 year positive responses were reported in six people; all began to improve within a week of stimulation commencing.³⁰

Despite these apparently favourable outcomes, the small patient numbers, bewildering array of brain targets, variable follow-up times, and the impossibility of the double-blind placebo control methods, may lead many to conclude that the efficacy of this approach is far from proven. Although Lévêque considers the efficacy of DBS in OCD to be established, in relation to MDD he concedes that ‘although the benign nature of these techniques is in the process of being established, their efficacy remains difficult to demonstrate’.²⁹ Nonetheless, he and others offer several reasons why these outcomes should be taken seriously.

1. The patients treated have severe conditions that have failed to respond to all other treatments over a prolonged period.
2. Some studies target structures that had proved effective in lesion-based surgery (stimulation being used to simulate a lesion).
3. DBS allows for a form of ‘double blind’ methodology as the stimulating device may be turned on and off, the status at any point being kept from patient and assessor.
4. In some clinically improved cases temporary deterioration followed battery failure or inadvertent disconnection.^{30,31}

Although the reversible nature of DBS makes it more acceptable than lesion surgery, is it as effective in psychiatric applications, and does it result in fewer side-effects? The technique may only simulate a lesion, but if the patient requires that simulation to be in place for the rest of their life, what is the difference, apart from indefinite maintenance costs? A recent paper addressed that question by reviewing outcomes in 20 studies of treatment-resistant OCD.³² 108 patients who underwent capsulotomy were compared with 62 patients who received stimulation to the internal capsule or the nucleus accumbens. Of those undergoing capsulotomy 62% responded favourably, compared with 52% of those undergoing stimulation, but the difference was not statistically significant. Weight gain, which was common after lesion surgery, did not occur with stimulation. Apathy and disinhibition were also experienced by a small number of patients after lesion surgery but not during DBS.

Adverse effects reported after DBS include postoperative problems such as wound infection, haemorrhage (asymptomatic or resulting in transient motor signs), single seizures and syncopal episodes.³³ Additional undesirable effects develop when the stimulator is turned on but seem generally to disappear once the stimulation parameters are altered (voltage, frequency, etc.). These include physical symptoms such as paraesthesia, muscle contractions, dysarthria, diplopia and strabismus, and psychiatric features, particularly excitement, irritability and occasionally hypomania. Cognitive function is usually assessed before and during treatment and a recent review concluded that no adverse cognitive effects had occurred. In fact, as time progressed improvements in scores tended to occur, mirroring improvements in mental state.³⁴ The most common longer-term problems in psychiatric and movement disorder applications seem to be device-based. For example, one study of 84 patients with Parkinson’s disease recorded hardware-related complications in 8.4% of patients each year, including lead fractures, migrations and disconnections.³⁵ Technical improvements have doubtless occurred since that report, but the consequences of such mishaps in patients with severe psychiatric disorders may be grave, and are among the reasons that regular ongoing follow-up is deemed important.

A further stimulation technique that does not involve penetrating the brain has recently been tried in people with MDD.³⁶ Electrodes were placed in the epidural space over the dorsolateral frontal cortex in a single-blind study of 12 patients who were followed up for 2 years, with results comparable to the best DBS studies. A later paper discussed the combination of this technique with psychotherapy, a fascinating subject, sadly beyond the scope of this review.³⁷

The major advantage of DBS over lesion-based surgery is that if it does not work the hardware can be turned off and removed. In the longer term, stimulation could be stopped temporarily to assess whether it is still necessary. But as we now know, the brain is not 'immutable' and unresponsive to such challenge. It adjusts and adapts, chemically and structurally to changing circumstances and, in fact, the delayed onset of improvement in some of these applications seems to depend on such adaptation. The long-term implications of such changes are not clear.

In light of the relatively low side-effect profile of DBS in these early trials and apparently favourable outcomes, the technique has been extended to a number of other conditions including addiction,³⁸ eating disorder,³⁹ posttraumatic stress disorder (PTSD),⁴⁰ early Alzheimer's disease⁴¹ and, most controversially, aggressive behaviour disorder.⁴² Each of these has a defining clinical feature that suggests a particular brain target (in turn, nucleus accumbens, hypothalamus, amygdala, mammillary-fornix-hippocampal complex/nucleus basalis, hypothalamus). Although it is probably too early to comment on the outcome of this work, the target selections in two of these conditions are illustrative of the current approach and will be described briefly. The amygdala is being targeted in PTSD as a result of post brain-injury MRI and fMRI evidence (amygdala damage protecting against developing the condition and evidence of increased metabolic activity), and a positive response to amygdala stimulation in an animal model. The fornix is being targeted in early Alzheimer's disease as a way into the mammillary-fornix-hippocampal complex. This follows the serendipitous finding of improved memory and increased hippocampal volume following stimulation of the anterior hypothalamus undertaken for an unrelated condition, and animal studies showing stimulation-related neural growth.⁴³

The future

In 2013 President Obama launched a US\$100 million research programme with the acronym B.R.A.I.N (Brain Research through Advancing Innovative Neurotechnologies).⁴⁴ 'Emerging technologies' would be applied to the investigation of brain function and the treatment of disorders. This would include nanotechnology and, in relation to treatments, 'wireless fully implantable neural interface medical devices for human use ... closed loop systems able to deliver targeted neural stimulation'.⁴⁵ A patient group singled out for such innovative treatments was injured war-fighters, particularly those with treatment-resistant PTSD and memory problems due to acquired brain injury. This was a remarkable proposal, not least because at that point no 'wired' device-based treatments had been found useful or even trialled in either condition, and closed loop technology had only been used in cardiac dysrhythmia and epilepsy.⁴⁶

Closed loop technology has been more widely identified as important for the future of this work. In the context of epilepsy, implanted closed loop devices monitor an area where seizure originates, detect electrical activity that indicate a seizure is due, and respond with electrical stimulation or cooling to interrupt it.⁴⁶ In the psychiatric context, the possibilities of such devices include using nanotechnology to measure neurotransmitter levels and trigger therapeutic outputs.⁴⁷

Another development of possible importance is optogenetics. Light-sensitive ion channels that respond to different colours are delivered to and incorporated into individual neurons via a virus. Light channelled into the brain via fiberoptics can then be used to turn on and off such channels. Although this sounds the stuff of science fiction, a similar procedure has apparently succeeded in animal studies and trials in humans are expected in due course.^{48,49}

Conclusions

Given the torment of severe treatment-resistant depression, OCD and other psychiatric conditions, and the enthusiasm for DBS in relation to movement disorder, it is reasonable to ask why the technique has not been more widely adopted in psychiatry? A neurosurgeon recently addressed this question and identified a number of reasons: the legacy of ‘old-fashioned’ psychiatric surgery, the complexity and heterogeneity of psychiatric symptoms, and the multitude of brain circuits likely to be involved in them, ‘tricky ethical questions related to potential manipulation of the mind’, difficulty in conducting large trials in these conditions, and inconsistent results.⁵⁰ He might have added lack of consensus over targets in the conditions most often treated and the limited number of ‘placebo’ (sham treatment) controlled trials. Nonetheless, the US Food and Drug Administration gave approval for DBS in treatment-resistant OCD in 2009, albeit through a ‘humanitarian device exemption’.³³

In the UK, new medical procedures tend to be adopted and funded following pressure from patients and their interest groups, clinicians, medical Royal Colleges and the media. It is difficult to envisage such pressure for psychiatric DBS at the moment. The legacy of mid-20th century psychosurgery includes not only public and professional distrust (the charity OCD-UK ‘do not recommend DBS as a treatment for OCD *and remain concerned that the dangers associated with the procedure continue to be overlooked by the medical community*’⁵¹ – my italics) but also ethical and methodological rules that require complex, expensive, multiprofessional teams. In 2013 the NHS Commissioning Board published DBS guidelines for the treatment of movement disorders. They included an estimated cost of £26 070 for each procedure, but acknowledge that savings resulting from clinical and quality-of-life improvements offset ongoing maintenance costs.⁵²

In an afterword to the psychosurgery text mentioned at the beginning of this paper, and a related article, Marwan Hariz, a particularly cautious and thoughtful ‘functional’ neurosurgeon, warns that ‘hying’ DBS in psychiatry at this stage could lead to its demise.⁵⁰ He also expresses concern at recent suggestions that the technique could be used to enhance ‘normal’ functioning or even control antisocial behaviour. ‘Neuromodulation’ he concludes, ‘should not be allowed to become neuromanipulation’.⁵³ It remains to be seen whether a new generation of ‘millennial’ psychiatrists and neurosurgeons armed with these emerging technologies will follow his advice.

1.6.78 Teaching provision for old age psychiatry in medical schools in the UK and Ireland: a survey

Abstract

Aims and method This work builds on a survey first done in 1999 to understand how old age psychiatry teaching is embedded in undergraduate medical schools in the UK and Ireland and the influence of academic old age psychiatrists on teaching processes. We invited deans of 31 medical schools in the UK and Ireland in 2015 to complete an online survey to reassess the situation 16 years later.

Results Response rate was 74%. As found in the original survey, there was variation across medical schools in how old age psychiatry is taught. Half of schools stated there was not enough space in the curriculum dedicated to old age psychiatry, and not all medical school curricula offered a clinical attachment. Medical schools that involved academic old age psychiatrists in teaching (59%) showed a greater diversity of teaching methods.

Clinical implications There is a need to recognise the importance of old age psychiatry teaching, with the consensus of opinion continuing to be that more curriculum space needs to be given to old age psychiatry. To achieve this we advocate increasing the number of old age psychiatrists with teaching roles, as relying on academics to teach and lead on curriculum development is challenging given their greater research pressures.

With the ageing population and high prevalence of mental health burden in the UK, it is becoming increasingly important that medical school undergraduate curricula for old age psychiatry advance in line with future demographic needs. This has been recognised by the General Medical Council (GMC) in *Tomorrow's Doctors*,¹ which stresses the importance of students learning about the special problems associated with older people's health. The Royal College of Psychiatrists has subsequently mapped the core undergraduate psychiatry curriculum outcomes² on to the competencies listed in *Tomorrow's Doctors*. Other UK national drivers, including the National Health Service (NHS) Outcomes Framework³ and the prime minister's dementia strategy,⁴ have highlighted the need for the future workforce to be competent in caring for the needs of the older person.

More broadly, there is also an increasing recognition that there is a shortage of old age psychiatrists, and recruitment of trainees is less than for other specialties (fill rate is 67% for training posts compared with 80% in psychiatry as a whole). The Centre for Workforce Intelligence (CfWI) in their in-depth review of the psychiatry workforce⁵ highlighted old age psychiatry as a particular concern, with the strongest risk of a larger demand–supply shortfall due to weak workforce growth. Currently, there are 1.1 full-time old age psychiatry certificate of completion of training (CCT) post holders per 100 000 population, but the workforce growth is not proportional to the growth in the older population, and baseline demand and supply projections anticipate a shortage of around 315 CCT holders in old age psychiatry by 2033.

In 2012, the Royal College of Psychiatrists published its recruitment strategy,⁶ with the primary aim of increasing recruitment into core psychiatry training, but the recommendations can be extended to old age psychiatry specialty training. Arguably, the concept of increased exposure to old age psychiatry and looking at the undergraduate experience

could be key to understanding why medical school graduates may or may not consider this specialty as an appealing career choice.

This study builds on a previous survey, carried out in 1999, which found that schools with established old age psychiatry academic departments devoted more time to undergraduate teaching of old age psychiatry, covered more topics and used a wider range of teaching methods.⁷ The aim of the current study was to determine how old age psychiatry teaching is embedded in undergraduate medical schools in the UK and Ireland. More than 15 years on from the original survey, we sought to demonstrate how undergraduate provision of old age psychiatry teaching has changed nationally and identify any ongoing gaps. Similar surveys have been carried out by other non-psychiatric specialties facing similar recruitment concerns, in particular geriatric medicine.^{8,9}

Method

The study took place between January and November 2015. A questionnaire (available in the *appendix*) was developed and published in electronic format using the Survey Monkey software (www.surveymonkey.com). It enquired about the teaching provision of undergraduate old age psychiatry, covering whether or not the curriculum included teaching of old age psychiatry; where in the curriculum this teaching took place; whether academic old age psychiatrists (i.e. person(s) working in old age psychiatry but with a significant aspect of their job plan including research and/or medical education) were involved in the organisation of teaching; the duration of attachment to the specialty; the form and content of the teaching; and the nature of the student assessment. There were free-text spaces for respondents to qualify their answers if necessary. The questionnaire was reviewed and the study endorsed by the Faculty of Old Age Psychiatry of the Royal College of Psychiatrists.

The deans of all 31 UK medical schools were contacted by email and letter, asking them to identify a respondent with sufficient awareness of the undergraduate curriculum to allow completion of the survey, and requesting that the letter or email be forwarded to them. Where initial approaches and reminders were unsuccessful, members of the undergraduate leads forum were contacted through the Faculty of Old Age Psychiatry and invited to identify a respondent. As this was a survey requesting information already in the public domain, no formal consent procedure was undertaken and implied consent was assumed through participation.

The project met the Newcastle University preliminary ethical assessment guidelines, indicating that a full university ethics committee review was not required.

Results

Responses were received from 23 (74%) medical schools. No schools responded that they did not wish to participate but 8 did not respond to any form of communication (written, electronic and/or telephone). One (4%) response was from a dean, 9 (40%) from a senior lecturer, 5 (22%) from a consultant psychiatrist or programme director, 3 (13%) from a reader in old age psychiatry, 4 (17%) from a professor and 1 (4%) from a consultant physician.

Overall, 50% of respondents felt that there was not sufficient curriculum space designated to old age psychiatry; however, many appreciated the overlap with other specialties, including adult psychiatry, neurology and care of the elderly.

Staffing establishment of academic old age psychiatry

Figure 1 shows the current staffing establishment of academic old age psychiatry. More than half of schools (59%) reported that academic old age psychiatrists were involved in the organisation and delivery of undergraduate teaching, compared with 40% in the original survey. We found that 41% of schools have an academic old age psychiatrist represented on the board of studies or equivalent.

Fig. 7: Staffing establishment of academic old age psychiatrists.

Organisation and delivery of teaching

A designated clinical attachment in old age psychiatry was present in 86% of schools. Of those, in 13% the duration of the clinical attachment was dependent on individual student choice and in 41% there was the opportunity to spend more time in old age psychiatry. All respondents indicated that the majority of the teaching on cognitive assessment and dementia was delivered by an old age psychiatrist. There was no consistency between schools on when these topics were first covered, with 14% covering them in the first year, 23% in the second year, 36% in the third year, 23% in the fourth year and 5% in the fifth year.

With regard to time spent teaching old age psychiatry in the undergraduate curriculum, again there was no consistent standard, and reports ranged from a 1 h formal lecture to 25 days if the teaching on dementia/delirium covered by other specialties was included. This amount of time overlaps with that found in the original survey, in which time ranged from 1 to 40 days. Both the present and previous survey⁷ found that other, more informal/unstructured teaching was also given, but there was difficulty in quantifying the amount as this tends to depend on the clinical attachment. Some schools also offered self-directed teaching through podcasts or e-lectures (lectures delivered online), which depended on student interest and motivation.

A variety of teaching methods were used (*Table 1*), but with a large proportion primarily using lectures and tutorials as the main format of teaching (82% and 86%, respectively, v. 73% and 55% in the original survey). As with the original survey, schools where academic old age psychiatrists were involved in the organisation and delivery of teaching showed greater teaching method diversity and more use of innovative methods of teaching, such as interprofessional learning, e-learning and simulation, than those schools where there was no academic involvement. However, the overall figures were low (*Table 1*) and significance was only reached for simulation ($P = 0.03$) and home visits ($P = 0.02$). Of all schools, 50% responded that they involved carers or patients when delivering organised teaching sessions.

Method of teaching delivery

	<i>n</i> (%)		
Lectures	12 (92)	6 (60)	0.13
Tutorials	11 (85)	8 (80)	0.57
Bedside teaching	10 (77)	7 (70)	1.00
Problem-based learning	5 (38)	4 (40)	1.00
Interprofessional education	7 (54)	3 (30)	0.40
e-learning	8 (62)	2 (20)	0.09
Simulation	5 (38)	0 (0)	0.03*
Home visits	13 (100)	6 (60)	0.02*
Joint teaching	6 (46)	2 (20)	0.38
Other	0 (0)	1 (10)	0.43

Binomial probability $P = 0.03$ for all the teaching methods where there is academic involvement.

$P < 0.05$.

Content and assessment of old age psychiatry teaching

In 95% of schools the undergraduate curriculum contained specific old age psychiatry outcomes, compared with 100% of schools in the original survey, where the undergraduate curriculum contained some theoretical or clinical teaching of old age psychiatry. All schools were teaching cognitive assessment and dementia (95% in the original survey) but, as found in the original survey, fewer indicated that they covered affective disorders (82% v. 91%) or psychotic disorders (77% v. 82%). Even fewer covered service organisation (36% v. 59%) (*Table 2*). A variety of assessment methods are used (*Table 3*), with the most common (82%) being the observed structured clinical examination (OSCE). In the original survey, student assessment was most commonly by 'formal examination' (68%) and assessment of performance during the clinical attachment (64%).

Teaching content

Topic	Schools with academic old age psychiatrist involvement (<i>N</i> = 13)	Schools without academic old age psychiatrist involvement (<i>N</i> = 10)	χ^2 (<i>P</i>)
Cognitive assessment	13 (100)	10 (100)	1.00
Dementia	13 (100)	10 (100)	1.00
Delirium	10 (77)	10 (100)	0.23
Affective disorders	10 (77)	8 (80)	1.00
Psychotic disorders	9 (69)	8 (80)	0.66
Service organisation	4 (31)	4 (40)	0.69

Logbook	10 (45)
Essay	4 (18)

MCQ, multiple-choice questions; OSCE, observed structured clinical examination.

Table 2 also shows the content of teaching according to whether there is academic involvement which did not reach significance for any topic.

Discussion

Arguably, the most powerful message from this survey is that 50% of respondents did not feel that sufficient curriculum space is designated to old age psychiatry. This had been a concern in the original survey, in which 57% of schools had reported that there were significant obstacles to introducing and maintaining old age psychiatry teaching in the undergraduate curriculum. This raises the question of how much progress has been made over the past 15 years. Similar surveys done in elderly care medicine, a specialty facing a similar recruitment problem, have also found that inadequate time (<2 weeks) is spent teaching about subjects related to ageing, including dementia, which does not reflect the predominance of older patients in most doctors' workload.^{8,9,10}

The main finding in the original survey undertaken in 1999 had been that those medical schools with established academic old age psychiatry departments provided more teaching of old age psychiatry and are more likely to embrace new teaching methods.⁷ Our survey showed that 59% of schools have academic old age psychiatrists involved in the organisation and delivery of undergraduate teaching and 41% have an academic old age psychiatrist represented on the board of studies or equivalent. Similar to the original survey the main finding from the current survey is that schools where academic old age psychiatrists are involved in the organisation and delivery of teaching are more likely to use a greater diversity of teaching methods; however, only the use of simulation and home visits were found to be significant.

These results should be interpreted in the context that academics now may be less engaged in organising teaching (unless they are specifically medical educators) as they have predominantly research roles and greater research pressures. This highlights a need to drive up the number of other old age psychiatrists with teaching roles.

In the original survey all of the schools reported that the undergraduate curriculum contained some theoretical and/or clinical teaching of old age psychiatry and in our survey 95% of schools reported that their undergraduate curriculum contains specific old age psychiatry outcomes. Worryingly not all schools offer a clinical attachment in old age psychiatry (86%, slightly higher than in the original survey (82%)), and in those that did, the organisation of this is variable. As with the original survey, the amount of time offered varies considerably, and in some schools student exposure to old age psychiatry depends on individual clinical attachments. A wide range of teaching formats are reported, with the commonest methods being lectures and tutorials. Other methods, such as interprofessional teaching, e-learning and simulation, are less common (*Table 1*). Similarly, there was relatively low patient and carer involvement in teaching (50%).

Low use of interprofessional teaching and involvement of patients and carers in particular are missed opportunities, as evidence has shown that interprofessional education (IPE) can be used to significantly improve confidence and change attitudes in staff managing older patients with dementia or delirium.¹¹ This style of teaching delivery could therefore also be applied to undergraduates, especially at a time when the expectation from the GMC is for greater IPE within curricula to improve team-working skills.^{1,11} As such, teaching on topics relevant to old age psychiatry could be the hook through which it is possible to drive up the amount of IPE, and hence development of team-working skills within the broader medical curricula, as well as fostering more positive attitudes towards the older patient and improving recruitment into this specialty.

As regards the content of teaching, all schools are delivering teaching on dementia and cognitive assessment and the majority (91%) are teaching on delirium. It is concerning that not all schools cover affective and psychotic disorders (82% and 77%, respectively) in this age group as, unlike dementia and delirium, these topics are less likely to be covered by other specialties, and their presentation and management differ considerably compared with general adult psychiatry. As with the original survey,⁷ cultural issues were covered less (50%). Academic involvement in teaching did not lead to any significant difference in the content of teaching, which should be expected if medical schools are using a standard curriculum and is perhaps reassuring given that not all medical schools will have academic old age psychiatrists involved in the organisation of teaching.

In contrast to the original survey, where student assessment was most commonly by a 'formal examination', this survey showed that an OSCE was the most commonly used method of assessment, with other techniques, such as assessed

coursework and portfolios or logbooks, less frequently reported (*Table 3*). The need to ensure that teaching and assessment in medical schools is done to a high standard is crucial as assessment drives learning. However, we do not advocate a standardised assessment process as there are contextual variations in teaching nationally. What is important for educators is to understand what is being assessed and thereby select the correct assessment format as per the Millers Pyramid,¹² i.e. multiple choice questions to test knowledge, OSCEs to assess performance. This would enable assessment processes to be undertaken in an appropriate manner and for schools to demonstrate that learning outcomes have been achieved by students.

Implications for recruitment

Given the concerns about recruitment into old age psychiatry, it is important to consider the influence of the undergraduate curriculum experience of old age psychiatry on postgraduate career choice. A survey of graduates from Liverpool University 5 years post-qualification¹³ found that the majority felt their career choice was primarily dictated by their postgraduate experience rather than their undergraduate clinical attachments. However, in another survey of graduates, Goldacre *et al*^{14,15} found that factors during undergraduate experience significantly outweighed any inclinations before entry to medical school concerning the influence on career choice. They also found that career choices were greatly influenced by a particular teacher or department. The importance of a good role model has also been identified by surveys in other specialties,^{16–18} highlighting the importance of individuals in fostering enthusiasm and interest in a specialty.

Specialties with similar recruitment problems to old age psychiatry have found that the most significant factors influencing final-year medical students in their career choice were clinical mentors and specialty-themed, problem-based learning cases.¹⁸ However, for psychiatry as a whole, other studies have found that attitude changes towards considering a career in this specialty were similar whether students were taught with problem-based learning or with a more traditional curriculum.^{19,20}

In elderly care medicine, a study done at the University of Aberdeen²¹ found that an intensive 8-day programme increased the likelihood of fourth-year medical students considering this specialty as a career. Several US studies have shown that a positive attitude towards older people increases the likelihood of pursuing a career in care of the elderly and that increased exposure to this specialty during medical school has a positive influence on attitudes.^{22–24} This supports the view that the most effective interventions to increase recruitment of elderly care physicians should focus on positively influencing medical students' attitudes during medical school through meaningful experiences during clinical attachments, findings which could be extrapolated to include old age psychiatry. Indeed, US and Canadian surveys looking at factors that influence medical students choosing old age psychiatry as a career have found that one of the key factors is completing an old age psychiatry rotation alongside specific teacher attributes and training experiences.^{25,26} These findings support our key recommendations (*Box 1*).

Strengths and limitations

The response rate to this survey was good (74%), although it must be acknowledged that there may still have been a response bias, with a poorer return from the schools without a strong academic old age psychiatry department or representative for undergraduate teaching provision in old age psychiatry. Consequently, we may have underestimated the poorest end of the spectrum.

Box 1 Key recommendations

1. Old age psychiatry should be offered as a clinical attachment in all medical schools.
2. All schools should deliver specific old age psychiatry outcomes in the undergraduate curriculum including affective and psychotic disorders, legal and cultural issues.
3. A minimum time delivering formal teaching and time spent on clinical attachment should be agreed by the College with medical schools to ensure adequate exposure in old age psychiatry.
4. Schools should strive to drive up the number of old age psychiatrists with teaching roles and ensure they are supported in delivering a greater diversity of teaching methods and acting as positive role models.

5. There should be greater use of patients and carers in teaching to help foster positive attitudes.
6. The use of interprofessional learning should be recognised in driving up the status of old age psychiatry and ability to practise effectively in collaboration with other professions.
7. There is a need to ensure that schools teach and assess to a similar high standard in order to demonstrate that old age psychiatry outcomes have been addressed.
8. Future surveys should look at surveying medical students on their opinion and experience of old age psychiatry as well as career intentions.

Of the responding schools, data were collected from only one representative, with the hope that the respondent identified from each school would be whoever had suitable knowledge of the undergraduate curriculum. There is a possibility, however, that some of these representatives may have had an inadequate or biased overview of the undergraduate curriculum and that not all information was reported or accurate.

It was apparent through some of the free-text responses that some schools found it difficult to quantify the length of time spent teaching curriculum outcomes specific to old age psychiatry. For medical schools with an integrated curriculum, it may have been difficult to extract this information, as there is an overlap with other specialties who may have delivered this teaching.

It must be acknowledged that a limitation in the comparisons of academic old age psychiatrist involvement is that results reported were uncorrected and it is likely that there may have been no significant difference due to the overall numbers being low, and the number of comparisons being made. A further limitation was that the survey explores the taught curriculum and does not cover student-selected topics or the fact that some medical students may choose to do a research period in old age psychiatry. There are also no data regarding the opinion of medical students, and subsequently the influence of individual schools' undergraduate experience on career intention. Consequently, the assumption could not be made that medical schools with a mandatory clinical attachment in old age psychiatry and embracing more innovative methods of teaching delivery had a positive effect on intention to pursue old age psychiatry as a career. Further research is needed to explore the experience of the curriculum on paper and the 'hidden curriculum' experienced by the students by means of surveys and focus groups of undergraduate students as well as following up cohorts of students into their chosen career.

Recommendations

With the ageing population and increasing complexity of their needs, it is imperative that the future generations of doctors are suitably equipped with the knowledge, skills and attitudes for dealing with future challenges. It is especially important that the undergraduate experience fosters positive attitudes about old age psychiatry as a specialty and potential future career to try to address the workforce crisis we currently face. This survey of teacher practice has highlighted that there is still variation across medical schools in how old age psychiatry is taught, and made recommendations in how undergraduate experience of old age psychiatry can be enhanced. The value of interprofessional learning, as well as more involvement of patients and carers, should be recognised in improving the attractiveness and status of old age psychiatry. Although there may have been progress over the past 15 years in embedding old age-specific outcomes in the undergraduate curriculum, the consensus of opinion does continue to be that more curriculum space needs to be given to old age psychiatry.

1. Which medical school are you responding on behalf of? _____
2. What is your job title? _____
3. What is the current staffing establishment in academic old age psychiatry?
(number of posts 0 1 2 3 4 5 >5) (professor/reader/senior lecturer/lecturer/research fellow/research assistant)
4. Which of the following best describes the style of teaching at your medical school? (traditional (i.e. lectures and tutorials during years 2–3 followed by the clinical years), integrated (i.e. clinical attachments from year 1), problem-based (i.e. student-centred teaching), other.)
5. Does the undergraduate curriculum contain specific old age psychiatry outcomes? (yes/no/don't know)

6. Which topics are covered? Tick all that apply (cognitive assessment/dementia/delirium/affective disorders/psychotic disorders/depression/service organisation/Mental Health Act/cultural issues/other/none of the above)
7. How much time is spent teaching old age psychiatry in the undergraduate curriculum? (e.g. approximate number of days) _____
8. When is dementia and cognitive assessment first covered? (first year/second year/third year/fourth year/fifth year)
9. Are there plans to incorporate the recent Health Education England dementia curriculum into the teaching program? (yes/no/don't know)
10. Who delivers the majority of the teaching on cognitive assessment and dementia? (old age psychiatrist/other (please specify))
11. Is there a clinical attachment in old age psychiatry? (yes/no)
12. Is the duration of a clinical attachment in old age psychiatry dependent on individual student choice? (yes/no/compulsory attachment with opportunity to spend more time on old age psychiatry/compulsory attachment with no further opportunity to spend more time on old age psychiatry)
13. Which teaching methods are used for old age psychiatry teaching? Tick all that apply (lectures/tutorials/bedside teaching/problem-based learning/inter-professional/e-learning/simulation/home visits/joint teaching/other)
14. Are carers or patients involved in the delivery of teaching? (yes/no)
15. Which methods are used to examine students on old age psychiatry? (formal examination/OSCE/long case/MCQ/coursework/e-portfolio/logbook/essay/other)
16. Are academic old age psychiatrists involved in the organisation and delivery of undergraduate teaching of old age psychiatry? (yes/no/don't know)
17. Are academic old age psychiatrists represented on your board of studies or equivalent? (yes/no/don't know)
18. Do you think that there is sufficient curriculum space given to old age psychiatry? (yes/no)
19. Any other comments re: teaching of old age psychiatry? _____
20. Would you like a copy of the results? (yes/no)

1.6.79 Profile: Derek Summerfield – politics and psychiatry

- *Profile: Derek Summerfield – politics and psychiatry*
 - *The personal and the political*
 - *Problem with the concept of global mental health*

Preparing for this interview, I was aware of Dr Summerfield's political commitment. After all, he was the principal psychiatrist for Freedom from Torture (Medical Foundation for the Care of Victims of Torture) from 1991 until 2000. He is an outspoken critic of what he describes as the complicity of the Israeli Medical Association (IMA) and Israeli doctors posted to interrogation units in relation to the torture of Palestinian refugees, which has led to him receiving many accusations of anti-Semitism and becoming the subject of a libel suit by the President of the IMA. He is a member of the Critical Psychiatry Network. Before training in psychiatry, he worked as a government medical officer in Zimbabwe to 'repay his debt' to Africa. This was clearly going to be an encounter with a man of the left, passionate about social justice.

The personal and the political

I was curious about how Dr Summerfield sees the personal and the political. Can they ever be separated? What exactly is the role of the psychiatrist in relation to social justice? Should what I will call 'ethico-political awareness' be part of psychiatric training, given the huge relevance to mental health of the context in which our patients live?

If senior psychiatrists should be leading the profession, can this ethico-political thinking be encouraged by example only, or more explicitly within the syllabus? And how does Derek Summerfield see his role within the profession? Is he an individual firebrand, grit in the oyster, provocateur, thinking iconoclast, leading by example and seeking influence via publication, or does he have a more intergenerational mission? (It emerges that he has recently canvassed the juniors at the Maudsley Hospital and recommended they should not comply with trust training in relation to the controversial government Prevent strategy of 2015, intended to detect early radicalisation in pupils, students or patients, which he regards as outrageous state intrusion into clinical confidentiality and a form of McCarthyism.)

More widely, in the recent climate of junior doctor strikes, dire warnings from the British Medical Association, hot controversy over the National Health Service as a public service, what, if any, are the political obligations of (a) doctors in general and (b) psychiatrists in particular? I got my answer loud and clear in a note he sent me a few days after the interview: "There is the doctor as doctor, but also (ethically imperative) the doctor as sentient citizen . . . To do with a fundamental duty to attend not just to the particulars of the patient sitting in front of us, but also to the political and socioeconomic factors that produce distress and disease. Doctors have largely not done this. End of sermon . . ." Dr Summerfield is actually not preachy: he is amusing, not pompous, but self-deprecating – yet utterly (and perhaps unfashionably) serious. Of course he knows that not all doctors or psychiatrists share his views. Indeed, he is realistic: "With exceptions, doctors are not politically engaged. The average doctor doesn't have a social activist bone in his body. . . as a profession we are closer to those in power than those without it. . . medicine is basically an entrenched profession, and we behave like one . . . after the revolutions in places like Cuba, Mozambique, the vast majority of doctors left the country . . ." I wonder how he was viewed by the international and non-homogeneous group of South London and Maudsley NHS Foundation Trust (SLAM) junior psychiatrists when they received his open letter about the Prevent strategy training. Is he admired as a model of the thinking critical psychiatrist, or dismissed as eccentric or even dangerously insurrectionist?

Derek Summerfield was born 68 years ago in Cape Town, South Africa, into a non-medical family, but grew up in Bulawayo, the second city, after Harare, of Zimbabwe (then Rhodesia). He studied physics initially ('the headmaster persuaded bright White boys to do science'), then worked in a shipping company in Cape Town, and did some teaching. He always wanted to be a journalist (and now thinks he'd do law and anthropology if he was starting out again), but nevertheless began medicine, aged 24, at St Mary's Medical School in Paddington, London.

'I failed everything, and nearly left in the first year. I had no interest or feel for science in the preclinical years, but when I got onto the wards I felt an intellectual thrill at last.'

He did house jobs (i.e. FY1) in Oxford and Cambridge, and went on to become a medical registrar with MRCP Part 1. During this period he did several stints in Zimbabwe during and after the civil war, no walk in the park. In Chiredzi, in the war-ravaged rural south-east, there were 200 beds and 2 doctors. He was the paediatrician, 'with 50 desperately sick kids at any one time ... 5 of whom died each day'. He saw up close and personal the effect of poverty on health: 'even measles was 80–100 times more fatal in these malnourished kids'.

He finally decided on psychiatry in 1982, now aged 34, and went to St George's Hospital. While working there he met a beautiful and much younger woman, now a consultant clinical psychologist and psychoanalyst at the Tavistock, Francesca Huhne. They have a 20-year-old daughter, who is reading History at university. He and Francesca subsequently studied war-wounded men from both sides of the civil war in Nicaragua together. He has been a consultant to Oxfam, and for many years was a research associate at the Refugee Studies Centre, University of Oxford.

He joined Freedom from Torture (Medical Foundation for the Care of Victims of Torture) full-time in 1991, where he treated around 800 patients, often seeking asylum in the UK: Bosnians, Sri Lankans, Iraqis, Turkish Kurds, Africans and Palestinians, with 95% of consultations requiring interpreters. But with his lifetime history of independent thinking and acting on principle, this appointment did not end amicably: he was 'asked to leave' Freedom from Torture in 2000 because the organisation was concerned that his widely published questioning of the category of posttraumatic stress disorder (PTSD) might deter funders.¹ He sees the diagnosis of PTSD in the context of refugees as the 'pseudo-scientific pathologising of people affected by war ... the medicalisation of their situation diminishes the importance of work and the rebuilding of social networks ... the broken social world is the lot of the asylum seeker'.²

After leaving Freedom from Torture, he contacted Dr Maurice Lipsedge, who suggested that he should consider applying for his job in SLAM, from which he was retiring. This was in the HIV mental health team, initially part time, then full time.

The HIV team at its zenith had four psychologists and acted as a community mental health team with an HIV focus. He enjoyed the interest of the 'two different groups of patients ... African women and British gay men'. The service was greatly reduced in 2016, owing to both financial constraints and the mainstreaming of HIV. He accepts this process as reasonable, given the changes in HIV treatment and prognosis, with life expectancy being almost normal now, if the medicines are taken reliably. (And many African women don't always do this, and he would like to understand why.)

He has no immediate plans to retire and is busy with a variety of work outside the 'day job'. He's involved with the new medical school in Bulawayo, his home town, helping with the undergraduate curriculum, and will teach there: 'I still feel a debt to Africa'. He advises Oxfam: In the 80s they suddenly got very interested in the mental health of victims of war'. Derek Summerfield helped evaluate their projects in Bosnia, and steered Oxfam away from a PTSD-centred approach to victims of that war: 'I persuaded them not to go down the counselling route ... if you ask Muslim adolescents in Tuzla what they want, they want a bit of normality. They actually requested some fabric so they could put on a fashion show'.

Problem with the concept of global mental health

He has published widely from the standpoint of a fundamental opposition to the medicalisation of human distress and the assumption that Western psychiatry is universally valid, which he sees as a kind of cultural imperialism.^{3,4}

He offers a critique and deconstruction of international attitudes to the mental health of victims of war.² He stresses how the global effects of wars are largely experienced by people living in poverty, and he sees the danger of the PTSD diagnosis as pathologising of the individual rather than attending to the effects of poverty and the need for reconstruction of the social fabric.²

He makes a more general critique of the concept of 'global mental health', highly critical of 'taking depression into a country which has no such concept, followed by the marketing of antidepressants ... Western cultural values parading as medical facts'.^{3,4} His critique extends to the cultural relativism of psychiatric diagnoses in general: as if disease had an objective existence, independent of the gaze of the diagnostician.

The origin of PTSD as a diagnosis was for disturbed Vietnam war veterans in the USA with the benign intention of lobbying to get decent care for them by emphasising the traumatogenic nature of war, thus legitimising a position of victimhood, moral exculpation and receipt of disability pensions. In Summerfield's view, the development of this concept of PTSD needs to be understood in the wider social context of the 'rise of expressive psychologically minded individualism, personal rights, entitlement and grievance,' as opposed to the previously socially sanctioned stiff upper lip self-management of trauma. Now PTSD has become a 'certificate of impairment'. It is the only diagnosis which contains its aetiology within itself, while in fact, he claims, premorbid factors such as psychiatric history or a negative thinking style are more important than the actual event itself in the aetiology of symptoms.¹

Conflating normality and pathology 'devalues the currency of true illness'.

He is an old fighter, brave and almost proud of his battle scars: 'No-one has been called an anti-Semite in the medical press more than me'. He feels the campaign he convened against medical complicity with torture in Israel is the 'best thing I've done in my career'. So the life and views of Derek Summerfield are a challenge to all doctors, even those with different political views: is it acceptable for doctors to absent themselves from political engagement as being outside their remit, or are we ethically obliged to be properly aware of the sociopolitical context of our work? People with unflinching integrity have always made others uncomfortable: consider the unpopularity of Jesus overturning stalls in the temple market.

If we take our ethical obligations as doctors seriously, we need intellectually rigorous and dogged colleagues like Derek Summerfield to point up our innate conservatism and political passivity.

1.6.80 Paul Haydon Rogers FRCP FRCPsych

: Formerly Consultant Psychiatrist and Medical Director, St Crispin Hospital, Northampton

Don Williams

date

2017-10

Contents

- *Paul Haydon Rogers FRCP FRCPsych*

– : *Formerly Consultant Psychiatrist and Medical Director, St Crispin Hospital, Northampton*

Paul Rogers died on 11 February 2016, aged 96, after a short illness. For the last 10 years of his life he lived independently and happily in a support and care complex in the grounds of St Crispin hospital (now converted into apartments) where he had worked from 1955 to 1979. During his time at St Crispin, where he established community-based services, he was responsible for the introduction of new treatments, particularly the newly developed psychotropic drugs. He developed child guidance clinics in the area and was also involved in the planning of Princess Marina Hospital for people with learning difficulties. After retirement from the National Health Service (NHS) he worked with the Health Advisory Service and as a member of the Mental Health Review Tribunal dealing with difficult issues at Broadmoor and Rampton high-security hospitals. In Northampton, he pioneered the recognition of stress at work and helped to create a local charity to advise employers and provide counselling for employees.

A son of the manse, he was born in Cardiff in 1919 and from an early age wanted to be a doctor. After attending Caterham School and Christ's College Cambridge, he qualified in 1943 at the London Hospital, now The Royal London Hospital. Shortly afterwards, he served as captain in the Royal Army Medical Corps in Normandy, Egypt and Palestine. On demobilisation in 1947 he returned to the London Hospital to pursue his ambition to become a consultant physician. Unfortunately, at this time, there was ferocious competition for promotion because of the high number of doctors returning from the forces after the Second World War. So, instead, he retrained at the Maudsley Hospital to become a psychiatrist. Nevertheless, he remained a physician at heart, adopting a medical approach and placing great emphasis

on diagnosis and the use of physical methods of treatment. Although he was insistent that he did not do psychotherapy, he had all the personal qualities of an excellent psychotherapist: empathy, non-possessive warmth, genuineness and a supportive non-judgemental approach.

Paul was a consummate professional dedicated to his work and the NHS, and as a role model he influenced several younger colleagues to take up psychiatry. He had no time for private practice or medical politics. His focus was the care and management of his patients. They loved him and on the rare occasions I took his clinic their disappointment was palpable. Modest, unassuming, understated and unassertive, he combined the qualities of an English gentleman with attributes of Welsh nonconformity and liberalism, reflecting his deep roots in west Wales. Basic Christian values guided his life and he had no regard for social class – a good example of this was his lifelong friendship with his batman, the only link he maintained with his time in the army. The Guardian was his newspaper and he espoused its core values.

He was devoted to his family and only looked for the good in everyone. He supported many charities and was pre-occupied with people, who, as he put it, were ‘less fortunate than I am through no fault of their own’. In retirement, activities linked to psychiatry gradually declined and were replaced by his only hobby – gardening. He enjoyed growing food for the house and his garden was always a pleasure to see. Over the years and into advanced old age he enjoyed excellent health; so much so that his close relatives were lulled into thinking that he would always be around and that his support, consideration and wise advice would always be available. He grew old gracefully in every way, retaining his core liberal values to the end.

Marjorie, his wife, and his younger daughter, Helen, predeceased him. He is survived by his sister, daughter and son.

1.6.81 Costas Stefanis MD

: Formerly Professor of Psychiatry and Head, Department of Psychiatry, University of Athens Medical School; Director, Eginition University Psychiatric Hospital, Athens

Nick Bouras

date

2017-10

Contents

- *Costas Stefanis MD*
 - : *Formerly Professor of Psychiatry and Head, Department of Psychiatry, University of Athens Medical School; Director, Eginition University Psychiatric Hospital, Athens*

Costas Stefanis, who died recently at the age of 88, was the leading figure in psychiatry in Greece for 30 years, from the time of his appointment as professor of psychiatry in 1970. In collaboration with British-trained colleagues he transformed Greek psychiatry and mental health services, steering away from a previously narrow traditional psychoanalytic approach towards a much broader biopsychosocial direction. He expanded the provision of generic and

specialist mental health services and was quick to adopt the new emerging trends of community care by developing the first community mental health centre in Greece. He developed a strong research programme, having himself – early in his career, while in the USA and Canada – carried out pioneering work on the functional role of pyramidal neurons in the sensorimotor cortex. He had an international reputation as an expert on the mode of action of neurotransmitters functioning on central nervous system synapses.

Several generations of Greek psychiatrists and allied professionals were trained by him, including me. Many became his associates and were inspired to go on to acquire international recognition and reputation. In 1989, in Athens, he founded the University Mental Health Research Institute – which undertook much neurobiological and psychosocial research into mental disorders – and remained president and director until his death.

He also played a major part in international psychiatry. As president of the World Psychiatric Association (WPA) from 1983 to 1990, he was responsible for an organisation in crisis. The political use of psychiatry in the Soviet Union to incarcerate political dissidents on the grounds of mental illness led to an explosive climate within the WPA. In 1983, after major criticism from societies in other countries – which made it likely that it was facing expulsion – the All-Union Society of Psychiatrists and Neuropathologists of the USSR withdrew from the WPA. Years later, at the WPA congress held in Athens in 1989, the general secretary of that Society publicly acknowledged that political abuse of psychiatry had indeed taken place and the organisation was reinstated as a member. This by no means ended the unhappy situation in the Soviet Union, which to some extent continues to this day, but a greater degree of openness was achieved. Costas Stefanis was among those responsible for reaching a conciliatory approach on issues with significant ethical and political dimensions.

Costas Stefanis became active in the political life of his country. Between 1996 and 2000 he served as honorary member of the Greek Parliament in the reformist social-democratic government and was Minister of Health and Welfare from 2002 to 2004. During his ministerial tenure, he was president of the Council of Ministers of Health of the European Union and succeeded in achieving approval for anti-stigma legislation regarding mental illness. On behalf of the EU member states, he signed the World Health Organization's International Treaty on Tobacco Advertising. In Greece, he was responsible for four major bills passed by Parliament – on public health; reform and decentralisation of health services; the organisation of primary health care and provisions for prevention and social reintegration. Unfortunately, most of them are still awaiting implementation.

He received numerous distinctions and awards. In 1994 he was elected life member of the Athens Academy of Sciences and Arts – the highest level of scientific recognition in Greece – and served as its president in 2006. He was awarded the Medal of the Cross of the President of the Hellenic Republic in recognition of his distinguished service to the country. In acknowledgement of his contribution to psychiatry, the World Federation of Societies of Biological Psychiatry and International Neuropsychiatric Association established an international prize: the Costas Stefanis Award for Excellence in Psychiatry and the Neurosciences. He was elected honorary member and fellow of several scientific associations and he authored numerous peer-reviewed articles as well as books and articles in the lay press.

Costas Stefanis was born in Greece in 1928 and graduated from the Medical School of Athens University in 1953. He trained in neurology and psychiatry in Athens and subsequently served as a fellow in basic neurophysiology at McGill University, Montreal, and as a research scientist at the National Institute of Mental Health and Saint Elizabeth Mental Hospital (Bethesda, Maryland and Washington, DC).

He was a highly intelligent, conscientious professional who, during difficult times, strove to improve psychiatric and mental health service provision not only in Greece but worldwide, thus improving the lives of thousands of people. He died on 29 October 2016 after a long illness stoically borne, remaining active in offering advice and ideas to the end. He was devoted to his family and is survived by his wife Adela, two sons – Nicos, professor of psychiatry, and Leonidas, professor of neurology – his daughter Evanthia, a film maker, and four grandchildren.

The death of Costas Stefanis will be felt as a great loss to psychiatry by many clinical, academic and international colleagues who had the privilege of knowing and working with him.

1.6.82 Kurt Schapira MD FRCP FRCPsych DPM

: Formerly Consultant Psychiatrist, Newcastle Health Authority, Honorary Lecturer in Psychiatry, University of Newcastle

Kenneth Davison Hamish McClelland Alan Kerr Martin Schapira

date

2017-10

Contents

- *Kurt Schapira MD FRCP FRCPsych DPM*
 - : *Formerly Consultant Psychiatrist, Newcastle Health Authority, Honorary Lecturer in Psychiatry, University of Newcastle*

Shortly after completing his house officer posts and national service in the Royal Army Medical Corps, Kurt Schapira, who died recently aged 87, was appointed a research fellow to the eminent neurologist Henry Miller. More than 1150 patients with multiple sclerosis resident in Northumberland and Durham on 1 January 1958 were reviewed by Dr Schapira. Using this material, he jointly wrote 16 scientific articles on various aspects of multiple sclerosis – including its epidemiology and clinical features – many of which are still cited today. The study made a major contribution to knowledge of this condition.¹ Subsequently, fascinated by the emotional effects of multiple sclerosis on the patients, Dr Schapira decided to switch to psychiatry. He participated in Martin Roth's landmark studies on anxiety and depression and undertook his own research into suicide and attempted suicide, as well as on the treatment of anorexia nervosa. His longitudinal studies relating suicide rates to social factors and the availability of lethal methods were influential in demonstrating the importance of a public health preventive approach to suicide.² He published several articles on these and other topics, including, with others, a much-quoted paper on the influence of tablet colour in the treatment of anxiety and depressive states.³

Born in Vienna to orthodox Jewish parents, Kurt's childhood was disrupted by the death of his mother when he was aged 7 years. This was followed by the incarceration of his father by the Nazis in Dachau and then Buchenwald concentration camps. Fortunately, his father was released from Buchenwald and allowed to travel to England before the Second World War. Kurt lived in Berlin with a maternal aunt until the age of 10, when he obtained a place on a Kindertransport train to England. Having successfully negotiated a path through the British educational system, Kurt was admitted to medical school in Newcastle – then part of the University of Durham – and qualified as a doctor in 1952.

He trained in psychiatry in the university department of psychiatry in Newcastle, headed at that time by Martin Roth and James Gibbons. Within the department he was promoted to first assistant and then senior lecturer. In 1974 he became consultant psychiatrist to the Newcastle Health Authority while retaining his university connection as an honorary lecturer. He continued in this position until his retirement from the NHS in 1989.

He lectured widely both in the UK and abroad, as far afield as Brisbane, Minnesota, Montreal and Jerusalem. During his retirement he remained active in research, especially into factors influencing the incidence of suicide in Newcastle over three decades. His last published article on the subject⁴ – in collaboration with others, including his son Martin – appeared as recently as June 2016.

He undertook many responsibilities in both National Health Service and university administration and was a member of several university committees. Within the Royal College of Psychiatrists, he was a member of Council (1979–82), the Education Committee (1979–82) and the Board of Assessors of the *British Journal of Psychiatry* (1970–75), as well as examiner for the membership and various other psychiatry-related degrees at home and abroad. He was also elected President of the Section of Psychiatry, Royal Society of Medicine (1980) and President of the North of England Medico-Legal Society (1982).

Kurt enjoyed teaching and regularly topped the students' ratings for the quality of his lectures, which were notable for their combination of wit and erudition. These attributes rendered him a popular speaker to non-medical audiences, especially on the art of Chagall, Salvador Dali and Van Gogh, and the artistic portrayal of doctors and lawyers. He was a connoisseur of opera and classical music, particularly Verdi and Mozart.

He was generous with his time in acceding to invitations to speak about his childhood experiences to a variety of audiences, from schoolchildren to prisoners, and was proud to meet Prince Charles recently at a reception for Kindertransport survivors. A genial extrovert and renowned raconteur, whose personality raised the spirits of his friends and colleagues, he had a fund of humorous anecdotes, enhanced in the telling by a trace of a Viennese accent. He often expressed his indebtedness to England for accepting him as a refugee. Considering his many contributions to the sum of human health and happiness, any debt has been more than repaid.

He leaves Eva, his wife of 51 years, 3 children, 5 grandchildren, 4 great grandchildren and an older sister.

- *Women in Academic Psychiatry: A Mind to Succeed*

As a female academic psychiatrist I asked two questions of myself about this book. Did I identify with the problems described here? And second, would I have found it valuable to read at an earlier stage in my career? The answer to both of these is a (qualified) yes.

The book is in two parts. The first consists of 16 interviews with eminent female psychiatrists and psychologists, which were almost certainly conducted by email. The questions are standardised, the responses polished and there is no in-depth probing of replies – which as a qualitative researcher I would have found more revealing. The second part of the book is a series of rather brief chapters which provide a helpful template for recognising the barriers and considering how to overcome them. These include putting yourself first, projecting confidence even if you don't feel it, being memorable, persistent and something I've found to be particularly important – networking.

The problems described are all too familiar – I've been subjected to mansplaining, '*a man compelled to explain, especially to a woman, something that she already knows better than him.*' I've held back in conversation, fearful of asking questions. I've been the only woman in a committee room except for the person taking the minutes. Yet, all of these very talented women demonstrate how a combination of real passion for what you are interested in and the ambition to push yourself forwards, even when times are challenging, has resulted in outstanding academic success.

Almost all the interviewees are now at the pinnacle of their careers. Many came from similar professional families and more than a few acknowledge the role played by a supportive partner with the kind of job that made it easier to be both an academic clinician and a mother. There is no one still 'finding their way' that a younger me might have identified with and the majority work in biological psychiatry – the editors' own field – in the USA. I might have found it helpful to read their stories when I was younger, but on the other hand, I might have been more than a little intimidated too.

1.6.84 Mental health law across the UK†

Tony Zigmond

Correspondence

Tony Zigmond (aszigmond@me.com)¹

date

2017-12

Abstract

The criteria governing medical treatment without consent in the three legal jurisdictions of the UK – England and Wales, Scotland and Northern Ireland – is discussed.

Contents

- *Mental health law across the UK†*

'A doctor is not that sinister figure which in former times he was represented to be, anxious simply to confine a man in a dungeon for life. He is treating mental disorder in exactly the same way as he treats any other disease.'

Lord Russell 1928¹

Nearly 20 years ago I wrote an editorial in this journal that there should be a medical incapacity act to 'provide for the medical treatment, both mental and physical, of those who lack capacity from whatever cause. It would establish a statutory framework offering the same protections to all patients who are unable to consent to medical intervention, from both physical and psychiatric conditions, and permit investigation and treatment of both the physical and mental

illnesses of such patients'.² Szmuckler & Holloway have not just argued for a single piece of legislation for all nonconsensual care and treatment saying that a mental health act is harmful,³ they have written a draft act under the heading of 'Fusion Law'.⁴ We may soon know whether we were right.

There are three distinct legal jurisdictions within the UK: England and Wales, Northern Ireland and Scotland. Until recently all had a mental health act to regulate the care and treatment of people with a mental illness while relying on common law to do the same for the physically ill. The powers given to doctors and other healthcare professionals by the two regimes was very different.

Within a year or two either side of the turn of this century, all the jurisdictions started to review their relevant legislation, not only their mental health law but also the necessity for replacing common law with statutory provision for the non-consensual treatment of physical illness, not least to ensure compliance with the European Convention on Human Rights as required by the Human Rights Act 1998. Scotland passed its Adults with Incapacity (Scotland) Act 2000, England and Wales its Mental Capacity Act 2005, Northern Ireland its Mental Capacity Act (Northern Ireland) 2016. For their mental health acts, each started with a review: Richardson for England and Wales published in 1999,⁵ Millan for Scotland in 2001⁶ and Bamford for Northern Ireland in 2007.⁷ Each considered whether or not their mental health act should include a 'capacity' criterion for medical treatment without consent.

The courts have been consistent about the role of capacity when adults make a decision about medical treatment. Lord Reid in 1972 said: "There is no doubt that a person of full age and capacity cannot be ordered to undergo a blood test against his will. ... the real reason is that English law goes to great lengths to protect a person of full age and capacity from interference with his personal liberty. We have too often seen freedom disappear in other countries not only by coups d'état but by gradual erosion: and often it is the first step that counts. So it would be unwise to make even minor concessions".⁸ Lord Donaldson, then Master of the Rolls, in 1992 said: "Prima facie every adult has the right and capacity to decide whether or not he will accept medical treatment, even if a refusal may risk permanent injury to his health or even lead to premature death".⁹ Ten years later Dame Butler-Sloss said the same: "A competent patient has an absolute right to refuse to consent to medical treatment for any reason, rational or irrational, or for no reason at all, even when that decision may lead to his or her death".¹⁰ They all emphasised the importance of autonomy. Although common law has now been replaced by statute law, the provisions of capacity legislation fully reflect these sentiments. I note that all the Judges were, of course, incorrect. A competent person with a mental illness may have no right to refuse treatment.

To return to the reviews. The first principle of Recommendation 3.3 in the Millan report is 'Non discrimination – People with mental disorder should whenever possible retain the same rights and entitlements as those with other health needs' (p. 23).⁶ So, should capacity be a criterion as it is for those with other health needs? The report sets out the arguments against the capacity criterion including that there were difficulties assessing capacity, particularly in patients with mood disorders, obsessive-compulsive disorders and eating disorders; 'Such patients might retain legal capacity but be at such risk as to justify intervention' (p.55).⁶ The committee was also told by some psychiatrists that "incapacity was a concept which they would find difficult to measure and apply. The British Medical Association (BMA) suggested that a capacity test would make it harder for GPs and doctors in, for example, Accident and Emergency Departments to come to a decision, and might lead to a reluctance to use the Act. The United Kingdom Central Council for Nursing, Midwifery and Health Visiting (UKCC), while in favour of making the justification for non-consensual interventions more explicit, suggested that professionals were not equipped to apply sophisticated tests of capacity fairly' (p.55).⁶ These comments about difficulties assessing capacity are noteworthy because no individual or organisation said they could not operate or abide by the provisions of that country's incapacity act which, of course, requires assessment of capacity.

The Millan committee advised "that it should not be possible for a compulsory intervention to be made under mental health law unless there is evidence that the person's judgement is significantly impaired, as a result of mental disorder, so as to justify the intervention. This expresses a broadly similar concept to incapacity, but is felt to be a less legalistic formulation, and one which may be easier to apply in practice' (p. 57).⁶ Significantly impaired decision-making as a result of the mental disorder (SIDMA) is a criterion for compulsion in the Mental Health (Care and Treatment) (Scotland) Act 2005. Millan had asked the question as to whether a mental health act was necessary and decided it was. Richardson also considered the question of capacity. Similar to Millan, 'The principles governing mental health care should be the same as those which govern physical health' (p. 21)⁵ wherever possible. Although deciding that incapacity should not be a criterion because 'Mental disorder unlike most physical health problems may occasionally

have wider consequences for the individual's family and carer, and very occasionally for unconnected members of the public' (p. 19),⁵ the report suggested a form of words which would require the assessment of, and taking into account, the patient's capacity. Patients with capacity could only be detained if they presented a higher degree of risk compared with patients who lacked capacity. The government rejected this proposal. That a distinct mental health act was required was not questioned. There is no 'capacity' or 'SIDMA' criterion, nor a distinction between patients who retain capacity and those who do not, in the Mental Health Act 1983 (amended in 2007). To have such a criterion would have meant, according to Lord Hunt during the debate on the 2007 Bill, 'abandoning one of the most fundamental objectives of the Act, namely that compulsory intervention should be based on need and risk'.¹¹ To spell it out, in England and Wales a person can be forced to accept treatment for their mental illness if there is a health risk to themselves or others despite retaining full decision-making capacity. The equivalent law for physical illness, the Mental Capacity Act 2005, only applies if the person cannot consent because they lack capacity to do so. Patients with capacity who refuse consent cannot be forced to accept treatment no matter what the risks.

Northern Ireland has taken rather longer to determine their way forward. The outcome of the Bamford review and the provisions of their new act are detailed by Lynch *et al.*¹² There is to be no mental health act. The Mental Capacity Act (Northern Ireland) 2016 gives exactly the same legal framework for the non-consensual medical treatment of all citizens no matter what their illness.

Parity of esteem, a flagship policy of the Royal College of Psychiatrists, is best described, according to the College, as: 'Valuing mental health equally with physical health' (p. 3).¹³ The College has described a range of equalities which need to be achieved although, perhaps surprisingly, there is no mention of equality under the law. Northern Ireland now has equality under the law. The day after the judgment in the case of Ms B,¹⁰ *The Independent* newspaper wrote 'Never again may a clinician administer treatment against the will of a mentally competent patient'.¹⁴ In Northern Ireland that will soon be true.

Earl Howe, in his closing statement during the passage of the Mental Health Bill 2007 (England and Wales), quoted the Millan committee, 'It should not be the function of mental health law to impose treatment on those who are clearly able to make decisions for themselves' and then continued, 'As it is we are, in a real sense, back in the world of Enoch Powell and 1959. Patient empowerment and respect for the wishes of the patient are acknowledged features of good clinical practice in all other areas of healthcare – but not, it seems, in mental health'.¹⁵ The Mental Health (Northern Ireland) Act 2016 gives psychiatrists the same legal powers as all other doctors, and psychiatric patients the same autonomy and respect as all other patients. Where Northern Ireland has led surely other UK jurisdictions, and countries across the world, will follow.

1.6.85 Newspaper depictions of mental and physical health

Marian Chen Stephen Lawrie

Correspondence

Stephen Lawrie (s.lawrie@ed.ac.uk)¹

date

2017-12

Abstract

Aims and method Media portrayals of mental illness have long been recognised as being misleading and stigmatising. Following the campaigns of several advocacy groups to address this issue, we aimed

to evaluate the impact on mental health reporting over time. We repeated a survey we did 15 years ago using the same methods. Nine UK daily newspapers were surveyed over a 4-week period and coded with a schema to analyse the reporting of mental health compared with physical health.

Results In total, 963 articles – 200 on mental health and 763 on physical health – were identified. Over half of the articles on mental health were negative in tone: 18.5% indicated an association with violence compared with 0.3% of articles on physical health. However, there were more quotes from patients with mental disorders than physical disorders (22.5% v. 19.7%) and an equal mention of treatment and rehabilitation.

Clinical implications Mental health in print media remains tainted by themes of violence, however some improvement in reporting in recent years is evident, in particular by providing a voice for people with mental illness.

Newspapers and other forms of mass media are influential in transmitting key information and ideas, including social commentary.^{1,2} Consequently, their role in reporting on mental illness is seen as one of the main conduits through which the public, especially those without personal exposure to mental illness, learn and come into contact with issues surrounding mental health.^{3,4}

For many years it has been recognised that media reporting of mental illness is heavily biased in representing a misleading link between mental illness and violence, with preferential reporting for sensationalist stories depicting individuals with mental disorders as being aggressive, dangerous and unpredictable.^{1,4-7} Such widespread negative portrayals have reinforced the continued stigmatisation and lack of acceptance among those with psychiatric diagnoses, possibly increasing social distance and contributing to morbidity and distress. Of particular concern is the potential ‘internalisation’ of prejudices portrayed by the media, such that people with mental illnesses also begin to take on the view that they are dangerous and unstable.⁸ Furthermore, there is a corresponding lack of voice for people of mental illness,^{6,8} with few personal accounts of their burden of disease and similarly little representation from qualified healthcare professionals.^{6,9} All of this contributes to creating a stereotyped, isolated group without social status and acceptance.¹⁰

In a similar vein, there is a disappointing lack of coverage of stories on recovery and rehabilitation following mental illness.^{5,6} This potentially leads both the public and policy makers to erroneously believe that recovery is rare. We highlighted this in a newspaper survey 15 years ago in which we found that the reporting of mental illness and people with mental illness tended to be negative, whereas that of physical illness was much more likely to be positive in tone.¹¹ This may even influence health resource allocations to conditions that have a higher perceived chance of cure.⁴

As far back as the 1960s, Nunally noted that mental health representations in media were few and distorted, limited to ‘neurotic behaviour’ in evening dramas where ‘the afflicted person often enters the scene staring glassy-eyed, with his mouth widely agape, mumbling incoherent phrases or laughing uncontrollably’.¹² Steadman & Coccozza¹³ also showed

that media depictions are often skewed towards extremes. Their findings on public perception of the ‘criminally insane’ (mentally disordered offenders) are salient, with 61% of the public surveyed responding that they feared former mentally disordered offenders ‘a lot’.¹³ However, as the authors noted, the mentally disordered offenders named by the public following intensive coverage tend not to have any legal claim to be ‘criminally insane’, and are merely assumed to be as such by the media.

Although those with mental illness are reportedly 2–6 times more likely to commit violence than matched controls,^{5,14} the National Confidential Inquiry into Suicide and Homicide by People with Mental Illness¹⁵ found that only 5% of the homicides carried out in the general population between 2001 and 2011 were by those with an abnormal mental state ($n = 52$). However, an additional 14% had been in contact with mental health services in the preceding 12 months. Therefore, the vast majority of perpetrators of homicide do not have a mental illness at the time of the offence ($n = 951$). Contrast this with the statistics for suicide in the same report: 30% of all completed suicides in the 10-year period analysed were by patients already known to mental health services ($n = 2678$). The figures identified are 14 times higher than for homicide. From this, it is reasonable to infer that an individual with a mental health disorder is far more likely to self-harm than harm others. This important point is also often missing from media reports seeking to capitalise on the sensationalist angle and, by doing so, dehumanise the patient to the extent that they are defined by their illness. Similarly, it is clear that people with mental illness are much more likely to be ‘victims’ of crime than perpetrators.^{16,17} This discrepancy in public perception between perpetrator and victim among those with mental illness has also been highlighted in other studies,^{18,19} acknowledging the need to shift attention away from the perceived threat to the public, to providing support and protection for the truly vulnerable. In this regard, the media has been counterproductive in reinforcing misleading stereotypes about public safety while simultaneously underreporting key statistics on mental health.

Although viral campaigns such as Rethink Mental Illness’ ‘Find Mike’²⁰ have been highly successful in bringing mental illness to some public attention, it is difficult to assess their impact. Based on our previous survey,¹¹ we hypothesised that: mental health reporting would still be consistently more negative in tone compared with reporting of physical health issues, and patients would be consistently underrepresented in media depictions compared with physical health reports. Additionally, regarding the link with violence and criminality, we further hypothesised that the association between mental illness and violence would continue to pervade mental health reporting.

Method

The method followed that of Lawrie.¹¹ Nine weekday UK daily newspapers (Scottish editions) were surveyed over a period of 4 weeks between 4 March and 4 April 2014. The papers chosen represent a selection of popular broadsheet (*The Times*, *The Telegraph*, *The Independent*, *The Guardian*, *The Scotsman*, *The Herald*) and tabloid (*Daily Mail*, *The Sun*, *Daily Record*) publications in the UK, with a reported range in circulation of between 64 279 (*The Independent*) and 2 048 977 (*The Sun*) in February 2014.²¹ Only national newspapers were included in this analysis, as they have the widest distribution.

Print copies of the newspapers were obtained from the Reference Library of Edinburgh on the day of publication and manually screened for headlines relating to mental health or psychiatry and general health issues. Two tabloids, *The Sun* and *Daily Record*, were purchased each day, as they were not subscribed to by library services, yet have the highest circulation figures in the UK.

Articles relating to mental health and physical health were identified initially through headline screening. The main body of text was then read and coded as positive, negative or neutral, if the article was mainly stating facts or had mixed elements. As such, it is possible to have a disparity between tone of headline and article. Each article was then analysed and coded to a schema with eight variables, which noted key themes (*Table 1*).

Coding schema for newspaper articles

Variable	Description
Quote from patient, relative or charity	Direct or paraphrased quote from a patient with the illness in question, relative or advocacy organisation
Quote from professional	Quote from a healthcare professional in charge of the patient's care or spokesperson for government organisations, etc.
Association with violence	Any article where a person portrayed as having a mental illness or under the influence of drugs/alcohol engages in criminal or dangerous activity where others are put at risk or harmed. Suicide or self-harm is not included in this category
Mention of treatment/rehabilitation	Either specific (e.g. Prozac), general (anti-depressants, cognitive-behavioural therapy), alternative (mindfulness, yoga) or relating to the Mental Health Act 1983 where treatment is noted under a compulsory treatment order
Substance misuse	Articles relating to addiction, overdose or psychiatric effects of substance misuse were classified as relating to mental health. Physical effects of drug usage, including side-effects, were classified under physical health
System failure/negligence	Any article where substandard care is delivered by a single person or on an organisational level, resulting in adverse outcomes. Shortcomings range from IT failures and changes in social policy to deliberate mistreatment
Innovations in research	Articles where a new diagnostic method, treatment or better understanding of a named disease is reached
Medical advocacy/raising awareness	Where the primary purpose of the article is to transmit information about a particular disease profile or set of symptoms or charity efforts. For example Autism Awareness Week, United Nations World Down Syndrome Day, 'Check 'Em Tuesday' – a campaign run by <i>The Sun</i> to increase uptake of self-screening for breast cancer

Inclusion and exclusion criteria

The sports and business sections were surveyed, however property and automobile inserts were excluded due to likely lack of relevance. Primary newspaper articles, editorials and opinion pieces were included in the data collection. Advertisements, letters to the editor, film and entertainment reviews and obituaries were omitted. Articles with only a passing or chance reference to mental or physical health were also omitted.

All articles concerning mental disorders recognised by the DSM-5,²² psychiatry or psychiatrists were included, as well as generic, undefined mental conditions with the exception of paedophilia and the paraphilias, as their classification as a mental illness in DSM-5 is controversial. For physical health, all articles relating to other general medical issues were collected. Articles concerning the National Health Service (NHS) or other organisational bodies were included only if there was a demonstrable mention of impact on patient health and safety.

Results

In total, 963 health-related articles were collected during the 4-week period. Of these, 763 (79.2%) concerned physical health, whereas 200 (20.8%) were about mental health. Although there was a slight preponderance towards neutral pieces (38.0%) in the physical health category, compared with positive (28.6%) and negative (32.9%) reporting, the majority of articles concerning mental health were negative in tone (50.5%), with only a small number of positive (22.0%) or neutral articles (27.5%) (*Box 1*). This striking disparity between mental and physical health reporting underscores a key finding that mental health reporting remains consistently more negative than physical health, which is in line with the results from Lawrie's¹¹ study over a decade previously (ratio of positive to negative articles for physical health: 218/251; and for mental health: 44/101; odds ratio (OR) 1.99, 95% confidence interval (CI) 1.34–2.97). In addition, we found a prominent and stigmatising association between mental illness and violence as 18.5% of mental health articles featured violence as a major theme, compared with 0.3% of physical health articles (OR = 86.37, 95% CI 20.60–362.1) (*Table 2*).

Comparison of variables between physical and mental health reporting

Variable	Physical health, <i>n</i> (%)	Mental health, <i>n</i> (%)
Total number of articles	763	200
Positive	218 (28.6)	44 (22.0)
Negative	251 (32.9)	101 (50.5)
Neutral	290 (38.0)	55 (27.5)
Quote from patient/charity	150 (19.7)	45 (22.5)
Quote from professional	285 (37.4)	58 (29.0)
Association with violence	2 (0.3)	37 (18.5)
Mention of treatment/rehabilitation	217 (28.4)	48 (24.0)
Substance misuse	31 (4.1)	22 (11.0)
Medical advocacy/raising awareness	131 (17.2)	26 (13.0)
System failure/negligence	118 (15.5)	25 (12.5)
Innovations in research	184 (24.1)	22 (11.0)

Although previous studies have shown that patients with mental illness are underrepresented in newspaper articles,^{6,8} we found this not to be the case, with a higher proportion of quotes from patients with mental illness, their relatives or mental health charities (22.5%) compared with physical health (19.7%) (ratio of quotes in physical health: 150/613; mental health: 45/155; OR=0.84, 95% CI 0.58–1.23). There appears to be comparatively fewer quotes from professionals in relation to mental health however, highlighting the need of the psychiatric profession to make a conscious effort to engage with the media, and vice versa.²³ Interestingly, whereas previous studies have highlighted a lack of reporting on treatment and rehabilitation for mental health,^{4–6} here we found the rates to be comparable to that of physical health articles (24.0% v. 28.4% respectively) and previous reports.⁶

Box 1 Examples of positive, negative and neutral headlines for mental and physical health

Physical health

Positive

‘US Aids baby may be cured’

‘Cholesterol drugs may slow MS, study shows’

Negative

‘Three-year old died after hospital delay’

‘“Sickness culture” claim as 1 in 3 has long-term illness’

Neutral

‘Statins have no side-effects, study finds’

‘Smoking link to breast cancer in older women’

Mental health

Positive

‘Depression and self-harming are taboo ... that’s why I’m determined to speak out’

‘Ketamine trial provides fresh hope for long-term depressed’

Negative

‘Mentally ill man in bus knife attack’

‘School accused of excluding girl with anorexia to avoid copycats’

Neutral

‘Give dementia patients trial drugs en masse’

‘Depression must be seen as a societal disorder’

The disorders most commonly associated with violence were personality disorders as well as undefined ‘mental illnesses’ and post-traumatic stress disorder, which make up 13.5% of all articles pertaining to mental health. Surprisingly, sensationalist stories about schizophrenia were minimal and comparable to reporting on other mental disorders, whereas dementia and eating disorders were least likely to be reported as associated with violence (*Table 3*).

A breakdown of newspaper articles according to diagnosis and association with violence

Diagnosis	Articles <i>n</i> (%)	Association with violence, <i>n</i> (%)
Suicide	31 (15.5)	0
Mood disorder	26 (13)	2 (1.0)
Dementia	32 (16)	0
Eating disorder	12 (6)	0
Developmental disorder	17 (8.5)	3 (1.5)
Substance misuse	13 (6.5)	2 (1.0)
Personality disorder	11 (5.5)	14 (7.0)
Schizophrenia/psychosis	10 (5)	3 (1.5)
Other ^a	49 (24.5)	13 (6.5)

Includes multiple disorders, undefined and post-traumatic stress disorder.

Based on the previous data that show people with mental illnesses are more likely to be victims of crime rather than perpetrators, we were interested to see whether this correlated with media reports. We found that people with mental illness are twice as likely to be portrayed as a perpetrator (34/200) compared with a victim (17/200), in direct contrast to the available data.^{16,18,19,24}

Given that 18.5% of articles on mental health concern violent acts and are seen as a threat to the public, we asked what made up the rest of the negative reporting. On further analysis, it appears that a significant proportion of the negative articles pertain to the stigmatisation and abuse of people with mental health within society, as well as lack of funding and adequate care provision. Examples include headlines such as: ‘The great mental health betrayal’ (*The Independent*, 13 March 2014), an article about the unlawful detaining of people with mental health illnesses in care homes and hospitals, and ‘Mental health and race – the blight of dual discrimination’ (*The Guardian*, 26 March 2014), which highlights the additional burden of being an ethnic minority with mental illness. The remainder of the negative articles are reports on suicide (15.5%).

Overall, there was no significant difference between mental health reporting in broadsheets compared with tabloids.

Discussion

We found that mental health reporting makes up a fifth of all articles concerning health in a selection of UK print media over the course of a month. This is lower than found in a similar study by Pieters *et al*²⁵ in Belgium but comparable to the figures obtained by Lawrie in the UK¹¹ over a decade ago, reflecting little change in the frequency of reporting on mental health. Half of all articles on mental health are negative in tone, which is a much greater proportion than for physical health, but nonetheless represents a small reduction compared with Lawrie's study. On the other hand, the association with violence remains prominent, with 18.5% of articles carrying a theme of danger or criminality.

In the intervening 15 years, several campaigns by mental health charities both in the UK and abroad have sought to lessen the stigma attached to mental illness and encourage open dialogue about mental health. Media coverage is important to the success of such campaigns in influencing public opinion and increasing exposure. In light of this, we asked whether there is any evidence that media reporting on mental illness is improving (see below). Although previous studies have commented on the lack of voice for people with mental illness, we have found this not to be the case with a higher proportion of quotes from patients with mental illnesses compared with physical health. Although there are fewer representations of healthcare professionals in psychiatry, this may reflect reluctance among the profession as a whole to engage with the media, as psychiatrists too are affected by stigma.^{26,27}

Mental illness and violence

The link between mental illness and violence is unfortunately still pervasively reported – being part of about a fifth of all articles on mental health. The figure obtained in this study (18.5%) is lower than previous reports of association with violence.⁶ However, other studies have utilised more restricted search criteria, only using specific keywords such as 'schizo', 'mental', 'deranged' and 'psycho', which does not encompass the whole spectrum of mental illnesses.^{5,6,28,29} As most studies also used a computerised database programme (such as the LexisNexis) to generate articles, limiting the search criteria to only the above keywords will bias the results to find articles on schizophrenia or those that include derogatory terms such as 'psycho' or 'deranged', which are inherently stigmatic and more likely to be associated with violence.²⁹ In contrast, mental illnesses not usually considered violent, such as eating and mood disorders, would be excluded from the analysis.

In our study we found that schizophrenia and psychotic disorders make up a minority (5%) of reporting on mental illness and only 1.5% of these articles featured violence. Although there is little contention that mental disorders are disproportionately associated with violence in the media, one possible explanation for the strength of the association between the two is that it is an artefact created by selective searching among newspaper databases. We suggest the effect would be diluted if all articles on psychiatry, including conditions such as mood and anxiety disorders, were incorporated in the analysis.^{30,31}

In this study, we also found that people with mental disorders are twice as likely to be portrayed as a perpetrator of crime compared with a victim. This is another illustration of how the media can be misleading on key facts. Education for journalists and guidance on the reporting of mental health issues is central to bringing about a change in reporting trends. However, this may be easier said than done. One study attempted to correct journalists' erroneous views about mental illness with a short presentation on schizophrenia prior to a press conference regarding a high-profile assault carried out by a man with a serious mental illness. Although they found that journalists had a good recall for the details several weeks later, the presentation did not ultimately affect the writing of the article.³² This suggests that collaborations with the media will have a greater chance of success and change in reporting if they are mutually beneficial and desired. One example of this is UK mental health charity, Mind, which has set up a series of media awards for responsible and ethical reporting of mental health issues (www.mind.org.uk/news-campaigns/mind-media-awards), as well as reporting guidelines for different conditions.^{33,34}

Strengths and limitations

The main strength of the study is that all papers were hand-searched according to the criteria set out in the Method. This abolishes the need to search based on keywords, potentially increasing the yield of articles. Similarly, the scope and definition of 'mental illness' is wider than in previous studies, allowing for a greater overview of the subject in media. In the current study, the use of one investigator to locate and rate the articles, is both a potential advantage – in reducing interrater variability – but also a disadvantage in that no interrater reliability could be established (although we did discuss and resolve any uncertainties between the authors). The main limitation is that the coding schema used is a relatively blunt tool and cannot convey the complexity or depth of a newspaper story. Second, the categorisation of articles into mental and physical health does not allow for overlap in coverage, although that only occurred in a small minority of articles. Furthermore, the short time frame of the study means it can only provide a snapshot of mental health reporting in the UK. Last, there were two mental health stories that garnered a considerable amount of media attention in this time period and subsequently have the ability to bias the data. One was the suicide of a famous fashion designer and another, the death of a woman who had murdered her three children and was subsequently labelled as having a personality disorder. Both stories were extensively reported on over multiple days. However, they were included in the analysis as this study was designed to encompass all the news on mental health over 4 consecutive weeks, rather than the sampling of random time points, and different reports had different foci as new information about the cases came to light.

Conclusions

Despite several prominent government-led and charity campaigns, mental illness and individuals with mental illness continue to experience stigmatisation and stereotyping. Although it is encouraging that people with mental disorders are being increasingly represented in print media, and there appears to be an overall increase in non-stigmatising articles,³⁵ much remains to be done to address the inaccurate and stigmatising association with violence, and raise the profile of mental illness as a whole.

The particular reasons for the ongoing negative headlines about mental illness, and what could or should be done about them, are beyond the scope of this study. Our results do however indicate that there is a clear need for more reporting about mental health in general, and for more accurate reporting about violence and for more accounts of innovative research developments in particular. We therefore suggest that there is much to be gained from further ongoing engagement between patients and psychiatrists and the media, with an emphasis on realistic depictions of the lives patients lead and of recent research advances.

Many thanks to the staff at the Reference Library of Edinburgh for meticulously collating the newspapers used each day.

1.6.86 Implementation of a novel primary care pathway for patients with severe and enduring mental illness

Abstract

Aims and method New collaborative care models with an emphasis on primary care are required for long-term management of patients with severe and enduring mental illness (SMI). We conducted a descriptive evaluation of clinical outcomes of the first 3 years of a novel enhanced primary care (EPC) service. Data from 2818 patients and staff survey results were analysed.

Results 2310 patients were discharged to EPC (508 not assessed as clinically suitable or patients/general practitioners declined the transfer); mean length of stay with secondary care service of the cohort was 9.8 years (range 0–24). 717 patients (31%) have been discharged to primary care only out of the EPC services and 233 patients (10%) have been transferred back to secondary care. Patient and staff satisfaction with the new EPC model was high. No severe untoward incidents were recorded.

Clinical implications The data suggest that EPC can be safely provided for a significant proportion of patients with SMI, who traditionally received long-term secondary care support. The novel EPC model can be utilised as a template for the provision of cost-effective, recovery-oriented and non-stigmatising care in the community.

* *Limitations and outlook*

Mental healthcare for the majority of patients with severe and enduring mental illness (SMI) was historically provided predominantly by specialist secondary care services in the UK. Hereby, most patients with long-term chronic conditions received open-ended health and social care support and relatively few were discharged back to primary care for ongoing case management. More recently, patients with SMI are increasingly considered for clinical management by less specialised, generic primary healthcare services and in collaborative care models.¹⁻³ Most of these schemes have not been robustly evaluated through clinical and controlled trials. There is however good evidence to suggest that collaborative chronic care models foster patient self-management and can improve mental and physical outcomes for patients with mental health problems.³

In England, the introduction of clinical commissioning groups (CCGs) in 2013⁴ and the significant public spending savings plan with annual targets for all National Health Service (NHS) provider organisations⁵ resulted in a nationwide review of mental healthcare provisions and piloting of novel care pathways. Secondary mental healthcare providers have started to reduce the number of cases held by specialist community mental health teams, including assertive outreach and community rehabilitation teams. The NHS policy paper *No Health Without Mental Health*⁶ emphasised the need for integration of care for physical and mental health needs; provider and commissioner organisations therefore started to engage in various local service redesign projects. In East London, enhanced primary care (EPC) services for patients with SMI were developed and implemented in 2012, following a whole system review which attempted to address the issue of plateauing resources. The overall aim of the EPC service is to foster recovery of patients with SMI, to safely discharge them to primary care settings that attend to their mental healthcare needs. Three years after its launch, clinical outcomes of the novel care pathway for patients with SMI, patient/staff satisfaction were evaluated and are reported in this paper.

Method

Data collection and analysis

This evaluation is based on a retrospective data analysis of routinely collected data on all the patients referred to and/or fully discharged from secondary care to the EPC service since its inception (reporting period from 1 August 2012 to 31 July 2015). Electronic clinical data-sets included: total number of identified/discharged patients; number of patients who refused to be transferred to the new service and where either general practitioners (GPs) or consultant psychiatrists assessed patients as not suitable; diagnoses and ICD-10⁷ codes, gender, ethnicity, duration of service provided by secondary care, number of admissions to hospital; number of patients re-referred to secondary care or readmitted/relapsed analysis of main characteristics of this subgroup of patients.

In addition we conducted an analysis of available information collected regarding staff satisfaction (semi-structured interviews and questionnaires) and summarised data from a patient satisfaction survey (Client's Assessment of Treatment Scale⁸) for the new service from one of the three localities (Newham).

Description of the new EPC service

The model was developed in partnership between East London NHS Foundation Trust and the three East London CCGs (Newham, City & Hackney, Tower Hamlets) across primary/secondary care teams by interdisciplinary working groups; those involved were people participation leads, GPs, consultant psychiatrists, senior community psychiatry nurses, psychologists and social work leads. The initial target was defined as 300 patients per year per locality. The EPC care pathway allows providing mental healthcare flexibly according to patients' needs and to step up (secondary mental health services) or step down (generic primary care) in a seamless way without administrative hurdles.

EPC care pathway elements

Elements of the EPC care pathway were as follows: Regular GP reviews (in addition to quality and outcome requirements), the development of a recovery care plan, practice nurse administration of depot medication, and specific assessment of risk factors for physical illness, signposting into healthy lifestyle services. Enhanced support to primary care from consultant psychiatrists with regular practice-based mental health multidisciplinary review meetings. Training and education to GPs on managing SMI in primary care, and for practice nurses on psychopharmacology and therapeutic depot administration. EPC mental health teams consisting of registered mental nurses, employed by East London NHS Foundation Trust but working within general practice, to support discharge into the EPC and provide recovery-oriented support to patients on an ongoing basis.

The philosophy of the service operationally distinguishes clearly between: specialist acute and rehabilitation treatment for patients with severe or complex needs and/or those identified as presenting with significant risks to self or others associated with their illness (continued to be provided by secondary care services); and long-term condition management aiming to provide monitoring and maintenance support for patients with stable chronic SMI (provided by the new EPC teams). Inclusion criteria for the EPC transfer were defined as follows: Aged 18 years or older, resident in one of the three East London boroughs and currently under the care of secondary care services. Established diagnosis of an SMI that would warrant their inclusion on the practice severe and enduring mental illness (SEMI) register. Identified care needs above those that would ordinarily be provided for under normal primary care, either medical or social needs, that require additional support. Patient agrees to the support offered via the EPC clinic. Sustained clinical progress with less frequent support from secondary care and no identified need for specialist interventions and treatments. Last acute psychiatric hospital admission more than 12 months ago, no current risks to self or others identified; patient is well-established on a medication regime and requires minimal assistance with concordance, but does require regular monitoring and review. Patient has settled accommodation, is able to meet their own basic living needs. Patients requiring lithium prescribing or depot injections in primary care are included.

Teaching, training and supervision

Primary care liaison nurses (PCLNs) of the EPC teams were recruited from secondary care services and all had experience in providing mental healthcare to patients with SMI. A list of essential competencies, skills and experiences were identified as significant requirements for the recruitment of the EPC workforce and included the following areas: history taking/mental state examination, engagement skills and basic knowledge of principles pertaining to a positive therapeutic relationship, risk assessment and management, recovery care and social psychiatry, and psychiatric emergencies. Additional training was offered to PCLNs.

The provision of the EPC service is supported through weekly team meetings, monthly supervision sessions, and six monthly appraisal/reviews, aiming to maintain and update knowledge and skills.

The three localities agreed on mandatory training requirements for primary care staff as part of the EPC contract with their primary care practices and the EPC team provided training for staff in GP practices including mental health awareness training for practice reception staff and depot training for nurses.

Subsequently, in 2015 a website with a wide range of teaching and self-learning materials for all primary care staff was developed with funding from Health Education England North Central and East London, launched into public domain in 2016 (<http://primary-mentalhealth-care.elft.nhs.uk>).

Service aims and expected outcomes

- To support patients to achieve their recovery goals through a process of joint planning that places patients at the centre.
- To empower people to self-manage their own recovery journey and reach a position where they can reduce their contact with mental health services.
- To mark the recovery journey by recognising achievements while being transferred to receive care in EPC and at the point of discharge from EPC.
- To improve the patient experience and outcomes through enhanced multidisciplinary team working that addresses mental health, physical health and social need as part of an integrated approach.
- To improve patient experience and outcomes through the provision of care in a normalised setting, close to home and to assist the navigation of patients towards resources that supports their recovery.
- To enable the development of capacity, confidence and competence in relation to mental health treatment and care in the primary care workforce.

The service elements were developed accordingly, centred on a 'My Recovery Plan' and associated 'My Safety Plan' documents for time-limited EPC interventions according to recovery goals set by the patient (with a recommended duration of up to a year after which the patient is supposed to be discharged into generic primary care services). The time-limited nature of the service was to be made clear to the patients at the outset and the service provides a fast-track option back to secondary care services if needs change.

Team composition

The service is predominantly delivered by psychiatric PCLNs. The three localities agreed on different staffing compositions according to local variations of service needs and/or perceived requirements in respect of multidisciplinary inputs from health professionals.

In Newham, psychiatrist input is provided by one consultant with protected time in the job plan and by catchment area consultants as required based on a sectorised/practice-aligned service model; in Tower Hamlets consultants with a primary base in general practice deliver psychiatric expertise; and in City & Hackney a model with a dedicated EPC service consultant was established.

Following a 12-month review the team of healthcare professionals was complemented by a group of peer support workers, who provide patients with emotional and practical support as they approach discharge from secondary care services. All the peer supporters have personal experience of in-patient and community mental healthcare and support patients flexibly based on their own experiences of recovery. A summary of the current team structures and allocated posts is provided in *Table 1*.

Staffing composition in enhanced primary care (EPC) teams in each locality

Directorate	Total WTE per team	Admin Band 4	Occupational therapist	Clinical psychologist	Nurse Band 6	Nurse Band 7	Consultant	Peer/supervisor Band 3/4	Service manager Band 8a	Team case-load capacity

CH, City & Hackney; NH, Newham; TH, Tower Hamlets; WTE, whole time equivalent.

Original and current from 2016. Phased increase in size of service with new investment following a service review in 2014–2015.

Consisting of each of the four current primary care consultants devoting 2.5 sessions a week to the EPC service and primary care liaison.

Consisting of time dedicated to EPC and primary care liaison by the four assessment and brief treatment consultants providing support to practices and one consultant with 0.1 WTE leading on EPC.

Consisting of a dedicated consultant providing two sessions a week to provide clinical support to the EPC team and the Compass Primary Care Psychology service, and each of the community mental health team consultants providing one session a fortnight to supporting the primary care practices to which they are aligned.

EPC provides an open general advice service to GPs to assist in the treatment of patients that have been discharged from EPC and secondary care. The arrangements vary between the three East London boroughs but all include case-based discussions between GPs and consultant psychiatrists during regular multidisciplinary clinical meetings at primary care level.

Results

Service activity summary

As per 31 July 2015, the three East London EPC teams provided care for 1370 patients. Since August 2012 the services considered in total 2810 patients, of which 480 were not proceeded with because the patients declined transfer ($n = 149$), the GP declined the transfer ($n = 90$) or the secondary care eventually decided the transfer was not clinically appropriate ($n = 241$). Therefore, 2330 patients have received an active service from EPC services since their inception. In total, 717 patients were transferred to primary care only from EPC with variations across teams. The total number of patients discharged from EPC to primary care alone has significantly increased beyond the reporting period of this service evaluation due to changes in operational policy and as a result of the teaching and training efforts to upskill GPs, resulting in increased throughput.

All referral and case-load data with developments to 30 October 2016 are summarised in *Table 2*.

Patient characteristics

The majority of patients referred to EPC had a significant history of SMI with an average (mean) duration of care provided under care programme approach (CPA) standards by secondary care services (community mental health teams) of 9.7 years (range 0–24). The mean age of patients was 45.7 years (range 18–65; 12.1% 18–30 years and 77.3% 30–60 years); 54% of patients were female and 46% were male. Overall, 47.4% were single/living alone, 26.3% were married/civil partner and 11.6% were separated/divorced/widowed/surviving civil partner. Given the high percentage of Black and ethnic minorities living in East London, the distribution of ethnicity across the sample reflects the diversity: Asian or Asian British 24%, Black or Black British/African–Caribbean 19.8%, White British or other White 38.5%, other ethnic groups 17.8%.

The main diagnoses of patients were: schizophreniform or other psychotic disorders (ICD-10 codes F20–29) 37.2%, mood (affective) disorders (F30–39) 32.1%, anxiety/stress-related/somatoform and other non-psychotic mental disorders (F40–48) 11% and disorders of adult personality and behaviour (F60–69) 4.1%.

According to Department of Health guidance⁹ the main cluster codes on transfer to EPC were: cluster 10–13: 48.9% (11: 19.4%; 12: 21.5%; 13: 7.1%); cluster 4–7: 26.1%. The number of patients referred back to secondary care due to clinical issues (relapse concerns) was 237 (City & Hackney $n = 65$, Newham $n = 124$, Tower Hamlets $n = 48$).

Feedback from patients

Both EPC staff reports and results from questionnaire surveys suggest that the vast majority of patients regarded the new service arrangements as both helpful and adequate according to their needs. We conducted a more detailed survey in one of the three localities (Newham), using the structured Client's Assessment of Treatment Scale. Results from 126 patients who completed the survey (mean age 49.2 years, range 26–71; 66 female, 60 male) are indicative of comparatively high levels of patient satisfaction (most scores across the group rated with a mean of 8–9 out of 10) (*Table 3*).

Results from 126 patients who completed the Client's Assessment of Treatment Scale

	Mean	Range	s.d.
Do you believe you are receiving the right treatment/care for you here?	8.8	4–10	1.6
Does your general practitioner understand you and is she/he engaged in your treatment/care?	8.4	1–10	1.9
Does your named nurse understand you and is she/he engaged in your treatment/care?	9.0	2–10	1.5
Are relations with other staff members here pleasant or unpleasant for you?	8.5	0–10	2.0
Do you believe you are receiving the right medication for you?	8.9	0–10	1.7
Do you believe the other elements of treatment/care here are right for you?	9.4	4–10	1.3
Do you feel respected and regarded well here?	9.0	4–10	1.5
Has treatment/care here been helpful for you?	9.0	4–10	1.4

Feedback from GPs

GPs across all three localities engaged very well with the three EPC teams and expressed high levels of satisfaction; they acknowledged that the EPC service improved care for their patients. A brief survey questionnaire distributed to 61 GP surgeries in Newham was returned by 52 GPs. All but two GPs stated that the EPC helped to change their perception of/and relationship with mental health services.

Another GP survey was conducted in Tower Hamlets and revealed the following feedback (first figure 6 months after service implementation based on 61 responses (from 36 surgeries), second figure 1 year later based on 23 responses); this survey indicates that the EPC model contributed to developing GP's skills and knowledge of psychotropic prescribing (Very confident 3.3/13%, Confident 44.3/47.8%, Neutral 33.4/34.8%, Not confident 18.0/4.4%). In addition, satisfaction rates with practice-based multi-disciplinary meetings as well as the network-linked PCLNs was largely positive and increased over time.

We conducted a subgroup analysis of patients from Newham EPC who were re-referred to secondary care from EPC due to a relapse (significant increase in symptoms) of their mental disorder or other reasons; $n = 124$ out of 787, 15.8%.

Relapse due to a range of stressors (iatrogenic, non-adherence, etc.) was $n = 69$; relapse with acute admission to hospital, $n = 8$; and non-engagement and requests to be discharged from GP, $n = 9$. Requests for medication review by secondary services/GP referred back: $n = 26$; social circumstances: $n = 4$; and patient demanding to be referred back to consultant: $n = 3$.

Only for 3 out of 124 re-referred patients with a change in prescribed dose of medication were identified, all others had been on stable medication as per discharge plan from secondary care. The number of EPC face-to-face contacts for this group varied from 0 to 8, most patients had been seen on 1–3 occasions by their PCLN. The diagnostic codes, PCLN clinics and GP surgeries were equally distributed across this group.

Discussion

The data-set considered for this service evaluation comprised of a large sample of over 2000 patients with predominantly chronic severe mental illness (schizophreniform, psychotic or severe affective disorder, care clusters 10–13 and 4–7) and the observation period of 3 years seems adequate to allow for a critical appraisal of performance data. The overall results from this service evaluation suggest that a significant proportion of patients with SMI, who were traditionally seen long term with open-ended care plans in secondary care, can be successfully discharged to enhanced primary mental healthcare services. This is even more so significant given the fact that prior to transfer of care, patients had been receiving specialist mental health services for on average of nearly 10 years. The number of relapses and referrals to secondary care services has been low, even though the overall referral rate to EPC has risen. A significant number of patients who received EPC services are now supported by primary care alone.

The success of this novel care pathway is based on very close collaboration between primary and secondary care health professionals and service characteristics that provide seamless care across boundaries: all PCLNs were employed through secondary mental health services and mostly recruited from existing mental health teams, which enabled them to provide clinical expertise into the new service – quick access to secondary care for crisis management was built into the service structure.

Only about 14% of patients were not taken into EPC clinic care following the initial referral and this is indicative of a carefully conducted and initially conservative selection process, also taking patient preferences into account. Patient feedback was very positive and no severe untoward incidents occurred during the observational period.

Although mental healthcare services for patients with SMI have traditionally been regarded as too specialised for primary care, most patients regard primary care provisions as a significant milestone in their recovery journey.¹⁰ The care pathway development was conducted based on a much clearer distinction between elements focusing on supporting people to maintain stability and monitor symptoms versus elements providing active recovery-oriented treatment. This allowed refocusing of specialist services and deconstructing the 'shifted out-patient clinic' model,¹¹ essentially a replacement model, which does not provide opportunities for enhanced linkage and face-to-face consultations between

the primary care physician and the psychiatrist.¹² By contrast, the consultation-liaison collaboration model provides regular face-to-face contact between the psychiatrist or mental health worker and the GP.¹³

The survey results suggest that the support primary care doctors receive from consultant psychiatrists is a vital part of the scheme. The precise arrangements vary across the three boroughs but each primary care practice has an aligned consultant who visits the surgery regularly, is available for advice especially on potential referrals to secondary care and who assists the surgeries to become more mental health sensitive and informed.

The main difficulties with the new care pathway identified in the context of this service evaluation are related to the wider context of recovery-focused care with an emphasis on integration with mainstream community services, such as employment, training and leisure activities. Depending on pre-existing skill and knowledge base within each of the participating GP surgeries, the quality of mental state monitoring and therapeutic engagement is likely to vary significantly. More emphasis must therefore be given towards developing robust and ongoing teaching and training curricula for primary care practitioners. Another significant challenge is the variation in access to psychological therapy services and social care from locality to locality depending on the level and specification of integrated care pathways. This is a crucially important issue for the success of EPC services, safeguarding against compromising the quality of care.

A further significant increase of the number of people who experience a mental health problem in England has been predicted (i.e. 14.2%, from 8.65 million in 2007 to 9.88 million in 2026) as a result of population growth.¹⁴ More research of innovative and collaborative schemes for high-quality cost-effective mental healthcare is required, assessing the impact of working across primary and secondary care.¹⁵

The promotion of psychological resources and capabilities at a family and community level to support people experiencing mental ill health appears to be a promising complementary strategy for both primary and secondary prevention. Last but not least there seems to be a real case to extend the role of district nurses, to strengthen the role of GP champions in mental healthcare¹⁶ and to involve patients as teachers in interprofessional learning as already pointed out by Lester *et al*¹⁷ in their discussion paper on integrated primary mental healthcare more than 10 years ago.

Limitations and outlook

This is a retrospective analysis of routinely collected data for service evaluation, not a formal research study. Patients were identified by their secondary care clinicians as potentially suitable for transfer to the EPC clinic and there was no control condition. The Client's Assessment of Treatment Scale satisfaction scores and relapse indicator analysis was only available for one of the three localities and only a subgroup of about 25% of patients open to the EPC service completed the survey.

Empirical research is needed to establish detailed patient characteristics as predictors for successful transfer of care. Longer-term and controlled follow-up studies are required to establish care quality and effectiveness issues across various components of the health and social care pathway (e.g. social inclusion, subjective quality of life, psychopathological symptom levels) following discharge from secondary care services, compared with continuing specialist treatment. It will be important to assess differences between inner-city and more rural areas to establish as to whether the claim, that the delivery of mental healthcare in primary settings is 'more accessible, affordable and acceptable for the population'¹⁸ can be substantiated.

1.6.87 National survey of training of psychiatrists on advance directives to refuse treatment in bipolar disorder

Abstract

Aims and method To determine features associated with better perceived quality of training for psychiatrists on advance decision-making in the Mental Capacity Act 2005 (MCA), and whether the quality or amount of training were associated with positive attitudes or use of advance decisions to refuse treatment (ADRTs) by psychiatrists in people with bipolar disorder. An anonymised national survey of 650 trainee and consultant psychiatrists in England and Wales was performed.

Results Good or better quality of training was associated with use of case summaries, role-play, ADRTs, assessment of mental capacity and its fluctuation. Good or better quality and two or more sessions of MCA training were associated with more positive attitudes and reported use of ADRTs, although many psychiatrists would never discuss them clinically with people with bipolar disorder.

Clinical implications Consistent delivery of better-quality training is required for all psychiatrists to increase use of ADRTs in people with bipolar disorder.

The Mental Capacity Act 2005 (MCA) in England and Wales provides a legal framework for personal welfare and financial decisions to be made in advance by individuals, who later due to an impairment or disturbance of functioning in the mind or brain, may be unable to make these decisions for themselves. If capacity is not present, a decision can be made on behalf of the person based on what is in their best interests taking consideration of their wishes using three specific provisions of the MCA for advance decision-making: advance decision to refuse treatment (ADRT), a legally binding provision preventing specific treatment; advance statement of wishes and feelings, a non-legally binding statement of preferences for treatment, and/or personal and financial affairs; lasting power of attorney, a legally binding direction identifying who will look after the person's personal and financial affairs. Clinicians and their employers, especially psychiatrists, are legally required to 'have regard to' MCA guidance and, if later asked, prove that they did.¹

Therefore there is an expectation that psychiatrists receive training in the MCA. However, the methods and amount of training that psychiatrists should receive are not specified, nor has the quality or amount of training been related to attitudes or use of ADRTs in practice. We chose to examine the attitudes to and use of ADRTs by psychiatrists as these may be seen as restrictive in terms of treatment offered by psychiatrists to people with bipolar disorder. In a national survey of general adult and old age psychiatrists in England and Wales, we wished to explore how the quality and amount of training they have received may be associated with their implementation of ADRTs in people where capacity is lost (e.g. mania, severe depression) and regained (e.g. bipolar disorder) to complement a survey of patient experience in bipolar disorder.²

Method

Objectives and design

Our objectives were: to determine what aspects of training in the MCA were associated with higher or lower perceived quality of training in the view of psychiatrists; and to examine whether the quality and amount of training were associated with reported attitudes or use of ADRT in people with bipolar disorder. We anticipated that high-quality training may be required to overcome professional resistance to the use of ADRTs should any be present.

Participants

Inclusion/exclusion criteria were: participants practice within England and Wales, i.e. the jurisdiction of the MCA specialise in either general adult or old age psychiatry they were consultant psychiatrists or in training grades (CT1-CT3, ST4-ST6).

Procedure

We aimed to recruit a national sample of 500 psychiatrists in a 12-month period for the survey. No data were available for a formal power calculation. The study was advertised with the help of the National Institute of Health Research-funded Mental Health Research Network (MHRN) and the Royal College of Psychiatrists. The College agreed to publicise the study by tweeting the link to the survey and the study team also attended a national conference organised by the College to publicise the study. Consultants, senior and junior trainees in general adult and old age psychiatry were selected from different regions to ensure maximum variance of practical clinical experience. To maximise the participation rate of psychiatrists and the frankness of their responses, we anonymised the survey, not asking for personal information such as age, gender or workplace, and placed it online or if they preferred we administered it face to face, by telephone or posted it.

Measures

The survey was divided into nine sections that addressed the following topics: Section A: Preliminary information – position, years since qualification, place of work (e.g. in-patient, crisis team), geographic location. Section B: MCA training – how many sessions attended, whether mandatory, how recent, whether training considered advance decision-making that included ADRTs, nature of training, quality of training (e.g. in your opinion how much of the training focused on advance decision-making (including ADRTs) – a significant amount, a reasonable amount, a minimal amount, none?). Section C: ADRTs and bipolar disorder – whether psychiatrists had experience of patients making ADRTs, whether they had advised on making ADRTs, content of ADRTs, factors influencing their decision to advise regarding ADRTs. Section D: ADRTs and other conditions – content of ADRTs. Section E: ADRTs and the Mental Health Act 1983 – whether psychiatrists had encountered ADRTs in context of patients admitted to psychiatric units or sectioned under the Mental Health Act. Section F: ADRTs in clinical practice – how often should they be discussed (e.g. in your opinion how often do you feel that discussion of ADRTs should take place – at every consultation, every 6 months, at care programme approach meetings, only when I think I might be relevant, only when another health or social care

professional raises the topic, only if the patient or carer raises the topic or never?).Section G: Advance statement of wishes and feelings – whether psychiatrists had experience of patients using these; what was contained, whether the frequency was changing among people with bipolar disorder.Section H: ADRTs and implementation of the MCA – whether psychiatrists had experience of patients using ADRTs and their contents.Section I: Lasting power of attorney – whether psychiatrists had experience of patients making lasting powers of attorney, who advised on these.

Analysis

Descriptive statistics were employed in the survey to explore the professional characteristics of psychiatrists and their experience of training. Univariate analysis indicated that several demographic or service provision factors may be associated with the use of the MCA. Binary logistic regression was applied to three separate analyses: the quality of training (dependent variable) perceived by psychiatrists was explored in relation to the methods, site and content of training the quality of training (dependent variable) was then related to attitudes and experiences of psychiatrists to implementing ADRTs in their clinical practice the amount of training (dependent variable) was related to their attitudes and experiences of implementing ADRTs. Checks for collinearity were applied by exploring the Spearman correlations between the independent variables that might enter the logistic regression. None of the independent variables were excluded because of collinearity. Odds ratios (ORs) and 95% confidence intervals (CIs) are presented for any significant variables.

Results

A total of 650 psychiatrists were recruited for the survey. *Table 1* shows the grade, work setting, country of medical training and duration of time since medical qualification of this sample. Within the sample, there were 374 (57.5%) consultants in general adult or old age psychiatry, and the remainder were trainees, with a slight majority qualified in medicine outside the UK. Psychiatrists were recruited for the study between May 2011 and June 2012. Of 607 respondents who identified the geographic location of their work, 133 (21.9%) were from the West Midlands, 116 (19.1%) from the East Midlands, 80 (13.2%) from the South West, 116 (19.1%) from the South East, 74 (12.2%) from the East of England, 46 (7.6%) from London and 10 (1.6%) from the North West of England.

ACT, assertive community treatment; EIP, early intervention in psychosis; NHS, National Health Service.

Categories are not mutually exclusive.

Table 1 shows the number of training sessions, methods used for training, source of the training, quality of training and reasons for attending the training: 595 (91.5%) had attended at least one training session on the MCA; 465 (71.5%) had attended two or more sessions; and 326 (50.1%) had been to a training session in the previous year. Of the 595

psychiatrists trained in the MCA 489 (75.2%) had been trained by their local National Health Service (NHS) trust. The quality of the training was perceived to be high, with 446 (75.0% receiving training) rating it as good, very good or excellent (Table 1). However, 209 (35.1% receiving training) psychiatrists stated that either minimal or no attention was paid to ADRTs in the training sessions.

Table 2 examines the binary multiple logistic regression associations between the quality of training and the methods of training, the site of training, the number of training sessions and topics covered in the training. Compared with average or poor training, good or better (very good or excellent) training was associated positively with the use of case summaries, role play, coverage of advance decision-making (including ADRTs) and assessment of capacity. Video feedback was only carried out in good or better quality of training (44 or 9.9%, Fisher's exact 2-tailed test $P < 0.001$). Average or poor training was associated with training in their own NHS trust compared with good or better training (Table 2). In relation to the specific use of advance decision-making including ADRTs and the need to be able to assess fluctuating capacity in conditions such as bipolar disorder with highly variable severity and therefore capacity, it is notable that even good or better-quality training covered these issues in only just over 45% and 37% of cases respectively.

NHS, National Health Service.

55 psychiatrists received no Mental Capacity Act training, 7 missing responses.

Including advance decision to refuse treatment.

Only 94 (14.5%) of surveyed psychiatrists had encountered a patient with bipolar disorder who had made an ADRT; 136 (20.9%) had encountered a patient with bipolar disorder who had made an oral or written statement of wishes and feelings; and 91 (14.0%) had encountered a patient with bipolar disorder who had made a lasting power of attorney relating to health or personal welfare. Of the 259 psychiatrists expressing an opinion, 208 (80.3%) considered that the number of people with bipolar disorder making ADRTs had remained the same since the implementation of the MCA in 2007, and 41 (15.8%) considered that it had increased by less than 10%. Of the 252 psychiatrists expressing a view regarding statements of wishes and feelings by people with bipolar disorder, 187 (74.2%) thought that the frequency remained the same since the MCA came into force, and 46 (18.3%) that it had increased by less than 10%.

Table 3 displays the binary multiple logistic regression associations between the quality of training and the discussion of ADRT with patients with bipolar disorder or other patients who may lose mental capacity but then regain it. Compared with average or poor training, good or better training was associated with fewer psychiatrists who never discuss ADRTs with patients, and fewer psychiatrists who believed that they had insufficient time to discuss ADRTs with patients. Table 4 shows that compared with only receiving one training session on the MCA receiving two or more training sessions was associated with more psychiatrists discussing ADRTs at care programme approach meetings and fewer psychiatrists who believed that they had insufficient training to discuss ADRTs with patients. There were no other associations between the quality of MCA training or number of MCA training sessions and reported practice or beliefs about implementing ADRTs.

Relationship between quality of training in the Mental Capacity Act 2005 and barriers to implementing ADRTs^a

	Q uality of tr aining

Di scuss ADRTs rout inely at care prog ramme app roach mee tings	77	16.6	11	8.7	2.372	1.17 –4.83	0.017
In suff icient tra ining to do ADRTs	178	38.3	80	63.8	0.41	0.27 –0.63	< 0.001

ADRTs, advance decisions to refuse treatment.

55 psychiatrists received no Mental Capacity Act training, 7 missing responses on quality of training and 3 missing responses on amount of training.

However, 206 (46.3%) psychiatrists would not discuss ADRTs even if the person with bipolar disorder or carer raised it, and even after good or better training 96 (21.5%) would never discuss ADRTs. Furthermore, 177 (39.7%) and 178 (38.3%) of psychiatrists still believed they had insufficient training and time to discuss ADRTs in clinical practice despite good or better training and two or more training sessions respectively.

Discussion

Although the need for training of psychiatrists and other clinical health staff in the MCA is often recommended or even required,^{1,3,4} and clinical guidelines also support the importance of considering the MCA in people with bipolar disorder,⁵ there is an assumption that all training is likely to help clinicians become more familiar with the MCA and that such training will improve attitudes and use in practice of the MCA by psychiatrists. We found that there was plenty of training in the MCA being offered to and taken up by psychiatrists at trainee and consultant level; 92% of trainee and consultant psychiatrists had received at least one training session on the MCA, with 50% receiving the training in the past year. Although 75% of psychiatrists rated their training in the MCA as good or better, ADRTs were only covered in 65% of the MCA training.

Psychiatrists preferred MCA training that was not didactic and merely information giving, rating training as good or better that utilised discussion of the MCA in relation to case summaries, used role-play, and covered topics such as ADRT, the assessment of capacity and the assessment of fluctuating capacity. Although the assessment of mental capacity was usually covered in MCA training, the topic of fluctuating capacity was rarely discussed, whereas the potentially challenging issue of ADRTs was discussed in only 39% of MCA training attended by psychiatrists. Therefore in the view of the authors, training of psychiatrists was rarely of sufficient quality to meet the needs of people with bipolar disorder under the MCA Training arranged by NHS trust was not perceived to be as good as training provided by the Royal College of Psychiatrists, law firms or other external agencies. The reasons for this view are unclear.

There was some evidence that good- or better-quality MCA training received by psychiatrists was associated with fewer psychiatrists reporting that they would never discuss ADRTs under any circumstances. Receipt of two or more sessions of MCA training was associated with an increased likelihood that ADRTs would be discussed routinely in

multidisciplinary care programme approach meetings. Both better quality and more training sessions were associated with a reduced likelihood that psychiatrists had insufficient time to address ADRTs. Although these data are associations and not a comparison of interventions delivered in a randomised controlled trial, there was some evidence that higher-quality training and more than one training session may be helpful in both improving the attitudes to and use in clinical practice of ADRTs by psychiatrists in patients with bipolar disorder or other patients who lose and then regain mental capacity. Another alternative explanation is that psychiatrists who are interested in helping people with bipolar disorder through the MCA attend more than one session of training and find better-quality training.

Nevertheless offering training in the MCA that psychiatrists perceive as good or better quality seems insufficient to improving their attitudes to ADRTs and their use in practice in people with bipolar disorder. Even after good or better training, 22% of psychiatrists would never discuss ADRTs under any circumstances, 46% would not discuss ADRTs even if the person with bipolar disorder or carer raised it, and 39% believed they had insufficient training and time to discuss ADRTs in clinical practice. These findings chime with the experience of people with bipolar disorder in a national survey we carried out² where neither knowledge nor use of ADRTs were associated with seeing a psychiatrist, although knowledge and use of ADRTs were associated with seeing other mental health professionals and attendance at peer support groups.

A strength of the survey was that to our knowledge it is the first of its sort inquiring into quality of training of psychiatrists and relating it to their attitudes and use of ADRTs with people with bipolar disorder. The survey was large, national and deliberately anonymised so that psychiatrists would feel able to comment frankly without any possible constraint. We judged that this advantage of the methodology outweighed the disadvantage that we do not know how many psychiatrists had the opportunity to take part in the survey but decided not to. We also do not know much about the characteristics of psychiatrists in terms of the demographic characteristics of who did or did not take part in the survey. A further limitation was that this survey was completed 4 years ago so the quality of training and use of ADRTs in clinical practice may have improved. Furthermore, by concentrating on MCA training in relation to ADRTs in bipolar disorder, we cannot comment on other aspects of MCA training on other forms of advance decision-making, application of ADRTs in people who are less likely to regain mental capacity and deprivation of liberty.

The findings confirm those of a 4-year re-audit study where increases in MCA training and improved documentation had a minimal impact on the recording of the MCA by psychiatrists in patient records.⁶ There seems to be some consistency in studies of advance planning that the therapeutic relationship between mental health professionals, including psychiatrists, and their patients is improved with advance planning.^{7,8} The House of Lords heard much evidence that the implementation of the MCA had failed to make much of an impact on clinical practice in the way that was intended, and made 39 recommendations to improve the implementation of the MCA³ We have not had the opportunity to study the effects of these recommendations but note that none of these relate to the quality or amount of training that psychiatrists or other health professionals receive in relation to the MCA. The Academy of Royal Medical Colleges were asked to report on measures to improve the uptake of the MCA^{3,4} So far it has organised educational events on the MCA but has not made recommendations on the content, form or amount or frequency of training that psychiatrists or other health professionals should receive in relation to the MCA.⁹

Therefore we conclude that there is a need to improve the quality of training that psychiatrists receive on the MCA so that fluctuating capacity and ADRTs are covered, and that techniques such as case summaries and role-play are employed to improve confidence and competencies of psychiatrists in its use. There may be a case for adding training in the MCA to mandatory training under the Mental Health Act section 22 training regulations. There is a need for further implementation research on ways to improve the knowledge and use of the MCA including ADRTs, by people with bipolar disorder or other conditions where capacity is lost and then regained, and also on how to improve the attitudes of psychiatrists and assist them further to discuss ADRTs with people who have bipolar disorder or similar conditions.

1.6.88 Assessing the second-hand effects of a new no-smoking policy in an acute mental health trust

Abstract

Aims and method To examine whether a new no-smoking policy in an in-patient mental health setting had any effects outside of smoking cessation. Our hypothesis stated that a forced smoking ban for in-patients may result in an increased susceptibility for clinical incidents, aggression and lower admission rates. All patients admitted to adult in-patient mental health services in Coventry and Warwickshire Partnership NHS Trust were included in the analysis. Data 6 months post-implementation of the smoking policy (1 July 2015 to 1 January 2016) were compared with the same period 1 year prior (1 July 2014 to 1 January 2015). Patient demographics, admission rates, ward occupancy, average lengths of stay, numbers of reported incidents and use of the Mental Health Act 1983 (MHA) were compared.

Results We analysed 4223 admissions. We found a significantly increased number of admissions under the MHA ($P = 0.007$), a significantly greater number of reported smoking-related incidents ($P < 0.001$) and aggression-related incidents in the psychiatric intensive care unit ($P < 0.001$). However, we found no significant difference in capacity of in-patient wards ($P = 0.39$), admission length ($P = 0.34$) or total aggression-related incidents ($P = 0.86$).

Clinical implications Although further comparisons over longer time periods are necessary, our results suggest that enforced smoking cessation on acutely unwell psychiatric patients admitted to the most restricted environments may have some negative effects. Nicotine replacement therapy should be offered to all patients to minimise the risk of clinical incident.

Smoking rates among those with a mental illness are 70% higher than in the general population.¹ In fact, although the prevalence of smoking in the general population has decreased, this has not occurred for those with a mental illness.² In particular, the highest smoking rates are found in those acutely unwell with a psychiatric illness, in in-patient units.³⁻⁶

Multiple explanations for such high smoking rates within the mental health sector have been put forward, including symptom control and amelioration,⁷ boredom or loneliness,^{8,9} an increased propensity to experience more severe nicotine withdrawal symptoms than the general population,^{10,11} for relaxation in a stressful environment,^{9,12} a common genetic vulnerability⁵ or that people with a mental illness are less susceptible to anti-smoking messages.¹³

As a result of relatively higher smoking rates, people with a mental illness also have higher mortality rates than the general population. Tobacco use contributes significantly to causes of ill health and mortality in those with mental health disorders.¹¹ Individuals at particular risk are patients with schizophrenia, who have a life expectancy 20% shorter than the general population.^{14,15} Tobacco use can also affect the effectiveness of some psychiatric medication, necessitating increased dosages and therefore purporting a higher chance of side-effects.¹⁶

The UK government implemented its smoke-free policy in July 2007, which extended to all ‘substantially enclosed’ public and work places. This included hospitals, with the aim of reducing the impact of second-hand smoke on patients and staff¹⁷ This was extended to all types of in-patient units from 2008.

Guidance from the National Institute for Health and Care Excellence (NICE), published in 2013, aims to support smoking cessation, temporary abstinence from smoking and smoke-free policies in all secondary care settings.¹⁸ In this guidance, ‘secondary care’ refers to all publicly funded secondary and tertiary care facilities, including buildings, grounds and vehicles. It covers in-patient, residential and long-term care for severe mental illness in hospitals, psychiatric settings, specialist and secure units.

Prior to the introduction of the legislation, a relatively large survey of National Health Service (NHS) staff found that a third of psychiatric staff disagreed with smoke-free legislation compared with only one in ten of general staff.¹⁹ A survey of mental health units in England in January 2007 found that the vast majority (91%) believed mental health premises faced particular challenges due to the high smoking prevalence among patients, associated safety risks, and potential interactions with antipsychotic medication.²⁰ However, despite the challenges, the smoke-free policy has been rated positive overall. Cited advantages include a reduced exposure of patients and staff to second-hand smoke, an enhancement and support in patients’ motivation to stop smoking, improved sleeping patterns among patients, and the conversion of former smoking rooms into new recreational spaces.²⁰

Since the development of non-smoking policies within the NHS, debate has evolved around any potential infringement

this might have on a patient's human rights. A patient at one of Scotland's high-security forensic hospitals recently won a court ruling that a blanket ban on smoking breached his human rights.²¹ According to Article 8 of the Human Rights Act 1998, everyone has the right to respect for his private life and his home. With regard to mental health units, lengthy hospital admissions may qualify as breach of one's private and home life.

The introduction of a non-smoking policy to mental health services remains a relatively novel practice. We are yet to fully appreciate its impact on in-patient services. Coventry and Warwickshire Partnership NHS Trust in the UK introduced a no-smoking policy within its mental health units on 1 July 2015. The Trust is one of the first to implement this policy following the growing evidence of high smoking rates and adverse health implications within the mental health population. Although the benefits of smoking cessation are widely acknowledged, there exists an assumption that enforcing smoking cessation on unwilling patients results in increased stress levels and therefore higher rates of aggression-related incidents.

Voluntary admission to an in-patient mental health ward requires the patient to agree to certain ward policies and procedures explained by the clinician. Within the Trust it is standard procedure to explain the non-smoking policy for both voluntary and involuntary admissions. The impacts outside of smoking cessation caused by a forced no-smoking policy has previously been analysed in a medium secure unit, finding no significant difficulties and that the widely anticipated problems did not materialise.²² We have been unable to find another study analysing similar changes in a typical psychiatric unit (mixed voluntary and involuntary patients).

Aims and objectives

The aim of the study was to examine whether a newly implemented no-smoking policy for patients in a typical in-patient mental health setting had any effects outside of smoking cessation. The objectives were first to compare admission rates and bed occupancy/capacity levels at comparable time periods pre- and post-implementation of the new no-smoking policy in a specified mental health trust. We also sought to compare the numbers of reported incidents occurring on the wards at comparable time periods pre- and post-implementation, focusing particularly on aggression-related and smoking-related incidents. In addition, we wanted to ascertain whether there was any significant difference in the use of the Mental Health Act 1983 at comparable time periods pre- and post-implementation of the new policy, and whether this was related to the change in smoking policy.

Method

Study location and Trust smoking policy

Data were collected from all patients admitted to mental health beds in Coventry and Warwickshire Partnership NHS Trust during the 12 months before and 6 months after implementation of the smoking ban. The change in policy was implemented on 1 July 2015, therefore data were collected between 1 July 2014 and 1 January 2016. The Trust smoking ban states that 'all staff, patients and visitors are not able to smoke tobacco products in Trust buildings or on Trust land.'²³ The Trust maintains a policy of offering nicotine replacement therapy to admitted patients, comprising of either an e-cigarette or nicotine transdermal patch.

Adult in-patient mental health services in the Trust comprise of three acute psychiatric units: the Caludon Centre in Coventry (112 beds), St Michael's Hospital in Warwick (41 beds) and the Pembleton Unit in Nuneaton (12 beds), with adult rehabilitation services provided at multiple sites (40 beds), for a catchment area of around 850 000 people.

Inclusion and exclusion criteria

All patients admitted to adult in-patient mental health services, both acute and rehabilitation, in Coventry and Warwickshire Partnership NHS Trust were included in analysis. To account for seasonal variation, data 6 months post-implementation of the smoking policy (1 July 2015 to 1 January 2016) were compared with the same 6 months the year prior to implementation of the smoking policy (1 July 2014 to 1 January 2015). There were no specific inclusion criteria for diagnosis or length of admission to help prevent selection bias. All sites within the Trust were included in the analysis.

Ethics

The study was approved by Coventry and Warwickshire Partnership NHS Trust as a service evaluation and as such did not need formal ethical approval from an NHS research ethics committee. Data were collated in an anonymised format from routine clinical records, by the authors.

Data collection

First, basic demographic data such as mean age and gender were obtained. Second, monthly admission rates and ward occupancy levels between the dates were collected. Third, monthly total numbers of reported incidents were obtained. All data were collected by data analysts within the Trust.

Statistical analysis

For the count data (number of admissions under the MELA, total incidents, aggression-related incidents, psychiatric intensive care unit (PICU) incidents and smoking incidents), Poisson regression was used to generate a significance value. Where data were provided as percentages (i.e. capacity), we converted to mean n based on the total Trust capacity ($n = 205$). The Shapiro-Wilk test for normality allowed a decision as to whether to use parametric or non-parametric statistical comparisons. All statistical comparisons were made using IBM SPSS Statistics 24.

Since we were measuring six outcomes in our analysis, a Bonferroni correction was applied. The α -value (0.05) was therefore adjusted to a significance value of $P = 0.008$.

Results

Demographic data

Table 1 outlines the demographic data comparisons during our two selected periods of analysis. *Table 2* outlines the findings from our other objectives.

PICU, psychiatric intensive care unit.

Number of patients admitted under the Mental Health Act 1983

Poisson regression found that the number of admissions under the MHA increased (1.13, 95% CI 1.03–1.23) at the boundary of our corrected α -value, $P = 0.007$, in the same 6 months the year following the introduction of the new smoking policy.

In-patient ward capacity

Our findings show that the bed capacity was at maximum or over-maximum at each month studied. Using the data adjusted into mean capacity, the Shapiro-Wilk test for normality ($P = 0.306$) allowed us to proceed with an unpaired t -test, which showed no significant difference ($P = 0.99$).

Average duration of in-patient admission in days

The Shapiro-Wilk test for normality ($P = 0.068$) allowed us to proceed with an unpaired t -test, which showed no significant difference ($P = 0.34$).

Total number of in-patient aggression-related incidents

Poisson regression revealed no significant difference in total aggression-related incidents following the introduction of the new smoking policy (1.02, 95% CI 0.90–1.12; $P = 0.70$).

Aggression-related incidents (PICU only)

Poisson regression revealed a significant increase in aggression-related incidents in PICU following the introduction of the new smoking policy (1.59, 95% CI 1.26–2.01; $P < 0.001$).

Smoking-related incidents

Poisson regression revealed a significant increase in smoking-related incidents following the introduction of the new smoking policy (3.10, 95% CI 2.55–4.46; $P < 0.001$).

Discussion

Main findings

We aimed to ascertain whether a new no-smoking policy for in-patients at a specified mental health trust might result in any less favourable effects outside of smoking cessation. We found a statistically significant increase in the number of admissions under the MHA, total number of reported aggression-related incidents on PICU, and a statistically significant increase in the number of reported smoking-related incidents. The majority of these findings may be expected. In consideration with our finding that in-patient bed capacity was at or over 100% for each of the months studied (potentially due to patients being ‘on leave’ from hospital but still named in beds), one might argue that the acutely stressed state necessary to be granted an admission into bedspace at a premium would have been of considerable severity. Such patients may also have been admitted against their will, further heightening stress levels. One may therefore consider that immediately and forcefully removing the right to smoking, a past-time that can bring comfort, reduce stress, ameliorate psychiatric symptoms and help to fight boredom, may be poorly timed.

Perhaps a more surprising finding is the statistically significant increase in patients admitted under the MHA. This was included as an outcome measure as it was hypothesised that patients may refuse informal admission based on the no-smoking policy. Although patient refusal for informal admission may have contributed to the effect, it is likely not the whole story, as that hypothesis relies on the provision of adequate information to patients, i.e. the new smoking policy is explained prior to admission. Other work²⁴ has shown that this is not always the case. It is also well known that detentions under the MHA have been on the rise across the UK over the past 10 years,²⁵ due to a multitude of factors (not smoking related) which we were unable to analyse in this study. In-depth case-note analysis may have allowed us to qualitatively ascertain whether the smoking policy played a part in this significant finding, and future research analysing this perhaps legitimate question could take this into account.

We found no significant difference in the total number of reported aggression-related incidents. At face value, this finding suggests that in an open-ward environment, the new smoking policy did not cause an increase in agitation or aggression, which contradicts the finding we obtained from PICU only. There are several possible explanations for this. First, the patients that are admitted to PICU are likely to be more acutely stressed than those admitted to an open ward and therefore the potential to cause an ‘incident’ might be increased. Second, the more strictly controlled environment in PICU may lend itself to better adherence of the smoking policy than for informal patients on an open ward (who may

be allowed out for 'grounds leave' each hour, or more), thus the new smoking policy may be felt more among patients on PICU. Third, there is the very likely possibility that not all incidents are reported. Incident reporting can sometimes be viewed as an arduous process, especially for staff with busy in-patient ward roles. Although this could affect the results both in the open-ward environment and on PICU, one could suggest that staff on PICU might be more familiar with and better trained to deal with incidents, thus incident reporting might be better adhered to.

We also found no significant difference in patients' length of admission, suggesting that the new no-smoking policy did not positively or negatively affect the patient journey through mental health services. This might be an expected finding as the benefits of smoking cessation are known for long-term rather than short-term health. However, it is useful to address this result in light of our findings of increased smoking-related and aggression-related incidents, as it suggests that the new policy's potential to predispose to aggression or agitation does not necessarily result in prolonged in-patient stay. We also found no significant difference in in-patient ward capacity, which could be expected considering capacity was at maximum or above maximum for each month studied.

Strategies and limitations

We believe this study is one of the first to assess the effects of a new no-smoking policy of psychiatric in-patients in the UK, in an age where the importance of physical health in psychiatric patients is becoming increasingly recognised, such that many more healthcare trusts may in future choose to adopt a similar policy. In using the entire sampling frame over a 6-month period, we have ensured a large sample size which may help to reduce the potential for type I or II statistical errors. We have reduced the impact of seasonal variation by comparing the same 6 months both in the year of introduction of the new no-smoking policy and the year preceding it. In comparing data across time, we can demonstrate a temporal association with the positive findings. Furthermore, regarding the new no-smoking policy being more strictly enforced on PICU, a dose-response relationship may be observed when comparing the non-significant open ward aggression-related findings with those obtained from PICU. In addition, we have included a range of measures that were chosen prior to commencing data collection.

There are however a number of limiting factors that should be taken into consideration. First and most importantly, we cannot show that the new no-smoking policy is causal to the positive findings. There could be many other causes for increased aggression-related incidents on PICU and it is therefore not clear how much (if at all) the change in smoking policy contributed. It is however less probable to consider reverse causality as a factor in this study, as it is unlikely that the no-smoking policy was enacted because of significant aggression-related incidents.

In addition, we are unable to determine the effect of any poor reporting practice on our findings. We have mentioned that reporting might be better in certain areas of in-patient psychiatric care than others which may skew our results and invalidate comparisons. Despite our efforts, we were unable to obtain a comparison of total number of reported incidents between the two time periods. This would have better highlighted the reporting practices in the Trust across the two time periods and may be useful for future work.

It may also be possible that the timing of our data collection may have affected the validity of our results. We chose to measure the 6 months immediately following the introduction of the new no-smoking policy. It is likely that group practice takes time to adapt and this may be an explanation for some of the negative findings in our results. It may have been more appropriate to choose a length of inclusion greater than 6 months to better visualise this, however we were limited by time and resources. Both adherence to the Trust smoking policy and the reporting of incidents (if common) may improve over time, and it therefore may be useful to repeat this study in the future to compare the results.

Finally, since our study only measured outcomes during in-patient stay, we were unable to ascertain any longer-term effects of the new smoking policy, such as the increased achievement of smoking cessation among patients admitted under the new no-smoking policy. Further work might seek to establish the longer-term effects of such a policy.

Other research has been carried out on this topic internationally, which correlates partially with our results. A 2002 systematic review²⁶ including studies from several countries found no significant behavioural effects when smoking bans were enacted in psychiatric units, although the review also notes that in the included studies, smoking bans were not associated with long-term smoking cessation among patients. More recently, a 2005 study²⁷ from the USA found no significant increase in aggression with the introduction of a new smoking ban. Furthermore, a survey²⁸ of mental health staff working at an Australian healthcare trust in 2013 found that although most staff preferred to work in a

smoke-free environment, around half of survey respondents found the smoking ban to be detrimental to acute patient care, which may give the impression of increased agitation or behavioural problems among patients involved.

Our results are therefore broadly in line with the findings of others. However, it is notable that we have shown a potential difference in the effects of a smoking ban on different patient groups across different settings. Further work might seek to clarify and further examine the reasons behind this finding.

Overall, the reasoning behind a smoke-free hospital environment is clear. The long-term health benefits of smoking cessation are numerous and well documented, and other work has shown staff to prefer a smoke-free working environment. However, there is the legitimate debate as to whether the acutely stressed state is the right time to impose this lifestyle change, and whether it is even ethical to do so. Our results show that, in general, a new smoke-free policy did not result in significant changes of reported aggressive behaviour or incidents, and did not affect the patient journey through mental health services. However, we found significantly increased smoking- and aggression-related incidents in more restricted environments. It is possible that the most highly agitated psychiatric patients are most susceptible to cause incidents with this enforced lifestyle change. Our finding of significantly increased use of the MHA may be explained by other factors, but also may warrant further research. Therefore, to reduce the impact this may have on both patients and staff tasked with dealing with any resultant incident, nicotine replacement therapy should be considered for all relevant patients.

The authors would like to extend their thanks to the data analysts of Coventry and Warwickshire Partnership NHS Trust for their support in obtaining the data used in this study, and to Pascal Perry-Cheung for his kind assistance.

1.6.89 A service evaluation of outcomes in two in-patient recovery units

Abstract

Aims and method To evaluate outcomes for patients during their admission or in the first year of treatment in two in-patient recovery units. Changes in health and social functioning, service use and need (rated by patients and staff) were evaluated.

Results In 43 patients treated, there was a large (30%) increase in patients discharged to their own tenancies, rather than supported accommodation. There was minimal change in Health of the Nation Outcome Scales (HoNOS) scores in the course of the admission but staff- and patient-rated unmet needs reduced and met needs increased. Needs changed mainly in domains relating to social functioning. Reductions in risk to self and others were rated by staff but not patients. There were no cases of patients being readmitted to acute hospital during the study period.

Clinical implications Although these results offer some support to the treatment approach described in these in-patient recovery units, further research in larger samples is needed to identify how these

From the start of 2011 it was decided to develop greater understanding of the outcomes of the work of our two Together Foundation National Health Service (NHS) Trust recovery in-patient units, by evaluating outcomes assessed by staff and patients at admission, mid-point and discharge from the units. These services have in the past decade adopted a strong recovery-based model of practice, in line with the UK government policy *No Health Without Mental Health*.¹ A major strategic aim in this policy is for more people with mental health problems to recover, defined as: ‘a greater ability to manage their own lives, stronger social relationships, a greater sense of purpose, the skills they need for living and working, improved chances in education, better employment rates and a suitable and stable place to live’.¹ The literature on personal recovery emphasises the individual journey in recovery, in which regaining hope, taking back control and finding new opportunities are key processes.² It has been argued that a transformation of mental health services is required for this to occur;³ mental health professionals recognising patients’ strengths and expertise as experts in their own health and acknowledging the importance of personal narratives, alongside other forms of evidence. The increasing focus in UK and international healthcare policy on recovery has occurred at a time of generally increasing personal autonomy in wider society while health services have shifted their focus towards helping every individual to make the most of their health, rather than relating mainly to those with illness.⁴

The recovery units studied provide active rehabilitation for 10 and 13 residents respectively. The units are remote from the main psychiatric hospital services but provide full in-patient support and are registered to take detained patients. The focus of the work in the units is with patients who have complex, severe mental illness, predominantly psychosis, characterised by treatment resistance and other complications. Treatment is provided through a full multi-disciplinary team and includes approaches to optimise health through use of medication, talking therapies including family work, guidance on healthy living, and treatment and support for substance use problems. A wide range of social approaches include help with daily living skills including budgeting, self-care, shopping and cooking, help with finances, benefits and accommodation, and support to develop interests and activity such as sport, leisure activities and work. The work in these units differs from acute in-patient work in focusing more on treating long-term, disabling mental health problems and impaired social functioning over longer time periods, rather than dealing with brief, episodic illness. Typical admissions last approximately 9 months, rather than just over 1 month in acute units (based on November 2016 Together Foundation NHS Trust data).

The original model of the recovery units described was developed to help patients in their rehabilitation from long-stay hospitals,⁵ aiming to support patients with complex illness to reintegrate into the community. They have subsequently evolved to work mainly with patients who need longer-term rehabilitation after acute psychiatric admission or any

patients who have developed disability due to severe mental illness. Over the past 20 years in the UK, in association with NHS and local authority funding changes, there has been a disinvestment in these services,⁶ despite recognition in recent commissioning guidance⁷ that this form of treatment is needed as part of a spectrum of care provision in each district.

The evidence from research in this field has previously been reviewed,⁸ showing that in-patient recovery units can effectively support most patients accepted by them, the majority of whom can be resettled to less dependent community placements over a period of months or years. The research indicates that treatment in recovery units is associated with improvement in social functioning and social networks and reduced levels of negative symptoms in schizophrenia. Placements are associated with relatively few long-term readmissions. These findings have been replicated in other countries such as Australia, the USA Northern Ireland, Norway and Italy.⁹ The quality of the research evidence is however variable and there has been very little formal research carried out in this area.⁵ A recent study of outcomes 5 years after in-patient rehabilitation¹⁰ found that around 40% of patients had remained in stable accommodation or moved to independent placement and sustained this.

Although UK commissioning frameworks have consistently argued the need for services of this type to help patients with complex needs in their pathway from acute or secure hospital to the community, there still seems to be a shortage of appropriate residential places in some areas, particularly for those with the most severe and enduring mental health problems. A study of hospital services in Birmingham, UK,¹¹ showed that long-stay (more than 6 months) patients were consistently found to occupy 20% of acute beds. The authors noted that where staff made recommendations for community placements, 'by far the majority' required 24-hour residential care, suggesting a need to improve access to this sort of provision. A recent paper¹² noted that problems may arise from the fragmentation due to use of private sector psychiatry and made a strong case for local, well-organised, NHS rehabilitation services. A survey¹³ of English rehabilitation services showed that despite closures of nearly all NHS long-stay hospital beds, most areas still had active rehabilitation units available to help people with complex, treatment-resistant illness. In 93 local authority regions, most (77%) had short-term (up to 12 months) rehabilitation units, with an average of 13 beds. It appears that although services are available in most areas, the level of provision is variable and patchy. Hospital services in the UK continue to be under pressure and there are often suggestions of a need for more beds. However, it has been argued¹⁴ that alternatives to acute in-patient admission could reduce this pressure and that around one in four cases in acute units could be managed in a unit run by nurses or care workers.

Aims of the evaluation

This service evaluation aimed to describe, prospectively, aggregated outcomes for new residents over the duration of their admission or in the first year of treatment. The evaluation considered changes in health and social circumstances from admission to the units, to discharge or 1 year after admission. Utilisation of acute hospital treatment was monitored before and during treatment in the recovery units.

Method

This project was carried out as a service evaluation with a formal protocol and a project steering group which met regularly during the project's work. The County Research and Development Support Unit assessed and gave written agreement for the project, prior to commencement. The use of aggregated data was preferred to other methods, such as the use of within-participant findings. This was a pragmatic decision, as the introduction of routine outcome monitoring was hoped to improve and make more systematic individual care planning, as well as to enable individual and service-level evaluation of outcome. The measures used in the project were selected to support the new way of working.

Participants

At the point of admission to the unit, demographic and health-related data were collected for all patients, on a specially designed form. The patient's key worker rated the Camberwell Assessment of Need Short Appraisal Schedule (CANSAS)¹⁵ and Health of the Nation Outcome Scales (HoNOS)¹⁶ scores at the time of admission. CANSAS forms were given by key workers to patients for self-completion, with an explanation about how to complete them. Key workers were instructed to ensure that patient rating of need was independent of their own rating and access to support from local advocacy services was offered if this was considered helpful. Where a carer had a significant role with the patient, this individual was also approached to assess the needs of the patient (with consent, following the usual clinical permissions pathway).

To be included in the evaluation, patients were required to have continuous treatment for a minimum of 3 months in one of the units. This was to ensure that patients who were occasionally admitted briefly from the acute ward, due largely to problems such as homelessness leading to delays in discharge, but were not assessed to require the therapeutic approach of the recovery unit, did not bias the sample. It was also felt that patients discharged before 3 months would not have had time to engage meaningfully with the therapeutic work of these services.

The same ratings were repeated 6 months after admission and at discharge, or at the end of the first year of treatment. Demographic and health-related data were collected at the point of discharge from the unit or at the end of the first year of admission.

Measures

The CANSAS¹⁵ rates need as 'absent' (no problem), 'met' (problem addressed by services) or 'unmet' (significant, ongoing problem) across 22 social and healthcare domains. The HoNOS¹⁶ is a 12-item scale that rates various aspects of health and social functioning on a 5-point Likert scale to measure levels of problem severity.

Data management

At admission, patients were allocated a number for identification purposes and from this time all data were held anonymously, with the identification number only used on forms, held securely by the unit administration lead, who managed the data collection processes. Data sheets were held in a locked office in secure filing cabinets or on a password-protected Trust PC.

Statistical analysis

C.F. advised on the use of descriptive, demographic and illness-related information and the analysis of change scores from admission to discharge using aggregated HoNOS scores and CANSAS total, met and unmet need total scores. Data were entered into SPSS for analysis (SPSS version 18 for Windows). Non-parametric Wilcoxon matched pairs signed ranks tests were used to assess changes in mean HoNOS and CANSAS ratings.

Ethical consideration

This work was an attempt to evaluate whether the recovery units were effective in their intended work. It was a service evaluation and did not have a randomised controlled design. Information was collected as part of the work of the units and it was used at an individual level to more systematically understand patient need and plan treatment. There was no intention to use experimental tools or to compare units or employ a control group. As a result of the design it was noted that results would not be generalisable, although it was hoped that they may be of value at a time of greater attention to treatment outcomes and considering issues of service quality and innovation. Patient consent was not formally taken but was considered to be given by participation, where patients gave individual ratings of need and this was always explained to be optional and unrelated to the rest of the patient's treatment. Prior to starting the project, the need for

formal ethics committee submission was considered by our County Research Support Unit, which advised that this was not required and gave written approval for the project.

Results

Data collection was carried out in the two units from April 2011 to June 2014. During that time a total of 43 patients were admitted for a period of at least 3 months. Data were collected on the patients over this period, the gaps in data being largely due to the challenges of managing data collection within a standard clinical setting, rather than (with the infrastructure permitted by research funding) as a research project. Gaps in the data-set are reported within the results presented below. These related often to patient choice and willingness to participate in routine data collection. Although access to advocacy was freely available and advocates were working regularly in both units through the project, we do not know how often they provided specific support to patients in completing outcome measures. We believe this was rare and in the great majority of cases patients completed forms independently or with minor support from staff.

The study group of 43 patients included 28 (65%) male patients, aged 18–62 years (mean 36.5, s.d. = 10.3); 39 (91%) were single, 2 (5%) married and 2 (5%) divorced. Most patients ($n = 23$, 53%) were admitted from an acute psychiatric ward, the remainder ($n = 20$, 47%) direct from the community. In the year prior to the recovery unit admission, patients had spent a mean of 20.7 weeks (range 0–52, s.d. = 24.5) in a psychiatric hospital. Patients had experienced a mean of 1.0 admissions in the year before entering the recovery unit (range 0–4, s.d. = 0.55).

At the time of admission all patients were unemployed, and 23 (53%) lived in supported accommodation, 19 (44%) in their own tenancy and 1 (2%) with family. Overall, 27 (63%) were under an assertive outreach team, 11 (26%) under a community recovery team (community mental health team) and 5 (12%) under early intervention services.

Patients spent a mean of 380 days (s.d. = 177) in the recovery units; there were no recorded episodes of acute psychiatric readmission during this time. In total, 38 of discharges (74%) were planned and 5 patients (12%) were discharged for other reasons.

At the time of discharge, 42 (98%) were unemployed, 1 patient being a part-time student. Overall, 32 (74%) had their own tenancy, 4 (9%) were living in supported accommodation and 2 (5%) were living with family. In total, 29 (67%) were under an assertive outreach team, 11 (26%) under a community recovery team and 3 (7%) were under early intervention services.

The main changes over the course of this evaluation were: there was a small increase in employment following treatment in the units; there was a 30% increase in patients living in their own tenancy; and some patients were taken over by assertive outreach teams during their admission, mostly moving from early intervention teams.

No individuals were readmitted to acute in-patient care during their recovery in-patient admission.

Baseline and final mean HoNOS and CANSAS met/unmet need scores are presented in *Table 1*.

Mean HoNOS and CANSAS ratings at baseline and discharge/12-month follow-up

	Baseline rating Mean (s.d.)	Discharge/12-month rating Mean (s.d.)	Wilcoxon signed ranks 2-tailed test
HoNOS	19.9 (8.2)	18.5 (9.0)	Z= 1.46, P>0.05
Staff-rated CANSAS met need	7.2 (4.3)	7.3 (3.9)	Z= 0.41, P>0.05
Staff-rated CANSAS unmet need	3.7 (3.6)	3.4 (3.0)	Z= 0.76, P>0.05
Patient-rated CANSAS met need	3.9 (4.5)	4.8 (4.4)	Z= 1.39, P>0.05
Patient-rated CANSAS unmet need	2.8 (3.3)	2.2 (2.5)	Z= 1.32, P>0.05

CANSAS, Camberwell Assessment of Need Short Appraisal Schedule.

There were improvements in patient-rated met needs in domains relating to accommodation, social life, care of the home and daytime activity, most other domains showing no change or minor increases and decreases. There were reductions in patient-rated unmet needs in accommodation, daytime activity budgeting and intimate relationships, with about half the domains showing minimal change. It can be seen that the main changes in patient-rated need were in domains relating to social functioning.

There were increases in staff-rated met needs in domains relating to accommodation, social life and information about treatment. Apparent reductions in staff-rated met need in the domains safety to others, safety to self and use of non-prescribed drugs appeared to be explained by comparable increases in levels of 'no need' in these domains. Staff-rated unmet needs showed smaller levels of change, the domains which reduced most being accommodation, daytime activities and psychotic symptoms.

Discussion

We have shown that it is possible as part of routine clinical outcome measurement to assess longitudinal outcomes in a standard recovery in-patient setting, using staff- and patient-rated measures. The results included some gaps in data which were due largely to patients declining to complete CANSAS ratings of need or incomplete participation by staff members. However, the results seem likely to be reasonably representative of the patients admitted to the units over this time, other than those patients who were admitted and then discharged or readmitted to the acute ward within a short time (these patients were excluded from the study population).

Results and limitations of research

We found minimal change in HoNOS scores in the course of the recovery unit admission but overall staff and patient assessed unmet needs tended to reduce and met needs tended to increase, although not at a statistically significant level. This may have related to the relatively small sample size. The main changes in need found over the study period rated by staff and patients related to improved social functioning, a finding which accords with the primary clinical aims of these services; to help individuals to regain life skills lost through periods of severe illness and ideally to try to achieve the most independent living situation possible. Our evaluation included patient and staff evaluations of need, both being included as the research indicates that they differ, and that the patient's perspective may be particularly important.¹⁷ The reduction in staff-assessed risk to self and others was encouraging and may have linked to reduced substance misuse, as these units have a strict drug-free policy and during admission patients are supported to remain drug free. A recent survey¹⁸ of in-patient rehabilitation units in Birmingham, UK, found chronically high levels of

problematic and socially inappropriate behaviours and suggested that new approaches, focusing on engagement and the management of challenging behaviour, may be helpful.

A number of limitations result from the method of this service evaluation. There was no control group and, as a result, the findings cannot be generalised. We are only aware of the existence of one, small, randomised controlled trial in this area,¹⁹ and arguably this type of research is not really feasible in this setting,⁵ although it remains vital to learn more about outcomes in these important and relatively expensive services. The numbers in our study group were small and it would be helpful to compare our results with studies using similar outcome measures in other settings, ideally with larger patient groups. Further limitations arise from the lack of data relating to progress at different time points during the treatment in the recovery units: it is possible that greater benefits occur early or later in the treatment process, which we were unable to evaluate. The scales used allow limited understanding of the patient experience, which could be more fully accessed through the use of qualitative studies and a number of tools assessing aspects of patient-rated recovery are now available.²⁰ Qualitative studies in this area have emphasised the importance of choice and autonomy for many patients²¹ and have shown the potential for personal recovery to be facilitated through appropriate supported living accommodation.²²

Of interest, poorer outcomes were associated with non-adherence to medication and our finding that most patients were discharged to assertive outreach teams suggests that many patients will continue to need a high level of support following treatment in recovery units. A recent study using retrospective care records⁹ found significantly reduced hospital admission 2 years after in-patient rehabilitation and that a substantial proportion of the sample went into more independent living. We found a large increase (30%) in the number of patients discharged to their own tenancies, rather than supported accommodation.

Consideration of findings against previous research

At a time of increasing pressure on in-patient services, our findings accord with previous research²³ suggesting that alternatives to acute in-patient care could reduce this pressure and that many cases could be managed in facilities such as recovery units. More than half the admissions to our in-patient recovery units were from acute wards and their ability to manage cases effectively without return to hospital and, most importantly, achieve clinical improvements, emphasises the importance of having these services available in each region/district where acute units operate. Our findings were in line with previous research¹⁴ showing improved outcomes in terms of accommodation and stable social functioning following treatment in recovery units. It is important to have a long-term perspective due to the ongoing, high levels of chronic morbidity in this population.¹⁰ There is a continuing need for different types of supported accommodation, although in our study a substantial number progressed to fully independent living.

Research in supported accommodation has been classified⁵ into three domains: quality of care; external evaluation and quality of life; and subjective satisfaction by the resident. In terms of quality of care, the most important factors appear to be the effectiveness of an individually centred, targeted programme of care and the quality of the physical environment. A systematic review of the quality of care in longer-term mental healthcare settings²³ found eight domains of institutional care that were key to recovery: living conditions, interventions for schizophrenia, physical health, restraint and seclusion, staff training and support, therapeutic relationship, autonomy and patient involvement. The two units investigated have both embraced the recovery approach, working alongside patients in pursuit of their goals and promoting autonomy and empowerment of the individual. Previous research²⁴ has shown that quality of care is heavily determined by the personality and orientation of project leaders and staff working in these units drew on extensive experience of local rehabilitation/recovery work, which has resulted in three major reviews and redevelopment of services and extensive staff training in recovery methods. The units were both accredited as 'excellent' in 2016 within the rehab-AIMS national benchmarking of rehabilitation units.²⁵ However, the results in our study show that the patient population is highly disabled with high levels of need and high usage of hospital care. Our results, showing clinical stability alongside progress in personal and social domains, was encouraging and hopeful. These units support many patients who due to their illness have difficulty creating their own structure, with consequent loss of internal security and often associated fears of losing control. The provision of support, treatment and therapeutic approaches available 24 hours provides an important support²⁶ which enables patients to feel stable, secure and then able to progress with rebuilding their lives. It is however important to consider differences between professional and patient preferences. When asked their view, patients have tended to prefer the option of their own, independent accommodation²⁷ over

rehabilitation or supported accommodation. Family members tend to align with the professional view and prefer their relatives being cared for in staffed environments.²⁸ An important criticism of staffed settings is the potential for institutional regimes and a poor rehabilitative culture, which could impede independence and autonomy.²⁹ Conversely, some patients and family members have reported that independent tenancies can be socially isolating²⁷ and it seems that many patients benefit from treatment in these units, particularly if they maintain a collaborative approach and provide a wide range of therapeutic options.

We would like to thank the recovery units' staff and patients for their support with this project and for completing the necessary rating scales required. We thank Natasha Wallace for her administration and support more widely for the project.

1.6.90 Weekend new patient reviews in psychiatry: evaluation of activity over 3 months

Michael Rutherford Mark Potter

date

2017-12

Abstract

Aims and method South West London and St George's Mental Health NHS Trust developed a system of weekend new patient reviews by higher trainees to provide senior medical input 7 days a week. To evaluate the effectiveness of these reviews, the notes for all patients admitted over 3 months were examined. The mean length of stay for patients before and after the introduction of the weekend new patient reviews were compared via unpaired *t*-test.

Results A total of 88 patients were seen: 84.4% of patients were seen within 24 h of admission. Higher trainees instituted some changes in 78.9% of patients. The most frequent action was to modify medication, in 47.8%. The average length of stay after the introduction of weekend reviews was not significantly different.

Clinical implications Weekend reviews of newly admitted patients by higher trainees is a feasible method for providing senior input to patients admitted out of hours.

– Discussion

* Conclusions

Medical specialties of various types are increasingly being requested to deliver senior-led care throughout weekends and bank holidays. This 7-day working is felt to be potentially beneficial for patient care and has been started by many acute specialties. The Academy of Medical Royal Colleges released a report in 2013 outlining how this could be achieved for different specialties, including psychiatry.¹ They recommended that 21–30% of psychiatric in-patients would benefit from a daily consultant-led review; mainly those who have been newly admitted or are clinically unstable. They stated that all new admissions, especially those under the Mental Health Act 1983, should receive a review the following day to initiate a treatment plan, including medication, observation levels, physical and psychosocial investigations and referrals.

The Academy of Medical Royal Colleges also advised that their recommendations were considered in light of the requirements of the local organisation as practice is likely to vary depending on geographic location, organisation size, on-call staffing and number of in-patient units. They also acknowledged that to achieve these outcomes, certain interventions and investigations would need to be available, such as pathology access.

Method

South West London and St George's Mental Health NHS Trust developed a system of weekend ward reviews led by higher trainees with consultant advice. The higher trainees in the Trust were on a full-shift on-call rota with 09:00 h to 21:00 h shifts on weekends and bank holidays. Patients admitted out of hours on Fridays, Saturdays or up to 09:00 h on Sunday morning are reviewed by the on-call higher trainee the next day. Patients admitted after 09:00 h on Sunday are reviewed on Monday by the ward team, unless it is a bank holiday, in which case they are reviewed by the higher trainee on call that day. After the higher trainee has completed their reviews for a given site, they contact the on-call consultant to discuss the cases and ensure the management plans instituted are appropriate. This occasionally led to changes in treatment plan. This provides an opportunity for supervision and training and ensures consultant input. The role of the reviews was to ensure that the patients received prompt assessment by a senior clinician and a comprehensive management plan could be instituted. They were not intended to facilitate immediate discharge, although it was hoped that earlier treatment would reduce the time patients had to spend on the ward.

To evaluate the activity involved in the weekend new patient reviews, the notes for all patients admitted between 17:00 h on Friday and 09:00 h on Sunday between 1 January 2016 and 31 March 2016 were identified via the RiO system used by the Trust. This provided information regarding the timing of their admission. The clinical notes of each of these patients were examined to determine the reason for their admission, when they were seen by the on-call higher trainee, the diagnosis made and any actions taken as a result of the weekend review. The mean length of stay for patients admitted between 17:00 h on Friday and 09:00 h on Sunday and 1 January 2015 to 31 March 2015 were also compared via unpaired *t*-test. The number of serious untoward incidents in each time period was also compared via Mann–Whitney *U*-test.

Results

A total of 88 patients were seen over the 3-month period. This equates to 6.8 patients appropriate for senior review each weekend.

Of those admitted, 46 (52.3%) were male. The average age was 41.9 years (range 18–84, s.d. = 17.8). For males the average age was 41.4 years (range 18–84, s.d. = 19.6) and for females it was 42.5 years (range 19–83, s.d. = 15.9). These differences were not significant on *t*-test.

The time from admission to senior review is indicated in *Table 1*. A total of 11 patients were not seen at all. Of these, 4 were admitted via the 136 Suite in the Trust.

Time from admission to senior review

Review within	Number of patients	Cumulative number	Cumulative percentage of patients seen
12 hours	17	17	22.1
24 hours	48	65	84.4
36 hours	8	73	94.8
48 hours	4	77	100

Diagnoses were made by the higher trainee in 73 patients. The other 15 patients were diagnosed during later assessments. These diagnoses are shown in *Table 2*. There were no significant differences between patients diagnosed by the higher trainee or at a later point on two-tailed *z*-tests.

Diagnoses made by higher trainees, the diagnoses of patients not seen or not diagnosed by the higher trainee

	Diagnosed by higher trainee	Diagnosed subsequently	Total diagnoses			
Psychosis	31	42.5	8	53.3	39	44.3
Depression	17	23.3	7	46.7	24	27.2
Mania/ hypomania	7	9.6	1	6.7	8	9.1
Alcohol or substance misuse	7	15.6	1	6.7	8	9.1
Personality disorder	12	2.6	3	20	15	17
Anxiety and stress-related disorders	2	1.3	2	13.3	4	4.5

No action	17	22.1

The length of stay for patients admitted between Friday 17:00 h and Sunday 09:00 h between 1 January and 31 March in 2015 was 26 days (s.d. = 37) and for the same period of time in 2016 the length of stay was 28 days (s.d. = 43). This was not significant.

The number of serious untoward incidents between January and March 2015 was 13, and during the same period in 2016 it was 28; this was significant ($P = 0.0652$). However, when serious untoward incidents were limited to those occurring in acute services and out of hours, there was 1 incident between January and March 2015 and 3 incidents in the same time period in 2016; these numbers were too low to be analysed and so did not reach significance.

Discussion

A substantial number of patients, 88 in total, were eligible for weekend review over the 3 months covered by the service evaluation and 77 of these were actually seen. A substantial minority of those not seen were admitted through the Trust's dedicated 136 Suite. This mode of admission may be a weak point in the current system, possibly as a patient detained to the suite could be viewed as having been admitted at that point, despite still awaiting formal assessment and possible admission. Patients admitted via the 136 Suite should still have been reviewed the following day.

Of those patients seen by the higher trainees, the vast majority (84.4%) were seen within 24 h and most of the rest, up to 94.8%, were seen within 36 h. Many of those seen between 24 and 36 h had been admitted during the morning on a Saturday and the higher trainee was unable to see them until the afternoon on Sunday. A small number (5.2%) were seen after 36 h had elapsed. The reasons for this are unclear but could be as a result of temporary limited provision of higher trainee cover due to illness.

The characteristics of the patients admitted do not appear to be remarkable, although it would have been useful to have a comparison group of patients admitted during the week to determine whether there were significant differences between the two, in terms of demographics, admission reason and diagnosis. It is unclear why some higher trainees did not formulate diagnoses for the patients they reviewed, but there appears to be no significant differences between those diagnosed during the weekend or following later assessments.

Higher trainees performed or recommended a wide variety of interventions for patients, instituting some changes in 78.9% of cases. The most frequent action was to start some form of medication; this was done for 31.2% of patients. If increasing and stopping medication is also considered, then medication changes were performed in 47.8% of cases seen by the higher trainees. These were in addition to prescriptions made by admitting core trainees.

The next largest group of interventions were recommended physical investigations and interventions, again, which had not been instituted on admission. This occurred in 14.3% of patients reviewed. These varied from instituting monitoring of fluid and food intake to obtaining specific investigations, such as lithium levels.

A variety of other interventions were performed. It is reassuring that only 2 patients needed to have a recommendation for detention under the Mental Health Act completed. The others appear to be appropriately informally or already detained under the Mental Health Act. The limited number of discharges would be at least partially explained by this not being the proposed aim of the weekend reviews.

In 22.1% of patients seen over the weekends no action was taken by the higher trainee. This could be due to all reasonable interventions already having been performed by an experienced core trainee or patients requiring a period of observation before any definitive management plans are made.

Despite these interventions being initiated earlier than expected, there was no change in the average length of stay for patients who were eligible for new patient reviews. This could be explained by the interventions only being delivered

24–48 h earlier than they otherwise would have been. The reviews were also not intended to facilitate immediate discharge. A greater focus on expediting discharge over the weekend may have led to a reduced length of stay.

Although the overall number of serious untoward incidents was significantly higher in 2016 than 2015, there was no significant difference when they were restricted to those associated with acute out-of-hours services which would appear most clearly related to the introduction of weekend new patient reviews. The overall increase in incidents may be due to a continuing Trust drive to improve reporting with a view to improving services, rather than a true increase and so the figures are difficult to interpret accurately in this context.

This system did not require any changes in rota patterns for higher trainees. The system was such that the reviews were carried out during the scheduled 09:00 h to 21:00 h shift, with reviews ceasing at 21:00 h so that patients could rest adequately without their evening or night being disrupted. On rare occasions when all the planned reviews could not be completed, they were postponed until the next day. Furthermore, as mentioned above, the focus of the reviews was not discharge; this prevented difficulties in coordinating with social care and other agencies during the weekend. The system used by the Trust enabled it to provide senior medical input 7 days a week in acute services without disrupting weekday working or leading to any of the other concerns raised by some authors.²

Conclusions

There has been increasing emphasis on providing more senior weekend medical input across all specialties.¹ In psychiatry, the recommendations were mainly in terms of newly admitted patients.

Weekend reviews of newly admitted patients by higher trainees, with consultant support, is a feasible and appropriate method for providing senior input to these patients who could potentially remain on a ward for more than 48 h without being seen by any clinician more senior than a core trainee. This would not be considered appropriate in any other medical specialty. If we are to be committed to parity of esteem in healthcare, then it is reasonable for patients admitted to psychiatric wards to be reviewed by a senior clinician within 24 h, as they would in any other hospital.³ This is particularly pertinent as the higher trainees provided some intervention in most patients, modifying medications in just under half of those admitted. It may be valuable to determine how this compares with patients reviewed during medical or surgical post-take rounds.

1.6.91 New models of care: a liaison psychiatry service for medically unexplained symptoms and frequent attenders in primary care

2017-12

Abstract

Aims and method This paper describes the process of setting up and the early results from a new liaison psychiatry service in primary care for people identified as frequent general practice attenders with long-term conditions or medically unexplained symptoms. Using a rapid evidence synthesis, we identified existing service models, mechanisms to identify and refer patients, and outcomes for the service. Considering this evidence, with local contingencies we defined options and resources. We agreed a model to set up a service in three diverse general practices. An evaluation explored the feasibility of the service and of collecting data for clinical, service and economic outcomes.

Results High levels of patient and staff satisfaction, and reductions in the utilisation of primary and secondary healthcare, with associated cost savings are reported.

Clinical implications A multidisciplinary liaison psychiatry service integrated in primary care is feasible and may be evaluated using routinely collected data.

Medically unexplained symptoms (MUS) and comorbid physical and mental health conditions place a significant burden on individuals and the economy.^{1,2} Annual costs of MUS have been estimated at £3.1 billion³ and of comorbid conditions at £18 billion.⁴ Policy makers suggest innovative approaches be deployed to improve care for patients and make savings across the system.⁵

The Authors own the copyrights to the individual articles.

These patients frequently return to general practitioners (GPs) with unresolved and new complaints. Despite being referred to specialist services their problems remain, which is demoralising for all. Current primary care configurations do not adequately provide for this population. Standard secondary care mental health services rarely have staff with relevant expertise and are insufficiently close to primary care services to influence presentations. Improving Access to Psychological Therapies (IAPT) services are unsuitable due to these patients' high level of medical complexity. Access problems are further compounded by patients not meeting the referral criteria for specialist mental health services.

The skill base in liaison psychiatry services renders them an ideal source of expertise. Until recently such services were hospital-based but they can be integrated within primary care services.⁶⁻⁸ We report a novel pilot primary care liaison psychiatry service – the Primary Care Wellbeing Service (PCWS) in Bradford and Airedale, West Yorkshire. The service was targeted to frequent attenders with MUS or psychological difficulties associated with their underlying long-term conditions. This report is a description of the planning, set up and evaluation and feasibility of the preliminary project.

Method

A partnership board of clinical experts, academics and commissioners met monthly to develop and have oversight of the service; the original impetus came from local Clinical Commissioning Groups (CCGs).

A rapid evidence review helped identify service models, staffing and skill mix, patient selection and outcome measures for the service. Review findings in the context of local practitioner preferences and resources were used to agree the service configuration. The Project Board secured 15 months' funding for the preliminary project. An evaluation by the Commissioning Support Unit (CSU) assessed the feasibility of service design, implementation, collecting the data and effectiveness.

Data collection

Electronic patient health records (primary and secondary care and mental health) and measures of patient-reported outcomes, experience, and staff experience, were collected as follows: Healthcare utilisation: defined as any patient event recorded in the electronic record system; a specific Read code for the service was applied to the patient record at each practice and anonymised data extracted for 12 months prior to and 9 months following referral for secondary care data, and 11 months following referral for primary care and mental health data, providing healthcare activity and costs. Clinical effectiveness: at referral and then every 2 months during follow-up using the 9-item Patient Health Questionnaire (PHQ-9),⁹ 15-item Patient Health Questionnaire (PHQ-15),¹⁰ 7-item Generalised Anxiety Disorder scale (GAD-7)¹¹ and the EuroQol 5-dimension, 5-level health status measure (EQ-5D-5L).¹² A clinician-reported outcome measure assessed perceived improvement in the patient's condition by referring clinician. Staff experience: a referrer satisfaction scale, 6 months after the referral or at patient's discharge from the PCWS; and a survey administered at the end of the pilot. Patient experience: a brief patient-reported measure at discharge comprising (a) patient satisfaction with the service; (b) two questions asking what was good about the service and what could be improved; and (c) would they recommend the service? Case studies were used to illustrate individual formulations and negotiations that took place.

Data analysis

Feasibility of data collection was judged by the completeness of measures, using summary descriptive statistics. For healthcare utilisation and costs, a before-and-after 'time series' approach provided an indication of service effectiveness. Data points were taken from the 12-month period prior to the start of the PCWS and were truncated at 9 months post intervention for secondary care data, giving data points for months 1–21 and 11 months post intervention for primary care and mental health service data at months 1–23. Qualitative data were collated and themes reported.

The service

The literature review confirmed there was no ‘off the peg’ solution, providing information about key issues to consider when designing the service.

Service model and setting

An integrated service with specialist mental health professionals based in and collaborating with three GP practices was established. Practices were selected on the basis of expressions of interest, willingness to commit time and resources. Practices were of average size and served areas of high socioeconomic deprivation. One practice also had a high minority ethnic population.

Staffing

The team comprised a team manager, mental health occupational therapist, physiotherapist, psychology assistant, consultant psychiatrist, consultant psychologist, psychologist and administrator. Specialist advice was provided by the consultants. GP practices contributed both GP and practice nurse time.

Patient selection and referral

Most studies in the published literature used some combination of case-finding measures for mental disorder alongside frequency or cost of healthcare to identify the target population. A preliminary study in a local practice used the PHQ-9 and a search of GP electronic databases to identify distressed patients and frequent attenders. Of the 100 patients assessed with the PHQ-9, only 6 were identified who were not already in contact with services and who also had significant mood symptoms. They all declined referral. Using standardised case-finding measures failed to identify relevant candidates for this service.

Instead, GPs identified patients using a combination of their own knowledge of patients alongside a risk stratification tool. They focused on those who had a presumed diagnosis of MUS or patients with long-term conditions experiencing significant psychological difficulties, and who were also frequent attenders in primary and secondary care. Attendance was considered to be frequent when a patient had more than the average number of primary care consultations or hospital admissions and when patients’ problems remained unresolved and were escalating in cost. A discussion of potential candidates helped achieve consensus about appropriate referrals and practices were then asked to refer ten patients each, providing information on goals for referral and a summary of the patient’s health record.

Outcomes

Organisational level outcomes (health service use, healthcare costs, medication use) and patient-level outcomes (mental and physical health, physical functioning, and quality of life).

Results

In total, 28 patients were referred, with 27 appropriate referrals. One was unsuitable due to alcohol dependency and substance misuse. There was a delay of 6 months in receiving referrals from one practice, as the GP lead for the pilot left the practice. Complete data for healthcare utilisation and cost were available for 19/21 patients in 2 practices.

Health issues

A range of difficulties were identified including neuro-developmental problems; undiagnosed autism; significant health anxieties or preoccupation with illness; chronic pain and overuse of opioids; non-epileptic attacks and medically unexplained loss of movement and pain; and other maladaptive behaviours (e.g. misuse of insulin). Most patients had significant psychosocial difficulties including relationship problems, recent and past life adversity. High levels of physical morbidity such as ischaemic heart disease, chronic obstructive pulmonary disease, arthritis and head injury were also found.

Patient engagement

Patients were offered an initial joint assessment by two team members; the choice of health professionals took account of referral information about the presentation and degree of readiness to engage. For example, patients reluctant to see a mental health specialist were contacted first by the physiotherapist or occupational therapist. A flexible approach to timing and location of appointments was taken. We were able to engage with 22 of 27 patients either fully or partly with the service.

Interventions

Initial formulation developed for each patient was reviewed iteratively as alternative interventions were trialed, focused on referral goals. There were four components to interventions as follows: Taking stock and formulating the problem: review of medical notes to reconsider evidence for established diagnoses and medication reviews. Developing a function-based approach, occupationally oriented and focused on improving activities of daily living by accessing community resources; adaptations to home and mobility; introducing non-medical ways of managing pain. Psychological approaches included negotiation of a shared formulation and approach to management, with basic stress and anxiety management. Where indicated, specific therapies such as mindfulness, eye movement desensitisation and reprocessing (EMDR), trauma-focused work and acceptance commitment therapy (ACT). Service-level approaches included non-contingent access to practice staff to manage escalating demands and avoid unscheduled hospital and Accident and Emergency attendance; liaison with GPs and other specialists to agree a consistent approach.

Feasibility of data collection

Of the 19 patients for whom data could be collected there were only 8 complete data-sets for EQ-5D-5L, GAD-7 and PHQ-9, and 7 complete data-sets for PHQ-15 and EQ-5D-5L.

Healthcare utilisation data from the clinical system were readily available, although it was not possible to collect out-of-hours data. However, gathering information on prescriptions and costs of medication was prohibitively resource intensive.

Feasibility and effectiveness of the service

Across the whole patient cohort, secondary care activity reduced by an average of nine events per month. In the 9 months after the implementation of the PCWS, 177 fewer events occurred in secondary care (*Fig. 1*).

Nine months after implementation the total cost of activity was £63 950 less than the previous year (*Fig. 1*). The cost of secondary care activity reduced by an average of £3702 per month after the implementation of the PCWS (*Fig. 2*). Primary care activity had also reduced across the whole patient cohort by an average of 11 events per month.

Primary care

Time spent delivering care reduced by an average of 7 min per month. A substitution effect was observed in primary care with GPs delivering an average of 12 appointments and 127 min less to the patient cohort since the implementation of the PCWS. In contrast, other clinical staff delivered one additional appointment and 120 min more to the patient cohort.

Primary care costs were reduced across the whole scheme by an average of £171 per month for the cohort of 19 patients. In some cases, interventions led to significant changes in symptoms and health-seeking behaviours (*Box 1*). In others, work is still ongoing and longer-term intervention will be needed.

Discussion

What works in a research study does not easily translate into routine clinical practice in the National Health Service (NHS). In this study, academics and GP commissioners worked with specialist mental health providers to consider the evidence and identify local resources to design the best service configuration for patients with MUS, long-term conditions and frequent attenders in primary care. There is no short-term solution for these complex patients but a liaison psychiatry service based within primary care and as part of a long-term care plan shows great promise.

Identifying the patient group for the service and managing complexity

The service presented here addresses a common problem for GPs, which traditional diagnostic categories do not describe well and standard mental health services do not currently manage well. This is not the first attempt at establishing primary care-based liaison services. The service described, however, is unique because it eschews traditional collaborative care approaches¹³ and screening for anxiety and depression widely described in the research literature.^{13,14} In clinical practice that type of screening does not identify the right candidates to work with. The GPs and practice staff identified patients for this study by focusing on those patients with MUS or long-term conditions who were struggling to cope and that were returning with unresolved physical and emotional problems with rising healthcare costs. This was facilitated by a discussion of the case and the development of the vignette prior to referral to the PCWS. There was a level of detail in identifying this type of patient that required consideration and scrutiny by practice staff which could not be picked up by electronic systems or case-finding measures alone.

Patients with such complex conditions cannot be managed in standard ways following a protocol. They require a creative approach to person-centred care that supports their identification and management. In almost all cases the GPs were correct in identifying the right patients for the service via their clinical presentation, the exception being someone who required support from specialist addiction services.

Box 1 Case study

Patient A was a frequent attender at Accident and Emergency, the GP practice and mental health services, with a range of physical and non-psychotic mental health symptoms. She had a suprapubic catheter due to incomplete bladder emptying and detrusor overactivity; she found it too distressing to self-catheterise using a urethral catheter because of a history of sexual abuse. As she was struggling with the suprapubic catheter, an operation was planned to create a conduit between the skin and bladder to make catheterisation easier. However, there was concern that this would not address the underlying reasons for her frequent presentations, and would in fact increase her physical health problems, for example,

increasing her risk of urinary infection. Following referral to the Primary Care Wellbeing Service (PCWS), a review of her case notes revealed that her urodynamic studies had been normal. The team liaised with the surgeon, who agreed to a trial of bladder retraining. The team worked to engage patient A and to develop a shared formulation with her about the reasons for her urological difficulties and accept that her physical health difficulties could be managed in a non-operative way. We recognised the importance that all staff conveyed the same message to the patient and that care did not suddenly decrease while other changes in care took place. With input from the practice nurse and the PCWS team, she was able to start passing urine again without the catheter.

Challenges to service delivery and data collection

Our findings suggest that such services are feasible to deliver but that practices can struggle without sufficient staff to deliver the service. This accords with the literature¹⁵ which suggests an assessment of practice readiness be performed but this might not account for unexpected changes in practice staffing and infrastructure. Patients and staff that completed satisfaction measures were satisfied with the service, although it is possible that those that did not complete measures did not have such a positive experience. Further, it was not possible to routinely collect self-reported outcome measures in routine practice for this service. Given that these practices were highly motivated to take part, it is unlikely that collecting self-report measures, as part of an evaluation package, would be feasible in less motivated practices. Feedback from staff suggested that they were not able to collect this additional data. Any additional work to use self-report measures in practice needs to consider the burden of additional work for practice staff against the need to collect this information. However, routinely collected data on service use and cost proved to be feasible to collect as this is already part of the existing monitoring systems. Again, out-of-hours information was not collected as part of this. Case studies enabled practitioners to consider how well the patient progressed helping to sustain the service in its early phases using cases as a feedback loop as proposed in the literature.¹⁵

Implementing new service models requires a long-term view

There are challenges in setting up and maintaining such services, however. We cannot be sure that they will be cost-effective in the longer term, as the full costs of the service were not examined here only salary costs. This type of analysis would need to be evaluated in a larger study of effectiveness taking account of the commissioning cycle and utilising an economic evaluation. This pilot was only conducted in one metropolitan district in England. Population demographics, health service configurations and commissioning arrangements vary across the UK, and our findings and experience may not be generalisable. Moreover, GP practices taking part were selected for their willingness to engage with the pilot, with one out of the three being unable to launch the proposed service within the project time frame.

Findings from the evaluation are not definitive, but rather provide important data to inform the next stages of service development and evaluation. This pilot demonstrates that service developments can be implemented using NHS resources and commissioning processes, and evaluated using routinely collected data. However, including patient self-report and staff measures, which are not part of usual care, requires additional resources. Administering and collecting paper-based measures for patients and staff proved onerous, with incomplete data collection from all practices despite concerted efforts to collect these by the team.

Questions of sustainability and scaling up need to be considered. In this feasibility study, there were significant reductions in secondary care activity and cost. If such a service could be extended then a further study including full economic costs would be of interest. Such transformation requires commissioners to take a long-term view and to accept that cost savings may be negative or neutral in the first year or more.

Future proposals

To maintain the momentum and build on this project and other innovative pilots in the UK,^{6,7} we propose setting up a network of interested colleagues to critically consider the future development of primary care liaison psychiatry services. The purpose would be to share experience and to inform further implementation projects and design approaches to the particular problems of scaling up and managing the needs of patients with complex problems who are prone to relapse and likely to require repeated specialist help or longer-term care plans.

The Clinical Commissioning Groups of NHS Airedale, Wharfedale & Craven and NHS Bradford Districts commissioned the Health Economics, Evidence and Evaluation Service (HEEES) of Yorkshire and Humber Commissioning Support to evaluate the Primary Care Wellbeing Service pilot.

1.6.92 Systematic review into factors associated with the recruitment crisis in psychiatry in the UK: students', trainees' and consultants' views

Abstract

Aims and method To review the literature to examine the factors that may be affecting recruitment into psychiatry in the UK. We systematically searched four databases to identify studies from 1974 to 2016 and identified 27 papers that met the specified inclusion criteria.

Results Most papers ($n = 24$) were based on questionnaire surveys. The population in all studies comprised of 1879 psychiatrists, 6733 students and 220 746 trainees. About 4–7% of students opt for a career in psychiatry. Enrichment activities helped to attract students more towards psychiatry than just total time spent in the specialty. Job content in terms of the lack of scientific basis, poor prognosis and stigma towards psychiatry, work-related stress and problems with training jobs were common barriers highlighted among students and trainees, affecting recruitment. Job satisfaction and family-friendly status of psychiatry was rated highly by students, with lifestyle factors appearing to be important for trainees who tend to choose psychiatry.

Clinical implications Negative attitudes and stigma towards psychiatry continue to persist. Teaching and training in psychiatry needs rethinking to improve student experience and recruitment into the specialty.

Psychiatry as a career has been negatively regarded and unpopular among medical students. About 3.6% of British graduates decide on a career in psychiatry whereas about 6% are needed.¹ From 2000 to 2011, the absolute number of consultant psychiatrists in England rose from 2904 to 4394 (an increase of 51%), with similar increases in Scotland and Wales, in line with the expansion of the consultant workforce in most secondary care specialties.¹ A need for more psychiatric consultant posts has been predicted based on projections of increasing workloads due to the increased population needs.² A perceived fall in the proportion of UK medical school graduates choosing a postgraduate career in psychiatry, and low competition ratios for first-year core specialist training (CT1) posts in psychiatry,^{3–5} has led to many questions about the way in which psychiatry is taught at medical school and how psychiatry could be made as an attractive career option.^{6–8}

Low recruitment in psychiatry is a global issue, highlighted in a number of publications.^{9,10} However, the problem also has country-specific dimensions, as each country has different factors such as the pay scale for the specialty, medical education system and training programmes, which may attract or dissuade medical students from a career in psychiatry. The subject has not been reviewed systematically especially in the context of recruitment in the UK. The review question was: what are the factors that influence recruitment to psychiatry as a career choice and how can this be improved? The aim of this paper is to systematically review the literature from the UK on psychiatry as a career choice. We are specifically interested in identifying the factors that influence the recruitment into psychiatry with emphasis on barriers and facilitators affecting recruitment. A greater understanding of the views ranging from medical students to trainees and consultants working in the UK may enable curriculum developers and recruitment leads to design programmes that attract students and trainees to psychiatry as a career and improve students' attitudes towards psychiatry in the long term.

Method

We followed the PRISMA statement¹¹ as a guide for conducting the systematic review. The following electronic databases were searched from 1974 onwards: Medline, EMBASE, CINAHL, PsycINFO. These databases were selected in view of the fact that almost all the literature published from the UK would be covered in these databases. Keywords used in the searches included: medical students, trainees, doctors, consultant, attitudes, psychiatry, career, undergraduate psychiatry. Boolean operations and truncations were added to allow for alternative endings in the keyword searches. The search was last updated in August 2016.

We included studies that described a UK sample, were published in English in a peer-reviewed journal and provided original data on careers in psychiatry or factors affecting recruitment in psychiatry. We excluded studies that had the primary objective of addressing other issues that were not directly relevant to recruitment in psychiatry but only mentioned their effects on career choice as a secondary effect. Studies which provided data on medical careers in general were included if these provided data relevant to psychiatric careers or recruitment.

The electronic search returned 601 relevant abstracts and titles. We screened the titles and abstracts and excluded the studies that were not directly relevant to the objectives of the review. Therefore we excluded the studies that did not describe a UK sample or did not provide the original data. We also excluded the studies that described the recruitment to certain subspecialties and therefore not relevant to the recruitment to psychiatry in general. After screening these titles and abstracts we decided to examine 56 full text papers. Finally, we included 27 papers in the review. Further details are provided in *Fig. 1*. The studies were conducted in a number of different populations, settings and periods, and also used diverse methodologies varying from surveys to statistics derived from databases. The 30-item Attitudes Towards Psychiatry (ATP-30),¹² a validated tool used to assess attitudes of students towards psychiatry, was used in four papers; other papers used different questionnaires to assess attitudes. Due to the diverse methodologies it was inappropriate to pool the data to produce a statistical summary. We therefore describe the main findings and produce a narrative summary of results.

Results

Characteristics of included studies

Table 1 shows the characteristics of the 27 studies included in the review. The majority of studies ($n = 24$) were surveys and questionnaire-based studies. The other studies included one database study of doctors entering training posts and two retrospective cohort studies, which looked at which medical school psychiatrists had attended. These reported on medical students ($n = 12$), trainees ($n = 10$), medical students and trainees ($n = 1$), trainees and consultants ($n = 1$) and consultants ($n = 3$). One of these studies looked at data from postgraduate departments in different medical schools, and one study reported on the database of applicants to MMC (Modernising Medical Careers) for training posts.

Data not used from this paper just broad findings in review.

In survey-based studies response rates varied from 16% to 100%. Mean response rate from the papers which had figures available ($n = 20$) was 63.3%. The population in all studies comprised of 1879 psychiatrists, 6733 students and 220 746 trainees. One database study¹³ looked at 31 434 trainee doctors, and studies by Goldacre *et al* were aimed at all doctors in training, accounting for large numbers of respondents in the trainee subcategory.^{14–18}

The influence of the medical school and teaching practices

Most of the research addressing the influence of the medical school and teaching practices on selecting psychiatry as a career was carried out in the 1970's and 1980's. Two studies by Brook *et al*^{19,20} looked at the medical school of origin for 531 psychiatrists between 1961 and 1970 and reported no significant relationship between schools that had a professional unit or specific teaching programme and students pursuing psychiatry in the long term. However, it was noted that those schools that produced fewer psychiatrists tended to have either a recently established professional unit or none.¹⁹

No clear pattern emerged in terms of the type of teaching offered at each university and the impact this had on choice of psychiatry as a career in the long term.¹⁹ All four Scottish schools, and Cambridge and Oxford were noted to be higher in terms of producing psychiatrists, attributed possibly to the well-established professional units such as the Maudsley and Bethlem Royal hospitals.¹⁹ The personality, charisma and enthusiasm of teachers were associated with an increase in the uptake of psychiatry in the long term.^{19,21}

Brook *et al*²¹ found that the effectiveness of teaching rather than the amount of teaching had an effect on student attitudes and recruitment into psychiatry. The attitude of non-psychiatric teachers appeared to be influential with doctors experiencing negative attitudes of other doctors towards psychiatry.²¹ The two hospitals which ranked top in terms of producing psychiatrists had changed their teaching model. One stressed the importance of psychiatry as being part of general medicine, emphasising the effectiveness of physical therapy, whereas the other placed emphasis on liaison psychiatry and psychotherapy.²¹

More recent work by Collier *et al*²² looked into the teaching time allocated for psychiatry in foundation programmes across the country. They found that only 2.3% of teaching was dedicated to psychiatry compared with 44.1% to medical and surgical topics.²² Exposure to psychiatry remained limited with 4 out of 17 hospitals in the survey not having any teaching on psychiatry for medical students.²² Doctors generally led a higher proportion of medicine and surgery teaching sessions (63%) compared with psychiatry (48%).²²

Medical students' views of psychiatry and factors affecting career choice

Twelve studies examined the factors affecting medical students' career choice and one study looked at both medical students and trainees. Petrides *et al*²³ studied the theoretical understanding of how different medical specialties are perceived and how choices are made. Psychiatrists were found to have a more artistic approach to medicine, seeing interpreting and responding imaginatively to a range of medical, social, ethical and other problems. This is in keeping with early work by Levine *et al*²⁴ who also found that there was a group of students who were 'psychologically minded' and they could be identified and encouraged to make psychiatry as career choice.

Budd *et al*²⁶ found that job satisfaction (98%, $n = 128$) and family-friendly status of psychiatry (79%, $n = 103$) were important for students who rated psychiatry as one of their top three choices.²⁶ The academic status was significantly less important (48%) for students who placed psychiatry as their top three specialty schools *v.* 63% for those who did not place psychiatry in their top three choice.²⁶

Choice of psychiatry as a career among medical and sixth form students

The number of students choosing psychiatry has remained fairly stable at around 4–7%.^{25–27} Three per cent of students from six medical schools placed psychiatry as their first choice, with 18% seriously considering it.²⁰ Halder *et al*²⁸ found similar results in 18 medical schools; 16% chose psychiatry as a future career on entering medical school but by the final year only 3% had decided to pursue a career in the subject. These results were replicated by Farooq *et al*²⁷ In a survey of sixth form students, Maidment *et al*²⁹ reported that 60.9% ($n = 363$) indicated that it would be very likely or they would definitely want to pursue psychiatry as a career. In terms of overall intentions to pursue a career in a specialty, the ratings for psychiatry was similar to general medicine at 12.4% ($n = 72$) *v.* 12.2% ($n = 69$) respectively.²⁹

Effect of undergraduate attachment and education on choosing psychiatry as a career

Positive attitudes towards psychiatry and the influence by a teacher during the attachment correlated with an intention to pursue psychiatry as a career in the long term.^{29–31} Three studies highlighted the importance of psychiatric attachment. Student attitudes improved as the attachment progressed.^{26,30,31} Maidment *et al*²⁹ found 1.4% of fourth-year medical students expressed a definite intention to pursue which rose to 4.7% after their attachment.²⁹ McParland *et al*³⁰ reported that 19% ($n = 58/309$) of students were very attracted to psychiatry or had a definite intention to pursue psychiatry at the start of the placement, which increased to 27% ($n = 101/373$) of students at the end of the attachment. The importance of the undergraduate experience was highlighted by a recent study showing 50% of consultants and 37% of trainees surveyed decided on a career in psychiatry while still at medical school.³²

Calvert *et al*³³ looked into the attitudes of medical students towards psychiatry and psychiatric patients at year 1, 3 and 5 in medical school. First-year medical students were more likely to have stereotypical views compared with third- and fifth-year students, and were more likely to agree with statements such as 'Psychiatry deals with imaginary illness' (mean 1.4, s.d. = 0.9, $P < 0.5$).³³ Fifth-year students (mean 3.2, s.d. = 1.4) showed lower agreement than third-year medical students (mean 3.6, s.d. = 1.2, $P < 0.5$) with the statement 'Psychiatry is as a challenging career'.³³ As they progressed through medical school, students recognised that mental illness has serious morbidity and that people do recover from mental illness,³³ showing that attitudes towards psychiatric patients improved with greater clinical experience but possibly became more negative towards psychiatry as a career.

Other factors that appeared to affect students positively included enrichment activities, i.e. activities beyond standard teaching and clinical placements led to a significantly increased interest in psychiatry.²⁸ These included research experience in psychiatry (13% v. 4% in those not interested in psychiatry, $P = 0.001$), university psychiatry clubs (38% v. 11%, $P < 0.001$), psychiatry electives (14% v. 1%, $P < 0.001$) and psychiatry special study modules (38% v. 16%, $P < 0.001$).²⁸

McParland *et al*³⁰ identified factors which increased interest in psychiatry, including: influence or encouragement by someone during the attachment (74%, $n = 282$), particularly the influence by consultants (43%, $n = 163$), exposure to interesting and stimulating ideas (29%, $n = 110$), liking someone's approach (27%, $n = 103$), feeling someone believed in their ability (11%, $n = 41$) and having formed close working relationships (9%, $n = 33$).³⁰ Other factors that had a significant impact were: receiving encouragement from the consultants ($n = 374$, $P < 0.001$, $r = 0.26$), seeing patients respond to treatment ($n = 374$, $P < 0.001$, $r = 0.20$) and having a direct role in the involvement of patient care ($n = 374$, $P < 0.001$, $r = 0.26$).³⁰

Factors which did not affect career choice of medical students

Seeing patients in different settings or different phases of the illness had no effect on career choice of medical students when deciding their career intentions.²⁸ Interestingly, one study found that the earning potential and status of psychiatry had no effect on selecting psychiatry as a career choice.²⁶ Other factors related to teaching such as quality of rating of small group teaching and lectures,²⁸ the curriculum type used^{30,31} and performance at viva examinations and multiple choice questions also had no effect on the career choice.³¹

Factors discouraging medical students to choose psychiatry as a career

Curtis-Barton *et al*²⁵ in their survey ($n = 467$) found that the factors discouraging students to pursue a career in psychiatry included: prognosis of patients (62%), perception that there is a lack of evidence in diagnosis (51%), lack of scientific basis (53%) and the amount of bureaucracy and paperwork in the specialty (48%). Other discouraging factors included the stigma towards psychiatry (30%), the standing of the profession among medical colleagues (31%) and comments by other specialists (26%).^{25,34} Psychiatry scored the lowest among the specialties as a career choice. Students described psychiatry as boring, unscientific, depressing, stressful, frustrating and 'not enjoying the rotation'.³⁵

Many students experienced psychiatry as being different to other specialties. For some this was a reason not to pursue psychiatry as a career but for others it was a positive aspect of the specialty. Students felt ward rounds focused on 'social

issues' rather than medical conditions. Some found it an 'emotional burden' and others felt that psychiatry could not 'fix' people and no one is being cured.³⁴

A survey by Korszun *et al*³⁶ examined the views of trainee, academics and clinicians on students not taking up psychiatry. The following factors were identified as deterring the students from psychiatry: negative attitudes towards psychiatrists from other doctors and health professionals (57%), stigmatisation of psychiatry (40%), stigma associated with mental health disorders (39%), poor teaching and role modelling from psychiatrists (37%), psychiatry not seen as medical or scientific enough (26%) and poor morale among psychiatrists (26%).³⁶

Factors affecting trainees' and consultants' choice of psychiatry

Fazel *et al*¹³ found that psychiatry was the sixth most popular specialty out of ten specialty groups for trainees applying for training places. A higher proportion of female graduates were shown to choose psychiatry between 1974 (32%) and 1999 (59%).¹³ However, a more recent survey showed a slight decline in the number of women choosing psychiatry over the last decade, 4.9% (1999) v. 4.6% (2009).¹⁷

Goldacre *et al*¹⁴ examined career choices for medical students over the past 40 years. The number of doctors choosing psychiatry as a career has hardly changed and remains around 4–5%, which is similar to figures from 1975.¹⁴ It was noted that students who went on to work in psychiatry 10 years after graduation, 52% (224 out of 428) had chosen psychiatry in the first year after graduation and 71% (308 out of 434) had chosen it in year 3.¹⁴

In common with the factors attracting students towards psychiatry, numerous studies identified factors that appear to attract trainees towards psychiatry. The major attractions for choosing psychiatry are listed in *Box 1*. Denman *et al*³² found that the most common factor influencing core trainees' (60%) and consultants' (70%) decisions to specialise in psychiatry was emphasis on the patient as a whole.³² Trainees highlighted that mental health was an area of need (53%) and empathy and concerns for people with mental illness (53%) were important reasons for choosing psychiatry.³²

Box 1 Factors attracting medical students and trainees in pursuing psychiatry as a career

Medical students

- Encouragement by colleagues^{24,26,30,31}
- Influence by someone during the placement^{24,30}
- Females are more likely to favour a career in psychiatry^{24,27,30}
- Family history of mental illness was associated with choosing psychiatry²⁴
- Quality of experience^{26,27,30,33}
- Role models can have a positive impact on students pursuing a career in psychiatry^{28,30,33}
- Enrichment activities^{27,28}

Trainees

- Hours and conditions of work^{17,31,32}
- The doctor's personal assessment of their aptitudes and skills,^{17,31,32} for example recognising factors such as using one's intellect to help others³⁷
- Experience of the subject as a student^{17,31}
- Inclinations before medical school and a positive student experience^{17,37}
- Attitudes and inclination to psychiatry as a medical student^{24,31,37}

- Lifestyle factors^{32,37}
- Encouragement from consultants and senior doctors³¹
- Emphasis on the patient as a whole person and empathy/concern for mentally ill people³²

Barriers associated with not choosing psychiatry as a long-term career choice for trainees

Barras & Harris³⁸ explored trainee's experiences ($n = 359$) within psychiatry. Trainee attitudes were grouped into different categories. The attitudes towards psychiatry (12.6%), professional role (12%) and day-to-day working (11.3%) were identified as the main negative factors. Trainees raised concerns with the training programmes in psychiatry, such as problems with the rota and not having enough time with patients.³⁸ Many trainees felt frustrated with the Annual Review of Competence Progression (ARCP) process and workplace-based assessments, as well as the duplication of paperwork being a constant frustration.³⁸

The studies identified a number of barriers against choosing psychiatry as a career (*Box 2*).

Trainees felt improvements were needed in terms of training opportunities and felt this could be enhanced by providing a variety of jobs, increasing research opportunities and increasing medical aspects of training.³⁸

Work looking into consultant psychiatrists' views into why they chose psychiatry was limited to two papers.^{32,39} Dein *et al*³⁹ found that the majority of consultants (46%) chose psychiatry as a career soon after leaving medical school, and a recent study surveying consultants in the West Midlands found that 50% had made their choice by graduation from medical school.³² The main reasons cited by consultants for choosing psychiatry as a career included: empathy for those with a mental disorder (36.1%), interface with neuroscience (25%), expectation of better working conditions in psychiatry (20%) and influence of teaching at medical school (19.4%).³⁹ Denman *et al*³² highlighted several 'very important' reasons for consultants choosing psychiatry including: career in psychiatry would be intellectually challenging (60%), sense of fulfilment expected from seeing patients improve (47%) and enjoyment of problem-solving (47%). Lifestyle factors such as salary, better working conditions and quality of life were shown to be more important reasons for choosing psychiatry for trainees compared with consultants.³²

Box 2 Barriers associated with not choosing psychiatry as a career

- Job content (71.7%) ($n = 71$) (including the lack of scientific basis, job not being clinical, poor prognosis)^{15,17,25,35,36,38}
- Poor public image of psychiatry^{15,25,36}
- Lack of respect towards psychiatry as a specialty by other specialties^{15,25,36}
- Work-related stress cited by (49%)¹⁵ trainees in psychiatry³⁸
- 25–50% of trainees leaving psychiatry as a specialty cited lack of resources as one of the main reasons which was significantly more than those rejecting general practice and trauma and orthopaedics^{15,38}
- 25–50% of trainees leaving psychiatry^{15,16,38} highlighted:
 - a. lack of adequately supervised training
 - b. lack of evidence base to diagnosis and treatment
 - c. lack of improvement in patients
 - d. work-life balance
 - e. work not clinical enough
- Physical risks involved in the job¹⁵
- Sense of eroded professionalism^{36,38}
- Too much paperwork and duplication^{25,36,38}

- Problems with rota and not enough time with patients³⁸
- Trainees leaving the scheme felt frustrated with workplace-based assessments³⁸
- Low morale among workforce³³
- Future role of psychiatrists being eroded³³

Discussion

This is the first systematic review of literature which examined factors that influence the choice of psychiatry as a career in the UK. The main findings are that enrichment activities help to attract students more towards psychiatry than just total time spent in the specialty. Job satisfaction and family-friendly status of psychiatry was rated highly by students who tend to choose psychiatry. Role models and encouragement from consultants may increase the number of students who want to pursue psychiatry as a career. The major factors that appeared to dissuade medical students/trainees from pursuing psychiatry as a career included: an apparent lack of scientific basis of psychiatry and work not being clinical enough, perception that psychiatry is more concerned about social issues, the bureaucracy, paperwork, apparent poor prognosis of patients, stigma towards psychiatry as a specialty, low morale, and onerous workloads as a consultant.

We are aware of one previous systematic review that examined medical students' attitudes towards psychiatry internationally.⁴⁰ In common with our study this systematic review alongside another survey of psychiatrists³⁶ highlighted the stigma towards mental illness as a major barrier influencing negative medical views towards psychiatry.⁴⁰ Stigma towards psychiatry as a specialty arises from a variety of sources, notably from medical students themselves. In addition, this stigma could arise from ward staff attitudes towards patients and from other doctors in other specialties, which detract students.^{13,25,34}

Other reviews have looked at one aspect such as the effect of clinical experience of psychiatry on medical students' attitudes towards the specialty.⁴¹ Lyons⁴⁰ highlighted the impact of poor-quality teaching leading to negative attitudes towards psychiatry and highlighted the need to address psychiatry curricula and introduce novel teaching strategies.⁴⁰ El-Sayeh *et al*⁴² have previously highlighted the importance of teaching and the various methods which could be utilised to try to improve the student experience and in turn help attract students towards psychiatry. The recent survey by Korszun *et al*³⁶ highlighted that the number of clinicians compared with academics and trainees agreed that they did not have time to teach medical students ($P < 0.001$). Both clinicians (42%) and academics (47%) felt that teaching medical students did not contribute to their future career prospects compared with 21% of trainees ($P < 0.001$).³⁶ Fewer clinicians considered teaching to be a significant component of their appraisal compared with trainees and academics.³⁶ The combination of poor teaching practices due to lack of resources or commitment and the stigma reinforce the poor image of psychiatry.

We feel that the findings of our study support the recommendations made by Mukherjee *et al*⁴³ which identify a number of steps to address the crisis in psychiatry recruitment at different nodal points in a medical career, i.e. prior to entry to medical school, during medical education and after graduation.

Improving recruitment

This study highlights the need to change the experience of psychiatry at undergraduate and postgraduate level in keeping with work by Shah *et al*⁴⁴ who highlighted early medical experience, influence of seniors and the aspects related to working environment as areas that could be affected positively which in turn could have a positive effect on choosing psychiatry as a career. Kelley *et al*⁴⁵ highlighted the impact of foundation programme experience in psychiatry, with a significantly higher proportion of trainees pursuing a career in psychiatry compared with those without any exposure to psychiatry (14.9% v. 1.8%). This correlates with earlier findings by Shah *et al*⁴⁴ that found a significant correlation between those Scottish students considering psychiatry as a career and having held a psychiatry post.⁴³ A recent survey by Denman *et al*³² showed that 43% of psychiatry trainees made their decision to specialise in psychiatry during the foundation years, correlating with increased exposure to psychiatry during the foundation years with 80% of trainees in this survey completing a post in psychiatry during the foundation years. Specific enrichment activities beyond standard teaching and clinical placements such as research experience in psychiatry, university psychiatry clubs, summer

schools,⁴⁶ psychiatry electives and psychiatry special study modules appear to be a way in which medical students will gain invaluable experiences and improve their attitudes to psychiatry. These need to be adopted and evaluated in future programmes to enhance recruitment in psychiatry Collier *et al*²² found that only 2.3% of teaching was dedicated to psychiatry compared with 44.1% to medical and surgical topics, which does not help the poor image of psychiatry. This and similar issues need to be addressed at institutional level.

A number of studies found that psychiatry has a perception that it is not a 'scientific' or 'medical' discipline.^{15,36,38} Medical students and trainees expressed the views about the weakened medical identity of psychiatry. The erosion of the role of the psychiatrist was cited by some psychiatry trainees as a potential factor that would make them consider leaving psychiatry training.³⁸ This unfortunately is not helped by negative comments or 'bad-mouthing' of psychiatry.^{36,47}

Interventions such as anti-stigma films and Medfest⁴⁸ have been shown to improve medical students' attitudes to psychiatrists, serious mental illness and psychiatry, at least in the short term.^{48,49} However, it appears that there is need to reconsider the content of psychiatric training and the undergraduate curriculum. It has been suggested that moving undergraduate teaching from in-patient to general hospital settings such as liaison psychiatry will allow students to see patients with problems that are relevant to medical practice.⁴⁷ Setting up and evaluating such programmes that have the potential to offer a different and enjoyable experience for medical students and foundation doctors should be a priority to improve the image of and recruitment into psychiatry.

Limitations

A limitation of the study is that almost all data are based on surveys and databases. This represents a cross-sectional view on the subject. The lack of any comparisons with other specialties, which may have similar recruitment rates, is particularly concerning. The focus on UK studies is also a limitation but was necessary to understand the factors affecting recruitment in this country. We noted with some concern that there are only a few studies that address the positive aspects of psychiatry,^{26–28,30–33} which may attract students and trainees towards psychiatry, and how these can be used for improving the recruitment. Future studies need to address this gap in the literature. Finally, we feel that the problems underlying the recruitment in psychiatry perhaps also reflect the lack of parity of esteem. Unless mental health is valued equally with physical health, the misconceptions and distorted perceptions about psychiatry as a discipline in which a medical career can be fruitfully pursued will linger on and will hinder aspiring physicians from considering psychiatry as a career option.

1.6.93 Mental Capacity Act (Northern Ireland) 2016†

Abstract

Mental health legislation in Northern Ireland has always been separate from legislation in the rest of the UK; the Mental Health (Northern Ireland) Order (MHO) had been in place since 1986. In common with other jurisdictions, this legislation utilises the presence of mental disorder and risk as criteria for detention and involuntary treatment. The MHO has been replaced by the Mental Capacity Act (Northern Ireland) 2016 (MCA), an example of ‘fusion’ legislation in which impairment of decision-making capacity and best interests are the only criteria to be used when making decisions across health and social care. In this paper, we outline the development of the MCA to date, and discuss its potential to improve mental healthcare by placing the treatment of mental illness within the same legislative framework as physical illnesses.

The Mental Capacity Act (Northern Ireland) 2016 (MCA) is an example of a ‘fusion’ legislation – a generic law applicable across all medical specialties and social care where an intervention is proposed and the person has impaired decision-making capacity.

The MCA was enacted in May 2016. Since then, the Department of Health has completed phase 1 of the implementation work; creating a first working draft of a code of practice, and working on forms and draft regulations associated with the Act. This work has been shared with a ‘virtual’ MCA Reference Group, composed of a wide range of stakeholders. The first full draft of the code of practice, forms and regulations have recently been circulated to the MCA Reference Group and the second phase, a pre-consultation phase on the full draft, has just begun.

Background

The Bamford review of mental health and learning disability, established in 2002, was a wide-ranging examination of the delivery of mental health and learning disability services in Northern Ireland.

In addition to the examination of service delivery, the review also undertook a review of the mental health legislation, the Mental Health (Northern Ireland) Order (MHO), which had been on the statute books since 1986. Criteria for involuntary treatment of mental illness under the MHO were based on diagnosis and risk; the presence of mental illness or severe mental impairment, and failure to detain leading to a substantial risk of serious physical harm to self or others. In addition, certain conditions were specifically excluded – no person could be detained solely on the grounds of personality disorder, dependence on alcohol or other drugs, or sexual deviancy.

There was no specific or separate mental capacity legislation in Northern Ireland. Decisions on the treatment of incapacitous patients are taken under common law, with decisions based on a presumption of capacity and the doctrine of necessity (best interests).

The Bamford review decided that the legislation was not compliant with essential principles (autonomy, justice, benefit and least harm). In 2007, it recommended that:¹ There should be a single comprehensive legislative framework for the reform of mental health legislation and the introduction of capacity. The framework should be based on agreed principles. These principles should apply to all healthcare decisions, as well as welfare and financial needs. Impairment of decision-making capacity should be a mandatory prerequisite for any interference with a person's autonomy without their consent. Individuals who are subject to the criminal justice system should have access to assessment, treatment and care which is equivalent to that available to other people.

A public consultation was held in 2011. There was strong support for the proposal of a single legislative framework. It was therefore decided to fuse mental capacity and mental health law into a single bill. The resulting draft bill was the subject of another consultation in 2014, followed by its introduction to the Stormont Assembly. There, it underwent further consideration and amendment, and was passed as the Mental Capacity Act (Northern Ireland), receiving Royal Assent in May 2016.

Aims and principles

Fusion legislation provides equally for all circumstances in which a person's autonomy might be compromised on health grounds. It puts impaired decision-making capacity at the heart of all non-consensual interventions. By treating mental and physical illnesses equally under the law, it reduces stigma associated with separate mental health legislation, and is respectful of a person's autonomy and decision-making capacity whether they have a mental or a physical illness.

Compatibility with international statements on human rights, particularly the European Convention on Human Rights (ECHR)² and the United Nation's Convention on the Rights of Persons with Disabilities (CRPD),³ is an issue for any legislation dealing with involuntary treatment. Conventional mental health legislation, which uses a diagnostic test for involuntary treatment, could be regarded as being incompatible with Article 14 (1) (b) of the CRPD – 'the existence of a disability shall in no case justify a deprivation of liberty'. No UK mental health legislation is currently compliant with the CRPD.

Proponents of fusion legislation argue that capacity, as the test for involuntary treatment, is a functional test, i.e. a particular ability at a particular time, and therefore not directly linked to diagnosis or disability. However, the MCA retains a 'diagnostic' element; the person is unable to make a decision because of an impairment of, or a disturbance in, the functioning of the mind or brain. It therefore arguably still fails to satisfy Article 14 (1) (b) of the CRPD. Nevertheless, the MCA is fully compliant with the ECHR, and its strong rights- and principles-based ethos moves the legislation significantly towards CRPD compliance.

Content of the MCA

The MCA revokes the MHO for those aged 16 and over and puts common law into statute.

Capacity test

Statutory decision-making will come into play when a person lacks capacity. There is a presumption that the person has capacity, there must be no unjustified assumptions based on age, appearance or condition, there must be a respect for decisions even if unwise, the person must be given all practical help and support, and the act must always be in the person's best interests.

There are two tests to be satisfied in reaching a decision about a person's decision-making capacity: a diagnostic test – there must be an impairment of, or a disturbance in, the functioning of the mind or brain, and; a functional test – the person is unable to understand the information relevant to the decision, to retain the information long enough to make the decision, to appreciate the relevance of that information and use or weigh the information as part of the process of

making that decision, and communicate the decision. There must be a causal link between the two tests – the person is unable to make a decision because of impairment or disturbance in the brain or mind.

Looking at the functional test, the specific difference between this and other definitions of lack of capacity is the use of the word ‘appreciate’. The consultation document⁴ emphasises the importance of the inclusion of the appreciation element: its inclusion moves a decision about capacity from a purely cognitive test (p. 13, para. 2.22). The consultation document gives as an example: ‘A person whose insight is distorted by their illness or a person suffering from delusional thinking as a result of their illness may not, therefore, meet this element of the test’ (p. 13, para. 2.22).⁴

Protection from liability

The legislation puts into statute the common-law definition of necessity and protects the person (D) doing the act from liability if D takes reasonable steps to establish whether the person (P) lacks capacity in relation to the matter in question and D reasonably believes that it is in P’s best interests for the act to be done. There is therefore a shift in emphasis from the MHO, which confers statutory powers, to a situation where non-consensual intervention is predicated on protection from liability for D.

Future decision-making

The Act includes a robust lasting powers of attorney system. A lasting powers of attorney must be registered with the Office of Public Guardian before being activated and extends to health and welfare decisions, when the attorney reasonably believes that the person lacks capacity and must always act in the person’s best interests.

In addition, advance decisions to refuse treatment must be complied with, if valid and applicable under common law. This means that an effective advance decision to refuse treatment for a mental disorder (or indeed any disorder) cannot be overridden, if made when P had capacity. However, the Act allows that, if there is doubt, D will be protected from liability if he or she gives life-sustaining treatment or treatment required to prevent a serious deterioration in P’s condition. Advance decisions were not put into statute in order for the courts to continue to develop the law in the light of the MCA.

Safeguards

The Act provides for a proportionate increase in the number of safeguards that must be met if D is to be protected from liability as the seriousness of the interventions or acts being done to P increases. These additional safeguards must be met in addition to the general safeguards.

- For acts of restraint, D must reasonably believe that there is a risk of harm to P, and that the act of restraint is proportionate to the likelihood and seriousness of that harm.
- For serious interventions or treatment with serious consequences, there must be a formal assessment of capacity and a written statement of incapacity by a suitably qualified person, and a nominated person must be in place, who should be consulted and whose views should be taken into account. Serious interventions include, but are not limited to, serious treatment for physical illness, any intervention that causes the person serious distress or serious side-effects, affects seriously the options that will be available to P in the future or has a serious effect on his/her day-to-day life. The decision whether or not an act is a serious intervention or treatment with serious consequences rests with D. However, some acts are always serious interventions. These are: (a) deprivation of liberty, (b) attendance for certain treatments requirement and (c) community residence requirement.
- Certain serious interventions must be authorised by a trust panel. These include acts (a), (b) and (c) above, or the act is the provision of treatment with serious consequences and the nominated person objects, P resists or it is being done while the person is being deprived of their liberty.
- For attendance for certain treatment requirements, D must reasonably believe that failure to impose the requirement would be more likely than not to result in P not receiving the treatment.

- For community residence requirements, the prevention of harm condition must be met.

The trust panel will be made up of three persons with relevant expertise. The application will be made by a ‘prescribed person’ and must include a medical report and a care plan. The statutory criteria will differ depending on the measure for which authorisation is being sought.

- For treatment with serious consequences when the act amounts to a deprivation of liberty, the ‘prevention of serious harm’ condition must be met. D must reasonably believe that failure to detain P in circumstances amounting to a deprivation of liberty would create a risk of serious harm to P or serious physical harm to others, and the detention of P is a proportionate response to the likelihood of harm and the seriousness of the harm concerned.
- For attendance for certain treatment requirements, D must reasonably believe that failure to impose the requirement would be more likely than not to result in the person not receiving the treatment.
- For community residence requirements, the ‘prevention of harm’ condition must be met.
- For compulsory treatment with serious consequences against the wishes of the nominated person, the ‘prevention of serious harm’ condition must be met.

A second opinion is required when the act is the provision of electroconvulsive therapy or is a treatment with serious consequences where the question of best interests is finely balanced, or is the continuation of medication beyond 3 months (if the medication is treatment with serious consequences) when the person is an in-patient or in a care home, or is subject to requirements to attend for treatment in the community.

The Act provides for the provision of an independent mental capacity advocate (IMCA). An IMCA must be in place when the Act requires an act to be authorised or, although not requiring authorisation, is a serious compulsory intervention. The role of the IMCA is to support and represent P; the IMCA must be consulted but is not a decision maker.

Where an authorisation has been granted, an application can be made to a review tribunal in respect of the authorisation. This provides a judicial review of the decision to ensure that it has been made in accordance with the law and that the criteria for the authorisation have been met. Applications to the tribunal can be made by P and the nominated person. Cases may also be referred to the tribunal by the Department of Health, the Attorney General or the High Court. The trust must refer to tribunals when authorisation has been extended for 1 year (for those aged 16–17) or 2 years (for those aged 18 or over).

The clauses describing the additional safeguards to be put in place do not apply when the situation is an emergency. D is protected from liability if there is a reasonable belief that delay would create an unacceptable risk of harm to P. However, D is expected to take reasonable steps to ensure that the safeguard is met by the relevant time.

Children and young people

The Act cannot be applied to children under the age of 16 because it puts into statute the common law presumption of capacity. For those aged 16–17, the MCA will operate alongside the Children (Northern Ireland) Order 1995, and additional safeguards will be put in place. The original MHO will continue to be in place for the small number of under-16s who require compulsory assessment/treatment in hospital for mental disorder. This has been the subject of some controversy; if the current legislation is discriminatory and stigmatising, it is difficult to argue for its continued use in one particular group. It has been argued that a legislative framework for those under 16 must be brought forward. This will be a difficult task, not least because a capacity-based framework will have to grapple with the complex question of emerging capacity in young people. The government has indicated that their intention is that there will eventually be legislation for those under 16, but at present, this is some way off.

Criminal justice provisions

There are new disposal options following a finding of unfitness to plead or insanity, including public protection orders (PPOs) and supervision and assessment orders. There are powers to remand an accused person to hospital, to transfer prisoners to hospital for treatment, for interim detention orders and for immediate hospital direction on conviction. Although the MCA contains powers for involuntary admission to hospital in various circumstances, treatment decisions are based on capacity to consent and subject to the core provisions of the Act. This means that there are circumstances under which a person can be admitted to hospital against their capacitous wishes; however, they cannot be treated against their capacitous wishes.

New criteria form the basis for entry into the criminal justice provisions. A ‘disorder’, a ‘disorder requiring treatment’ and ‘an impairment of, or disturbance in, the functioning of the offender’s mind or brain’ replace mental illness and severe mental impairment. A disorder is broadly defined to include any disorder or disability, whether mental or physical: a disorder requires treatment if any of its symptoms or manifestations could be alleviated or prevented from worsening by treatment.

A person can be remanded to hospital if the medical report condition or the treatment condition are met. The medical report condition is that the person has or may have a disorder, that a report should be made into that person’s condition, that an assessment would be impracticable in custody, and that it would be practicable to assess the person in hospital. The treatment condition is that the person has a disorder requiring treatment, that failure to provide in-patient treatment would ‘more likely than not’ result in serious physical or psychological harm to the accused person or serious physical harm to others, and that remanding the person to hospital would be likely to result in significantly better clinical outcomes.

PPOs replace hospital orders. A PPO can be made when detention conditions are met. These are that: ‘there is an impairment of, or a disturbance in, the offender’s mind or brain’, that ‘appropriate care and treatment is available’, that dealing with the person without detention ‘would create a risk, linked to the impairment or disturbance, of serious physical or psychological harm to others’ and that depriving the person of their liberty would be a proportionate response to the likelihood and seriousness of that harm. Restrictions may be added where the restriction conditions are met.

A prisoner can be transferred to hospital where they have a disorder requiring treatment, failure to provide treatment would be ‘more likely than not’ to result in serious harm to the person or serious physical harm to others, and appropriate treatment is available.

Patients admitted to hospital under the MCA criminal justice provisions will remain there following tribunal only if the ‘prevention of serious harm’ condition is met. The criteria for the ‘prevention of serious harm’ condition differ for those subject to PPO and for transferred prisoners or those subject to hospital direction. The criteria for those subject to PPO are: the person has ‘an impairment of, or a disturbance in, the functioning of the mind or brain’; releasing the person would create a risk of serious harm to others; and depriving the person of their liberty is proportionate to the likelihood and seriousness of the risk.

The criteria for transferred prisoners or those subject to hospital direction are: the person has the disorder for which they were transferred; effective treatment can be given; and it is ‘more likely than not’ that discharging the person to prison would result in serious harm to the person or serious physical harm to others.

Discussion

The MCA is unique in that it repeals separate mental health legislation, replacing it with a single piece of legislation applicable across all medical specialisms and social care, whereby involuntary treatment is only permitted when the person (a) has impairment of decision-making capacity and (b) the intervention proposed is in the person’s best interests.

The arguments for and against replacing conventional mental health legislation with a law based on capacity have been well rehearsed in a recent debate.⁵

The removal of mental health legislation that makes decisions about involuntary treatment based on diagnosis and risk will require a significant change in practice for professionals working in mental health in Northern Ireland. It is some-

what ironic that such a radical piece of legislation, based on non-discrimination, is being introduced in a jurisdiction that spends the lowest proportion of its health budget on mental health of any UK nation.⁶

The Act must work across a wide and diverse range of settings – care homes, mental health services (both in-patient and community) and general hospitals. It will affect staff who have little previous knowledge or experience of the principles behind capacity assessment. It is therefore imperative that a comprehensive training and supervision programme is put in place, which will have considerable resource implications.

The inclusion of the ‘appreciation’ element introduces a difference in the definition of capacity in the MCA compared with that used in other jurisdictions. The addition of the ‘appreciation’ element moves the definition of capacity away from purely cognitive terms towards the concept of capacity being affected by factors such as emotional colouring, delusions and lack of insight.⁷ Because of this difference, it cannot be assumed that studies that have demonstrated the reliability of capacity assessments⁸ will automatically apply in the case of the MCA. The reliability of the use of capacity assessments using this definition of capacity in routine clinical mental health practice requires to be evaluated.

The shift away from compulsory intervention based on in-patient treatment when a particular threshold of risk is reached may facilitate earlier intervention and allow for a proportionate response across a wide range of treatment and care settings. On the other hand, there is a more widely expressed concern that capacity legislation may delay appropriate treatment.

Trust panels can authorise a very wide range of interventions. As health and social care professionals work under the principle of beneficence, there is a risk of ‘slippage’, with staff making decisions about impaired capacity based on a person making foolish or unwise choices. This could lead to the unintended consequence of the Act leading to a greater rather than a lesser restriction of a person’s autonomy and self-determination.

There is a plethora of issues that could potentially affect clinical practice; for example, exactly what constitutes serious interventions, how to manage fluctuating capacity, the question of decision-making capacity in patients with personality disorder, patients who retain capacity but present a risk to self or others, and the potential conflict between human rights (especially the right to life) and autonomy. Some of these issues may be addressed by the code of practice, others may be left to clinicians or courts.

Conclusions

Fusion legislation (of which the MCA is an example) is a radical change in the approach to involuntary psychiatric treatment. It is an exciting and innovative development and there are substantial potential benefits, including the reduction of stigma, the protection of patient autonomy, and the removal of confusing parallel mental health and mental capacity legislation. It is also more compliant with CRPD and ECHR. Much of the practical impact of the MCA depends on the development of a comprehensive code of practice and the provision of a comprehensive training and supervision programme. In addition, as Szmulker & Kelly have pointed out,⁵ the gathering of data on its implementation is vital and the MCA must be subject to a rigorous and comprehensive evaluation.

1.6.94 Measuring relational security in forensic mental health services

2017-12

Abstract

Aims and method Relational security is an important component of care and risk assessment in mental health services, but the utility of available measures remains under-researched. This study analysed the psychometric properties of two relational security tools, the See Think Act (STA) scale and the Relational Security Explorer (RSE).

Results The STA scale had good internal consistency and could highlight differences between occupational groups, whereas the RSE did not perform well as a psychometric measure.

Clinical implications The measures provide unique and complimentary perspectives on the quality of relational security within secure services, but have some limitations. Use of the RSE should be restricted to its intended purpose; to guide team discussions about relational security, and services should refrain from collecting and aggregating this data. Until further research validates their use, relational security measurement should be multidimensional and form part of a wider process of service quality assessment.

 - * *Conclusions*

Serious incident investigations in forensic mental health services have been linked to relational security breakdowns.¹ However, relational security has been described as the ‘poor relation’² when compared with physical or procedural security. This is most likely due to definition difficulties. Chester & Morgan³ noted that numerous conceptualisations of relational security exist, all referencing different phenomena, such as ‘therapeutic relationships’ and ‘boundaries’, without describing how such concepts can affect security.³ The authors noted that the most practically useful definitions

Articles published from BJPsych Bulletin are open-access, published under the terms of creative commons Attribution licence (<http://creativecommons.org/licenses/by/4.0/>), which permits unrestricted re-use, distribution, and reproduction in any medium, provided the original work is properly cited.

The Authors own the copyrights to the individual articles.

emphasise exactly how relational issues affect security, in two stages: (1) staff knowledge of patients and therapeutic relationships; and (2) how patient knowledge and therapeutic relationships are used to foresee potential and manage actual security incidents, for example: ‘The professional relationships between staff and patients so that ... the staff to get to know ... their patients, their moods and problems, to facilitate interventions before these become major problems, or lead to incidents of a security nature’ (p. 171).⁴ As such, relational security is intrinsically linked to short- and long-term assessment and management of risk in mental health and forensic services.

Relational security is therefore a service quality indicator of interest within forensic and general mental health services. Its measurement should allow practitioners to explore background causes and respond accordingly with appropriate interventions. Due to the definitional complexities, there are subsequent challenges to measurement. Previously available tools only measure partial aspects of relational security or individual patient needs.³ However, two tools have been developed in recent years, the Relational Security Explorer⁵ and the See Think Act scale.² As limited research has examined the clinical utility of these measures, the present study examines their psychometric properties to support the aim of relational security measurement.

Method

Design

The study employed a within-participants (reliability testing) and between-participants (assessing the measures’ ability to identify differences between occupational groups according to the variables level of security, ward gender and length of experience working in secure services) cross-sectional questionnaire design.

Participants

Participants were recruited from a forensic service for people with intellectual disability. As guidance recommends that relational security implementation should involve all occupational groups working within secure services,⁶ the study invited all staff who have contact with patients as part of their role to take part in the study ($n = 216$), and of these 41% ($n = 89$) responded. The majority of the participants were female (63%), and the average length of service working in secure services was 6 years (range 0.12–20). The majority of participants were from the nursing department (57%), followed by occupational therapy (16%), psychology (9%), social work (6%), psychiatry (2%) and housekeeping (8%), and two participants identified their occupation as ‘other’. The level of security in which respondents worked in at the time of the study was medium (23.6%), low (27%) and locked rehabilitation (16.9%). There are no national data available which describe the demographics of the forensic mental health workforce, although the reported characteristics reflected the socio-demographic and occupational breakdown of the study service and the broader mental health workforce as a whole,⁷ being predominantly female and with nursing staff comprising the largest department followed by other members of the multidisciplinary team. As participants responded anonymously, it was not possible to undertake any analyses comparing participants with non-responders.

Measures

See Think Act (STA) scale²

The STA scale is the first attempt to create a direct measure of relational security. The 28 items were developed from the Department of Health conceptualisation of relational security,⁶ and reflect relational security scenarios (e.g. ‘We speak up if we think we can see that a colleague has been put in a difficult position that could weaken security’). Individual staff members complete the questionnaire in relation to the ward they work on, and select how closely their ward team resembles provided statements on a 4-point Likert scale, with scores of 3 ‘Just like our team’, 2 ‘Quite like our team’, 1 ‘A little like our team’ and 0 ‘Not like our team’. A principal components analysis confirmed a four-component structure of the measure: Therapeutic Risk Management, Pro-Social Team Culture, Boundaries and Patient

Focus.² Initial examinations indicated good convergent validity with related measures (e.g. EssenCES⁸), and internally consistent subscales.² There is currently no normative data available for the STA scale.

The Relational Security Explorer (RSE)⁵

The RSE is a tool designed to help clinical teams working within secure settings to communicate and assess their competence in relational security. The tool requires users to provide a numerical score of their team's confidence in eight areas of relational security: Therapy, Boundaries, Patient Mix, Patient Dynamic, Personal World, Physical Environment, Visitors and Outward Connections on a scale ranging from 1 (no confidence) to 10 (extremely confident). The RSE was not developed as a psychometric measure; however, the tool requests clinical teams to provide a numerical score of their confidence in each of the eight areas. In doing so, the tool lends itself for use as an outcomes measure and, anecdotally, the authors are aware of service's collecting and analysing this data, despite it not being validated for this purpose. This is in line with the suggestion that when numerical indices and cut-off points are available, clinical decisions tend to be reduced to those numbers.⁹ Participants were asked to complete the RSE on an individual, rather than a team basis, to investigate the tool performance as an outcomes measure.

Procedure

The researcher arranged one-to-one meetings with staff eligible for the research, at which informed consent was sought. Once obtained, staff members were asked to complete and return the questionnaires. A debrief form was provided for participants, which detailed further information about the study.

Ethics

Ethical approval was obtained from the London Metropolitan University Research Ethics Review Panel. The National Research Ethics Service Committee for the East of England – Norfolk was also approached for ethical review of the project, who advised that as the relational security measures were being used in routine clinical practice within the study service, the study does not require National Health Service ethical approval.^{10,11}

Data analysis

Prior to analysis, assumption testing for parametric tests was completed. The assumption of homogeneity of variance was violated, and the data were negatively skewed, violating the assumption of normal distribution. Transformations of the data were attempted, but this did not reduce the skew. A number of cases appeared as outliers for all outcome variables, and notably, these cases were all from the housekeeping department. Data were therefore examined using non-parametric methods. This point was discussed with our statistician, who assured us that the loss of power associated with the non-parametric tests was small.

Therefore, internal consistency was examined using Spearman's Rho correlation to calculate the Corrected Item-Total Correlation (CITC) coefficient values for subscales of the STA and the RSE. Convergent validity was analysed by correlating subscales of the STA scale and the RSE using Spearman's Rho. The Sidak adjustment was used to adjust for multiple comparisons.

Non-parametric statistical tests were used to examine the association between scores on the STA and the RSE, and the variables requested in the demographic questionnaire (length of experience working in secure services, the ward and level of security worked on, the gender of the patients on their ward, and staff department/occupational discipline). Analysis between individual wards and staff occupational discipline could not be completed due to small and unequal numbers between the groups. To examine the association between level of security and the subscales of the two measures, the Kruskal-Wallis test was used. The Wilcoxon Mann-Whitney *U*-test was used to examine the association between gender of patients and the subscales. To examine the association between length of experience working in secure services and the subscales, Spearman's Rho correlation was used.

Results

Internal consistency

Internal consistency was assessed using CITC coefficients. A CITC value above 0.5 is considered high, but if less than 0.3, items within a subscale may be measuring more than one construct. All RSE subscales exceeded the CITC 0.30 cut-off, although there was some variation, with the Personal World subscale having the highest internal consistency at 0.80, and the Physical Environment subscale the lowest at 0.49. All the STA subscales had CITC scores over 0.9. *Table 1* displays the CITC coefficient values for each subscale of the two measures.

Corrected Item-Total Correlation (CITC)

Pro-Social Team Culture	0.96
Boundaries	0.92
Patient Focus	0.92

Convergent validity between measures

There was little convergent validity between the subscales of the two measures. All four subscales of the STA scale correlated significantly with each other, whereas subscales of the RSE did not. The Spearman's Rho values are detailed in *Table 2*.

Between-groups analysis

Level of security

Significant differences in scores on the two measures were found between staff working in different levels of security. Staff working on medium secure wards tended to have the lowest scores on both measures, followed by staff on low secure wards, with the highest scores on rehabilitation wards. On the STA scale, this reached statistical significance on the Therapeutic Risk Management ($P < 0.001$), Boundaries ($P = 0.012$) and Patient Focus ($P = 0.034$) subscales. There were also significant differences on the RSE, on the Patient Mix ($P < 0.001$), Patient Dynamic ($P = 0.008$) and Personal World ($P = 0.011$) subscales. Descriptive data for this variable are presented in *Table 3*.

Descriptive statistics for level of security on the See Think Act scale and Relational Security Explorer

Outward Connections	7.23 (1.36)	7.17 (1.74)	8.07 (1.59)

The scale for the See Think Act scale is 0–3.

The scale for the Relational Security Explorer is 1–9.

Ward gender

There were no differences in STA scale scores between staff working on wards caring for male patients, as compared to female patients. However, on the RSE, staff working with male patients reported higher scores on the Patient Dynamic ($P = 0.024$) subscale, compared with staff working with female patients.

Length of experience working in secure services

There was no correlation between the number of years staff had been working in secure services, and their confidence in relational security, on the STA scale or the RSE.

Discussion

Serious incidents within forensic mental health services can be linked to breakdowns of relational security.¹ Available measures should therefore provide insight into the quality of relational security within services, direct exploration of strengths and weaknesses, and prompt timely, appropriate interventions before an incident occurs. Furthermore, tools should be accessible to all occupation groups.⁶ This study therefore evaluated the psychometric properties of the STA and the RSE, including internal consistency, convergent validity and their ability to highlight differences between groups.

Study limitations include a relatively small sample size, and participants being drawn from a single service, which limit generalisability. It is categorised as a preliminary study for these reasons. However, the study reports interesting findings in relation to the specific tools examined and the wider task of measuring relational security by investigating the perspectives of staff members across occupational professions and levels of security. The study setting, a secure intellectual disability service, may be viewed as a strength, as previous studies have been completed only within generic forensic psychiatric services, and as a weakness, due to the extent of the study findings generalising to non-intellectual disability services. Research comparing patient characteristics between mainstream forensic and specialist intellectual disability services is scarce, however there are a number of notable differences between the two populations which may have an effect on relational security. These include communication difficulties which could affect the development of therapeutic relationships, increased levels of behavioural incidents,¹² and higher assessed risk on structured clinical judgement tools.^{13–15} That said, the present research reports many findings which echo those of previous research.²

Test–re-test reliability was not examined in the present research, although it may be an interesting area for further study. At present, the stability of relational security levels are unclear, and it may not be realistic or relevant to expect stability over time, as relational security is a fundamentally a dynamic concept.

The internal consistency aspect of reliability was examined, with the STA scale demonstrating high levels in accordance with previous research.² Its subscales correlated significantly, suggesting they are statistically related concepts. Internal consistency for the RSE was adequate but its subscales did not all correlate significantly, possibly indicating that some of the concepts measured are statistically unrelated. Although the RSE and the STA both aim to measure relational security, convergent validity was low. Collectively, these findings suggest that the RSE does not perform as well as the STA as a psychometric outcome measure. This raises questions regarding the practice of collecting and analysing data from the RSE, despite not being validated for this purpose. Lodewijks *et al*⁹ explicitly advise against the use of numerical indices and cut-off points, due to clinicians' tendency to reduce clinical decisions to numbers if they are available.

Particular subscales of the two measures were able to detect differences between groups in relational security confidence, thus facilitating the comparison of wards and staff disciplines within a service, potentially between services comparisons, and directing intervention as necessary. Significant findings were reported between wards of different levels of security, with relational security confidence lowest on medium secure wards, increasing on low secure wards, and highest on rehabilitation wards. Tighe & Gudjonsson² also reported this effect, as well as authors investigating social climate in secure settings.^{16,17} A possible explanation for this is that medium secure wards represent the beginning of the care pathway accepting newly admitted patients and, as such, staff have had less opportunity to develop the knowledge of patients and therapeutic relationships necessary to achieve good relational security. As patients progress

through the low secure and rehabilitation stages of the care pathway, this provides an opportunity for the components necessary to relational security to develop.

The study also compared relational security confidence between staff working with male and female patients. This was examined as authors have documented difficulties in building therapeutic relationships with women, due to their clinical complexity.^{18,19} However, there were few differences between these two groups on the subscales of the two measures, although staff working with male patients reported higher scores on the Patient Dynamic ($P = 0.024$) subscale of the RSE.⁵

It was expected that staff with more experience working within secure services would be more confident in their judgements of relational security, but there were no significant associations. However, relational security relies on knowledge of patients and therapeutic relationships, within a dynamic environment. For example, if a new patient is admitted to a ward, all staff, regardless of experience will begin to develop their knowledge and their therapeutic relationships with this patient at the same time. Furthermore, if an experienced staff member is asked to move onto a different ward, they will know little about the patients on that ward and have to develop new knowledge and therapeutic relationships. In this sense, all staff members, regardless of experience, are repeatedly beginning and developing their knowledge of individual patients and new therapeutic relationships.

Housekeeping staff felt less confident in relational security, as compared to all other departments. This is probably due to the measures tapping into areas of clinical practice that housekeeping staff would not be involved in, and the comparable lack of training offered to this group. However, guidance recommends that relational security implementation should involve all occupational groups working within secure services.⁶ As housekeeping staff are a daily presence on forensic wards, they are equally as vulnerable to relational security issues and in a position to witness threats to security. Further research should investigate ways to support all occupational groups with relational security.

Measuring relational security: further considerations

Some points are of note when interpreting data obtained from relational security measures. Initial assumption testing indicated negatively skewed data, suggesting that most participants rated their confidence in relational security at the top end of each measures' respective scale. This could indicate that staff working in this particular service are highly confident in their relational security practice. However, it is unclear how confidence scores relate to the actual quality of relational security within a ward, for example is a highly confident team an experienced team or a complacent team? It could also indicate positive responding, as essentially, measures are asking individuals to rate themselves in an aspect of their role in which they are expected to be competent. Introducing some negatively worded items could improve this.

High scoring may also be due to the way the two tools conceptualise relational security. Both measures are based on the STA conceptualisation of relational security,⁶ which places much of the responsibility onto staff and teams, thus neglecting the 'quantitative' aspects of relational security, for example 'staff-to-patient ratio and amount of time spent in face-to-face contact' (p. 434)²⁰ and the supportive role and responsibility of service management. For example, to achieve quality therapeutic relationships with patients, ward staff and teams need to be stable, with minimum staff ward moves, turnover and absenteeism,³ factors outside of staff members' control. Incorporating items reflecting such aspects of relational security could provide a more comprehensive picture.

Normative data are not currently available for either of the two measures, which limits the interpretability of the results. Both measures are designed to be used by staff members in relation to one specific ward. However, many employees work across multiple wards in secure services, with 27% respondents in this sample working across wards. These participants were typically from occupational departments other than nursing, such as psychology, psychiatry, social work and occupational therapy.

Conclusions

The increased attention relational security is receiving within the forensic field is a welcome advance. There is growing awareness around the importance of this concept, and resources aiming to raise awareness and support the implementation of relational security are widely available.²¹ However, until recently there have been few mechanisms to assess the quality of relational security within services. The results of this study suggest that the STA scale and the RSE hold unique and complimentary roles attempting to support relational security. The RSE did not perform well as a psychometric measure, and therefore its use should be limited to its intended purpose – as a tool to guide team discussions about relational security – and services should refrain from using the RSE as an outcomes measure. However, deciding on a numerical score of relational security confidence may serve a function within the context of a team discussion, for example, if one team member feels the ward should score highly, whereas another member feels the ward should be given a lower score, this could suggest team splitting and form a basis for discussion. At present, the STA scale is best placed to provide insight into the quality of their relational security, while taking into account the aforementioned issues when interpreting the data.

Further research is needed in all areas of relational security: definition, implementation and measurement. This research should examine the relationship between relational security and negative outcomes, such as institutional aggression or serious incidents. Future studies should evaluate the clinical utility of the RSE, examine the psychometric properties and provide normative data for the STA. Until more is known about relational security, the approach to implementing and measuring it should be multidimensional,²² i.e. incorporating staff, patient and service management perspectives.

- *Profile. The constant psychiatrist: an interview with Michael Kopelman*

From his journal-lined office in St Thomas' Hospital Professor Michael Kopelman could quietly yet assiduously observe the powerful in their Palace of Westminster just across the Thames. Following retirement in 2015 he has become ever more alarmed by the spectacle: “Our society, in my view, is becoming more and more authoritarian. It's very worrying the direction we are moving in. Even within our university system and the NHS things have become much less democratic than they used to be, and much more authoritarian. It's both sad and frightening.” A perpetually crumpled mac under his arm, the Professor appears much like an MI6 officer in a le Carré novel grown disillusioned with the culture of edicts, diktats and target-driven performance for the workers while those in positions of power sit removed and aloof.

‘Now it’s really the chief executive and his executive team who run things. With no disrespect to any particular individual, some of whom are very good, I can’t see that they have proper accountability. We doctors have accountability. We can be hauled before the GMC. But managers and commissioners, who are changing the healthcare environment, often for the worse, are not held to account in the same way.’

The Professor’s comportment is at one with his assertion, ‘These are matters I feel strongly about.’

Indeed. For just as the anti-heroes in le Carré’s novels battle with the bureaucracies in which they work, Professor Kopelman is exasperated by perceived wisdom, particularly with regard to a matter close to his professional heart, the modern memory clinic. ‘The memory clinics that are being set up under the Dementia Strategy are not what I would advocate.’ A Fellow of the Academy of Medical Sciences and founding member of the Memory Disorders Research Society, Professor Kopelman appreciates the diversity of problems that have an impact on cognition.

‘There is a wide range of memory disorders to be diagnosed, and the early diagnosis of dementia, even by the very experienced, is difficult. There are very sad implications if you get it wrong. The earlier we go for diagnosis the more likely we are to get it wrong, whatever the clinical/genetic/biomarker tools that we have.’

Criticising the consensus again, he says: “‘I think, and I’m not popular for saying this, that nurse-led diagnostic teams making early diagnosis is not the direction to go in. The direction to go is better care for those with established diagnoses of dementia. What we have at present is shameful, and in my view it’s actually now worse than in the 1980s.’” Professor Michael Kopelman. It is perhaps this disillusionment that partly drives his medico-legal work, in which he is fearless in tackling injustice head-on. On many occasions he has been involved in headline-grabbing courtroom dramas that could themselves be the stuff of fiction. Interestingly, he highlights a radical human rights lawyer as the anti-establishment role model for his own legal work.

‘Gareth Peirce is superb at using the legal rules to beat authoritarians and government. She plays within the system, but she does it better than the government lawyers and beats them. That fits my temperament. Not shouting or protesting on the streets, but playing the system to get justice for people.’

Clashes with the establishment have seen Professor Kopelman fight for the falsely convicted and for Guantánamo detainees. He said: “‘I got into false confession cases, which I see as a form of memory disorder, and was involved in overturning convictions; one from 50 years ago, another after 25 years, and a delusional memory case at 26 years.’” He added: “‘Then with two others – a therapist and a GP – I wrote a report in 2010 on people who had come back from Guantánamo, including some prominent names, and this resulted in them getting substantial amounts of compensation. Ken Clarke announcing this in Parliament made the somewhat ambiguous statement, “We must never let this happen again.” I feel in some ways I have done more good from this sort of work than anything else, and that’s what I’m going to do in my retirement.’” His colleagues obviously agree as Professor Kopelman has previously been elected to serve as president of the British Academy of Forensic Sciences.

This ability to perform scalpel-sharp analyses of intricate legal cases and their relation to esoteric psycho-pathology originates in his wide-ranging reading list at medical school and a first degree in psychology. ‘I had gone into psychology and enjoyed it, and before that – oh I hate to say the cliché – I was interested in people, and enjoyed literature from the psychological angle. So this is what I was curious about.’ Upon gaining a place studying medicine at Middlesex University, he was not your typical medical student: ‘I read Luria quite early on, when I should have been reading anatomy textbooks!’

Paradoxically, a contemporary model of memory claims that it evolved to enable planning for the future, or mental time travel.¹ Professor Kopelman’s forays into the science of memory were thus doubly prescient: “‘I’d been interested in the neuropsychology of memory, which was just developing at the end of the 60s and 70s. I was reading quite a lot of the amnesia stuff at an early stage and I was interested in the more biological aspects of psychology. I knew I would either do neurology with an interest in cognitive neurology or psychiatry with an interest in neuropsychiatry, and I’ve ended up in the middle discipline.’” That’s rather too modestly put given that Professor Kopelman actually ended up as president of both the British Neuropsychological Society and the International Neuropsychiatric Association, and is currently Presiding President of the International Neuropsychological Society.

The influence of psychology so early in his academic career may well contribute to his continued aversion to reductive thinking about mental disorder: ‘I get a bit anxious about what I call naive reductionism, the kind of approach that

thinks that all PTSD and depression are just disorders of the hippocampi or the frontal lobes or whatever. I think that is very simplistic.’ Adding, ‘We have to remember the brain is operating within a social context and not to underplay the importance of our social context.’ It is to his own social context that his mind now turns. Between confrontations with government barristers and completing research programmes at St Thomas’, where he can still be found a few days of the week, Professor Kopelman divides his time between a beautiful 18th-century home in Surrey and a cottage in Norfolk. It is apparent that similarities to le Carré’s heroes don’t just end with the raincoat.

1.6.96 Handbook of Secure Care

Lindsay Thomson¹

date

2017-12

Contents

- *Handbook of Secure Care*

The *Handbook of Secure Care* is a useful book for those new to the field of forensic mental health and is most relevant to those practising in England and Wales. It examines the relationship between mental disorder and offending, with individual chapters on personality disorder, intellectual disability, autism spectrum disorder and acquired brain injury. Strangely, there is little on psychosis which is the fundamental diagnosis within secure care.

The work considers the needs of specific populations such as women, young and older people, and outlines the provision of secure psychiatric services for these groups. It focuses on the basic components of secure care and includes information on risk assessment and management, and on recovery. The latter chapter is of particular use in defining the challenges we face in secure care and ways to redefine our conventional thinking. The fundamentals of psychological treatment in secure care are clearly set out and there is a helpful description of the role of nursing within that setting.

There is discussion in the first chapter on the evolution of secure and forensic mental healthcare, as well as information on the number of secure beds, but I would have welcomed an analysis of the overall estate, the needs for planning and the methods of provision. Similarly, details on pathways into or out of secure care, or on the legislation that allows us to detain people within these settings would have been valuable.

Notably, there is a good chapter by Penny & Exworthy on human rights in secure psychiatric care – the Human Rights Act 1998 underpins much of what we do in secure care, making this especially relevant. It is followed by a chapter on quality assurance and clinical audit. It is my view that the human rights considerations and the quality improvement agenda are so crucial to our work that it would have been beneficial to place these chapters near the beginning of the book to emphasise their importance.

1.7.1 The access and waiting-time standard for first-episode psychosis: an opportunity for identification and treatment of psychosis risk states?

Richard Whale Andrew Thompson Rick Fraser

Correspondence

Richard Whale

(richard.whale@brighton.ac.uk)¹

date

2017-2

Abstract

Expansion of early intervention services to identify and clinically manage at-risk mental state for psychosis has been recently commissioned by NHS England. Although this is a welcome development for preventive psychiatry, further clarity is required on thresholds for definition of such risk states and their ability to predict subsequent outcomes. Intervention studies for these risk states have demonstrated that a variety of interventions, including those with fewer adverse effects than antipsychotic medication, may potentially be effective but they should be interpreted with caution.

Contents

- *The access and waiting-time standard for first-episode psychosis: an opportunity for identification and treatment of psychosis risk states?*

With the advent of the new access and waiting-time standard for first-episode psychosis published by NHS England in February 2015,¹ there is now a definite move to adopt service models aimed at preventing transition to psychosis in vulnerable individuals, as originally developed in 1994 by the Personal Assistance and Crisis Evaluation clinic in Melbourne.² There is an expectation that early intervention in psychosis services will now also offer interventions for at-risk mental state for psychosis (ARMS), based on our evolving understanding of best practice in this area.

This move is exciting for a number of reasons. It represents a commitment from the Government to support mental health service development and reform, especially preventive approaches, at a time when many services are experiencing cuts. Cost-effectiveness of ARMS services has been demonstrated.³ Second, as a treatment paradigm the preventive strategy represents a possibility that we can alter the trajectory of a potentially serious condition and improve outcomes in all domains, including symptoms and functioning. Third, we may be able to use, at an earlier stage of illness, more benign treatments that are potentially less costly, less stigmatising and better tolerated.² This preventive model also represents an opportunity to broaden treatment paradigms within mental health, not just for psychosis but for other disorders, fitting perfectly with another current health development strategy – low-stigma, accessible and responsive youth mental health services. Debate continues as to whether such services are appropriately placed within established early intervention for psychosis or whether new, dedicated teams with a more public health emphasis should be created. However, existing services have expertise in both defining first-episode psychosis thresholds and offering relevant clinical support packages for both ARMS and first-episode psychosis.⁴

The criteria commonly used in the UK for ARMS depend on the presenting clinical features, relative functional impairment and help-seeking.² Consistent quantification of distress relating to these features is currently lacking. It also remains unclear how these clinical risk features differ from more widespread psychotic phenomena in the general population. Psychotic experiences in non-help-seeking populations appear relatively common, affecting about 5%,⁵ and higher in child and adolescent samples;⁶ there is apparent sharing of aetiological risk factors with schizophrenia. Clinical outcomes of this non-help-seeking group are unknown. Psychosis transition threshold is commonly defined by three Positive and Negative Syndrome Scale items (delusions, hallucinations or conceptual disorganisation) achieving adequate severity for at least 7 days,⁷ but such psychosis thresholds are not without controversy.⁸ The large majority of those identified as ARMS do not cross this severity threshold within 3 years of follow-up, although many remain functionally impaired or develop other disorders.² Whether other transition criteria, or modifications of existing criteria, are better able to predict longer-term outcome remains to be established. The reliability of identifying such thresholds in clinical practice is also less than in research settings,⁹ despite using widely available tools.² This is further complicated by concurrent substance misuse, common in such clinical populations. However, the definition and adoption of such thresholds is clearly necessary to educate clinicians, decide when to appropriately intervene and support research. The complexity of the psychosis sub-syndrome groups (including individuals with a family history of psychotic illness, those with schizotypal disorder or the attenuated psychosis syndrome, those with brief limited intermittent notable severity psychotic episodes and those help-seeking or not) and their undetermined probable outcomes may lead to services primarily adopting a more discrete threshold for inception, such as the DSM-5 research-appendix-defined attenuated psychosis syndrome, which has marked clinical overlap with ARMS-defined populations.⁹

Without clear diagnostic robustness of a condition, and with a wide variation in clinical outcome, interpretation of intervention studies is problematic. Initially, randomised studies of diverse interventions for operationally defined ARMS (termed ultra high risk for psychosis) seemed to show similar beneficial effects *v.* control. Reviews pooling outcomes of these studies clearly advocated intervention.^{7,10} More recent randomised studies have demonstrated less clear benefits over control than earlier studies, as is often seen in health research (arguably ‘active’ controls were used in many of these studies). Primary intervention recommendations of supportive counselling/case management for this clinical group have emerged, as previously used as a control intervention. Several factors will need to be considered, with future investigations including previous low sample size due to recruitment problems, use of robust and consistent thresholds for group inclusion, and transition to psychosis to reduce heterogeneity of outcome, consistent inclusion of functional outcomes, translation of findings to usual clinical care (away from research clinics), ensuring timely publication of results and the importance of replication of existing findings.

While considerable progress has been made in this area, we remain at the early stages of defining a risk syndrome for psychosis. The currently adopted clinical threshold for ARMS seems to be a valid construct to identify clinical need but the heterogeneity of subsequent clinical outcomes is wide. Specific interventions for ARMS are unclear, aside from those for commonly identified comorbidities (such as anxiety, depression and substance misuse). Intervention studies to date highlight the importance of methodological rigour and consistency of diagnostic thresholds used, to which end the DSM-5 attenuated psychosis syndrome may be a positive step.⁹ Biological models for psychosis risk need replication, clinical validation and combining with clinical markers in larger, longitudinal studies to enhance risk determination.^{2,11,12}

Despite these caveats, this field of study represents an important advance in the development of preventive psychiatry. The current move to incorporate earlier psychosis states in more widespread clinical services, with appropriate threshold

definition and outcome monitoring, may also have important societal impact.

1.7.2 Plans, hopes and ideas for mental health

John R. Ashton Correspondence c/o BJPsych Bulletin (pb@repsych.ac.uk)

date

2017-2

Abstract

Mental health and the failings of the mental health services are in the spotlight as never before. Nowhere is this more apparent than in the often dire situation with regard to child and adolescent mental health. At the same time, there is a renewed interest in the scope for prevention of mental illness and distress, and in population approaches to mental well-being. It may come as a surprise to some that others have given such serious consideration to strategic approaches to public mental health as long ago as the 1950s. It appears that such consideration was squeezed out by the dominant concerns of serious and enduring mental illness and a prevailing biological view of psychiatry. The time is right to engage with this agenda in recognition of the importance of public mental health, not only for the individual and for families, but also for society as a whole and for the economy. The publication of a review of the subject by the Faculty of Public Health and the Mental Health Foundation is to be commended. Let us make sure it leads to action.

Contents

- *Plans, hopes and ideas for mental health*

The recent announcement by UK Prime Minister David Cameron of a new initiative for mental health, with a particular emphasis on parenting classes, ¹ is most welcome. It comes at the end of a year in which there has been an increasing concern for the state of the nation's mental health, with a flurry of documents and reports, a campaign led by *The Times* newspaper ² and an increasing demand for parity of resourcing between mental and physical health. Interestingly, some of the pressure to do something specifically about child and adolescent mental health is coming from the independent schools sector. The schools have been expressing increasing concern about the mental well-being of the young people in their care, faced by an apparently steady increase in the incidence of distress manifested by levels of general anxiety and depression, and specifically the levels of eating disorder, self-harm and other behavioural manifestations. Not for the first time in public health, something that has long been a problem for the most disadvantaged in society is being taken seriously once it becomes an issue for the privileged. Nor should we ignore the opportunity presented for progress by the mobilisation of enlightened self-interest by those in positions of power and influence. After all, in Victorian times, the fact that cholera knew no social boundaries led to sanitary reform which was of benefit to rich and poor alike. More recently, once it became apparent that HIV/AIDS was not only a disease of stigmatised minorities, the research dollars rolled in.

As a public health physician who began his career as a psychiatrist and family doctor and is finishing as President of the UK's Faculty of Public Health, I find particular poignancy in returning to the theme of public mental health for my swansong year, a theme which I have chosen for the Faculty to focus on in 2015–2016. I appreciate and welcome this

¹

Professor John R. Ashton CBE, President of The UK's Faculty of Public Health, London, UK.

opportunity to share some thoughts with clinical colleagues in psychiatry based on 40 years of trying to make sense of some of the questions raised within a public health paradigm.

My journey from psychiatric registrar in Newcastle in the 1970s offers some perspective. As a student I was one of those medics whose interests spanned the humanities as well as the sciences. History and politics were always as interesting to me as biology, and when I came across the prospectus for the public health masters course at the London School of Hygiene & Tropical Medicine sometime in third year, it was clear to me that sooner or later I would be signing up. For the next 10 years I would religiously send for the latest edition. Fortunately, my interest was nurtured and kept alive by the remarkable social orientation of the Newcastle course, not just in family and community medicine but also in such mainstream clinical areas as paediatrics, psychiatry and obstetrics. The school was imbued with the spirit not just of the pioneering, community-oriented paediatrician Sir James Spence, but also that of Aberdonian obstetrician Dugald Baird through his Newcastle disciples. The strong social and community base was reinforced by a series of Deans of Medicine, who, while hard-nosed neurologists and endocrinologists themselves, supported the work of those such as Donald Irvine, who was centrally involved in establishing the country's first general practice training programme and later oversaw the General Medical Council. When I signed up for the psychiatric training rotation under the formidable Sir Martin Roth, amazingly comprehensive and intellectually stimulating as it turned out to be with placements in all aspects of mental health services, I found myself frustrated at the failure of those services to focus upstream to prevention and the promotion of mental health.

While as a registrar in the heady years of the challenges posed to orthodox practice by the likes of R.D. Laing and Thomas Szasz, I was exposed to the whole spectrum of ideas, from Freud and Jung to Kraepelin, Sargent and Eliot Slater. Although we had opportunities to cut our teeth on individual, group and marital therapy, the broader public health agenda remained elusive. I came to the conclusion that what was on offer was all too little and too late, and as soon as I had finished my training I moved into general practice in the hope of finding more fertile soil for prevention.

My next move took me to Southampton, where the pioneering dean of the new medical school, Donald Acheson, had created an exciting opportunity which seemed tailor-made for somebody like myself. In a university-run health centre in the local community, based on lines recommended by the celebrated Birmingham professor of public health Thomas McKeown, there were to be specialoid general practitioners – GP paediatricians, GP mediatrians (caring for grown-ups), GP geriatrians and a GP psychiatrist (me). Part of the time we would teach medical students, and the remainder was spent providing a combination of general practice, including out-of-hours services, and specialist expertise to the practice patients as well as supporting each other. As far as possible, we would look after the population of the Aldermoor estate (a public health notion), and consume our own smoke.

It was a stimulating time, but there were problems reconciling the competing claims of medical school and service as well as staffing issues. Southampton was within spitting distance of the London School of Hygiene & Tropical Medicine, so it was time to make the logical step into public health, and it was quite clear that I had made the right move. Validation came from, among others, John Wing and Julian Leff from the Maudsley, who also taught social psychiatry at the school, from visiting teachers from the London School of Economics (LSE), such as Bryan Abel Smith, who confirmed what students suspected, namely that 'public health is the political wing of medicine' and that 'Parliament is the dispensary of public health', and others that placed population health at the centre. It was one of those group learning experiences which stays with you down the ensuing years as a highlight and a transformational experience. Yet there was something missing.

In those days students on the public health masters courses at the School had the enormous privilege of a 2-year course, 1 year spent in the classroom and 1 year on a dissertation. The dissertation was a kind of blank cheque that enabled you to pursue something of special interest that would hopefully be built on in future years. And this is where my problem reasserted itself. What would be a suitable dissertation that majored on prevention and mental public health? I was already a member of the social psychiatry section of the Royal College of Psychiatrists and I took advice from as many people as I could find, including Sir Martin Roth. I drew a blank. The nearest anybody could get was early diagnosis and treatment in the community, what I now knew to be secondary prevention in public health, tertiary prevention being rehabilitation. Primary prevention was nowhere to be found.

And so in the end I hit on planned parenthood, something much better understood in a holistic sense in global health circles, and I carried out a series of studies into family planning and abortion at the population level of Wessex. In my subsequent career as a public health academic, as a regional and county director of public health, as an adviser to the World Health Organization on the Healthy Cities project, and most recently, as President of The UK's Faculty of Public

Health, I have reconciled my angst that as a generalist with a population and environmental focus, all my work has ultimately to be judged by its impact on mental health and well-being. So what have I learned and what observations can I make faced with the promise that finally mental health is to be taken seriously?

One of the problems with mental health, as with physical health, is that the dominant approach is to work backwards, from a focus on treatment towards an interest in prevention. The exception is when there is an emergency, a disaster or a war, when needs must apply a public health population-based triage model if harm is to be minimised.

In the 1980s I attended a short course at the School for would-be volunteers to work in refugee camps in the Horn of Africa. One message stays with me almost 40 years later. If a small group of volunteers (doctors, nurses, engineers and so on) is deployed into a camp of 12 000 women and children in dire circumstances (the men are likely to be either already dead or off fighting somewhere), the first thing to do is not to start treating sick patients. Rather, it is to carry out a quick census of who is there and what skills they have, and to set about mobilising the expertise and supporting it.

This is not our traditional medical model, based as it is on putting up your plate outside a consulting room and offering services to those who can afford to pay, with no concern for the denominator of those with unmet need. Take the example of child and adolescent psychiatry. The large community surveys such as those on the Isle of Wight and in South London found that around 10% of children and adolescents suffer from such a level of emotional or conduct disorder as to require specialist help.³ In a borough of 500 000 population (about 70 000 children and adolescents), this will equate to about 7000 potential patients. In a fortunate district perhaps, optimistically, 1000 of those could be adequately managed by a typical child and adolescent mental health service (CAMHS). No district will ever have that kind of establishment. At the risk of being written off as a loony baby boomer, I would quote Mao Zedong: who is said to have claimed that 'If the practice doesn't work, the theory is wrong'. We are starting at the wrong end of the telescope or focusing on the wrong part of the pyramid of needs. So what would public health say and what is to be done?

In 1961 Gerald Caplan published a book titled *An Approach to Community Mental Health*. Caplan was educated at Manchester medical school and worked at the Tavistock Institute in London and the Hadassah Centre in Jerusalem before moving to the USA, where his work was hugely influential, not least with the programme of community mental health centres under President Kennedy. I came across his book in the 1980s and have carried it round with me ever since.

Reading it again now, it is as relevant and fresh today as it was when it was written, and it is a mystery to me why it has not been a blueprint for how we have approached mental health during the intervening years. Perhaps it is because it includes a (very sensible) chapter on ego psychology, when British psychiatry has for so long been under the shadow of organic theorists and psychopharmacology? In essence, what Caplan proposes is a comprehensive community approach to preventive psychiatry and the provision of services which builds on individual and community assets including those of what he calls 'caretaking agents' and those in special positions in everyday life. He includes in this not just doctors and nurses but clergy, teachers, policemen and so on, and advocates a system built on up-skilling those in a position to play a protective and supportive role in everyday life as a first line.

Caplan describes administrative actions that can protect and support good mental health as well as personal and clinical interactions and redefines the role of those with specialist psychiatric expertise in building and supporting both capacity and capability for mental health and well-being. For me, using the example of child and adolescent mental health, this translates into a life cycle approach that starts with planned parenthood, builds on it with the Prime Minister's parenting classes, and ensures that all those in key interactions with parents and children have adequate skills to promote mental health and respond quickly to signs of distress. This extends to children themselves having the opportunity at school to develop mental resilience and skills for mutual mental health assistance with their peers. The administrative part includes key action on wider determinants of health such as economic and social security, housing and access to good educational and work opportunities. If all this is implemented, the question then arises as to what the formal system should be offering in primary care, building on recent developments in Improving Access to Psychological Therapies (IAPT) and how serious breakdown and risk can be handled for the whole population of patients for whom this becomes necessary.⁴

One of the enemies of adopting this kind of comprehensive approach to mental health is the prevailing narrow and reductionist model of scientific evidence as illustrated by recent controversy over the concept of mental well-being as

a researchable paradigm. ⁵ For Caplan, ““Our lack of knowledge in regard to the significance of the different factors has to be remedied by a continuation of existing research into aetiology. But, meanwhile preventive psychiatrists have been able to learn a lesson from public health colleagues in regard to handling of the problem of the multifactorial nature of the picture ... The incidence of cases of clinical tuberculosis, for example, in any community is no longer conceived of in public health circles as being merely dependent upon the single factor of the presence or absence of the tubercle bacillus. It is recognised that there are many complicated issues that will determine whether a particular person exposed to the germ will contract the clinical disease: issues involving virulence of the germ, host susceptibility and various environmental factors’.” ⁶” In public health we have learned to take a whole-systems approach to whole and sub-populations and to use multiple interventions acting on the health ‘field’.

The list of factors of interest to those concerned with protecting and improving mental health, mental well-being and resilience, in addition to the proximal factors of those aspects of personal security already mentioned and the managed challenges that enable people to grow and thrive, includes a set of constructs such as locus of control, self-esteem and coherence. These can be difficult constructs to operationalise for research purposes, especially when they interact in complex systems, but tools can be developed, for example the Rosenberg Self-Esteem Scale, ⁷ and in recent years mixed-methods and compound outcomes such as those used in Social Return on Investment ⁸ have paved the way for practical interventions based on pragmatic considerations.

We must be careful to avoid the dangers of scientism. When John Snow took the handle from the Broad Street pump during the 1854 cholera epidemic in Soho, the cause of cholera was still believed to be the miasma. This was 20 years before Pasteur’s ground-breaking research. And still nowadays a whole system of education based on the evidence-free assumption that team sports are character forming underpins the British public schools system.

Caplan’s book concludes with a remarkably contemporary proposal for the development of comprehensive community psychiatry based on 11 concepts and assumptions that could well provide the starting point for a consideration as to how any new government funds might be committed. For myself, I have come to the conclusion that in addition to those things which government can and should do through ‘the pharmacy of public health’, there are three approaches, tried and tested in recent years, that should be regarded as delivery systems.

1. ‘Total place’ and ‘defined population’ as developed through Healthy Cities, Healthy Schools, Healthy Prisons and other settings. ⁹
2. Asset-based community development as proposed by John McKnight and colleagues in Chicago. ^{10,11,12,13} This approach maps and mobilises the gifts and talents of individuals, families and communities on the basis that:
 - they are half-full, not half-empty
 - it takes a village to raise a child
 - 90% of health and social care is lay care
 - unless professional practice supports self-efficacy it can be part of the problem rather than part of the solution.
3. Community-oriented primary (and secondary) care based on an epidemiological understanding of populations and responsibility for them, as practised by Sidney Kark and his colleagues over many years at the Hadassah Medical School in Jerusalem. ¹⁴

In conclusion, I am optimistic that we have an opportunity to re-launch mental health in this country at the same time as developing parity and integration with physical health. The Faculty of Public Health is playing its part by launching a new public mental health report in June to share best practice among public health practitioners. ¹⁵

There is a particular opportunity to pursue this approach in England, where NHS England’s *Five Year Forward View* ¹⁶ with its integrated ‘new care models’ is driving transformational change. However, the paradigm shift to a public health model with co-production at its heart is a precondition. More of the same just won’t do.

1.7.3 Capacity *in vacuo*: an audit of decision-making capacity assessments in a liaison psychiatry service

2017-2

Abstract

Aims and method We aimed to audit the documentation of decision-making capacity (DMC) assessments by our liaison psychiatry service against the legal criteria set out in the Mental Capacity Act 2005. We audited 3 months split over a 2-year period occurring before, during and after an educational intervention to staff.

Results There were 21 assessments of DMC in month 1 (6.9% of all referrals), 27 (9.7%) in month 16, and 24 (6.6%) in month 21. Only during the intervention (month 16) did any meet our gold-standard ($n = 2$). Severity of consequences of the decision (odds ratio (OR) 24.4) and not agreeing to the intervention (OR = 21.8) were highly likely to result in lacking DMC.

Clinical implications Our audit demonstrated that DMC assessments were infrequent and poorly documented, with no effect of our legally focused educational intervention demonstrated. Our findings of factors associated with the outcome of the assessment of DMC confirm the anecdotal beliefs in this area. Clinicians and service leads need to carefully consider how to make the legal model of DMC more meaningful to clinicians when striving to improve documentation of DMC assessments.

 - *Method*
 - *Results*
 - *Discussion*

All doctors are often required to make assessments of their patients' decision-making capacity (DMC). This role is prominent in liaison psychiatry services, as psychiatrists may be asked to provide a second opinion on DMC for other medical specialties (e.g. regarding consent for a surgical procedure). In the UK, psychiatric second opinion tends to be requested following refusal of treatment by a patient,¹ but also when the assessment is likely to be highly complex or

is driven by an underlying psychiatric disorder.^{1,2} DMC is also routinely assessed in the UK in psychiatric patients in emergency settings such as accident and emergency (A&E) departments. At the time of the audit guidance by the Care Quality Commission³ recommended that assessments regarding DMC to consent to treatment and admission should be made on all patients at the point of admission to a psychiatric hospital to clarify whether it was an admission authorised through the consent of a patient with DMC or under the ‘best interests’ procedures in a patient who is assenting but lacking DMC.

In England and Wales the legal criteria through which DMC is assessed are provided by the Mental Capacity Act 2005, with further guidance in its Code of Practice.⁴ Under the Act, for a person to lack DMC evidence is required that they suffer from ‘an impairment of, or a disturbance in the functioning of, the mind or brain’ (Section 2(1)), and that as a consequence of this they are unable to perform at least one of the following tasks: ‘(a) to understand the information relevant to the decision, (b) to retain that information, (c) to use or weigh that information as part of the process of making the decision, or (d) to communicate [their] decision’ (Section 3(1)). DMC is ‘decision specific’ rather than a ‘blanket’ or global ability: it is tailored to the specific decision at hand and recognises that different factors may influence different decisions.

There are additional considerations during the assessment of DMC, in that the assessor must also take heed of the principles of the Mental Capacity Act 2005 which include that ‘A person must be assumed to have capacity unless it is established that he lacks capacity’ and ‘A person is not to be treated as unable to make a decision unless all practicable steps to help him to do so have been taken without success’ (Section 1). Recently the House of Lords Select Committee on the Mental Capacity Act 2005 heavily criticised the implementation of the Act: ‘Our evidence suggests that capacity is not always assumed when it should be. Capacity assessments are not often carried out; when they are, the quality is often poor. [...] The presumption of capacity, in particular, is widely misunderstood by those involved in care’.⁵

We know that patients lacking DMC to consent to treatment are common in both general medical in-patient (around 40%)⁶ and psychiatric in-patient settings (around 60%).⁷ An assessment and decision regarding DMC has significant repercussions for the patient, either respecting autonomy or paving the way to surrogate decision-making under ‘best interests’. It is therefore important to document clear justification for a decision reached, under the statutory criteria of the Mental Capacity Act 2005. Previous work in the USA has shown poor documentation of DMC in a retrospective study of in-patient lumbar punctures authorised by a surrogate decision-maker (3 patients had DMC documented out of 25 procedures authorised by a surrogate, although in 21 cases there was enough information to ‘infer’ lack of DMC).⁸

Our aim was to audit the documentation of DMC assessments provided by our liaison psychiatry service against the Mental Capacity Act 2005 and its Code of Practice, and the guidance issued by contemporary literature.⁹ Subsequently, we employed an educational intervention in our service to see whether this improved documentation of the assessments. We collected detailed information on the factors influencing the assessment of DMC to see whether this had an impact on the quality of DMC assessment or of the intervention.

Method

All new referrals received by the King’s College Hospital Liaison Psychiatry Team, South London and Maudsley NHS Foundation Trust (SLaM), during the month of November 2011 were collated. The team is split into the accident and emergency team and the general in-patient team covering all referrals. In working hours there are also specialist child and adolescent mental health services (CAMHS), older adults, neuropsychiatry and perinatal psychiatry teams. All referrals outside of working hours are taken on by the general service. CAMHS referrals were excluded from this audit.

Assessments of DMC performed by members of the team are completed without a formal template or form and were documented in the SLaM electronic medical record (EMR) as free text. All patient contacts by the team need to be recorded in the SLaM EMR.

The EMR was searched for documentation of assessments of DMC by searching for the word ‘capacity’ and any statement declaring that the patient had or lacked DMC was taken to be an assessment of DMC. The entire duration of the patient episode related to that referral was audited. Statements that suggested the patient may or may not have DMC but that did not make formal declaration were taken by this audit to be an assessment of DMC. The exception to this were statements that suggested the person may lack DMC, but that formal assessment could be delayed.

We set our gold-standard to require documentation of: (1) justification of the timing of the assessment/attempts to maximise DMC in accordance with the principles of the Mental Capacity Act 2005 and; (2) the full statutory criteria of DMC (presence or absence of a disorder of ‘mind or brain’, and performance on the four key abilities). We excluded the need for an explicit statement linking psychopathological features of the disorder of ‘mind or brain’ to any deficit found in the four key abilities given that some patients were found to not have a disorder of ‘mind or brain’.

Further information was gathered, including: basic demographic information, whether the assessment took place in or out of hours, the decision for which DMC is being assessed, the professional background of the assessor, and whether the person agreed or objected to the intervention/option proposed. The severity of potential consequences to the patient regarding refusal of the intervention for which DMC was assessed was also quantified, and classed as mild, medium and severe risk of adverse outcome (by a psychiatrist with experience of DMC assessments and patient management in this clinical environment). An example of a severe risk is a refusal of admission into a psychiatric hospital by a patient with florid psychosis or refusal of life-sustaining medical treatment; an example of mild risk is a refusal to contact relatives for information-sharing regarding the patient’s clinical episode.

Following the audit in November 2011 (month 1), we analysed the initial results. Given that none had met our gold-standard (see below), we designed an educational intervention to improve clinicians’ understanding of the legal framework of the assessment of DMC and how to document this appropriately. The intervention took place during the week psychiatrists in training (senior house officers (SHOs)) change jobs (February 2013, month 16), and continued for the following 4 weeks. It involved the lead auditor (B.S.) meeting with the medical (SHO) and nursing (psychiatric liaison nurses (PLNs)) members of the liaison team and explaining the gold-standard of DMC documentation; presenting this to the on-call SHOs during their induction as they may cover the team out of hours; and emailing the SHO cohort and the senior doctors on call (specialist registrars (SpRs)) on a weekly basis with the guidance. Posters with the guidance were put up in the departmental offices seen by the PLNs and SHOs.

The 4-week period in February 2013 (month 16) during which the intervention was applied was audited, along with the month of July 2013 (month 21), using the methods described above. This audit was reviewed and approved by the trust Psychological Medicine Audit Committee in January 2012.

Results

In month 1, there were 21 (6.9%) assessments of DMC for 306 referrals, in month 16 there were 27 (9.7%) assessments for 278 referrals, and in month 21 there were 24 (6.6%) assessments for 365 referrals (*Table 1*). Overall, DMC was assessed in 72 (7.6%) out of a total of 949 referrals.

Frequency of DMC assessments, demographics, and number meeting audit standards by month *a*

	Month 1	Month 16	Month 21	Total sample
Total referrals, <i>n</i>	306	278	365	949
DMC assessments, <i>n</i> (%)	21 (6.9)	27 (9.7)	24 (6.6)	72 (7.6)
Age, years: mean (s.d.)	45.2 (14.8)	39.3(15.4)	45.6 (15.0)	43.1 (15.2)
Female, <i>n</i> (%)	12 (57.1)	14 (51.9)	14 (58.3)	40 (55.6)
Patients found to have DMC, <i>n</i> (%)	6 (28.6)	16 (59.3)	14 (58.3)	36 (50)
Assessments documenting the statutory criteria, <i>n</i> (%)	2 (9.5)	6 (22.2)	2 (8.3)	10 (13.9)
Assessments meeting the audit gold-standard, <i>n</i> (%)	0	2 (7.4)	0	2 (2.8)

Some patients had more than one DMC assessment. There were no significant differences between months.

None met the gold-standard in months 1 or 21, however, 2 (7.4%) did during the intervention in month 16 (*Table 1*) and both of these assessments were performed by the SHOs who had received the educational intervention. Results were similar when using our lower standard of documentation of the full statutory criteria: $n = 2$ (9.5%) in month 1, $n = 6$ (22.2%) in month 16 and $n = 2$ (8.3%) in month 21. The majority of those failing this standard missed out several elements; only 3 (4.2%) assessments missed reaching the standard through missing only one of the four key abilities, whereas 38 (52.8%) assessments documented none of the four key abilities. We therefore cannot conclude the educational intervention had any impact at all.

Where recorded, we looked at how frequently the key abilities to be tested were lacking in people who lacked DMC. Lacking the ability to 'use or weigh' information was most common ($n = 19$, 73.1% where recorded), followed by 'understanding' ($n = 10$, 43.5% where recorded), 'retaining' ($n = 8$, 57.1% where recorded) and 'communication' ($n = 4$, 33.3% where recorded).

The majority of assessments of DMC were performed by doctors ($n = 51$ (70.8%) *v.* $n = 21$ (29.2%) assessments performed by the PLNs). Of the PLNs' assessments only 3 (14.3%) patients were found to lack DMC, whereas of the doctors' assessments 33 (64.7%) patients lacked DMC (*Table 2*). PLN assessment was significantly more likely to result in a positive DMC than a doctor assessment (OR = 11.0, 95% CI 2.9 to 42.5). The doctors met the gold-standard ($n = 2$, 4%) and full statutory criteria ($n = 9$, 18%) more often than the PLNs ($n = 0$ and $n = 1$, 5% respectively).

Outcome of DMC assessment based on assessing clinician

	DMC present		
Assessing clinician, n (%)			
PLN	3 (14)	18 (86)	21 (29)
Doctor	33 (65)	18 (35)	51 (71)
Total, n	36	36	72

DMC, decision-making capacity; PLN, psychiatric liaison nurse.

We separated the types of decisions to be made by the patient into those that involved 'psychiatric admission or treatment' and 'medical admission or treatment'. For the purposes of the audit, decisions to start a new admission in hospital or discharge oneself from a current admission were seen as interchangeable. Medical and psychiatric decisions were not mutually exclusive and a proportion of patients were assessed for both. There were assessments of DMC that did not focus on these decisions, but they were a minority and focused on decisions not normally tested in this setting, such as DMC to make a decision around ongoing homelessness ($n = 1$) and ongoing abusive relationship/domestic abuse ($n = 2$). These non-treatment-focused assessments of DMC all occurred as part of the psychiatric assessment by a PLN or doctor rather than following a request for second opinion from the medical teams.

We found that the proportion of assessments of DMC for medical admission or treatment formed the majority of assessment at the start of the audit month 1 ($n = 17$, 81%), but this reduced over the course of the audit in month 16 ($n = 12$, 44%) and month 21 ($n = 8$, 33%; Pearson's $\chi^2 = 9.91$, $P = 0.007$) (*Table 3*). Conversely, assessments for psychiatric admission or treatment were the minority at the start of the audit ($n = 5$, 24%) and increased in month 16 ($n = 13$, 48%) and month 21 ($n = 13$, 54%), although the differences were not statistically significant.

Decisions for which DMC was assessed and numbers agreeing with the intervention by month

	Month 1	Month 16	Month 21	Total sample $n = 72$
Decisions to be made, n (%)				
Medical admission or treatment	17 (81) ^a <#TFN4>`__	12 (44) ^a <#TFN4>`__	8 (33) ^a <#TFN4>`__	37 (51)
Psychiatric admission or treatment	5 (24)	13 (48)	13 (54)	31 (43)
Agreement status, n (%)				
Agreeing	5 (24)	15 (56)	12 (50)	32 (44)
Not agreeing (or unable to express a choice/not documented)	16 (76)	12 (44)	12 (50)	40 (56)

DMC, decision-making capacity.

Pearson's $\chi^2 = 9.91$, $P = 0.007$.

We separated the choices of people who were having their DMC assessed into agreeing with the intervention proposed by the assessor/medical team and objecting/unable to express a choice/unknown. Fewer people were assessed who agreed with the intervention in month 1 ($n = 5$, 24%), but in months 16 and 21 they made up half of those assessed (Table 3). Agreement with the intervention was strongly associated with a finding of DMC: 26 (81%) of those agreeing with the intervention were found to have DMC, compared with only 10 (25%) of those who did not agree (either objecting or otherwise) (Table 4). This was highly statistically significant (Pearson's $\chi^2 = 22.50$, $P < 0.001$). Most assessments made by the PLNs were done in patients agreeing to the intervention ($n = 15$, 71%), contrary to doctor assessments ($n = 17$, 33%).

Outcome of DMC assessment based on agreement with the proposed intervention *a*

	DMC present		
Agreement status, n (%)			
Agreeing	6 (19)	26 (81)	32 (44)
Not-agreeing (or unable to express a choice/not documented)	30 (75)	10 (25)	40 (56)
Total, n	36	36	72

DMC, decision-making capacity.

Pearson's $\chi^2 = 22.50$, $P < 0.001$.

A logistic regression was performed to ascertain the effects of the assessor (PLN or doctor), agreement with the intervention and consequences of the decision. Initial models also included decision to be made and underlying mental disorder, however, these were removed from the final model as they had no effect.

The final regression model was statistically significant (Pearson's $\chi^2 = 45.81$, $P < 0.001$). The model explained 64.7% of the variance (Nagelkerke R^2) and correctly classified 81.2% of the outcome of the assessments of DMC.

Factors associated with the finding of lack of DMC were: more severe consequences of the decision (OR = 24.4, 95% CI 3.47 to 171.8), not agreeing with the intervention (OR = 21.8, 95% CI 4.0 to 118.8), and assessment by doctor rather than PLN (OR = 14.9, 95% CI 2.1 to 104.5).

Discussion

We have shown evidence that documentation of 72 DMC assessments in 3 sampling months in a liaison setting was poor, with only 2 assessments reaching our gold-standard. The impact of a legal education intervention was very limited and was not sustained beyond the month in which it was applied.

There are several possible reasons as to why the proportion of assessments meeting our gold-standard was so low, even after the educational intervention. Clearly, a lack of documentation of all components of the assessment of DMC does not necessarily equate to these components not having been considered by the clinician assessing DMC. However, there is limited documentary justification of the nature of the clinical assessment and the legal model of DMC. Perhaps elements of the education intervention itself (design, style, length etc.) may not have been an effective means of conveying the information, although our audit was not designed to evaluate this. The explicit reference to the principles of the Mental Capacity Act 2005 in our gold-standard might have set the standard too high, but even our more lenient 'full statutory criteria standard' was only achieved in 13.9% of assessments during the course of the audit.

Where lies the difficulty in translation of the legal model to clinical assessments? In situations where evidence is presented to the Court of Protection (the civil court in England and Wales with the jurisdiction for cases in which an individual lacks DMC), the Court requires completion of prescribed forms that demand a level of evidence similar to our gold-standard. In a busy clinical environment it is easy to see how documentation of the presence or absence of DMC could be considered to be sufficient by clinicians. A process that might slow the system down (or be perceived as such) can be expected to be powerfully resisted.

It is interesting that the assessments of DMC by PLNs result more often in the patient being concluded to have decision-making capacity. This finding needs to be approached with caution given that DMC assessments were triggered by several different reasons in our audit, including either: (1) a second opinion assessment of DMC, usually in the context of a patient refusing treatment, in which the assessment would be performed by a doctor; or (2) an assessment of DMC in the context of admission to psychiatric hospital performed by any clinician.

As doctors performed all second opinions of DMC assessment, usually in the context of a patient refusing treatment, and they assess all patients who will need compulsory admission to hospital, there is a referral bias. The majority of DMC assessments performed by the PLNs were in the context of a patient agreeing with the suggested intervention, and hence were used to support the clinical assessment. If there is no dispute around the intervention offered, then DMC assessment has little consequence and it is easier to presume DMC.

The strong association between lack of DMC, high severity of outcome, refusal and lack of assent is striking. To our knowledge this is the first piece of work that has clearly demonstrated this association in real clinical practice. It would seem to suggest that clinicians when assessing DMC in practice use an outcome test of DMC rather than the functional test the law requires. Kim *et al*¹⁰ have shown that assessments of DMC by clinicians using video simulations of consent discussions around involvement in research are risk sensitive. This echoes early work on conceptualising DMC as necessarily risk sensitive.² Owen *et al*¹¹ reported an association between treatment refusal and DMC assessed using the MacArthur Competency Assessment Tool for Treatment. Although the association is striking, we consider it to be largely expected, given the selection bias that assessments of DMC performed as a second opinion by our service are normally prompted by treatment refusal in the context of a possible mental disorder, when refusal is likely to result in significant harm to the patient. It is reassuring that there are a proportion of assessments where people are found to have DMC despite the refusal and high severity of consequences, and we submit that this is evidence of careful clinical consideration of each case on its own merits.

Our audit has shown that there are limitations in the recording of assessments of DMC, and that uptake of an educational intervention was limited. We consider that this is likely due to the perceived disconnect between the legal assessment and clinical assessment. We would recommend that the next step in the audit cycle should include an educational intervention on the assessment of DMC with a formal evaluation, with exploration and focus on clinical factors and their relationship to legal criteria in order to be more acceptable for clinicians.

In conclusion, we have found evidence for the anecdotal belief on the impact of severity of consequences and agreement status of the patient on the outcome on their assessment of DMC. Reassuringly, these factors were not totally deterministic of the outcome but they do suggest that, in practice, the functional test of DMC is yet to fully bed down.

We would like to thank Dr Lisa Conlan for her support and advice during the audit process.

1.7.4 Personality disorder: still the patients psychiatrists dislike?

Abstract

Aims and method In 1988, Lewis and Appleby demonstrated that psychiatrists hold negative attitudes towards patients with personality disorder. We assessed the attitudes of psychiatry trainees towards patients with borderline personality disorder and depression, expecting an improvement. 166 trainees were block randomised to receive one of four case vignettes that varied by diagnosis and ethnic group. We used Lewis and Appleby's original questionnaire and the Attitudes to Personality Disorder Questionnaire (APDQ).

Results We received 76 responses. Lewis and Appleby's questionnaire showed more negative attitudes towards personality disorder than depression, with no significant patient ethnic group effects, and the APDQ also showed a (weak) trend towards more negative attitudes to personality disorder. In subgroup analysis, only in the White British patient group were there significantly more negative attitudes to personality disorder. Factor analysis showed significantly less sense of purpose when working with personality disorder.

Clinical implications The perceived greater lack of purpose in working with personality disorder should be the target of clinical training and intervention. Targeted interventions that include training in managing personality disorder, supervision and practice in non-specialist, general psychiatry settings are important.

* *Limitations*

* *Recommendations*

Personality disorder is characterised by an enduring dysfunctional and distressing pattern of inner experiences, behaviours and interpersonal interactions.¹ Almost a quarter (24%) of people seen in primary care² and 50% of people in secondary mental health services meet the criteria for a diagnosis of personality disorder.³ Patients with personality disorder have high rates of comorbidity⁴ and service utilisation.⁵ A meta-analysis, which identified 391 relevant publications and finally included 14, showed significant differences in prevalence between Black and White groups (although no differences between Asian or Hispanic groups compared with White groups), raising the question of whether there is a neglect of diagnosis in some ethnic groups.⁶

Although there is good evidence that borderline personality disorder (BPD) is a helpful diagnostic construct,⁷ some studies contest the validity (but not the clinical utility) of the diagnosis.⁸ Potter¹ stresses that the psychological and interpersonal dynamics that patients with BPD bring to the clinical setting cause frustration and consternation among clinicians, such that BPD is now a diagnosis that can carry pejorative connotations and compound the stigma that such patients already face. Many patients with BPD feel rejected and disbelieved by clinicians.⁹ Improving clinicians' attitudes toward patients with BPD could bring them clinical benefit.¹⁰

Against this background, there have been systematic efforts to study clinicians' attitudes to personality disorder. A systematic review of the literature shows that healthcare professionals in general have negative attitudes towards such patients.^{11,12} A large study⁷ demonstrated that the clinician's occupational subgroup was significantly related to the attitude they adopted towards patients with BPD: staff nurses had the poorest self-ratings on overall caring attitudes, whereas social workers had the most caring attitudes. Social workers and psychiatrists self-rated highly on treatment optimism, whereas staff nurses rated poorly on empathy and treatment optimism. Overall, the authors suggested that education about the nature and treatment of BPD can lead to more positive attitudes, but also that clinicians with greater levels of experience in terms of both number of BPD patients and years of practice were more likely to express positive attitudes towards such patients. Bodner *et al*¹³ demonstrated that psychologists were less likely than psychiatrists and nurses to express antagonistic judgements towards patients with BPD and suicidal tendencies, whereas nurses were less likely to show empathy than psychiatrists and psychologists. They identified a number of factors influencing attitudes, including motivation to improve diagnostic skills, seniority, training and supervision, gender and familiarity with treatment modalities.

In 1997, Bowers *et al*¹⁴ developed a new instrument called the Attitude to Personality Disorder Questionnaire (APDQ). The APDQ is a reliable and valid measure of attitude to personality disorder, and is useful for outcome studies. It was tested among nurses and prison officers.¹⁵⁻¹⁷ One of these studies¹⁶ revealed that psychiatric nurses' attitudes were more negative than those of prison officers. Prison officers more often liked and showed an interest in prisoners with personality disorder, and they showed less fear and helplessness, less anger, more optimism about treatment and less frustration. The other studies found that nurses considered people with personality disorder difficult to treat; they were pessimistic about the efficacy and outcome of treatment and felt they were poorly trained to care for such patients.

Over 20 years ago Lewis & Appleby¹⁸ demonstrated that psychiatrists hold negative attitudes towards patients with a diagnosis of personality disorder, and that the diagnostic label was more influential on their attitudes than the patient's gender or class. Patients given a previous diagnosis of personality disorder were seen as more difficult and less deserving of care than controls. The authors concluded that a diagnosis of personality disorder carries enduring negative sentiments and is not used to guide effective treatment. For example, people with this diagnosis may experience difficulties when seeking help for psychiatric symptoms such as depression. The authors proposed that the concept of personality disorder be abandoned.

In 2002 the National Personality Disorder Development Programme was introduced in the UK, accompanied by the publication of *No Longer a Diagnosis of Exclusion*¹⁹ and *Breaking the Cycle of Rejection*,²⁰ policy attempts that aimed to improve the evidence base of effective interventions for patients with personality disorder in specialist personality disorder services and, it was hoped, would also mitigate stigma.

Given the above, it seemed timely to see whether the attitudes of psychiatrists towards BPD showed any change. We selected psychiatric trainees, despite the difference in seniority/experience compared with Lewis & Appleby's original study (mean 16.5 years of psychiatric practice), as they are on the front line of service provision and are the next

generation of consultant psychiatrists. Considering the findings of McGilloway *et al*⁶ and the multi-ethnic patient population in east and north-east London our sample was drawn from, we also examined the impact of ethnicity on attitudes.

Objectives

The objectives of the study were: to assess the attitudes of psychiatry trainees towards patients with BPD compared with depression to assess the impact of patient ethnicity on the attitudes of trainees to BPD.

Method

The study population consisted of the cohort of doctors training in psychiatry on the north-east London rotations (East London NHS Foundation Trust and North East London NHS Foundation Trust) between February and July 2013: core trainees 1–3, specialist trainees 4–6, general practice vocational trainees and foundation year 2 doctors. Overall, 166 doctors in training were block randomised in blocks of 8 to receive one of four different case vignettes (*Box 1*) that varied by previous diagnosis (BPD or depression) and ethnic group (White British or Bangladeshi). The case vignettes were modified versions of those used by Lewis & Appleby.¹⁸

Box 1 Case vignettes used in the study

Case 1

A 25-year-old White British woman is seen in out-patients. She complains of feeling depressed and crying all the time. She is worried she may be having a 'breakdown' and is requesting admission. She says she has thought of killing herself by taking an overdose of tablets at home. She has a history of an overdose 2 years ago after a relationship break-up, following which she saw a psychiatrist who diagnosed her with depressive episode. She recently lost her job and is worried about how she will pay the bills. She is finding it difficult to sleep and her GP prescribed nitrazepam, which she says has been helpful and which she would like to continue.

Case 2

Same as case 1, but the patient is Bangladeshi.

Case 3

Same as case 1, but the previous diagnosis is borderline personality disorder.

Case 4

Same as case 3, but the patient is Bangladeshi.

We used the following tools to measure attitudes:

Lewis & Appleby's 22 semantic differentials on a 6-point scale. Using the original scoring conventions, the semantic differentials were scored so that a higher score represented responses that were more rejecting or that indicated lack of active treatment.

APDQ: a questionnaire that consists of 37 affective statements about patients with personality disorder (e.g. 'I like personality disorder people', 'I feel drained by personality disorder people', 'I feel patient when caring for personality disorder people'). Respondents rate the frequency of their experiences of these feelings on a 6-point Likert scale: never, seldom, occasionally, often, very often and always. The responses can be summed to give a total score; the higher the score, the more positive the attitude towards patients with a personality disorder. Five subfactors can be scored: factor 1, enjoyment: warmth, liking for and interest in contact with patients with personality disorder factor 2, security: the lack of fears, anxieties and helplessness in relation to patients with personality disorder factor 3, acceptance: the absence of anger towards patients with personality disorder and a sense of being different from them factor 4, purpose: feelings of meaning and purpose in working with patients with personality disorder factor 5, enthusiasm: energy and absence of tiredness.

For the purposes of this study we modified the affective statements to ‘I like these patients’, ‘I feel drained by these patients’ etc. to correspond to the case vignette of either personality disorder or depression.

Analysis

As regards Lewis & Appleby’s 22-item semantic differentials, we compared mean and s.d. scores on items. We assessed the structure of the items by running a principal components analysis. We summed scores of the most dominant factors that explained most of the variance and compared them by diagnosis and by ethnic group.

The APDQ scores (mean, s.d.) were compared for trainees across the four case vignettes. These were compared as groups that differed by diagnosis or by ethnic group in logistic regression analyses, to assess the role of diagnosis and ethnic group. We used the original APDQ factors as an additional variable to assess differences by patient ethnic group and diagnosis.

The study was granted ethical approval by the South West London REC 3 (ref. 10/H0803/159). We obtained the names and positions of all trainees in the rotation from the core training scheme manager for the north-east London rotations. We contacted all trainees via email asking them to complete questionnaires online (on the SurveyMonkey platform, www.surveymonkey.co.uk). All respondents gave informed consent and all responses were anonymous.

Results

We received 76 responses (response rate 46%). However, a small number of respondents failed to answer a number of questions. We thus analysed data from 73 responses to Lewis & Appleby’s questionnaire ($n = 19$ for case 1, case 3 and case 4, and $n = 16$ for case 2) and 68 responses to the APDQ (17 for case 1, 15 for case 2, 20 for case 3, and 16 for case 4). Respondent characteristics are given in *Table 1*.

Lewis & Appleby's 22-item semantic differentials

The scale was subject to principal components factor analysis followed by an orthogonal rotation to identify 16 of the 22 items loaded (loading of greater than 0.5) on the first factor (eigenvalue 10.42, explaining 71% of the variance), with two further candidate factors (eigenvalue 1.68, explaining 11.5% and eigenvalue 1.00, explaining 6.1%, respectively) (*Table 2*). Only items from the first factor were summed to compare attitudes, as the second and third factors were accounted for by 3 items each and did not show a clear conceptual distinction between each other. The mean and s.d. score of factor 1 was compared by diagnosis and by ethnic group (case 1: mean 42.42, s.d. = 8.54; case 2: mean 48, s.d. = 8.71; case 3: mean 53.68, s.d. = 11.99; case 4: mean 51.53, s.d. = 10.51). The scores did not vary by ethnic groups. The rank sums showed significant differences by diagnosis, with higher scores (more stigma) towards personality disorder than depression (overall Kruskal–Wallis $\chi^2 = 11.38$, d.f. = 3, $P = 0.01$) (*Table 3*).

Principal components analysis

BPD, borderline personality disorder; BZ, benzodiazepine; NHS, National Health Service.

Means: higher values indicate greater agreement with statement; there was a 6-point scale between the two statements of the semantic differential.

Attitudes to BPD based on the four test vignettes (factor 1: Kruskal–Wallis equality-of-populations rank test)

Case vignette	Respondents, <i>n</i>	Rank sum
1	19	460.50
2	16	564.50
3	19	860.50
4	19	815.50

$\chi^2 = 11.38$, d.f. = 3, $P = 0.01$

APDQ

Multiple regression analysis of overall scores showed a weak trend towards lower scores in assessment of attitudes towards patients with a previous diagnosis of BPD compared with patients with a previous diagnosis of depression (lower scores indicate more negative attitudes in the APDQ and this is consistent with findings from the Appleby measure); however, this difference fell just short of statistical significance ($z = 1.75$, $P = 0.08$). There was no significant ethnic difference in attitudes towards patients. In subgroup analysis, only among White British patients with a previous diagnosis of BPD was there a lower overall score compared with White British patients with a previous diagnosis of depression ($z = 1.98$, $P = 0.047$).

This outcome had already been subjected to factor analysis by the original inventors of the measure. When we assessed scores on the basis of the five factors (using Kruskal–Wallis equality-of-populations rank) there was no statistically significant difference in scores for factors 1 (enjoyment), 2 (security), 3 (acceptance) and 5 (enthusiasm). However, there was a statistically significant ($P = 0.03$) difference found for factor 4 (purpose), with higher scores in attitudes (more positive) towards patients with depression (mean 4.60) compared with patients with a previous diagnosis of BPD (mean 4.15).

Discussion

Since the original study of Lewis and Appleby nearly 30 years ago, a number of studies spanning from 1993 to 2012, as summarised in the introduction, have consistently shown that clinicians hold negative attitudes towards personality disorder. Our finding of more negative attitudes towards personality disorder compared with depression among psychiatric trainees, using the same instrument as Lewis and Appleby, is in line with previous research. However, it is difficult to show and theorise a sense of longitudinal change. This is mainly because different studies have looked at different professional groups, including nurses, prison officers, social workers, psychologists and psychiatrists, with varying training and levels of experience, and in different countries and/or care settings. In addition, our study examined the attitudes of a less experienced sample of psychiatrists than the Lewis and Appleby study, and this has to be taken into consideration when comparing current attitudes with previous ones. However, the ongoing finding of more stigma towards patients with personality disorder, almost 14 years after the introduction of the National Personality Disorder Development Programme, is disheartening.

More encouraging is the lack of evidence of differences in attitudes to patients with personality disorder of different ethnicity. The greater negative attitudes to personality disorder than depression in White British but not in Bangladeshi

patients raises questions of differences in how clinicians may view the disorder in different ethnic groups, especially given that culture influences significantly what is considered to be a person and personality. Culture influences a number of factors relevant to the construct of personality disorder, such as learning inside and outside the family, the threshold when personality vulnerability cannot be compensated for by the person, and the social threshold when such decompensations are labelled pathological.^{21–23} If one accepts personality pathology as universal,²⁴ perhaps this finding can also raise further questions regarding under-diagnosis of personality problems in certain ethnic groups, although supporting such a link is beyond the scope of this paper and further research is needed looking into both the universality of personality disorder and issues of under-diagnosis or misdiagnosis.

The question of why psychiatrists stigmatise personality disorder is complex and not simple to answer. In addition to the issues discussed above in relation to caring for these often emotionally draining patients, it is of relevance that specific features of BPD can cause negative attitudes. It is known that a wide range of impulsive and potentially self-damaging behaviours are observed, especially early in the course of the disorder.^{25,26} These include gambling, irresponsible money handling, reckless driving and unsafe sexual practices,²⁷ as well as problematic substance use, self-harm, suicidal behaviour and disordered eating.^{28–31} Most of these behaviours carry strong moral connotations, sometimes challenging social norms, and can thus provoke negative reactions, triggering clinicians' implicit beliefs and possibly prejudices towards such behaviours.

While mounting anti-stigma campaigns may be required, the finding of a greater lack of purpose in clinicians in working with personality disorder allows for more modest and targeted intervention. Lack of purpose and therapeutic pessimism raise the importance of designing targeted interventions which may include training in personality disorder. As personality disorder is prevalent in all psychiatric settings, this is an important part of training for all psychiatrists.

Limitations

Limitations of the present study include the small sample numbers, which, despite a reasonable response rate for a questionnaire study, makes it difficult to rely on comparisons between the groups, and thus compromises the power of the study. Our study population is taken from only two mental health trusts in the UK. However, the trusts cover both inner and outer London areas, and the training programmes are similar to those of others in the UK, as there is a specific framework for postgraduate training in psychiatry.

Recommendations

Increased training in evidence-based practice for generalist mental health professionals in borderline personality disorder may address the issue of clinicians' lack of sense of purpose. The emphasis is thus on increasing the skills of clinicians in managing personality disorder in general psychiatric settings, which usually lack the structure, training and resources to deal with these complex patients. The difficulties faced by general psychiatry clinicians have been acknowledged in the literature, and in that respect 'structured clinical management' has been discussed as an effective way of working with BPD patients in non-specialist settings, as long as certain principles are followed and interventions implemented.³²

It has been shown that people with personality disorder present specific challenges to the therapeutic alliance.^{33–35} Training and supervision^{36–39} as well as participation in a Balint group⁴⁰ can improve negative attitudes.

Patients with personality disorder can provoke strong countertransference reactions, there is thus an ongoing need for clinicians to monitor their countertransference when working with such patients. This highlights the ongoing need for psychotherapy training. Evidence-based psychotherapy treatments have a documented applicability as a useful model for general psychiatrists.⁴¹ Supervision and further training is also necessary for consultants, as they often supervise trainee doctors and inevitably influence them through their own attitudes to these patients.

Recent research on stigma reduction has identified certain key ingredients that anti-stigma initiatives should take into consideration: a recovery emphasis and having multiple forms of social contact are especially important for maximising outcomes.⁴² These key ingredients can be taken up to introduce specific initiatives to reduce stigma against personality disorder. For example, Knaak *et al*⁴³ found that a 3-hour workshop on BPD and dialectical behavioural therapy (DBT)

was successful at improving attitudes and behavioural intentions towards persons with BPD. This is in line with those studies that show that training and education programmes tend to improve attitudes.

1.7.5 Pokorny's complaint: the insoluble problem of the overwhelming number of false positives generated by suicide risk assessment

Olav Nielssen Duncan Wallace Matthew Large

Correspondence

Olav Nielssen (olavn@ozemail.com.au)¹

date

2017-2

Abstract

Alex Pokorny's 1983 prospective study of suicide found that 96.3% of high-risk predictions were false positives, and that more than half of the suicides occurred in the low-risk group and were hence false negatives. All subsequent prospective studies, including the recent US Army Study To Assess Risk and Resilience in Servicemembers (STARRS), have reported similar results. We argue that since risk assessment cannot be a practical basis for interventions aimed at reducing suicide, the alternative is for mental health services to carefully consider what amounts to an adequate standard of care, and to adopt the universal precaution of attempting to provide that to all of our patients.

Pokorny's pioneering study

It is over 30 years since the publication of Alex Pokorny's landmark prospective study of suicide among consecutive first admissions to the Houston Veterans Administration Medical Center.^{1,2} Pokorny examined a cohort of 4800 men using a comprehensive array of relevant and reliable rating scales and assessed 803 (17%) to be at high risk of suicide because of the presence of a combination of risk factors. In the next 5 years, 30 (3.7%) high-risk patients and 37 (0.9%) of the 3997 lower-risk patients died by suicide, an odds of suicide that was 4 times greater in the high-risk group.

The 37 suicides among lower-risk patients were in effect false negatives. Pokorny considered false negatives to be inevitable because patients sometimes conceal their suicidal plans and their circumstances change over time. What concerned him more was the overwhelming proportion of false positives, because 96.3% of the patients categorised as high-risk did not commit suicide. He concluded: "We might tolerate 50% false negatives; if we could apply a screening test that would correctly identify only half of the future suicides without false positives that would be very helpful. However, with currently known tests to identify the actual suicides, we will also have to make a great many false-positive identifications, labeling up to a quarter of the total group as future suicides when only 1% to 5% actually are. From a cost-benefit standpoint, the application of such a test is simply not feasible."¹

Other prospective studies of suicide

There have been relatively few prospective studies of the factors associated with subsequent suicide, probably because of the methodological and logistical difficulties involved. Not long after Pokorny, Goldstein *et al*³ followed up a cohort of 1906 patients diagnosed with affective disorders and found that none of the 46 suicides occurred among the group, albeit smaller than in Pokorny's study, defined as being at high risk. More recently, two prospective studies examined the proportion of suicide deaths among those considered to be at high risk.⁴⁻⁶ Madsen *et al*^{4,5} reported a suicide rate of 0.14% among those defined as high risk in a national study of the suicide of psychiatric in-patients in Denmark, and Steeg reported the suicide of 0.5% of patients identified as being at high risk among a large cohort of people who presented to emergency departments in three English counties after self-harm.⁶

Faced with growing concern about suicides among veterans and current serving members of the U.S. Armed Forces, the U.S. Department of Veterans Affairs and the U.S. Department of Defense included the use of risk stratification in clinical practice guidelines.⁷ As part of the Study to Assess Risk and Resilience in Servicemembers (STARRS), Kessler and associates then examined factors associated with suicide among 53 769 American soldiers in the 12 months after discharge from military psychiatric hospitals,⁸ with the benefit of the very detailed longitudinal US Army personnel database and highly sophisticated statistical techniques derived from artificial intelligence research. They identified a high-risk group comprising 2689 admissions, or 5% of the sample, from which there were 36 suicides, corresponding to a 22 times increased risk of suicide in that group. However, in other respects the results were eerily familiar, as nearly half of the suicides occurred among the 51 080 low-risk patients, and only 1.3% of the high-risk group died by suicide, leaving an overwhelming number of false positive cases.

The problem remains of the disturbingly high suicide rates among psychiatric patients as a whole. For example, in the Madsen study, the rate of suicide of psychiatric in-patients was 72 times that of the general community, at 860 per 100 000 patient years, and in the Steeg study the suicide rate among all patients presenting to hospital after self-harm was 622 per 100 000 patient years. Hence, although we know that all of the patients under our care are at greatly increased risk of suicide compared with the wider community,⁵ our ability to distinguish between groups of patients with respect to the probability of subsequent suicide risk is, at best, quite modest.

Implications for mental health services

This observation has important implications for mental health services, given the unrealistic expectations for risk assessment to prevent serious adverse events, and the way risk assessment has changed professional practice.⁹ If risk stratification is to be a part of how mental health services approach suicide prevention, we need to carefully consider the interventions offered to patients believed to be at high risk but denied to those assessed to be at lower risk. Because the vast majority of high-risk patients will not die by suicide, any intervention has to be shown to be somewhat effective, but also benign enough so as not to infringe on the rights of the many with false positive assessments. However, if we do have an effective and benign intervention, it is then hard to justify denying this to low-risk patients, who, after all, are still many times more likely to die by suicide than the general community.

If there is no effective and yet benign intervention to justify offering different treatments to groups of patients on the basis of risk stratification, how can mental health services respond to the knowledge that our patients are at greatly increased risk of suicide compared with the wider community?

The alternative is the application of universal precautions to all patients, including the design of in-patient facilities that minimise the opportunity to attempt suicide,¹⁰ the provision of community treatment for all patients in the weeks after discharge from hospital,¹¹ and safety planning at the point of contact in emergency departments.¹² Most importantly, every patient should have access to timely, individualised, high-quality treatment for psychiatric disorder. Modifiable factors associated with suicide should be addressed in all patients, not only those considered to be at greatest risk. Moreover, no intervention can be justified on the basis of the assessed risk alone. We go so far as to suggest that the assessed risk of suicide on its own is not a sufficient reason for restrictive interventions such as involuntary detention in hospital or other coercive treatment,^{13,14} which would then need to be justified on additional grounds, including the patient's inability to recognise the potential benefit of treatment and their particular circumstances and treatment needs. In any case, preventive detention in hospital of all patients assessed to be at high risk of suicide would be impossible, because of the huge numbers of patients identified and the long duration of secure detention that would be required to protect such patients.

Addressing the modifiable risk factors in populations of patients involves ensuring the adequate identification, assessment and treatment of patients with a range of mental disorders, addressing substance use and, wherever possible, limiting the availability of potentially lethal means to die by suicide. Treatment should be with the patient's consent, or provided on the basis that the patient lacks the capacity to consent, rather than being based on perceived risk, which we now know we are not able to reliably assess.

A further implication for mental health services of the demonstrated limitation of risk assessment is in responding to lawsuits for failing to predict the suicides of individual patients. While the suicide of any patient might be foreseeable in the legal sense of being not fanciful or far-fetched, mental health services cannot be reasonably expected to be able to identify which patients will die by suicide. Expert evidence in one recent case on the estimated probability of suicide after discharge included absurdly high estimates of between a 5 and 70% chance of suicide within days of discharge.¹⁵ Instead of guessing the probability with the help of hindsight bias,¹⁶ negligence claims after suicides should hinge on the accepted standard for care of people with various psychiatric disorders, regardless of the presence of known risk factors. Services should be concerned about the adverse consequences of failing to provide an adequate standard of care to any patient they assess or treat, not only those considered to be at high risk.

Pokorny's complaint that the overwhelming number of false positives renders suicide risk assessment unfeasible is just as valid in 2016 as it was in 1983. His finding, which has been replicated in all subsequent studies, poses a challenge to military and civilian mental health services that have been developed around a model of identifying and managing risk. In response, we recommend abandoning attempts to design interventions based on risk stratification and instead aim to provide an adequate standard of care to all of our patients.

1.7.6 Juvenile delinquency, welfare, justice and therapeutic interventions: a global perspective

Abstract

This review considers juvenile delinquency and justice from an international perspective. Youth crime is a growing concern. Many young offenders are also victims with complex needs, leading to a public health approach that requires a balance of welfare and justice models. However, around the world there are variable and inadequate legal frameworks and a lack of a specialist workforce. The UK and other high-income countries worldwide have established forensic child and adolescent psychiatry, a multifaceted discipline incorporating legal, psychiatric and developmental fields. Its adoption of an evidence-based therapeutic intervention philosophy has been associated with greater reductions in recidivism compared with punitive approaches prevalent in some countries worldwide, and it is therefore a superior approach to dealing with the problem of juvenile delinquency.

Recent years have seen sustained public and academic interest in criminality and mental health, with attention often focused on antisocial behaviour by children and adolescents. The scale of the problem of juvenile delinquency has provoked mixed responses from governments and the media across the world, with calls for improved rehabilitation and support for juvenile offenders competing with voices advocating more punitive approaches.¹ Meanwhile, decades of rigorous academic scrutiny have shed light on the complex and diverse needs of children who come into conflict with the law.²⁻⁵ Much of the growing body of literature on juvenile offenders shows considerable overlap between criminological, social and biomedical research, with a consensus emerging around the significance of a developmental understanding of the emergence of juvenile delinquency.

Importantly, juvenile offenders have consistently been identified as a population that suffers from a markedly elevated prevalence and severity of mental disorder compared with the general juvenile population.^{6,7} Meeting the needs of these young offenders presents practical and ethical challenges concerning treatment and management, including liaison with other agencies.

What is juvenile delinquency?

Who counts as juvenile?

Juvenile delinquency is a term commonly used in academic literature for referring to a young person who has committed a criminal offence, although its precise definition can vary according to the local jurisdiction. The specific reasons underlying these differences are unclear, but they may arise from the lack of an agreed international standard.⁸

A 'juvenile' in this context refers to an individual who is legally able to commit a criminal offence owing to being over the minimum age of criminal responsibility, but who is under the age of criminal majority, when a person is legally considered an adult. The minimum age of criminal responsibility varies internationally between 6 and 18 years, but the age of criminal majority is usually 18 years.

In some cases individuals older than 18 years may be heard in a juvenile court, and therefore will still be considered juveniles; indeed, the United Nations (UN) defines 'youth' as between 15 and 24 years of age. The term 'child delinquents' has been used in reference to children below the age of 13 who have committed a delinquent act,⁹ although elsewhere 'children' are often defined as being under 18 years of age. The term 'young offenders' is broad, and can refer to offenders aged under 18 years or include young adults up to their mid-20s.

What is a crime?

A 'delinquent' is an individual who has committed a criminal offence. Delinquency therefore encompasses an enormous range of behaviours which are subject to legislation differing from one jurisdiction to another, and are subject to changes in law over time. Whereas acts of theft and serious interpersonal violence are commonly considered to constitute criminal offences, other acts including alcohol consumption and sexual behaviour in young people are tolerated to very differing degrees across the world. Sometimes these differences arise as a consequence of historical or cultural factors, and they may be underpinned by traditional religious laws, such as in some Middle Eastern countries. Some offences may be shared between jurisdictions but be enforced to differing standards – for instance, 'unlawful assembly', often used to prevent riots, is applied in Singapore to young people meeting in public in groups of five or more as part of police efforts to tackle youth gangs. Furthermore, 'status offences' – acts that would be permissible in adults but criminalised in children, such as consumption of alcohol or truancy – not only vary between jurisdictions, but contribute to discontinuity when comparing juvenile delinquency with adult populations in the same jurisdiction.

Lack of clarity can also arise in jurisdictions where a young offender is processed via a welfare system rather than a youth justice process. Countries with a high minimum age of criminal responsibility may not technically criminalise young people for behaviour that would normally be prosecuted and therefore classed as 'delinquent' elsewhere.

Not all incarcerated juveniles are 'delinquent', since some may be detained pre-trial and may not be convicted of an offence. Even if convicted, it would be wrong to assume that every 'juvenile delinquent' meets criteria for a diagnosis of conduct disorder; offences vary considerably and may not be associated with a broad repertoire of offending behaviour. Also, most 'juvenile delinquents' do not pose an immediate risk of violence to others, and the vast majority of convicted juveniles serve their sentences in the community.

To meet the diagnostic criteria of conduct disorder requires evidence of a persistent pattern of dissocial or aggressive conduct, such that it defies age-appropriate social expectations. Behaviours may include cruelty to people or animals, truancy, frequent and severe temper tantrums, excessive fighting or bullying and fire-setting; diagnosis of conduct disorder can be made in the marked presence of one of these behaviours.¹⁰

Overall, the term 'juvenile delinquent' is used extensively in academic literature, but requires some care. It can be a potentially problematic term, and in some contexts can strike a pejorative tone with misleading negative assumptions. For several years the UN has used the phrase 'children in conflict with the law' to describe the breadth of the heterogeneous group of individuals under the age of 18 who have broken the law or are at risk of doing so.

General principles of juvenile justice

Welfare v. justice models

The sentencing of an individual convicted of a criminal offence is largely driven by three key considerations: retribution (punishment), deterrence and rehabilitation. In the case of juvenile offenders the principle of rehabilitation is often assigned the greatest weight.¹¹

Special consideration for juveniles within the criminal justice system is not a new concept. In Roman law, the principle of *doli incapax* protected young children from prosecution owing to the presumption of a lack of capacity and understanding required to be guilty of a criminal offence. Most countries have some provision for special treatment of children who come into conflict with the law, however, the degree to which this is provided varies across the world.^{1,12} In some countries a 'welfare' model prevails, which focuses on the needs of the child, diagnosis, treatment and more informal procedures, whereas other countries favour a 'justice' model, which emphasises accountability, punishment and procedural formality.

Belgium is frequently cited as an example of a country with a strong welfare process, supported by a high minimum age of criminal responsibility of 18 years. Similarly, France built a strong welfare reputation by placing education and rehabilitation at the centre of youth justice reforms in the 1940s. New Zealand in 1989 established the widely praised system of Family Group Conferencing as an integral part of youth justice, with a focus on restoration of relationships and reduction of incarceration that would be considered part of a welfare approach. In contrast, the UK and the USA

have traditionally been associated with a justice model and low age of criminal responsibility – 10 years in England and Wales, and as low as 6 years in several US states.

Within welfare or justice models, a young person may at some point be ‘deprived of liberty’ – defined as any form of detention under official authorities in a public or private location which the child is not permitted to leave. Locations in which children may be deprived of liberty include police stations, detention centres, juvenile or adult prisons, secure remand homes, work or boot camps, penitentiary colonies, locked specialised schools, educational or rehabilitation establishments, military camps and prisons, immigration detention centres, secure youth hostels and hospitals.¹³

Between the less and more punitive systems

The UN supports the development of specialised systems for managing children in conflict with the law. When the first children’s courts were set up in the USA in the 1930s, they were widely praised as a progressive system for serving the best interests of the child. Although informality was championed as a particular benefit, in the 1960s substantial concerns arose about due process and the protection of the legal rights of minors. The subsequent development of formal juvenile courts occurred in the context of a continuing ethos of rehabilitation of young people, with a move away from incarceration of juveniles in the 1970s, especially in Massachusetts and California. However, following a marked peak in juvenile offending statistics during the 1980s and 1990s, public and political opinion swung firmly in a more punitive direction. This was accompanied by legal reforms that increased the severity of penalties available to juvenile courts and lowered the age threshold for juveniles to be tried in adult criminal courts.

When the UN Convention on the Rights of the Child entered into force in 1990, the USA was not a signatory owing to 22 states permitting capital punishment of individuals who had committed their crimes as juveniles. It is reported that 19 juvenile offenders were executed in the USA between 1990 and 2005. Although this number may represent a small percentage of the total who faced the death penalty in the USA during that period, the practice was widely criticised by international bodies and organisations.¹⁴ A landmark ruling in the US Supreme Court¹⁵ outlawed the execution of juvenile offenders in the USA, but to date a small number of countries worldwide still implement this practice, sometimes as a result of religious laws.

However, it would be wrong to assume that welfare systems are automatically preferable to a juvenile justice approach, since welfare arrangements can be equally coercive in terms of deprivation of liberty of juveniles. They may lack due process, safeguards for obtaining reliable evidence from young people, processes for testing evidence, and procedures for scrutiny or appeal following disposal.

Trends in youth crime

The USA witnessed a dramatic increase in arrest rates of young people for homicide and other violent crimes in the 1980s and 1990s, sometimes referred to as the ‘violence epidemic’.¹⁶ The ensuing moral panic led to harsh and punitive policy changes in juvenile justice and, although official statistics document a subsequent fall of 20% in court case-loads between 1997 and 2009, victimisation surveys have indicated a degree of continuity in high levels of offending, consistent with a reported increase in juvenile offending between 2000 and 2006.¹⁷

In common with the USA and several other high-income countries, the UK also experienced a rise in juvenile offending in the 1980s and 1990s, but figures from the Youth Justice Board for England and Wales appear to indicate a general improvement in recent years. Between 2009/2010 and 2014/2015 a 67% reduction has been observed in the number of young people entering the juvenile justice system for the first time, a 65% reduction in the number of young people receiving a caution or court disposal and a 57% reduction in the number of young people in custody.¹⁸ These figures support an overall decrease in juvenile offending noted since the early 1990s.¹⁹

Youth crime figures from Australia have documented a 4% reduction in the overall number of young offenders in 2013/2014,²⁰ although the number of violent offences committed by young people in the urbanised and densely populated region of Victoria has increased by 75% between 2000 and 2010.²¹

The Nordic countries have witnessed an increase in the number of law-abiding youths from 1994 and 2008.²² In Sweden, both objective levels of juvenile crime²³ and self-reported involvement in juvenile crime²⁴ have fallen between

1995 and 2005. Similarly in Finland, where, despite fluctuating trends in juvenile drug use, juvenile property and violent crime is reported to have decreased between 1992 and 2013.²⁵

To summarise, whereas regional and annual trends in juvenile offending are observed and expected, a global trend characterised by decreased juvenile offending appears to have emerged in recent years. Indeed, UN data from a sample of 40 countries lend support to this conclusion, indicating a decrease in the proportion of juveniles suspected (10.9% to 9.2%) and convicted (7.5% to 6%) of crime between 2004 and 2012, respectively.²⁶

Juvenile gang membership

Influence on crime involvement

One of the features of urbanisation across the world has been the rise of youth gangs, groups of young people often defined by geographical area, ethnic identity or ideology; recent reports indicate a rise in groups with extremist views. Explanatory models for the rise in youth gangs include factors such as economic migration, loss of extended family networks, reduced supervision of children, globalisation and exposure to inaccessible lifestyle 'ideals' portrayed in modern media.

Authorities in Japan attributed a surge in serious youth crime in the 1990s primarily to juvenile bike gangs known as 'bosozoku', who were deemed responsible for over 80% of serious offences perpetrated by juveniles, putatively bolstered by a crackdown on yakuza organised crime syndicates.²⁷ Although difficult to quantify, gang involvement appears to feature in a large proportion of juvenile offences, and there is evidence that gang membership has a facilitating effect on perpetration of the most serious violence including homicide.²⁸

Mental health

Compared with general and juvenile offender populations, juvenile gang members exhibit significantly higher rates of mental health problems such as conduct disorder/antisocial personality disorder, post-traumatic stress disorder (PTSD), anxiety disorders and attention-deficit hyperactivity disorder (ADHD).²⁹ Gang members, compared with non-violent men who do not belong to a gang, are far more likely to utilise mental health services and display significantly higher levels of psychiatric morbidity, most notably antisocial personality disorder, psychosis and anxiety disorders.³⁰ Gang membership has also been positively correlated with an increased incidence of depressed mood and suicidal ideation among younger gang members.³¹ Prevalence of ADHD is significantly greater in incarcerated youth populations (30.1%) than in general youth population estimates (3–7%),³² therefore it may be reasonable to expect a similarly increased prevalence in juvenile gang members. ADHD has also been associated with a significantly increased risk of comorbid mood/affective disorder.³³

Forensic child and adolescent psychiatric services

Increased awareness of constitutional and environmental factors that contribute to juvenile offending has strengthened a public health perspective towards the problem, and in the UK entry into the youth justice system has been adopted as an indicator of general public health.³⁴

Dictionaries frequently define 'forensic' as meaning 'legal', implying a relationship with any court of law. Indeed, many forensic psychiatrists, particularly in child and adolescent services, undertake roles that encompass multiple legal domains relevant to mental health, including criminal law, family and child custody proceedings, special educational tribunals, and immigration or extradition matters.

Specialist forensic psychiatric services vary considerably between countries,³⁵ but usually forensic psychiatrists assess and treat individuals in secure psychiatric hospitals, prisons, law courts, police stations and in the community under various levels of security, supervision and support. In some countries there has been a trend towards forensic psychiatrists working almost exclusively with courts of law, providing independent specialist opinion to assist the court.

In the UK, forensic child and adolescent psychiatry has emerged as a clinical subspecialty. Some services are based in specialist secure hospitals for young people and cater for the relatively small number of high-risk young offenders with the most severe mental disorders. In the absence of such specialist resources, young people may be managed in suboptimal environments such as juvenile prisons, secure residential placements or secure mental health wards for adults, or even fail to receive treatment at all.

In light of growing evidence-based interventions for juvenile offenders within a public health framework,³⁶ the role of child and family mental health services may increase over time. Aside from direct clinical roles, practitioners in forensic child and adolescent psychiatry are also well placed to work with a wide range of partner agencies on the planning and delivery of broader interventions for the primary and secondary prevention of juvenile delinquency.

Treatment

Prevalence of mental health problems among juvenile offenders

Rates of mental health problems among juvenile offenders are significantly higher than in their non-offender peers, with two-thirds of male juvenile offenders in the USA suggested as meeting criteria for at least one psychiatric disorder.³⁷ One in five juvenile offenders is estimated to suffer severe functional impairment as a result of their mental health problems.³⁸ Paradoxically, these needs are often unmet,^{39,40} despite evidence of increased contact with mental health services, particularly among first-time juvenile offenders.^{41,42} Of additional concern are the reported associations between mental health problems and mortality in incarcerated juveniles,⁴³ including an elevated suicide rate for males.⁴⁴ Mental health problems must be a target in interventions for juvenile offenders; however, treatments which focus solely on clinical problems are unlikely to result in benefit for criminogenic outcomes.⁴⁵ There is therefore a clear need for effective interventions which address both the clinical and criminogenic needs of these individuals.

Evidence-based treatments for mental health problems

Treatment of PTSD

Estimates regarding the prevalence of PTSD among juvenile offenders suggest that 20 to 23% meet the clinical criteria,^{46,47} with prevalence rates significantly higher among females than males (40% v. 17%).⁴⁶ Moreover, with 62% experiencing trauma within the first 5 years of life⁴⁷ and up to 93% experiencing at least one traumatic event during childhood or adolescence,⁴⁸ this should be a target for intervention.

Cognitive-behavioural therapy (CBT) is regarded as the most effective intervention for adults with PTSD⁴⁹ and also has demonstrated efficacy for juvenile non-offenders.^{50,51} There is limited evidence suggesting a significant reduction in self-reported symptoms of PTSD following group-based CBT in male juvenile offenders,⁵² and of an adapted version of CBT, cognitive processing therapy,⁵³ also resulting in a significant reduction in self-reported symptoms of PTSD and depression compared with waitlist controls.⁵⁴

A trauma-focused emotion regulation intervention (TARGET) has received preliminary empirical support for use in this population. TARGET resulted in nearly twice as much reduction in PTSD symptom severity as treatment as usual (TAU),⁵⁵ in addition to significant reductions in depression, behavioural disturbances and increased optimism.⁵⁶

Mood/anxiety disorders and self-harm

Juvenile offenders in the UK present with a high prevalence of mood and anxiety disorders (67% of females, 41% of males), self-harm (11% of females, 7% of males) and history of suicide attempts (33% of females, 20% of males).⁵⁷ Similarly high prevalence has also been observed cross-culturally, namely in the USA,^{37,58} Switzerland⁵⁹ and Finland.⁶⁰

Despite such high prevalence, there appears to be a paucity of high-quality evaluations regarding the effectiveness of interventions for juvenile offenders with mood and/or anxiety disorders, or problems with self-harm. However, the limited evidence that is available suggests that group-based CBT may aid symptom reduction.⁶¹ Recovery rates for major depressive disorder following group-based CBT are over double those for a life skills tutoring intervention (39% *v.* 19%, respectively), although no significant difference was noted at 6- or 12-month follow-up. CBT also resulted in significantly greater improvements in self- and observer-reported symptoms of depression and social functioning.⁶²

However, group-based CBT is not reported to be significantly different from TAU in reduction of self-harm,⁶³ whereas individual CBT is not significantly different from TAU in outcomes for depression, anxiety, conduct disorder or PTSD.⁶⁴ Yet recruitment to and retention in intervention seems good, suggesting that CBT is feasible to implement in juvenile offender populations.⁶⁴

Evaluations of alternative interventions have posited muscle relaxation as effective in improving juvenile offenders' tolerance of frustration.⁶⁵ Dialectical behaviour therapy (DBT) has also been reported to significantly reduce incidences of physical aggression in a juvenile offender population⁶⁶ and among juvenile non-offenders expressing suicidal ideation.⁶⁷ It significantly reduced serious behavioural problems and staff punitive actions among juvenile offenders within a mental health unit, although no similar significant reductions were observed for those without mental health problems.⁶⁸

Evidence-based treatments for conduct disorder: family approaches

Relationships with family and peers are recognised as key factors in the criminogenic profile of juvenile offenders.⁶⁹ Multisystemic therapy (MST) is a family-focused intervention targeting characteristics related to antisocial behaviour, including family relationships and peer associations,⁷⁰ with evidence from US and UK studies suggesting MST is a beneficial intervention for juvenile offenders. When compared with conventional services offered by juvenile offending services, MST was associated with a significant reduction in the likelihood of reoffending,⁷¹ maintained 2 and 4 years post-treatment.^{72,73} Offenders engaging in MST are reported to be significantly less likely to become involved in serious and violent offending.^{73,74} Significant improvements have also been observed in both self- and parent-reported delinquency,⁷⁴ family relations and interactions,⁷³ and home, school, community and emotional functioning.⁷¹ A cost offset analysis of MST among UK juvenile offenders suggested that combining MST and conventional services provides greater cost savings than conventional services alone, as a result of its positive effects on recidivism.⁷⁵ Qualitative impressions of MST from juvenile offenders and their parents indicate that key components of a successful delivery of MST include the quality of the therapeutic relationship and ability to re-engage the offender with educational systems.⁷⁶

Some evidence also exists regarding the efficacy of MST when delivered to non-offender antisocial juvenile populations outside the USA and the UK. Compared with TAU, MST resulted in a significantly greater increase in social competence and caregiver satisfaction, and a significant reduction in referrals for out-of-home placements, in Norwegian juveniles exhibiting serious behavioural problems.⁷⁷ However, no significant difference between MST and TAU was reported in outcomes for antisocial behaviour and psychiatric symptoms in Swedish juvenile offenders.⁷⁸ MST was also found to have no significant benefit over TAU in outcomes including recidivism in a sample of Canadian juvenile offenders.⁷⁹ These differing outcomes have been posited as the result of barriers in transferring MST from US and UK populations owing to differing approaches to juvenile justice between countries (i.e. a welfare *v.* justice approach).⁷⁸ The heterogeneous nature of studies concerning MST in juvenile offender populations prevent a firm conclusion being drawn as to its superiority over alternative interventions, although this does not diminish the positive outcomes which have been observed.⁸⁰

Substance misuse

Motivational interviewing represents a promising approach for juvenile offenders, particularly as a treatment for substance misuse.⁸¹ Group-based motivational interviewing has received positive feedback from participants when implemented with first-time juvenile alcohol or drug offenders,⁸² and compared with TAU, juvenile offenders in receipt of motivational interviewing have greater satisfaction and display lower, though not statistically significant, rates of recidivism at 12-months post-motivational interviewing.⁸³ There is therefore preliminary evidence for the acceptability and feasibility of motivational interviewing for substance-misusing juvenile offenders, but future research regarding long-term outcomes is warranted. To date, motivational interviewing for difficulties faced by juvenile offenders beyond that of substance misuse does not appear to have received much research attention. Juvenile offenders are known for their difficulty to engage in rehabilitative services, therefore further investigation of the effectiveness of motivational interviewing in encouraging engagement is warranted.

Preliminary investigations have also developed a conceptual framework for the delivery of mindfulness-based interventions (MBI) to incarcerated substance-misusing juveniles, with qualitative impressions suggesting this is a potentially feasible and efficacious intervention.⁸⁴ Although literature regarding the effectiveness of MBI in juvenile offenders is scarce, qualitative feedback has indicated positive reception of this style of intervention, with particular improvements in subjective well-being reported by juvenile participants.⁸⁵

Employment and education

Engaging juvenile offenders with education and skills-based training is an important component of successful rehabilitation, with positive engagement in meaningful activities associated with improvements in areas such as self-belief⁸⁶ and protection against future participation in criminal activities.⁸⁷ It is concerning therefore that an evaluation of the use of leisure time over a 1-week period by probationary juvenile offenders in Australia indicated only 10% of this time was spent engaging in productive activities, such as employment or education, with 57% used for passive leisure activities, a level 30% higher than that of their non-offender peers.⁸⁸

Efforts to engage juvenile offenders in vocational and/or occupational activities have shown benefits in a number of areas. A specialised vocational and employment training programme (CRAFT) emphasising practical skills was evaluated against conventional education provision to juvenile offenders in the USA. Over a 30-month follow-up period, those engaged in CRAFT were significantly more likely to be in employment, to have attended an educational diploma programme and to have attended for a significantly longer period of time.⁸⁹ Benefits have also been reported with regard to risk of reoffending, with an after-school programme in the USA incorporating practical community projects, educational sessions and family therapy resulting in a significant reduction in recidivism at 1-year follow-up.⁹⁰

Qualitative investigations of US juvenile offenders suggest there is not a lack of interest in pursuing education among this population, but rather a disconnection with educational systems when education providers are perceived not to care about students' progress.⁹¹ Ensuring education providers are perceived as proactive and caring in this regard may therefore be an important consideration for efforts to engage juvenile offenders with educational systems. Significant barriers to engagement include difficulties in obtaining accurate information regarding the offender's educational history, in addition to identifying community-based education providers willing to accept previously incarcerated juveniles on their release.⁹²

Language and communication

Difficulties with language and communication skills appear to be prevalent among juvenile offenders, with estimates of those falling into the poor or very poor categories ranging from 46 to 67%; overall, up to 90% of juvenile offenders demonstrated language skills below average.⁹³ Specifically, high rates of illiteracy are reported in this population,⁹⁴ with evidence to suggest that an awareness of such problems among juvenile offenders themselves is associated with dissatisfaction and poor self-esteem.⁹⁵ These difficulties may act as barriers to engagement in therapeutic interventions, particularly those delivered in group settings, as well as re-engagement with educational systems. Awareness of the challenges these young people face with regard to confidence and ability to communicate is important, and potential involvement of a speech and language therapist could be considered. Preventing deficits in language and communication through effective schooling and appropriate support in the early years of life may serve as an aid to effective engagement in rehabilitative interventions, and may also mitigate the risk of engagement in criminal activities in the first instance.

Delivery of therapeutic services

Common challenges to a therapeutic youth justice pathway

There are common obstacles to smooth care pathways between different parts of systems, such as in transitions between secure settings and the community, between prisons and secure psychiatric settings, and between child and adult services. In some jurisdictions individuals can only be treated pharmacologically against their will in a hospital setting, a safeguard which limits the extent to which individuals can be treated in prison, but there is still great scope for intervention by prison mental health teams in juvenile prisons.

Factors associated with good outcomes

A meta-analysis has revealed three primary factors associated with effective interventions for juvenile offenders: a 'therapeutic' intervention philosophy, serving high-risk offenders, and quality of implementation.⁹⁶ These findings are consistent with factors posited as correlating with good outcome in residential centres for troubled adolescents and juvenile offenders: good staff-adolescent relations, perception of staff as pro-social role models, positive peer pressure, an individualised therapeutic programme approach, developmentally appropriate programmes and activities, clear expectations and boundaries, and placement locations which allow for continued family contact.^{97,98}

In the community, coercive styles of engagement have been found to be less successful at achieving adherence among juvenile offenders than a client-centred approach.⁹⁹

Factors associated with poor outcomes

'Scared Straight' programmes expose juveniles who have begun to commit offences to inmates of high-security prisons, yet these approaches have been discredited due to evidence that risk of recidivism may in fact increase following such exposure.¹⁰⁰ Similarly poor outcomes have been observed in programmes modelled on military boot camps, in which harsh discipline is considered to be of therapeutic benefit,¹⁰¹ and initiatives such as curfew, probation and hearing juvenile cases in adult court were also shown to be ineffective in reducing recidivism.¹³

Over recent years it has been repeatedly demonstrated that exposure to juvenile court itself appears to have a detrimental effect on juvenile offending.¹⁰²⁻¹⁰⁴ This may be partially explained by effects of labelling, stigma and negative self-image associated with a criminal conviction, but also the practical consequences of sentences, including assortment of delinquent peers in community or prison sentences. Incarceration presents several additional harms, including disturbance of care and pro-social relationships, discontinuity in education, association with delinquent peers, and exposure to violence. Half of detained young offenders in the UK reported victimisation during their current prison term,⁵⁷ while 12% of incarcerated youth in the USA reported sexual victimisation in the previous year.¹⁰⁵ International agreements state that deprivation of liberty (such as juvenile prison) should be used as a last resort and for the shortest time necessary, so should be reserved for the highest-risk offenders. The cost of juvenile antisocial behaviour is known

to be high, and to fall on many agencies.¹⁰⁶ The current climate of austerity in public services demands that any interventions should be not only effective, but also cost-effective, raising a clear challenge – and opportunity – for the implementation of interventions for this population of vulnerable young people. For example, parenting programmes have demonstrated sustained benefits for this population,^{107,108} with economic analysis indicating gross savings of £9288 per child over a 25 year period.¹⁰⁹ Considered together with wider costs of crime, these gross savings exceed the average cost of parenting programmes (£1177) by a factor of approximately 8 to 1.

Conclusions

Many argue that we have a long way to go before arriving at ‘child friendly’ juvenile justice.¹¹⁰ Around the world there are variable and inadequate legal frameworks that are not age-appropriate, there is a lack of age-appropriate services and establishments, and a lack of a specialist workforce, leading to challenges around training and supervision to work with this vulnerable population. In the UK and other high-income countries worldwide, forensic child and adolescent psychiatry is a multifaceted discipline incorporating legal, psychiatric and developmental fields. This approach has navigated clinical and ethical challenges and made an important contribution to welfare and justice needs by its adoption of an evidence-based therapeutic intervention philosophy.

1.7.7 ‘Doc, can I fly to Australia?’ A case report and review of delirium following long-haul flight

Thomas McCabe

Abstract

Air travel is now a common feature of most of our elderly population’s lives. There is little by way of warnings, rules or recommendations for our patients with psychiatric diagnoses, in particular dementia, who intend to travel by plane, in contrast to other specialties. In this article I highlight an adverse outcome of long-haul air travel as a result of delirium and resulting accelerated decline in overall cognitive function. I review literature related to the topic and suggest ways to minimise precipitating factors for stressors prior to and during flights. This article suggests that more thought should be given to the title question.

- *Discussion*
- *Recommendations*

Short-haul and long-haul air travel are now commonplace among the elderly population. Evidence suggests such travel is on the increase from the late 1990s, with as many as 1 in 5 people above the age of 65 passing through the main UK international airports in 2014.^{1,2} Little thought is given to short weekend breaks abroad or long-distance holidays with family with mental and physical impairments. In-flight adverse events are difficult to ascertain from information and figures produced by airlines, and apart from the well-recognised morbidity they are not well reported.³ Syncope, respiratory problems and vomiting continue to provide the bulk of in-flight emergencies, with around 1 medical emergency occurring in every 600 flights.⁴ There are no data focusing on the elderly population or people with a diagnosis of mental illness, although one recent source cited ‘anxiety’ as a reason for non-traumatic in-flight complaints.⁵

In this case report I highlight an incident where a delirium has had a significant impact on an elderly patient, resulting in an accelerated decrease in function, long-term impairment and associated symptomatic control with medications that otherwise could have been avoided. I will highlight ways of minimising chances of negative outcomes following air travel in the elderly population.

Case presentation

A 73-year-old man was initially referred to the memory clinic in December 2013 with a history of gradual deterioration of short-term memory and increased dependence on family over an approximate 18-month period. This was with a background of stable multiple sclerosis with no other medical history of note. He was functioning well owing to a supportive family and positive routine activities undertaken mostly with his wife and had a strong academic background which could have contributed to masking of cognitive defects. He was given a diagnosis of a mild cognitive impairment based on impaired short-term memory, as evidenced by clinical evaluation and formal cognitive testing. He scored 80/100 on the Addenbrooke’s Cognitive Examination III; most points were lost in the memory parts (where he scored 10/26) and less so in the fluency part (scoring 10/14) of the test. He was referred to neuropsychology, for brain imaging and was to be seen back in the clinic in 6 months’ time. There were no treatable cardiovascular risk factors at this point; however, the patient was counselled on exercise and diet as well as basic activities to promote cognitive training in keeping with present guidance. The patient and his wife were informed it was difficult to give prognosis and although evidence is varied, a person with amnesic (memory loss) mild cognitive impairment would be at around 1 in 5 risk of being diagnosed with dementia at a later stage. From this presentation and clinical evaluation, it was thought that an Alzheimer’s dementia was the most likely future diagnosis.

The patient then travelled by plane from Scotland to Australia, which involved a short connecting flight to London. On descent from the air to Australia, he experienced an episode of agitation and bizarre, nihilistic delusions about Nazis taking over the plane. After landing, he was admitted to a large, well-known teaching hospital in Australia. He continued to exhibit challenging behaviours such as agitation, wandering and resistance to attempts at basic care from nursing staff. The patient required assistance with feeding and one-to-one nursing care for the majority of the in-patient stay.

The patient’s medical investigations included a positron emission tomography (PET) scan, magnetic resonance imaging (MRI) brain scan, lumbar puncture, electrocardiogram (ECG), chest X-ray, urinalysis, basic blood tests and whole-body computed tomography (CT) over the course of admission without an obvious cause being found for such a dramatic decline and previously unseen behaviours. Of note, any cerebrovascular accident, pneumocephalus, acute kidney injury, external and middle-ear disease and sepsis were ruled out on admission. It was noted that there were no particular risk factors in terms of family history, smoking, hypertension, dyslipidaemia and diabetes which could have increased the risk of most of the proposed diagnoses. Basic observations, including oxygen saturations, were largely unremarkable throughout his admission. He was reviewed by both the neurology and neuropsychiatric teams who came to a joint conclusion that he was experiencing a delirium and previously undiagnosed Alzheimer’s dementia.

He was treated with antipsychotics and given a short trial of intravenous steroid given the history of multiple sclerosis (although not indicated by way of imaging) without any improvement in clinical state.

The patient stabilised enough for repatriation to the UK with a nurse escort after approximately 4 months of in-patient care. At this stage he showed significant deterioration in executive functioning from baseline assessment, limited capacity for new learning, confabulation and required assistance with all personal needs. On descent of the aircraft the patient again deteriorated, with disorientation, agitation and paranoid features once again predominant. Admission to hospital and further investigations gave us no obvious clues to an ongoing acute event. Brain imaging in both Australia and the UK remained unchanged with CT showing generalised atrophy and MRI revealing a minor degree of small vessel disease and smaller than expected hippocampal volume, and suggested Alzheimer's as the only radiological explanation for the presentation.

Outcome

The episode has had a significant effect on the patient's level of functioning and a sizable knock-on effect on his family. He is now a patient in a National Health Service (NHS) long-term care facility requiring assistance with all basic activities of daily living and without much by way of coherent or meaningful conversation. He continues to be managed with antipsychotic medications and benzodiazepines which allow him to be settled on the ward and nursing staff to assist with his needs. It is difficult to ascertain whether there has been any further deterioration in the patient's disease process, however, there has not been any improvement seen. His family continue to harbour feelings of guilt at the original decision to fly to Australia without consultation with medical staff and disappointment at being unable to care for the patient in their home.

My overall aim for writing this case is for the reader to acknowledge the case of a patient with a likely dementia who has had a stark and accelerated decline in function as a result of a change in environment and residual delirium after going on two long-haul flights. Pinpointing the precise mechanism for the delirium continues to be a challenge owing to the number of medical staff involved and the difficulties with communication between continents. Prolonged hypoxia or changes in cabin pressure would seem to be the most obvious causative factors for the delirium given the collateral history, with particular focus on symptoms becoming pronounced on descent. However, this is without any firm scientific basis and is not backed up by anything discovered on clinical examination or investigation.

Discussion

Air travel has become a normal part of everyday life in the UK, with Heathrow, the third-busiest airport in the world, estimated to see approximately 1300 take offs and landings in an average day.⁶ The advent of 'no frills' airlines in the mid 1990s has seen a marked rise in short-haul flights and regional airports have expanded as a result. Combined with the total standardised prevalence of dementia syndrome in the 65+ population, which is thought to be 7.1% at most recent estimates,⁷ air travel is now a common component for a sizable amount of the older population.

From a literature search it would appear that air travel in the elderly population is a safe practice, given that there is little evidence to suggest otherwise. However, there have been a number of reports recently of people with dementia getting lost in airports resulting in national press- and social media-aided searches.^{8,9} Roberto Castiglioni, an adviser to the UK Civil Aviation Authority, has described the impact dementia could have on air travel as 'a ticking time bomb that medical research and the travel industry are yet to address'.¹⁰

There is one reported case of an older man in Australia, a seasoned traveller, who in 2009 developed delirium on a long-haul flight and spent a long period of time as an in-patient as a result.¹¹ The authors state that the patient's decline was precipitated by air travel, but they do not expand on this. They propose that a brief cognitive screening tool to be used prior to travel be developed.

A useful review, also from Australia,¹² summarises the physical hazards associated with air travel and states that people with early dementia may be more prone to developing delirium in flight. It sets out practical ways to minimise this risk.

In contrast to the above there are strict criteria for air travel for physical ailments which are well publicised and adhered to by all the major airlines. For example, the Civil Aviation Authority suggest 14 days have passed prior to air travel following a coronary artery bypass grafting (CABG) procedure and most airlines will not allow women with single pregnancies beyond 36 weeks to travel with their companies. Compare this with the less stringent statement that they would have 'concern' (rather than instruction not to travel) with patients who may exhibit or develop 'disorganised and

disruptive behaviours' in flight, as set out in the Civil Aviation Authority's 'fitness to fly' guidance.¹³ This is a likely reflection on the lack of morbidity and mortality figures available on the topic combined with the unpredictable course and variable stages of dementia and degree of severity of delirium.

It should also be noted that not only this case described but the others mentioned in the discussion involved movement to and from Australia. It would seem unlikely that this alone is a causative factor and indeed it is the length of flight or descent from high altitude that increases the likelihood of deterioration, but it is worth bearing in mind if the overall topic expands, as some have predicted.

Recommendations

Table 1 sets out practical ways to help minimise any air travel-related situations which may potentially cause upset to a patient. These can be addressed prior to travel by input from general practitioners (GPs) and optimising control of pre-existing conditions as well as assistance with travel insurance practicalities. Contact with airports and airlines with the aim of reducing transit time through airports and assistance getting on the plane as well as sensible seating choice (i.e. more leg room, access to lavatory) may also aid in reducing potential stressors.

A summary of recommendations

Pre-flight	In-flight
Attend GP	Stay well hydrated
Optimise chronic conditions	Comfortable clothing
Travel insurance	Familiar distractions
Consider group tours	Inform cabin crew
Assistance in airport	Assistance on/off flight
Extra leg room request	Avoidance of alcohol/unfamiliar foods
Minimise time through security checks	Aisle seating request

GP, general practitioner.

I believe GPs and old age psychiatrists should consider more extensive counselling when the title question is asked and indeed any questions around travel could be pre-empted by medical staff. Patients and carers should be made aware of the dangers posed by hypoxia, changes in pressure environments and barotrauma and the potential for adverse outcomes that these can have on mental state, particularly in those with pre-existing respiratory and ear, nose and throat (ENT) conditions. Little research has been carried out into the overall use, benefit or otherwise of anxiolytics in elderly (or indeed anxious) flyers and this should be explored. Informal discussions with colleagues in the community would suggest the use of benzodiazepines is accepted and relatively common.

1.7.8 Mental capacity and borderline personality disorder

Karyn Ayre Gareth S. Owen Paul Moran

Karyn Ayre (karyn.ayre@slam.nhs.uk)¹

date

2017-2

Abstract

The use of the Mental Capacity Act 2005 in assessing decision-making capacity in patients with borderline personality disorder (BPD) is inconsistent. We believe this may stem from persisting confusion regarding the nosological status of personality disorder and also a failure to recognise the fact that emotional dysregulation and characteristic psychodynamic abnormalities may cause substantial difficulties in using and weighing information. Clearer consensus on these issues is required in order to provide consistent patient care and reduce uncertainty for clinicians in what are often emergency and high-stakes clinical scenarios.

Contents

- *Mental capacity and borderline personality disorder*

 - *How does BPD affect capacity?*
 - *How this affects clinical practice*
 - *Conclusions*

Borderline personality disorder (BPD) is a severe mental disorder affecting around 1% of the population.¹ It is associated with significant psychiatric comorbidity,² impairment in social function³ and a high rate of service utilisation.⁴ Personality disorder as a whole is associated with reduced life expectancy.⁵ People with BPD may engage in self-harming behaviour as a way of regulating negative affect, particularly at times of crises.⁶ Assessing decision-making capacity in a patient with BPD who requires medical treatment following an act of self-harm is particularly challenging.⁷ In the overlap between the Mental Health Act 1983 and Mental Capacity Act 2005 (the Act), it is the decisions around physical healthcare treatment without consent, i.e. those that the Mental Health Act cannot be used to enforce unless treatment is recognised as treatment for mental disorder, that in our experience generate considerable anxiety. This is particularly true in a general hospital setting as exemplified in the tragic case of Kerrie Woollorton.⁸

The Mental Capacity Act is the legal framework used in England and Wales for assessing capacity. It also provides protection to a clinician who makes decisions on behalf of an incapacitous patient, providing its terms are satisfied and the clinician is acting in the patient's best interests. Assessment of capacity is time- and decision-specific, however, in our clinical experience there is inconsistency surrounding the use of the Act with BPD patients. This is partly the result of disputes relating to the nosological status of personality disorder as a whole.^{7,9} Such disputes are discordant with

increasing knowledge about the natural history of BPD and its neurobiological abnormalities and treatability. In this article we explore the key reasons for inconsistency on whether BPD has the potential to give rise to the ‘impairment of, or disturbance in the functioning of, the mind or brain’ criterion of the Act, as well as highlighting the need for clearer guidance on the use of the Act with such individuals.

Applicability of the Act in borderline personality disorder

As indicated by Section 2(1) of the Act, patients must demonstrate an ‘impairment of, or disturbance in the functioning of, the mind or brain’ for the Act to apply – sometimes known as the ‘diagnostic threshold’. Applicability to patients with a psychotic illness or a severe affective disorder is rarely questioned, presumably because these conditions are clearly described and widely accepted as constituting mental disorders that have the potential to impair or disturb function.⁷ However, in one of the few discussions of the impact of personality disorder on competence to refuse treatment, Winburn & Mullen¹⁰ point out that personality disorder, although classed as such under the Mental Health Act 1983, ‘has always been considered to be at the margins of what constitutes mental disorder’. Although it is by no means an exhaustive list, paragraph 4.12 of the Mental Capacity Act Code of Practice¹¹ does not include personality disorder among the other conditions it recommends as having the potential to cause impairment or disturbance in the functioning of the mind or brain. Indeed, as recently as the past decade, lingering doubts about the nosological status of personality disorders in general were still being voiced by senior figures in academic psychiatry.⁹

Over the past 10–15 years, the empirical evidence base for personality disorders in general and particularly for BPD has expanded substantially. Robust longitudinal studies have charted the natural history of BPD¹² and shown that while symptomatic improvement is common, enduring impairment in social functioning³ is a defining feature of the condition. Cost of illness studies have shown that the costs of managing people with BPD exceed the costs associated with managing people with depression.⁴ Other studies have shown that the life expectancy of people with personality disorder is markedly reduced and that the loss of lived years is at least equivalent to that seen in schizophrenia.⁵ There is also growing evidence of underlying neurobiological abnormalities associated with BPD.^{13,14} Finally, the increasing number of well-conducted clinical trials which show that effective treatment is possible provides further evidence supporting the validation of the construct of BPD.¹⁵

In summary, as a result of considerable research endeavour, we now know that BPD is, without doubt, a valid category of mental disorder. As such, it must be considered ‘an impairment of, or a disturbance in, the functioning of the mind or brain’. Therefore, not only is the Mental Capacity Act framework applicable to people with BPD, but it is clinically inappropriate not to consider its relevance when assessing people with BPD. There is a need for greater consensus regarding this, to eradicate the assumption that capacity assessments, *tout court*, cannot apply to such patients.^{7,11}

Perhaps another reason why this assumption has been so pervasive relates to Parsons’s notion of the ‘sick role’.¹⁶ This illustrates the link between illness and its social benefits: among these, the absolution of responsibility.¹⁷ The doctor’s role is key, as it is the doctor who confers this role on the patient and provides social sanction for receipt of those benefits.¹⁶ Doctors are often divided as to whether patients with BPD can be thought of as being ill and thus entitled to a sick role.^{9,18} As the Act requires the presence of an ‘impairment’ or ‘disturbance in function’ to be applicable, one might view its application to BPD patients as being synonymous with sanctioning an adoption of the sick role. Such a view may not sit comfortably with a clinician who may view a volitional act of self-harm as being ‘manipulative’.^{9,18}

The issue of volitional control and, by inference, manipulation, therefore seems the crux of the matter. Pickard¹⁹ points out that it is hard to accept that patients with a personality disorder completely lack control over their actions. She qualifies this by pointing out they ‘may not always have full conscious knowledge of why they are behaving as they do’.¹⁹ Similarly, Szukler has speculated that suicidal impulses may sometimes stem from ‘an inner disturbance the [person] finds difficult to describe’.⁷ The question for clinicians is that, in situations where high-stakes decisions must be made, how does the phenomenology of BPD impair an individual’s ability to understand and reflect on both the risks and benefits of treatment, and also the motivation underlying their behaviour?

How does BPD affect capacity?

Fuchs²⁰ identified that, at the extremes of emotional dysregulation, BPD patients become enveloped in that mental state to the extent that they are unable to view things objectively. Over time, repetition of this cycle leads to the chronic feelings of emptiness that characterise the disorder, meaning that patients ‘miss the experience of agency or authorship of their life’.²⁰ Broadly speaking, this key concept can be illustrated in two general clinical scenarios.

The first is a patient presenting as an emergency at the extreme of an episode of emotional dysregulation. Self-harming behaviours may serve an affect regulation function⁶ and assessment of capacity to accept or refuse treatment following a severe episode of self-harm is a common clinical scenario. The framework for decision-making, per the Act, requires the patient to understand the pros and cons of treatment for their condition. If the self-harm is life threatening, accepting treatment would therefore be life saving, and to refuse, by inference, a decision likely to result in death.

To ‘use or weigh’ relevant information about options in the process of deciding is the element of the capacity test that causes most interpretative difficulty in BPD. As Principle 4 of the Act states: ‘a person is not to be treated as unable to make a decision merely because he makes an unwise decision’. Deciding to refuse life-saving treatment may be unwise, but it is not the decision *per se* that we are assessing, rather how ‘accountable’ the patient is for the decision.^{21,22} Elliot has argued that in depression, even though patients may understand the risks, ultimately the disorder may affect whether they ‘care’ about that risk, thus reducing the ‘authenticity’ of the decision.²² If depression can lead to a pathological lack of ‘care’ about one’s own interests, could the drive to emotionally regulate via self-harm lead to a pathological ‘resistance’ to acting in one’s own best interests that robs BPD patients of decision authenticity?

Research has suggested that key interpersonal schemas in BPD include sadomasochistic behaviour, where patients hurt themselves in an internalised ‘punitive parent’ mode.²³ The relevance to treatment refusal here seems clear. In addition, as Szmukler points out, any capacity assessment is essentially a dynamic between the patient and the doctor.⁷ Refusal of the doctor’s recommendation could also be viewed within this sadomasochistic paradigm. This is surely the source of the sense of ‘manipulation’¹⁸ frequently felt by doctors treating these patients.

The great trap in these scenarios is assuming that refusal of life-saving treatment is equivalent to a wish to die and an acceptable ‘unwise’ decision. While this may indeed be the case in some instances, this *de facto* assumption endangers the lives of some BPD patients, as in some cases the decision to refuse *per se* may simply be a manifestation of the disorder, rather than a carefully considered wish to die. The risk to these patients is compounded by an intolerance of ‘manipulation’ felt by the doctor, who in turn may take this as evidence that the patient has full insight into the situation and accept their refusal as an unwise but capacitous decision. In summary, as a direct consequence of the mental disorder itself, BPD patients may unwittingly become caught up in a destructive iatrogenic cycle of harm.

A second clinical example which aptly illustrates the lack of ‘authorship’ of life¹⁹ that may occur for people with BPD while dealing with doctors has been provided by Winburn & Mullen.¹⁰ They describe the case of a BPD patient who was judged incapacitous to refuse a potentially life-saving blood transfusion. Her decision to refuse treatment was viewed as a consistent, chronic behavioural pattern and overall constituted a ‘disturbed form of engagement ... rather than an effort to disengage’. Case law reflects these views, as seen in the case of *B v Croydon Health Authority*,²⁴ where a young woman with BPD was starving herself to the point where enforced nasogastric feeding was considered. Lord Justice Hoffman wrote in his judgment that he found it difficult to conclude that the patient had capacity, despite her seeming to have a good understanding of the risks and options. It was this that made him question whether her choice was truly autonomous, because, while being able to make cogent and articulate statements about her wishes, it was hard for him to deem someone capacitous when she is ‘crying inside for help but unable to break out of the routine of punishing herself’.

How this affects clinical practice

The assessment of mental capacity in BPD patients is complex and may therefore cause clinicians significant anxiety where high-stakes decisions are to be made. It is conceivable that such anxiety may lead to risk-averse practices. In her review of suicide risk management in BPD patients, Goodman²⁵ highlighted the influence of medico-legal concerns on clinicians, by referring to a survey²⁶ that had shown that 85% of clinicians working with BPD patients had, within the past year, practised in a way ‘that would relieve their anxiety over medicolegal risks’. In our example of the BPD patient refusing life-saving treatment following self-harm and where capacity is marginal, risk-averse practice would presumably involve erring on the side least likely to result in death, i.e. a judgement of incapacity, detention and enforced treatment.

However, Pickard¹⁹ points out that it is particularly in the interests of patients with BPD that we attribute decision-making responsibility to them where possible, as this is the basis of some of the most effective psychological treatments for BPD, where self-control and mentalisation development are key. Szmukler suggests that when capacity could be argued from both sides, ‘one might conclude that ... the patient’s account, although not the one preferred by the clinician, is an adequate one, and sufficient to demonstrate that the patient has capacity’.⁷ Law states that ‘with regard to the degree of incapacity the nearer to the borderline the more weight must in principle be attached to [the patient’s] wishes and feelings’.²⁷ In application to BPD this would appear to imply that if the incapacity is only marginal the patient should, in effect, be approached as if with capacity.

So how do we balance over- and under-attributing capacity to BPD patients in clinical practice? Buchanan’s work²⁸ is relevant to this problem. He describes that when capacity is in doubt, we may vary our threshold for deciding what constitutes true incapacity, based on the stakes of the decision. Thus, when the negative consequences of a decision are likely to be severe, the clinician would require a more robust demonstration of capacity.²⁸ In essence, the clinician is balancing possible infringement of autonomy with negative consequences of the outcome of the decision. Ultimately, capacity is judged legally to be either present or absent, but as Lord Donaldson pointed out in the case of *Re T (Adult: Refusal of Treatment)*,²⁹ doctors should consider whether the capacity that is there is ‘commensurate’ with the seriousness of the decision.

One might argue that proportionality merely reflects the clinicians’ increasing anxiety about higher-stakes situations, thus not addressing the underlying problem: that there is little consensus and guidance on whether and how BPD may affect decision-making. Clearer guidance and consensus on how BPD may affect decision-making abilities in different clinical scenarios will reduce anxiety for clinicians and may help the Act become more predictable in its application.

Conclusions

Borderline personality disorder is a mental disorder. The use of the law in treating patients with BPD should be predictable and its application to clinical scenarios reproducible. The current use of the Mental Capacity Act 2005 in assessing decision-making capacity in such patients is lacking in these respects.

While BPD should be viewed as a mental disorder, this only means the Act is applicable; it is not synonymous with the view that people with BPD necessarily lack capacity for decision-making or responsibility for their actions. The psychopathology of BPD and specifically the way this affects the ‘using and weighing’ element of decision-making capacity is extremely complex and not acknowledged widely enough either in clinical practice or within the Mental Capacity Act itself. This leads to inconsistency in patient care. Further research into this field, along with clearer clinical consensus and legal guidance, is urgently required.

1.7.9 Perceptual distortions and deceptions: what computers can teach us

Matthew M. Nour Joseph M. Nour

Correspondence

Matthew M. Nour (matthew.nour@kcl.ac.uk)¹

date

2017-2

Abstract

The nature of perception has fascinated philosophers for centuries, and has more recently been the focus of research in psychology and neuroscience. Many psychiatric disorders are characterised by perceptual abnormalities, ranging from sensory distortions to illusions and hallucinations. The distinction between normal and abnormal perception is, however, hard to articulate. In this article we argue that the distinction between normal perception and abnormal perception is best seen as a quantitative one, resting on the degree to which the observer's prior expectations influence perceptual inference. We illustrate this point with an example taken from researchers at Google working on computer vision.

Contents

- *Perceptual distortions and deceptions: what computers can teach us*
 - *The problem of perception*
 - *Expectation is necessary for perception*
 - *Tipping the balance*
 - *Contemporary accounts of hallucinations*
 - *Limitations*
 - *Conclusions*

No mental state examination would be complete without a statement relating to abnormalities of perception. According to Fish, perceptual abnormalities may be classified as either sensory distortions (e.g. hyperacusis and dysmegalopsia) or sensory deceptions (e.g. illusions and hallucinations), with both categories deviating from veridical perception.¹ The clean simplicity of this definition underlies part of its clinical utility, but also gives the impression that the characteristics of 'normal' veridical perception are well understood. The nature of perception, however, has troubled philosophers for centuries,^{2,3} and has been the focus of intense investigation by neuroscientists and psychologists in recent decades.⁴⁻⁷ Just how does the brain transform the light hitting the retina into the infinitely complex three-dimensional world that we see when we open our eyes? How much of what we perceive is really present in the sensory data hitting our eyes, and to what extent do our prior expectations shape our perception? Do we perceive the world as it really is, and if not, does that mean that our normal perceptions are distorted or deceptive? If so, in what way does normal perception differ

from abnormal perception? These questions may seem to be only of philosophical relevance, but researchers working in the fields of perceptual neuroscience and computer vision are regularly confronted by them.

In this article we outline some exciting insights into how the brain may construct reality. Intriguingly, these findings have come from the field of machine learning, a branch of computer science and robotics.

The problem of perception

How does your visual system construct a representation of the world? Perhaps most readers would reply that the brain extracts the information about the physical world that is contained within incoming sensory signals. Much of the neuroscience of the past half-century has investigated perceptual processing starting from this assumption.^{4,8} The account of perceptual processing found in most undergraduate textbooks states that the sensory processing pathway (including the sensory epithelia, subcortical nuclei, thalamus, sensory cortices and heteromodal association cortices) extracts information from incoming sensory data in a stepwise manner. If all goes smoothly we perceive the world ‘as it really is’.

There are several problems, however, with the view that perception proceeds by extracting information from the incoming signals alone. Perhaps the most damning consideration was recognised by George Berkeley in the 18th century as the ‘inverse optics’ problem,^{2,4} which states that information collected by the sensory epithelia is insufficient to allow an unambiguous mapping back on to real-world sources. The light hitting the retina, for example, forms a two-dimensional image, which has an infinite number of possible three-dimensional ‘real-world’ sources. The image conflates information about object illumination, reflectance and transmittance.⁴ Computer vision faces similar problems. A car, for example, looks different from different viewing angles and distances, and in different lighting conditions. The problem of inferring the state of the world from sensory data alone is (mathematically) ill-posed.⁹ One powerful illustration of this principle is demonstrated by the famous Necker cube illusion,⁵ where the sensory information alone is insufficient to resolve the question of the orientation of the wire cube and there is no simple mapping between sensory data and perception (*Fig. 1*).

Expectation is necessary for perception

If sensory data alone cannot support perception, how does the brain create accurate perceptual representations of the world? It is now appreciated that ill-posed problems such as vision can be made tractable by using contextual information to impose constraints on the interpretation of ambiguous data. In the case of vision, for example, past experiences of seeing similar visual scenes sets up expectations about the likely current state of the world, and any new sensory data are interpreted in light of these expectations. Consistent with this hypothesis, the sensory processing pathways in the brain do not just support one-way ‘bottom-up’ information flow (from low-level data in the primary sensory cortex to more complex representations in heteromodal association cortices), but also support ‘top-down’ information flow, whereby information about the current expected state of the world cascades down from high cortical areas to influence information processing in low sensory areas.^{9,10} Some have argued that the ‘heavy lifting’ of perceptual processing is performed by these top-down pathways, which make predictions about the state of the world that are tested against sensory data.¹⁰

The ability of the brain to make sense of sensory information has inspired computer scientists working on computer vision and similar problems to take a similar approach. Recently, researchers at Google created an impressive visual recognition system using a processing architecture inspired by the human brain, called an ‘artificial neural network’ (ANN).¹¹ ANNs consist of artificial ‘neurons’ that are organised into layers, reminiscent of the brain’s hierarchical organisation. These networks are particularly good at detecting features and patterns in new data, and using these features to perform classification tasks. This is similar to what the brain does when engaged in perceptual inference, which may be thought of as the detection of objects and meaningful patterns in sensory data. New data enter the ANN at the lowest ‘input’ layer (analogous to light hitting light-sensitive neurons in the retina) and is processed sequentially by progressively higher layers of the network. At each layer the network attempts to extract patterns and features from these data, with higher layers of the network extracting increasingly more abstract features. At the highest layer a ‘decision’ is made about what the data represent.

Importantly, a new ANN must be adequately ‘trained’ before it can perform successful pattern detection and classification tasks. During training the network is exposed to many different data-sets (e.g. images) and attempts to classify the data appropriately. The network is able to self-calibrate, guided by its successes and errors, in a process analogous to synaptic plasticity. After exposure to thousands of images of, say, cats, the network learns to recognise cats in images to which it has never before been exposed.

The well-trained ANN is primed to recognise salient features and patterns in new data in much the same way that the brain is primed to recognise the patterns in sensory data that are most important for detecting behaviourally relevant objects. Prior to training, the ANN is essentially blind to meaningful patterns in new data. In both the well-trained ANN and the mature human visual system the final decision about what a new image represents is the product of a delicate balance between the information contained within the image itself and the readiness of the network to detect certain features within new data.^{9,10}

Tipping the balance

Perception is therefore the product of two sources of information: the sensory data and prior expectations about the sort of information that the sensory data contain. What happens, however, when prior expectations are given too much weight?

The Google researchers provide an intuitive example of the problems that inappropriately strong prior expectations can cause in their ANN.¹¹ As mentioned previously, the highest layers of the ANN contain latent representations of objects that the network has been trained to see. The Google researchers asked a network trained to see bananas to detect and enhance ‘banana-like’ features in an image that contained only meaningless noise. This manipulation inappropriately weighted prior expectation relative to sensory data. The result was that the network was able to ‘perceive’ objects where none existed in the image itself (akin to a ‘guided hallucination’) (see the Google Research Blog article for examples¹¹). Although the mechanisms employed by this simple network manipulation are not intended to be biologically plausible, the simple experiment demonstrates the power that inappropriately held prior expectations might have on resulting perception.

To what extent can inappropriately held prior expectations influence human perception? This question has relevance to descriptive psychopathology and psychiatry. Karl Jaspers, the father of descriptive psychopathology, postulated that ‘illusions due to affect’ and ‘illusions due to inattentiveness’ may arise when a person has a strong prior expectation about the state of the world and is confronted with noisy and ambiguous sensory data.¹² This exaggerated prior expectation may be informed by the semantic context of a situation (in what have come to be termed ‘completion illusions’), the observer’s current emotional state¹³ (in ‘affect illusions’), or active imaginative processes acting on inherently ambiguous sensory data (in ‘pareidolic illusions’).^{1,12,14,15} It may be argued that in these situations the observer comes to impose their prior expectations on the ambiguous sensory data.

Contemporary accounts of hallucinations

We have argued that perceptual inference always relies on both incoming sensory data and a prior expectation about what these data are likely to represent. Additionally, we have outlined the hypothesis that illusions and hallucinations may be the result of an imbalance between these two sources of information. This simple account is consistent with contemporary theories of illusions and hallucinations, which also implicate a miscalibration between these two sources of evidence.

One of the most influential contemporary accounts of perceptual inference is that of hierarchical predictive coding.^{9,16,17} At the heart of the predictive coding account is the notion that the brain maintains a dynamic representation of the world, which is the brain’s best prediction about the state that the world is likely to be in. Incoming sensory data are compared against this representation. If there is a good match between the prior prediction and the sensory data the current representation of the state of the world is reinforced. If there is a mismatch, a ‘prediction error’ signal drives an updating of the brain’s current representation of the world, which is subsequently re-tested against the real-world data. The iterative process of matching the brain’s predictions to sensory signals underlies perceptual inference.^{10,16,17} This process can become disrupted when the balance between prior predictions and incoming sensory data is changed. The brain’s internal representation of the world will be resistant to change, and thus dominate perceptual inference,

if the prior prediction is given a greater weight than the incoming sensory data, as may happen when the incoming sensory data are noisy.^{9,16,17} It has been proposed that in some pathological states the brain may mistake its own prior predictions for new incoming sensory data, resulting in perceptual and cognitive abnormalities that share some similarity to acute psychosis.¹⁸

Another influential account of complex visual hallucinations is the perception and attention deficit (PAD) model, which was developed after studying clinical populations who experience recurrent complex visual hallucinations.¹⁹ It was found that people in these populations had combined deficits in low-level sensory processing and attention. The PAD model proposes that in order to perceive an object, the perceptual object must first be selected from a pool of candidate ‘proto-objects’, in a process guided by sensory data, prior expectations and attentional processes. In people who have a combined deficit in sensory processing and attention it is conceivable that proto-objects from a misrepresentative pool become inappropriately bound to the visual scene, resulting in a hallucination.¹⁹

Both the predictive coding and PAD accounts of illusions and hallucinations propose that an overweighting of prior expectation relative to sensory data may underlie certain perceptual abnormalities. This overweighting may be a direct result of inappropriately held prior expectations (as can occur in states of high emotional arousal), or may be secondary to a decrease in the quality (or precision) of incoming sensory data (as may occur in states of low attention, fatigue or sensory impairment).^{19,20}

Limitations

There are several limitations and unanswered questions in this ‘expectation-based’ model of hallucinations and illusions. First, although Google’s ANN provides a nice visual example of the power of overweighted prior expectation, it has key structural and functional differences when compared with the human visual system. Among these are the fact that Google’s network hierarchy has many more layers than our current best estimates in the primate brain.^{11,21} Moreover, Google’s network was trained to ‘see’ objects in a ‘supervised’ way, whereby it was told what the images actually represented during training. This bears little resemblance to the ‘unsupervised’ learning that occurs in the brain.

Perhaps more importantly, expectation-based accounts of illusions and hallucinations fall short of explaining some of the most frequently encountered perceptual abnormalities in clinical practice. The hallucinations recounted by patients with psychosis or organic disorders are often bizarre, and seem entirely unexpected given the environmental context.¹⁹ Furthermore, although the account of hallucinations given above applies to all sensory modalities, it is unclear why perceptual abnormalities often occur preferentially in one sensory modality in clinical populations (e.g. auditory verbal hallucinations in schizophrenia).¹⁵ These questions remain unanswered, and pose an ongoing challenge for computational accounts of perceptual abnormalities in psychiatry.

Conclusions

Although psychiatrists ask patients about perceptual abnormalities on a daily basis, it is not often that we stop to ponder what actually distinguishes normal perceptions from perceptual distortions and deceptions. Current work in psychology, neuroscience and computer science paints a picture of normal perception as being inextricably linked to prior expectations about the state of the world. Perception depends on a delicate balance between the sensory information that we are confronted with, and the prior expectations we have about the world. If the balance is disturbed then perceptual inference becomes disrupted. Without prior expectations, perception is a mathematically ill-posed problem^{4,9} (as illustrated by *Fig. 1*), yet when prior expectation dominates the perceptual process, humans (and ANNs) can come to perceive objects which do not exist in the sensory data. As a result, the division between veridical perception and perceptual distortions or deceptions is more subtle than one of clear qualitative difference.

1.7.10 Adherence to medication in the community: audit cycle of interventions to improve the assessment of adherence

Saeed Farooq Abid Choudry

Correspondence

Abid Choudry (abidchoudry@doctors.org.uk)¹

date

2017-2

Abstract

Aims and method To investigate whether medication adherence is monitored during follow-up in out-patient reviews. A retrospective audit was carried out with a sample of 50 follow-up patients with a diagnosis of schizophrenia or schizoaffective disorder. Following this, interventions were made prior to the re-audit (including text messaging clinicians and prompt sheets in the out-patient department to encourage adherence discussions).

Results There was an improvement on all the standards set for this audit following the interventions. More doctors had discussed medication adherence (62% second cycle v. 50% first cycle) with their patient and there was increased discussion and documentation regarding medication side-effects (60% second cycle v. 30% first cycle). More clinicians discussed the response to medication (60% second cycle v. 46% first cycle).

Clinical implications Treatment adherence is not regularly monitored or recorded in clinical notes in routine psychiatric out-patient appointments. This highlights the need for regular training to improve practice.

The World Health Organization defines adherence as the extent to which a person's behaviour – taking medication, following a diet, and/or executing lifestyle changes – corresponds with agreed recommendations from a healthcare provider.¹ Although often used interchangeably with the term 'compliance', adherence is preferred by many as it

acknowledges the patient's role in the decision-making process.² It has been claimed that increasing the effectiveness of adherence interventions may have a far greater impact on the health of the population than any improvement in specific medical treatments.³

Non-adherence to treatment is a major barrier to effective treatment in psychiatry, particularly in individuals with psychotic disorders. Rates of non-adherence vary between 24 and 40% based on medication refill rates available from pharmacy records.^{4,5} This is understandable in view of the different populations, variety of diagnoses, variable follow-up periods and, most importantly, the different definitions and measurement methods used in research.⁶ It has been reported in the literature that non-adherence rates to medication for bipolar disorder typically range between 20 and 60%, with an average of 40%.⁷⁻⁹ In schizophrenia, a systematic review of 39 studies reported a mean rate of medication non-adherence at 41%.¹⁰ When the analysis was restricted to the five methodologically most rigorous studies, which included defining adherence as taking medication at least 75% of the time, the non-adherence rate increased to 50%.¹⁰ Non-adherence to treatment in schizophrenia is often associated with potentially severe clinical consequences.^{11,12} It is also estimated that up to 40% of the total annual cost of schizophrenia, which amounts to £400 million in the UK, could be due to non-adherence to treatment.¹³

The National Institute for Health and Care Excellence (NICE) guidelines^{14,15} recommend that treatment adherence be regularly monitored in patients with schizophrenia but there is relatively little information about how this is done in clinical practice. In general, doctors uniformly underestimate the degree of non-adherence in their patients.¹⁶

Aims

This audit was aimed at investigating whether medication adherence is monitored during the follow-up of patients diagnosed with schizophrenia or schizoaffective disorder. We also evaluated the ways in which medication adherence is discussed during out-patient reviews and recommend practice improvement.

Method

We conducted a retrospective audit in 50 patients presenting to the out-patient follow-up clinic in two UK community mental health teams providing treatment for patients within the complex care team. The clinics were based in the Black Country Partnership NHS Foundation Trust. Only patients with a diagnosis of schizophrenia or schizoaffective disorder who were currently under out-patient follow-up were included. A random sample of patients was generated by taking every fifth patient from the list provided by the clinic administrator. The last clinic letter was reviewed to collect data via the medical notes and electronic healthcare records.

The standards were identified using the NICE guidelines on medicines adherence and treatment of psychosis and schizophrenia.^{14,15} The guidelines have emphasised what should be reviewed and discussed in out-patient clinics. Specifically, they recognise that the treatment should be regularly and systematically reviewed to monitor treatment adherence. During the titration of treatment the following should be regularly monitored: response to treatment, including changes in symptoms and behaviour side-effects of treatment emergence of movement disorders weight waist circumference pulse and blood pressure adherence overall physical health.

The NICE guideline on treatment adherence explicitly states that when reviewing medication the clinician should enquire about adherence: “‘If non adherence is identified, clarify possible causes and agree any action with the patient. Any plan should include a date for a follow up review.’¹⁵” As a consequence, the standards set out for this audit were that: 100% of patients should have a discussion with the doctor regarding the medication, including response and side-effects 100% of patients should have a discussion with the doctor regarding adherence to medication if medication is stopped, reasons for this should be explored. In light of this we constructed a data collection tool for the audit (*Box 1*).

Box 1 Information gathering tool for the audit

- Was adherence to medication discussed?
- Did the clinician ask the patient about any periods when they had missed taking medication?
- Did the patient mention missing any medication and was this discussed with the patient?

- Had the patient missed any medication over the past month?
- Were side-effects of the medication discussed?
- Did the clinician ask the patient whether these side-effects had impact on their adherence?
- If non-adherence was noted to be a significant problem, were any strategies to improve adherence discussed?
- Was the response to medication discussed?
- If medication was stopped, were reasons for this explored?

Results

Audit cycle 1

Data were collected over a period of 4 weeks. The results showed that adherence was discussed and documented only in 50% of consultations, side-effects were discussed only in 30% of consultations and response to medication was discussed in 46% of cases. Further questioning in terms of assessing adherence appeared to be poorly done, with less than 10% of consultations assessing adherence in greater detail.

The results of this initial audit highlighted either a gap in clinical practice or poor documentation. The results were discussed with colleagues in the weekly audit meeting in the hospital and recommendations were made to improve the practice (*Box 2*)

Box 2 Recommendations following the first audit cycle

1. Provide formal training to doctors regarding assessing adherence during the induction for junior trainees and through a session delivered in the local teaching programme for the rest of the clinicians.
2. Provide a list of questions to be asked regarding adherence in clinics.
3. Provide a text reminder to doctors on clinic days to remind them to assess adherence.
4. Re-audit following implementation of changes.

As a consequence of the initial audit, a change in practice was brought about by introducing information sheets in each clinic room with possible questions concerning adherence to ask when assessing patients in clinic. A brief session on adherence was also added to the junior doctor induction. Then, a text message reminder was sent to colleagues. This included consultants, specialty doctors and trainees (core and foundation year 2) at the start of each clinic for a period of 3 months. The text message was very brief, reminding colleagues to discuss adherence with their patients in clinic. The colleagues' consent was sought prior to this 3-month trial. We initially planned to send the text reminders using [NHS.net](#), which provided such a service, but that stopped in early 2015. As a result, we sent out a group message using the work mobile phone.

Following this period a re-audit was carried out. It again focused on patients with schizophrenia and schizoaffective disorder but only spanned the intervention period of the prior 3 months.

Re-audit

As before, a random sample of 50 patients was selected. A similar procedure was carried out, but only patients reviewed after the initial audit were included. The same data collection tool was used (*Box 1*). The results are illustrated in *Fig. 1*.

Fig. 8: Comparison of key audit results.

The results indicated an improvement in all three key comparisons. More doctors had discussed medication adherence with their patient over the past 3 months (62% v. 50%, $P = 0.22$), and there was increased discussion with patients and

documentation of side-effects (60% v. 30%, $P = 0.0025$). More clinicians discussed the response to medication with their patients in the second audit (60% ($n = 30$) v. 46% ($n = 23$), $P = 0.16$). The results regarding further questions about adherence continued to be poor, with only 4% ($n = 2$) asking about whether the patient had missed any doses of medication. However, it was felt this may be secondary to a lack of documentation rather than being a true reflection of practice.

P -values revealed a significant difference in the two audits for the discussion about side-effects, with an improvement noted following the interventions. However, there was no significant difference on discussions about adherence and response to medication between the two audits.

Discussion

Improving treatment adherence is at the heart of clinical psychiatry. It requires building a therapeutic relationship with patients, understanding their needs and tailoring treatment accordingly. Monitoring treatment adherence is a continuous process during which the need to continue medication in the long term is regularly stressed. We need to identify the barriers and help patients and carers to overcome these. This can only be achieved if the treatment is regularly monitored for its efficacy, side-effect burden and acceptability to patients.

This audit presents a rather disappointing picture of the conversation about treatment adherence, which is not common in clinical encounters. Such discussions took place in just half of the consultations, whereas questions about possible side-effects and response to medication were raised even less frequently. The first variable improved to about 60% after regular reminders and inclusion of this topic in the junior doctor induction, but this result was not statistically significant. However, the results were statistically significant concerning discussions about side-effects, with a significant improvement noted following the interventions. This perhaps highlights the need for regular training to improve the monitoring of treatment adherence.

It has been shown that simple questions about different aspects of medication-taking behaviours can be effective in improving treatment adherence.¹⁷ Most of the information regarding assessment of adherence is based on clinical experience or limited research. Clinicians can start by asking patients ‘Have you missed any pills in the past week?’ A positive response indicates there may be a problem with adherence. Clinicians should bear in mind that patients tend to overestimate their actual adherence to therapy and that the accuracy of the self-report depends on the patient’s cognitive abilities, attitudes and openness towards the therapist.⁶ Some simple questions that can be asked in routine clinical care include: ‘How are you taking your medications?’, ‘Have you ever forgotten to take your medications?’, ‘Are you experiencing any adverse drug reactions?’, ‘How are you feeling since you started the medication?’⁶

The results of the audit should be interpreted in the light of some limitations. It is possible that these questions are asked but not regularly documented. Patient medication adherence was not directly measured in the audit. The study had a small sample size that represents a snapshot of clinical encounters, which may not be generalisable. The discussion about treatment adherence may have taken place in different settings such as the in-patient setting or with other members of the multidisciplinary team such as the community psychiatric nurse. We used text message reminders, which has helped the clinicians ask about adherence. Text messages have often been used to remind patients about medication, but they have not been commonly used to alter the clinicians’ behaviour, and can prove a simple and effective method for improving adherence with good practice.

1.7.11 Training in quality improvement for the next generation of psychiatrists

Elizabeth Ewins Rob Macpherson Geoff van der Linden Stephen Arnott

Correspondence

date

2017-2

Abstract

Quality improvement (QI) projects have been shown to positively influence patient care. They provide opportunities for trainees to present and publish their work locally and nationally, and to gain valuable leadership and management experience. We describe a pilot project to engage in QI trainees across a National Health Service trust and a school of psychiatry. After the first year of this programme over half of psychiatry trainees in the school (58% of core trainees and 47% of advanced trainees) are participating in 28 individual QI projects and QI project methodology is to become embedded in the core psychiatry training course. Specialty doctors, consultants, foundation doctors, general practitioner trainees, medical students and the wider multidisciplinary team have all become engaged alongside trainees, working with patients and their families to identify problems to tackle and ideas to test.

Foundation doctors and core medical trainees are being trained to undertake quality improvement (QI) projects and are doing so competently and effectively. ^{1,2} QI projects have been embedded in the Foundation Programme curriculum, ³ with an expectation that trainees plan, implement, complete and present a QI project as part of their training, using the results to improve patient care. QI projects have been widely adopted across medicine and are in many areas superseding traditional audit as a way to develop services. However, the development of this methodology has been slower in the mental health field and QI projects are new to most psychiatrists. Here we outline and summarise in simple steps how to undertake a QI project. We also describe our cross-deanery project led in Avon and Wiltshire Mental Health Partnership NHS Trust and the Severn School of Psychiatry, which aims to train and support psychiatrists of the future to become actively engaged in QI projects.

What is a QI project?

QI projects aim to improve patient safety, treatment effectiveness and efficiency, and the patient experience. They are real-time, dynamic processes involving focused, progressive, small-scale changes through a simple structured framework, which enable visible and effective change over a short period of time. QI projects are becoming increasingly important because of the limited resources available in the National Health Service (NHS). They can support service change and to achieve this may engage all professional groups, including trainees. Increasingly, evidence of QI is becoming a training requirement and is taking the place of audit as a subject to discuss at trainee reviews and job interviews.

Often the relationship between audit and QI projects is not clearly understood. Audit is also generally about quality improvement, beginning with identifying an audit subject, selecting audit standards and measuring the level of performance, then making improvements and re-auditing (*Fig. 1*). The focus is therefore on data collection.⁴ This area of practice has been criticised, as often the audit cycle has been left incomplete and the improvement part of the cycle left neglected.^{5,6} QI projects are advantageously placed as they can be seen as part of the improvement element of the audit cycle, where the focus of the project is explicitly on making a service improvement instead of collecting data.⁷ Although more complex than an audit, QI projects focus on changing complex adaptive systems and can empower doctors to investigate problems, identify solutions and work within a team to raise standards.

Practical steps to carrying out a QI project

The first step in developing a QI project is identifying a specific aspect of clinical practice that could be improved. This may be something that has been highlighted by an audit or identified by the wider team. It may be aligned to the local trust's quality and safety agenda, something that has been identified as a clinical incident or near-miss, or raised by patients or their families as a problem or idea to test. Finally, it may simply be an area recognised by local clinicians as something which is time consuming or frustrating and which could be improved. The project has a small focus initially, so rather than looking at 100 patient notes one might begin with just a single patient, or instead of trying to improve a whole hospital the focus may be on a single ward. Once an improvement has been proven to work on a small scale, it can be then tested on another patient or another ward, gradually being systematically scaled up and spread to become embedded in an entire hospital or trust. Depending on complexity, the projects can be undertaken within a 6-month training post.

The Institute for Healthcare Improvement recommend asking three questions⁹ based on the 'model for improvement' when planning a project: What are you trying to accomplish? This helps to set the aim of the project, which should be SMART (specific, measurable, achievable, realistic and timely). How will you know that a change is an improvement? This helps to think about what can be measured to illustrate the impact of the change. What would be an easy measurement? This needs to be done at baseline and then repeated at regular intervals so that the change can lead to learning and to show that it works. What changes can we make that will result in improvement? Possible ideas of changes to implement to make an improvement can be brainstormed. The current sequence of events already used can be examined and areas for improvement identified, for example by eliminating unnecessary tasks or steps, clarifying roles within the process, or by reducing delays and duplication.

Testing changes: the 'plan, do, study, act' (PDSA) cycle

The 'plan, do, study, act' (PDSA) cycles can be used as a way to develop, test and then implement a change on a small scale and in a real work setting (*Fig. 2*).^{9,10} Multiple PDSA cycles will be required to fully implement a QI project.

Stage 1: plan

The first stage is about planning a test of change. This involves taking a single idea and making a prediction as to what might happen when the change is implemented. A test and way of measuring whether what actually happens meets that prediction needs to be designed so that the impact of the change can be evaluated and learned from. This might be numerical data, such as increasing numbers of reviews of patients, or reducing numbers of critical incidents, and may also include patient and/or staff satisfaction scores or comments. Once you have determined what you are going to measure, make a baseline measurement. Determine what target you are aiming for: is it realistic? Plan the time you have available: for example, do you want to complete the project within the time frame of a training post? The planning stage can take time, but good planning will ensure a more successful project.

A useful tool for the early stages of planning a QI project is a driver diagram (*Fig. 3*), which can help to identify what steps could be taken to make an improvement. This has three columns: outcome (the aim of the project) and primary and secondary drivers. Primary drivers are the overall improvement areas that need to be addressed to achieve the desired outcome. Secondary drivers are the specific areas where changes or interventions can be made, motivated by the primary drivers.

Stage 2: do

Following careful planning, one small area of change can be identified. The second stage of the PDSA cycle is where the change is actually implemented. Measures of the impact of change should be taken from an early point and frequently to monitor the effect of the change. Any problems or unexpected results are noted while the change is carried out.

Stage 3: study

The third stage involves analysing collected data and comparing that with the predictions made. A graphical representation of the measurements taken can be a useful way of plotting results to illustrate the pattern observed as changes are made.¹² A goal line can be shown so one can see at a glance where the work is in relation to achieving the aim. Changes or improvements that are made (in repeated PDSA cycles) can annotate the graph to clearly demonstrate the impact of those changes (*Fig. 4*).

Stage 4: act

In the final stage of a PDSA cycle you can ask whether the change you made achieved your aim. If not, what modifications to the change could be made? Or what other ideas can be put in place? When you are ready to make another change, the next PDSA cycle can be outlined.

Implementing and spreading changes

By going through several PDSA cycles a small change can be tested and refined. Once a successful improvement has been proven on a small scale, it can then be tested on a larger scale. This might be across several wards or across several community teams. Once these pilot changes are proven to be successful, they can be embedded in everyday practice and incorporated into local trust policy.

Training in QI for the next generation of psychiatrists – a pilot programme

This is the first year of a pilot developed in the Severn Deanery to support core and advanced trainees to become involved in QI. The programme is being led by an advanced trainee (E.E.) as part of an Educational Fellowship awarded by the Deanery.

Until 2015 it has been a deanery requirement of trainees to carry out an audit project annually. This was amended so that all trainees are to be involved in either an audit or a QI project each year, and if an audit is undertaken trainees are encouraged to use QI methodology for the implementation of change part of the cycle. The structure of training and supporting trainees to undertake their own QI projects was adapted from the local Foundation School ¹ and the Royal College of Physician's 'Learning to make a difference' programme. ² A half-day training session was developed to teach trainees about QI and project methodology, including using PDSA cycles in practical examples, so that they could undertake their own projects. This was delivered by E.E. alongside the local trust audit and QI department lead. Trainees were encouraged to come up with their own ideas for projects and to work with other trainees to implement changes, under the supervision of a higher trainee, specialty doctor or consultant. They were supported in including the wider multidisciplinary team in developing and implementing projects, as it was felt that this would be more likely to lead to successful and sustainable changes being made.

Training was initially targeted at trainees, but a growing number of specialist doctors and consultants requested to attend and they were invited to a second training session. A resource handbook was developed and a series of short follow-up sessions put in place to provide further advice about QI methodology and to help support trainees' projects. Trainees were asked to register their projects by completing a short online form on the local trust audit and QI academy webpage so the trust can monitor participation.

Results so far

In the first year of this programme, QI projects (28 in total) are being undertaken by 58% of core trainees (21 of 36) and 47% of advanced trainees (16 of 34). A growing number of specialty doctors (6 of 54; 11% of the Trust's total), consultants (24 of 111; 22%) and colleagues from the wider multidisciplinary team, as well as foundation doctors and medical students, are becoming involved in projects. Examples of current projects being undertaken by trainees in the Deanery are shown in *Box 1*. Some trainees have chosen to undertake educational QI projects, which are being used to improve training and trainee representation in their organisations and are felt to be a way of engaging trainees in the trust.

Evaluation of the programme so far through post-course questionnaires and semi-structured interviews held at the end of projects has shown globally positive feedback from consultants and high engagement and enjoyment from trainees. Trainees report high satisfaction owing to being able to choose their own QI projects rather than being instructed what to do. All trainees report that training sessions and follow-up advice has been helpful, and feel that this should be provided to all staff across the multidisciplinary team. One trainee fed back that 'the quality improvements often end up involving other team members so it would be good to get them on side', whereas another trainee highlighted that 'training is needed for senior staff members who we may need to get on board.' Additionally, trainees reflected that most projects needed senior input to facilitate implementation and sustainability of successful changes, and several projects have needed advice on governance issues, which has been provided by the Trust's Quality Academy, responsible for audit and QI projects.

We have found that owing to the nature of our work in mental health, QI projects sometimes need to be structured in a different way than they would be in an acute hospital setting. Careful consideration is needed to find the most appropriate method of change measurement, as frequently qualitative data may be available and innovative methods of quantitative data have been required. We have also found that QI projects have often had to run over a longer period than they perhaps would in an acute hospital, perhaps owing to the longer in-patient stay in a psychiatric hospital.

During the pilot we found that forming close links with the trust Quality Academy provided invaluable assistance in setting up the scheme. The Academy has a QI project lead, who provides advice and training for trainees; they have been particularly helpful with guidance regarding governance and what permissions might need to be sought. Support

from trust medical management leads, including the medical director and director of medical education, has also been key.

As well as positively influencing patient care, trainees report that projects are providing them with invaluable opportunities for leadership and management experience. One advanced trainee leading a QI project reported they had gained ‘experience of leading a team as well as networking with other teams, management experience through attending meetings and presenting ideas, plus the project has provided opportunities to present at a departmental and regional level, as well as an opportunity for publication. This is in addition to positively influencing the future of mental health services’. Many trainees are beginning to present and publish their work and we encourage trainees to do so even if a project has not been fully successful, as much will have been learned by the trainees, and can be learned by the Trust, from all projects.

Box 1 Quality improvement projects being undertaken by trainees across the Severn Deanery

- Improving handover between trainees
- Ensuring physical health monitoring of patients prescribed antipsychotics
- Improving the quality of letters written to general practitioners
- Ensuring timely access to radiology results
- Promoting awareness of mental health in an acute hospital
- Providing support for new consultants
- Advance care planning in later life
- Improving the quality of ward rounds in forensic services
- Training nursing staff about physical healthcare issues
- Providing patients and their families with information regarding child and adolescent mental health services (CAMHS)
- Improving the local academic programme
- Developing an out-of-hours handbook for trainees on call
- Ensuring physical health assessments for patients in early intervention in psychosis
- Improving access to mental health assessments for women during the antenatal period
- Improving trainee representation across the mental health trust

Box 2 Useful resources

- The Institute for Healthcare Improvement website (www.ihl.org) provides many free resources to guide professionals through a quality improvement (QI) project (e.g. short videos which describe the steps involved).
- BMJ Quality (<http://quality.bmj.com>) has an online guide to implementing a QI project and then writing it up, producing a publishable paper as a result. It can be useful to buy a licence to do this and follow the steps (licences last for 1 year so in the case of longer-term projects it may be prudent to sign up later rather than at the start of a project). Note that demonstration of clear ‘plan, do, study, act’ (PDSA) cycles is required for successful publication. There is a growing database of published QI projects which may prove inspirational for ideas that can be developed in psychiatry.
- Local audit departments may be able to support projects directly and help identify potential QI project areas. Health Education England also publishes innovative ideas which can provide further inspiration (<http://hee.nhs.uk/>). Service user groups can be another source of ideas for QI projects.

Future plans

The training course is to be incorporated into the Deanery core trainees' course and it is expected that all new core trainees who have joined the Deanery in the 2015 summer intake will participate in a QI project each year. Formal evaluation of the impact of training and QI projects is to be undertaken for this cohort. Those trainees who have successfully completed a QI project will be encouraged to become mentors and local QI leads in their area for future projects, providing sustainability for the projects as well as supervision, teaching and leadership experience for trainees.

QI projects undertaken by trainees and their seniors are to be regularly presented at the Trust's Medicines Advisory Group meetings, which will not only spread innovative ideas but further encourage psychiatrists to become involved in projects. Connections are being developed with service user groups and local patient safety programmes to help trainees define problems to tackle and ideas to test. Links have been made with the West of England Academic Health Science Network and the Royal College of Psychiatrists' South West Division E-volution programme (www.rcpsych.ac.uk/workinpsychiatry/divisions/southwest/innovationinthesouthwest.aspx) to promote the wider spread of quality improvement and innovation.

We have compiled a list of useful resources (*Box 2*) and tips for developing a QI project (*Box 3*) drawing on our own experience in the Trust.

Box 3 Top tips for completing a quality improvement (QI) project

- **Take time to plan your project.** You may be keen to start putting in place changes and improvements, but ensuring careful planning will mean that a project is more likely to be successful.
- **Have a SMART aim.** Be clear and focused. Have a clear aim so that everyone knows what you are trying to achieve. Make your aim SMART (specific, measurable, achievable and agreed, relevant and time-bound).
- **Keep it small.** This will help ensure an improvement works. Once it is proven to work on a small scale, it can be rolled out more widely.
- **Think outside the box.** Get a group of interested trainees, consultants and the wider multidisciplinary team to think about the project with you and help brainstorm ideas for improvements. This will engage others and help the project to be a success. Get advice from your audit department.
- **Work in a team.** This is more fun, you will come up with more ideas and will feel more motivated.
- **Involve key stakeholders.** Who needs to know about the project for it to be a success? Do you need any approval to carry out changes? This might be a team consultant and team or ward manager, or it could include your clinical director, medical director or director of medical education or head of school. You could present your idea at a local academic meeting.
- **Sustainability.** Think about how you can make your improvements continue, especially if you are in a training post and will be moving on in 6 months or a year. You will need to involve your multidisciplinary team and local team managers.
- **Organise your time.** Think about how much time you have available to complete the project. Set yourself a time frame and stick to it. If you will be moving from a training post, think about whether you want to continue making changes after you leave or whether you need to do some succession planning.
- **Make the most of the opportunity.** After all that hard work, make sure you get some rewards! Present your work locally, submit a poster to a conference, and write up your work and get it published. QI projects frequently provide leadership and management experience, and often teaching opportunities which you can mention at your annual review of competence progression (ARCP), annual appraisals and at job interviews.

We are grateful to Janet Brandling and Emma Adams (AWP Quality Academy), Bridget Kelly (AWP Medical Education Project Manager) and Katherine Finucane (Consultant and QIP Lead, North Bristol Trust) for guidance and support in developing QI projects across the Severn Deanery.

1.7.12 The most important things I have learnt in my career as a psychiatrist

Julian Leff

Correspondence

Julian Leff (julian.leff@kcl.ac.uk)¹

date

2017-2

Abstract

This paper is something of a patchwork, incorporating many issues that have intrigued me during 34 years of research. I have included the importance of maintaining a solid base in clinical work, alongside research activities, and being alert to the possibility of a somatic condition contributing to psychiatric symptoms. I stress the value of careful observation of patients, their response to treatments and reasons for dropping out. In addition, I have included 14 more lessons, learned from my experience of research, which I hope will be of use to those readers who aspire to become researchers.

Contents

- *The most important things I have learnt in my career as a psychiatrist*

I was attracted to psychiatry by my experience as a medical student at University College Hospital. Students on the psychiatry firm were expected to take on a psychotherapy patient, supervised by one of the senior therapists. This was the first time in my medical training that I felt valued as a clinician and treated as a responsible adult. (There is an important lesson here for improving the very low recruitment of medical students to psychiatry.)

Having graduated as a doctor I was keen to begin my study of psychiatry and sought advice from Sir Martin Roth, president of the Royal College of Psychiatrists at that time. He was adamant that I had to obtain the Membership of the Royal College of Physicians before applying for training in psychiatry. This was daunting as the Physicians' exam had a very low pass rate. I spent 3 arduous years as house officer in hospitals in London's East End before passing the exam. However, in a strange way it felt like coming home. This was because my father and his family lived in a house in the East End, at least until it was completely destroyed by a German bomb. By working with East Enders I learned to appreciate the fortitude and strength of people in the lowest stratum of society, and I never forgot that.

Throughout my career I always continued with clinical work alongside my role as director of two research teams, holding weekly out-patient clinics and having consultant responsibility for half an acute admission ward at the Maudsley Hospital and later at Friern Hospital. In addition, I supervised community mental health teams for their work with families. In this paper I will present the important things I have learned from both my clinical and my research activities.

Becoming a Fellow of the Royal College of Physicians (FRCP), I applied to the Maudsley training scheme and was accepted. When I met the other trainees in my intake, I found to my chagrin that only half of them had passed the Physicians' exam. There was one occasion in my psychiatric practice when my medical expertise proved its value. An out-patient in my clinic was complaining of anxiety and breathlessness, specifically when leaving her home and being in crowds. Naturally, I diagnosed a phobic condition and prescribed an anxiolytic. As she was about to leave the clinic, she said, 'By the way, doctor, I have a rash on my legs'. I asked her to show it to me and immediately recognised the raised purplish bumps of erythema nodosum. I referred her to the medical specialists who took over the treatment of her medical condition and cured her of her breathlessness.

Lesson 1: always bear in mind the possibility of an underlying medical condition

There is an expanding literature on comorbidity between psychiatric and medical conditions that partly contributes to the high mortality rate in psychiatric patients.

Lesson 2: make careful observations on patients and their response to treatments

Observant clinicians remain curious about puzzling aspects of everyday psychiatry, and this attitude can stimulate research projects which have the potential to lead to breakthroughs in psychiatric treatments. For example, my concern about the failure of antipsychotic medication to suppress auditory hallucinations in one in four patients led me to develop avatar therapy, ¹ a novel and effective treatment for this debilitating condition.

Lesson 3: always listen carefully to the patient's narrative

Do not dismiss the patient's belief about the cause and nature of their illness. It has been shown that the greater the disparity between the patient's and the physician's understanding of the patient's illness, the less likely the patient is to adhere to the prescribed treatment. The same caveat applies to the family carers' beliefs about the patient's illness, even if they depart widely from your own understanding. UK psychologists were the first to adapt Beck's cognitive therapy for depression to treat psychosis (CBTp). My experience of working with family carers of people with schizophrenia taught me that many low expressed emotion family carers had developed effective coping strategies for dealing with the patient's difficult behaviour, for example, distraction, reality testing and time out, which closely resembled CBTp. If professionals had listened to these family carers, and given credence to their narratives, they would have introduced CBTp much earlier, saving considerable suffering. While CBTp alleviates the anxiety of patients with persecutory auditory hallucinations, it has little impact on their frequency or volume, as opposed to avatar therapy.¹

Lesson 4: the value of qualitative studies

Qualitative studies provide information of a different nature to quantitative studies, such as patients' experience of novel therapies, but they are of equal importance. Quantitative and qualitative studies are not in competition, but complement each other and are very informative when employed in tandem. An example is the current large-scale replication study of the value of avatar therapy.² Standard quantitative measures of the participants' assessment of the power and malignancy of their persecutory voices are augmented by the participants' accounts of their experience of standing up to the avatar they have created as a proxy for their persecutor.

Lesson 5: it is all too easy to become fascinated with esoteric research and to allow its demands to divert you away from basic clinical work

Working with patients is the crucible that generates the questions that inspire research projects. I cannot emphasise enough the importance of maintaining contact with everyday psychiatric patients, and not being lured exclusively by the glamour of exotic conditions. When I was granted a chair, I was the only professor in the Institute of Psychiatry (now Institute of Psychiatry, Psychology and Neuroscience (IoPPN), King's College London) who held clinics for local patients. Happily, that situation has now changed.

My research career began in earnest in 1968 when I was offered a position in John Wing's Medical Research Council Social Psychiatry Unit at the Institute of Psychiatry. I spent 34 years as a researcher, focusing mainly, but not exclusively, on psychosis. Many of the important lessons I learned were as a result of my research experiences, and it is these I wish to share with you, in the hope that they will inspire you to undertake your own research projects. There are so many unanswered questions in psychiatry that we need many more researchers to tackle these. Sir Aubrey Lewis, who founded the Institute of Psychiatry, was dedicated to promoting research and insisted that trainees conduct their own research project in order to pass their final exam. Sadly this requirement lapsed after Sir Aubrey retired.

Lesson 6: formulating a question

Junior colleagues would often approach me, eyes shining with excitement, saying that they wanted to do research 'with a capital R'. I would then ask them what they would like to do their research on and would be met by a baffled silence, clearly expecting me to spell out a project for them. If a topic engages your curiosity, you need to do some hard thinking and formulate a question that you want to answer. A well-constructed question can be developed into a series of hypotheses, which will determine the trajectory of your research project. A well-designed research study will always generate new unanswered questions that will then form the basis for the next study. The results of a research project you did not expect are as important as those you anticipated, and should lead you on to a new study. Consider the following sequence.

When Christine Vaughn joined the Social Psychiatry Unit, she decided that she wanted to embark on a PhD to replicate the findings of Brown, Birley and Wing that high expressed emotion in family carers significantly predicted relapse of schizophrenia.³ This pioneering study was surprisingly neglected by the psychiatric community, probably because of

the prevailing adherence to biological explanations for schizophrenia. Christine and I decided that a replication would attract the attention these findings deserved.

We discussed collaborating on this project and I suggested that it would add value to the research if we included a group of patients with depressive disorder to ascertain whether expressed emotion was a specific predictor for schizophrenia or whether it would predict relapse of depression as well. In the event it turned out to be a more potent predictor for relapse of depression than for relapse of schizophrenia, as shown by Jill Hooley in her PhD in the USA.⁴ In addition, our study replicated the protective effects of medication and low contact with the carer against the stress of high expressed emotion that the earlier study had revealed. This stimulated me to consider the possibility of intervening in high expressed emotion families to lower expressed emotion and contact between the patient and the family carers. There were two compelling reasons for this: primarily, to determine the direction of causality (do high expressed emotion attitudes cause relapse of schizophrenia or does the patient's disturbed behaviour provoke high expressed emotion attitudes?); and also to determine whether our family interventions could improve the outcome of schizophrenia.

For this project I assembled a team of therapists with different areas of expertise: a cognitive-behavioural therapist with experience of working with groups, a psychodynamic psychiatrist, a psychiatrist from Germany who was a trained psychoanalyst and myself as an eclectic therapist with no strong adherence to any one theory of family functioning. The therapy used by this heterogeneous team was remarkably effective, succeeding in reducing the patients' relapse rate over 9 months from 50% to less than 10%.⁵ The success of this trial led to two more randomised controlled trials (RCTs), including a cost-benefit study. The accumulation of this evidence plus ten replications in different countries led the National Institute for Health and Clinical Excellence (NICE) to recommend that family carers of a patient with schizophrenia must have professional input. This outcome justified the 15 years it took to complete the sequence of RCTs.

Lesson 7: the danger of linear thinking

Linear thinking results from the idea that causal action flows in one direction only, from cause to effect, from producer to produced, analogous to a series of billiard balls in motion. The issue of linear thinking in the social sciences, including psychiatry, merits some discussion.

Linear thinking forms the basis of almost all biological research in psychiatry. It has a long history, having been first formulated by the Greek philosophers Anaximander and Plato. In the modern era, Von Bertalanffy was the first to challenge linear thinking.⁶ He stated that we must think in terms of systems of elements in mutual interaction. At that time, the development of cybernetics promoted systems thinking. The process of feedback whereby missiles could monitor and correct their trajectory was recognised as analogous to the biological system's capacity to maintain and organise itself in nature. This formulation was seen as very relevant to the process of family therapy. The family theorist Gregory Bateson wrote: 'I think that cybernetics is the biggest bite out of the Tree of Knowledge that mankind has taken in the last 2000 years'.⁷ It is ironic that a technology developed to destroy human beings should contribute to our understanding of family relationships.

Homeostasis is a concept fundamental to systems theory. It is achieved by negative feedback loops, which stabilise the system by reducing deviation between goal and performance (cf. missiles). By contrast, positive feedback loops reinforce or amplify deviations, producing novelty and instability and an increase in the complexity of the system, leading to new properties. Applying this understanding to social relationships, which are of central importance to psychiatry, feedback represents the direct perceptual report of the effect of one's behaviour on others, for example, the perception of a smile in response to one's own smile.

Robert Dubin considers that the difficulty of avoiding linear thinking stems from our propensity to look for isolatable one-way causes.⁸ Feedback processes can easily be overlooked, not only because the linear perspective is the dominant mode, but also because they tend to be unnoticed owing to their very pervasiveness.

Earlier I stated that one compelling reason for working with high expressed emotion families was, I quote myself, 'to determine the direction of causality'. You will now recognise this as a prime example of linear thinking. In actuality I was aware that there were multiplex interactions between patients and their family carers, but this was too complex to investigate at that time.

Now I will give you some practical advice on initiating research and carrying it through to publication.

Lesson 8: searching the literature

Electronic databases have made this much simpler and more efficient. Decide on the criteria for your search, and be overinclusive rather than underinclusive (obviously, irrelevant papers can be deleted without needing to read them). Summarise what has been established. This requires a critical attitude to research by others, however eminent they may be. Weigh up the evidence and come to a conclusion. This may be that the question you formulated has been adequately answered, in which case, back to the drawing board!

Lesson 9: focus on a single topic

Avoid being too ambitious. If your initial project produces useful results, you can always extend it. Seek advice from experienced colleagues. They can warn you about pitfalls in your chosen area of research.

Lesson 10: applying for funding

When applying for funding, choose the funding body carefully, paying close attention to their mission statement. It is often worthwhile beginning with a pilot study which can be mounted with minimal or no costs. For instance, determining whether your catchment area will provide sufficient patients for your study. This will show potential funders that you are a serious contender.

Lesson 11: anticipate the concerns of the ethics and research and development committees

Gaining approval from these committees is now an obligatory hurdle to surmount. There are a number of actions you can take to improve your chances of being approved. Anticipate objections from committee members, and be prepared to be able to counter them. In my recent trial of avatar therapy, I anticipated that there would be anxiety in the committee about patients' response to being faced with their persecutor in the shape of the avatar. Therefore, with the aid of my IT specialist, we constructed a bright red 'stress button' which the patient could press in case of high anxiety or for any other reason. This switched off the avatar image on the monitor, which was replaced by an image of a tropical beach with *The Four Seasons* by Vivaldi playing in the background. In the event, only 2 patients out of 18 pressed the stress button, and both were able to continue with the session after reassurance.

Lesson 12: appreciate the value of user-researchers

Involve service users in your study. They should certainly be asked to read the instructions for potential participants, and to suggest changes to the wording. Users can be recruited to play a more important role in your study. The IoPPN has established a list of user-researchers. These are users who have largely recovered from a psychiatric illness and are willing and able to be trained in research procedures. For example, in my avatar therapy trial, I employed a user-researcher who had heard voices himself 8 years previously and was now completely well. I trained him in the assessment tools and he achieved high interrater reliability with me, enabling him to undertake the role of an independent assessor, for which of course he was paid. The employment of users will be greatly appreciated by the ethical committee. If you do appoint a user-researcher, they must be included as an author.

Lesson 13: team building

If you are ambitious and wish to undertake a major study you will need a team, preferably multidisciplinary in nature. Diversity of professional expertise is an asset, as we experienced in our development of working with families. Consult a statistician early on in designing the study. Statisticians are understandably grumpy if they are asked at the last minute to conduct the data analysis without having given any prior input. Develop a cohesive group and deal with rivalry. The media often depict research as a gentlemanly pursuit of the truth. That is a fallacy. There are glittering prizes to be won through research, and the world of research is as competitive and cut-throat as multinational capitalism.

Be fair to junior members of the team. Encourage and support them and give them experience in presenting and appropriate representation in publications. In mid-career I left the Maudsley to take charge of a dysfunctional research group working in a traditional psychiatric hospital. It had been managed by two absentee directors and was in a state of anarchy, with one member of staff suing the directors. The aggrieved staff member left and I had to dismiss another member of staff. I knew my intervention would be resented so introduced a Friday lunch-time picnic in the extensive grounds of the old psychiatric hospital, followed by a game of croquet on the lawn next to the former medical superintendent's villa. I reasoned that being able to knock my balls around would diffuse aggression, and so it did.

There were two reasons for my leaving the Maudsley to work in Friern, a typical 19th-century asylum. One was to emerge from the shadow cast by John Wing, the director of the Medical Research Council Social Psychiatry Unit. Although John left me to pursue my own research interests, he was nearing retirement and I knew that to stand a chance of taking over the directorship of the Unit, I would have to prove that I was capable of mounting important research independently from him. The other reason was the split in the profession of psychiatry between the academics and psychiatrists working in provincial hospitals; the latter felt overburdened by their workload and disregarded by the academics, whom they saw as existing in a 'cloud 9' environment, protected from the realities of jobbing psychiatry. Given that in that era the great majority of psychiatrists were working in antiquated buildings, with insufficient support from psychologists, occupational therapists and other ancillary staff, I felt that I needed to experience the reality of life in an asylum.

It felt to me like another world. The Italianate Gothic frontage was forbidding, as was the original plaque designating the building as the West Sussex Pauper Lunatic Asylum. The entrance corridor was a third of a mile long. At that time it was the longest hospital corridor in Europe. It had windows throughout its length, but they were so low I could only see through them by stooping uncomfortably. At the end of the corridor was a faint glimmer of light from the world outside. Despite the gloom that descended on me, in time I began to appreciate the good qualities of Friern. It was set in extensive grounds, which included a football field and a 9-hole golf course, on which I never saw anyone playing. There was a chapel and a synagogue, and a factory outlet where low-cost clothes were available. Although the main gate was always open, very few patients ventured out into the street. Patients wandered around the grounds unhindered and sexual liaisons were undoubtedly formed, as one of the long-stay patients in my care regularly developed gonorrhoea. I began to appreciate how easy it would be to become accustomed to the environment of the asylum and to forget the existence of the outside world.

Lesson 14: the staff in an institution are often more institutionalised than the patients

Not long after I moved to Friern Hospital the Regional Health Authority decided to close Friern and Claybury hospitals in accord with the government policy of that time. I realised that this was a unique opportunity to evaluate this policy. I succeeded in obtaining funding from the Regional Health Authority, later supplemented by funding from the Department of Health. This enabled me to form a group of researchers under the title of TAPS: The Team for the Assessment of Psychiatric Services. Friern Hospital had been opened in 1851 with 1000 beds. The number of patients grew exponentially, reaching 2500 in the 1940s. The discharges of many patients between 1940 and the beginning of the TAPS programme had reduced the number of long-stay patients to 800.

The first step in the TAPS project was to conduct a comprehensive assessment of the symptoms and the problem behaviours of all the remaining patients in the two hospitals who did not have dementia. Complete data on all 700 patients were collected by the team, a mammoth undertaking. A 5-year follow-up was conducted on this group of patients, of whom only a tiny number were lost to the study, thanks to the efforts of the excellent administrative assistant who made regular checks on the patients' locations in the community. Meanwhile, an extraneous researcher, not a TAPS

member, carried out a survey of all the nursing staff looking after the remaining patients, asking them to estimate the number of patients who could be resettled in the community. The total percentage estimated by the nursing staff was one-third. If this was accurate, the possibility of closing the two hospitals within the 10-year limit set by the managers was negligible. However, the TAPS team had already begun asking individual patients for their preferences when the hospitals closed: one-third wanted to leave the hospital and live in the community, one-third opted to stay in the hospital and one-third were uncertain. In the event, all the patients considered suitable to live in the sheltered homes in the community by the resettlement teams adapted well to life in the outside world, and when asked where they would prefer to live a year later, 84% wanted to stay where they were.⁹

Friern hospital did close on time 10 years after the decanting began. The Claybury closure was delayed because the consultants there went on strike against the closure decision, but the strike collapsed after 6 months and the closure went ahead. So psychiatrists can be as institutionalised as nursing staff.

Lesson 15: presenting at conferences

Always try out your presentations with a sympathetic audience and take note of their criticisms and comments. The golden rule for slides is ‘never put more on a slide than you can get on a T-shirt’. I am often amazed at seeing experienced researchers cramming a slide with illegible lists of data and *P*-values and then saying to the audience, ‘You probably won’t be able to read this but what it shows is ...’ – if it can’t be read, don’t show it!

Lesson 16: writing up the results

Avoid the pall of conventional scientific writing. Break through the conventional anonymity of the passive voice. Humanise your writing to make it attractive to the reader. Keep the language simple and avoid too many technical terms. Always spell out abbreviations the first time they appear in a paper, including the abstract. Pay special attention to the clarity and layout of tables and figures – ensure that they are essential for the understanding of your results. Editors dislike large numbers of tables and figures since they occupy space that could be used to publish another paper. Avoid duplicating results in the text as well as in tabular form.

Lesson 17: submission to a journal

Choose the journal carefully, surveying past issues for the types of papers published. Always read instructions to authors with great care and observe them, particularly the word limit – if you exceed this, your paper will bounce back rapidly. Find out the proportion of submissions accepted, if possible. Always treat the reviewers’ comments seriously and couch your responses respectfully, even if you think the reviewers are idiots. Don’t give up at the first rejection, but look for alternative journals. There are so many journals being published now that there is considerable overlap in their remit. If you are inexperienced, do not be too ambitious in choosing a journal with a high impact factor. I sent my recent paper on avatar therapy serially to *Nature*, *New Scientist* and *Archives of General Psychiatry*, all of which rejected it without sending it for review. So much for hubris! It was eventually published in the *British Journal of Psychiatry*. I was mollified when following a press conference the paper went global.

Maintaining safety

I am interpolating this issue, not to raise your anxieties, but to convey the important advice I received from a senior colleague early in my clinical career. What he said was ‘never let the patient get between you and the exit door of your clinic’. A colleague and friend of mine at the Maudsley Hospital was unaware of this advice and preceded the patient into his clinic; the patient then stabbed him in the back with a pair of scissors. Fortunately, the wound was superficial.

Finale

Do not be put off by the hard work and inevitable disappointments. They are more than compensated for by the intellectual excitement generated by research and the knowledge that you are improving the lives of your patients.

- *Dudleigh Oscar (John) Topp FRCPsych, MBBS, MFCM, DPM*
– : *Formerly Principal Medical Officer, HM Prison, Brixton*

John Topp, who died on 23 February 2016, was a Principal Medical Officer who was one of the first to draw attention to the increased rate of suicide among the prison population. In the late 1970s, he showed that suicide was three times as common in prisoners as in the general population, that it was most common in those with sentences longer than 18 months and that the greatest risk was in the first few weeks in custody. ¹ He subsequently advised on suicide prevention in prisons.

Topp always felt deeply that the prison medical services were often unfairly maligned. He knew that the antiquated estate and restrictive budget did nothing to enhance the practice of modern medicine; yet, he felt that on the whole prisoners were given good care within these constraints. He found the hospital officers of the Prison Medical Service to be generally excellent but felt that many were denied opportunities to achieve the nursing qualifications they desired. Much criticism, he felt, would have been spared if training had been far better resourced and achievement suitably rewarded. Nevertheless, his view was that although the service was not superficially attractive, for those prepared to put effort and interest into it, there could be considerable work satisfaction – something he enjoyed himself despite much frustration.

Dudleigh Oscar Topp, always known as John, was born on 11 September 1924 in Hove, the son of a bank manager. A practising Roman Catholic, he was educated at the Xaverian College in Brighton and attended King's College London, from where he went to Charing Cross Hospital Medical School, qualifying in 1949. After house posts at Oldchurch Hospital, Romford, he served as a captain in the Royal Army Medical Corps in Northern Ireland. He joined the Prison Medical Service in 1953 at Wakefield prison and later became Senior Medical Officer at Brixton prison, from where he was promoted to Principal Medical Officer to serve regionally and centrally, administrating various aspects of the prison medical services.

He retired on medical advice in 1984 but remained actively interested in prison affairs and wrote books on the history of the Prison Medical Service. His particular regret was that the Prison Medical Association, which he founded towards the end of his career with the object of promoting the highest standards of medical care in English prisons, did not survive his retirement. However, he lived to learn of the inception of an Academy of Prison Medicine which naturally had his full approval.

Living latterly in Weymouth, where he had the close companionship of two local retired hospital chief officers, he became the founder president of the Pickering Society, a nationwide group of retired hospital prison staff of all categories. It was named after a respected director of prison medical services under whom most of them had served.

Soon after qualifying, John married his childhood sweetheart Joyce Stoner, a nurse from Brighton. They had four daughters, three of whom trained as nurses at the Westminster Hospital, where two of them met and married doctors. There are now eight grandchildren and five great-grandchildren. Tragically, Joyce died in 1975 of carcinoma of the stomach, following which he married her friend Peggy Lange, then a Principal Nursing Officer in Sunderland.

1.7.14 Anthony Carl (Tony) Kaeser FRCP, FRCPsych

: Consultant in Old Age Psychiatry, Basildon sector, Thameside Community Healthcare NHS Trust

Mike Lowe

date

2017-2

Contents

- *Anthony Carl (Tony) Kaeser FRCP, FRCPsych*
 – *: Consultant in Old Age Psychiatry, Basildon sector, Thameside Community Healthcare NHS Trust*

Tony Kaeser, who recently died aged 84, was one of the pioneer consultant psychiatrists who from the 1960s onwards developed departments of psychological medicine in district general hospitals at the time when long-stay mental asylums were being phased out. In the years following his appointment in 1969 as a general adult psychiatrist to Runwell Hospital, he was involved in innumerable planning meetings with the then North East Thames Regional Health Authority to advance the new purpose-built department of psychological medicine at Basildon District General Hospital. This was eventually opened in 1977. It was Tony's attention to detail which improved the ward day areas for the patients – initially they were going to look out on to industrial sites, but with some reconfiguring of the layout the views were transformed to field and countryside vistas.

In the 1980's Tony was appointed convenor for training approval visits for the East Anglian Division of the Royal College of Psychiatrists. He provided liaison psychiatry services at Basildon District General Hospital and was the consultant psychiatrist for the Regional Plastic Surgery and Burns Unit at St. Andrew's Hospital, Billericay for 11 years. He was Chairman of the Basildon General Hospital District Consultant Staff Committee. For the last 7 years of his career he chose to work full time in psychogeriatrics. Despite his heavy clinical load, his professional services were extended willingly to staff and their families from all areas of the National Health Service (NHS) in South Essex.

He was a Foundation member of the Royal College of Psychiatrists. The College recognised his abilities by inviting him in 1984 to act as convenor leading the first team to visit the large Hong Kong training scheme. Shortly before retiring, Tony became a General Medical Council Examiner for doctors with health problems and for a number of years in retirement was one of two Lord Chancellor's Visitors for England. He was also an Area Visitor for the Royal Medical Benevolent Fund until he reached their retirement age.

Tony was born in London in 1932. He qualified at St. Mary's Hospital in 1957 and after house jobs in general medicine he obtained the MRCP and entered the Maudsley training scheme. After obtaining the DPM he was appointed senior

registrar at the Maudsley and Institute of Psychiatry. From there he was appointed consultant psychiatrist to Runwell Hospital.

A gentle, kindly, impressively ethical doctor, he was considered in his thinking and conversation but precise, soundly analytical and unfailingly wise. His manners to everyone he encountered were impeccable and right to the end he retained his genuine interest in people. When he became ill himself, he wanted to know about the lives of his carers.

His personal life was varied and fulfilling. He inherited his father's stamp collection. He loved a wide range of music and enjoyed playing his pianola. He joined in regular contract Bridge sessions with medical colleagues throughout his career and retirement, and these only came to an end 4 years before his death. Tony had a great sense of fun and participated in the staff Christmas show for patients. His performances in playing the femme fatale were such a success that he resigned himself to being typecast. He took delight in the achievements of the members of his family. His wife Wendy was an NHS health visitor and they had 2 children and 6 grandchildren, one of whom is a dancer with the Royal Ballet.

In the latter years of his retirement he experienced gradually declining health. He had been diagnosed with a rare hereditary form of amyloid heart disease and although his cognitive faculties were largely undiminished, progressive cardiac failure slowly developed and he died on 18 May 2016. In line with his commitment to humanistic principles, Tony donated his body tissues for the benefit of others and his brain for research into amyloid disease.

1.7.15 Klaus Minde MD FRCP(C)

: Formerly Chairman, Division of Child and Adolescent Psychiatry, McGill University, Montreal

Philip Graham

date

2017-2

Contents

- *Klaus Minde MD FRCP(C)*
– : *Formerly Chairman, Division of Child and Adolescent Psychiatry, McGill University, Montreal*

Klaus Minde, who recently died at the age of 82, was an academic child and adolescent psychiatrist renowned for his pioneering work in a variety of fields – especially infant psychiatry – and for the development of child mental health services in low-income countries. His early research was in the field of hyperactivity in children. Working with Gaby Weiss and John Werry, he was one of the first to carry out studies of medication in this condition.

In 1961, shortly after he had started his training in child psychiatry, his first child Thomas was born prematurely; he and his wife Nina, a psychologist, were not allowed to touch him – they could only gaze at him through the window of the nursery until they could take him home when he was 4 weeks old. This distressing experience stimulated Klaus' interest in the development of premature babies and the ways parents could be involved in their care. He carried out a number of observational studies¹ which – allied with the development of ideas on mother-infant bonding promoted

by two paediatricians, Marshall Klaus and John Kennell – helped to change practices in the nursing care of premature babies.

From 1971 he spent 2 years on secondment setting up a child psychiatric clinic at Makerere University, Uganda. As well as establishing a service, he carried out a significant amount of research, conducting comparative studies of disorders in Canada and Uganda.² Idi Amin, the brutal, idiosyncratic president of the country, was in power at the time. Klaus described how Amin, as chancellor of the university, required every professor to be present when he had decided to address them. While everyone was waiting for him, 3 empty limousines would arrive, followed – 3 minutes later – by Amin on a bicycle that he had mounted just before entering the university.

In 1983 he spent a sabbatical year in London, where he met John Bowlby, whose work on attachment had so impressed him. He was able to persuade Bowlby to visit Canada to talk about his ideas. After his official retirement from his chairmanship in 2000, he and his wife spent a year in Johannesburg, South Africa, where they worked with very disadvantaged children and families in the townships of Alexandra and Soweto. Once again he carried out research, this time on the assessment of attachment.³ In addition, Nina and he organised a mutual support group of grandmothers looking after their grandchildren (orphaned by the country-wide epidemic of AIDS), which became a model for similar groups in the area.

Klaus always had a strong interest in the plight of disadvantaged children and their need for psychiatric services. From 1994 to 1999 he worked with native Canadian children, acting as a consultant to the Cree Board of Health in Mistissini, Quebec; from 2009 to 2015 he was a consultant to Dans La Rue, an organisation caring for street children in Montreal.

Klaus was born in Leipzig in 1933 in the same year as Hitler came to power in Germany. His father was technical director of Germany's public radio and strongly opposed the Nazi movement. As one of the few senior people who had refused to join the Nazi party, his father was promoted after the war but was later sacked when a communist state was imposed in Eastern Germany in 1949. Klaus attended a humanist school and also rebelled against the ruling party. He wanted to study medicine but given his family background and outspoken political views, he had no chance of entering an East German medical school. Leaving his family behind – it was many years before his mother could join him – he travelled to West Germany and obtained a place to read medicine in Munich. After qualification he won a Fulbright scholarship which enabled him to go to New York and gain experience in paediatrics at Bellevue Hospital and psychology at Columbia University. He then undertook residency training in psychiatry at McGill University in Montreal, remaining in Canada, except for his sabbatical periods, for the rest of his professional life. He was Director of Research at the Hospital for Sick Children, Toronto, from 1973 to 1986 and after a spell at Queen's University in Kingston, Ontario, he was appointed Chairman of the Division of Child and Adolescent Psychiatry at McGill University from 1989 to 2000.

With his boundless energy and enthusiasm, Klaus could set audiences alight with his rhetoric, promoting the cause of better care not just for newborn babies but for children with physical and mental disabilities and for the socially disadvantaged. His whole body, especially his gesticulating arms and plentiful hair, seemed to be engaged in getting over his messages to his audiences, who loved it!

After retirement he continued to mentor colleagues and see patients until he suffered a major stroke shortly before his death on 6 July 2016. He is survived by Nina, his three sons and four grandchildren.

Contents

- *A Practical Guide to the Mental Capacity Act 2005: Putting the Principles of the Act into Practice*

The Mental Capacity Act 2005 (MCA) – which applies specifically to England and Wales – pervades several aspects of daily clinical care within many clinical as well as non-clinical environments, such as care homes.

The authors of *A Practical Guide to the Mental Capacity Act 2005* – whose backgrounds are social work and advocacy – observe that ‘Seven years on [...] the MCA is still not being adhered to nor fully embraced within practice’. Their aim was to produce a ‘theory-to-practice breakdown of the MCA’ and this was readily achieved with a fluent and erudite style of writing and continued emphasis on the practical aspects of implementing the MCA. There were useful case studies and checklists for practice, as well as practical top tips such as videotaping advance statements. A minor gripe would be that, if anything, such checklists and top tips could have been used more often throughout the book; for example, at the end of each chapter. The most useful chapter was that on best interests – very salient practical advice was afforded on the best interests process and assessments, including how to chair meetings and using documentation. This chapter tried to demystify the abstract concept of best interests by conceptualising such decisions as complex and less complex. Another strong chapter – probably reflecting the authors’ expertise in this area – was on advocacy and empowerment, which examined the various roles of the independent mental capacity advocate within the MCA process.

The undoubted highlight was the evocative account of the 2004 case of *HL v UK* which was the catalyst for the introduction of Deprivation of Liberty Safeguards (DoLS) legislation, to plug the now legally infamous ‘Bournewood gap’. HL was a patient with autism and challenging behaviour who was admitted to hospital on an informal basis. He was regarded as being compliant with care but unable to consent to admission; however, this was found to be a contravention of Article 5 of the European Convention on Human Rights (the right to liberty). The account is written by HL and his carers Mr and Mrs E. Although events regarding HL and his carers began in 1993, the account is a fascinating perspective of one of the most, if not the most, important mental health cases in legal history in terms of its potential impact on tens of thousands of people, carers and clinicians on a daily basis. The authors provide useful views on how and why the DoLS legislation has not been implemented well so far.

Overall, this is an excellent short text which should be required reading for those involved in care touching upon the use of the MCA, and would be ideal for medical and nursing students. But with the Court of Protection seemingly currently engaged in trying to crystallise the core essence of DoLS legislation – and with further recent key judgments emerging in the areas of best interests, end-of-life care and DNACPR (do not attempt cardio-pulmonary resuscitation) – it seems likely that this, as well as other similar guides, will need to be updated again in the near future to keep the readership up to date with key developments.

1.7.18 A Clinician’s Brief Guide to the Mental Capacity Act (2nd edn)

Martin Curtice¹

date

2017-2

Contents

- *A Clinician's Brief Guide to the Mental Capacity Act (2nd edn)*

This book aims to provide a comprehensive overview of the Mental Capacity Act 2005 (MCA) – which applies specifically to England and Wales – and its implementation in practice.

The authors are all practising psychiatrists and although the style and content is tailored for a medical readership, the guide is suitable for all grades of doctors and all specialties, not just psychiatry. It is also ideal for medical and nursing students. With a punchy and concise writing style, the book has copious amounts of practical advice for clinicians throughout, and at times uses a common sense question-and-answer format with questions that clinicians are likely to pose, which reflects real-life practice.

Importantly, this work sought to translate lengthy and wordy court judgments into concise and simplified reviews outlining key basic principles for clinicians to use in daily practice. Possibly the most interesting chapter was that regarding the role of the Court of Protection. This busy court – which according to the authors hears approximately 23 000 cases annually, a figure that will surely inevitably rise – is often referred to in the media as the secretive court. However, this excellent chapter goes a long way in debunking various perceptions. It also explains the court process and is infused with sage, detailed and practical advice, from how to handle requests for assessments, writing reports and interviewing patients to giving evidence in court and even finding your way there if you need to! The authors suggest that Court of Protection proceedings tend to be more ‘informal and inquisitorial than formal and adversarial’ but that they can still be stressful, which is why they wish readers ‘good luck’. But despite the suggestion that a degree of luck might be needed, anyone new to such court proceedings will be far more prepared having read this chapter than not.

Needless to say, the thorny issue of implementing Deprivation of Liberty Safeguards (DoLS) was discussed at length in a chapter that provided important context by describing the evolution of this legislation and case law. Notwithstanding, owing to a glut of more recent key DoLS judgments, the book is already a little out of date as DoLS case law and guidance have evolved rapidly. It seems likely that an update will be needed soon to keep readers informed of key developments. Nevertheless, there was a good description of practical issues in using and applying DoLS since the *Cheshire West* case in 2014, a case which triggered an upsurge in the use of this legislation. The authors aptly summed up the state of DoLS understanding from further case law since *Cheshire West* by saying it did ‘little to ease the quandaries of health and social care staff in their decision-making in relation to deprivation of liberty’.

Another notable chapter was the one on the assessment of capacity, which provided comprehensive and practical advice, breaking the process down into its components and getting into its minutiae, thus challenging the reader to re-evaluate their own methods for assessing capacity. Other useful sections included advice on how to resolve conflict emanating from complex best-interests meetings and on seeking consent. Although not concluded at the time of publication, the latter resonates with the 2015 seminal Supreme Court case of *Montgomery v Lanarkshire* which has redefined the rules of seeking consent and has implications for how clinical negligence will hence be assessed.

All in all, this is an excellent guide which would aid those involved in care touching upon the use of the MCA.

1.7.19 Motivational Interviewing: A Guide for Medical Trainees

Ed Day¹

date

2017-2

Contents

- *Motivational Interviewing: A Guide for Medical Trainees*

I first encountered motivational interviewing as a trainee when I read Miller and Rollnick's classic 1991 book *Motivational Interviewing: Preparing People to Change Addictive Behavior* and the key concepts have always resonated with me. Although it seems obvious that a man requiring major surgery due to cardiac disease should stop smoking, it is rarely helpful to insist that he does so. People have ambivalent feelings when it comes to changing entrenched behaviours and it is often better to elicit their own reasons for change. After all, it has been said that people believe what they hear themselves say. Perhaps because of its apparent simplicity, motivational interviewing has become an important technique for most UK addiction therapists and its influence has gradually spread to other areas of practice. Therefore, does the world need another book on motivational interviewing?

This book is written by a group of trainees spanning all specialties of medicine, with the goal of demonstrating how motivational interviewing can fundamentally improve the doctor-patient relationship. Motivational interviewing is a way of being rather than an intervention and the book reminded me of its roots in Carl Rogers' person-centred approach to therapy, based on building empathy, congruence and positive regard. As someone who bemoans the biomedical nature of British psychiatry, I was surprised that it succeeded in reawakening my interest in interviewing skills that not only elicit information but also provide therapeutic insights and direction.

Like the practice of psychiatry, motivational interviewing is straightforward to do but hard to do really well. It is not easy to learn from books and so the editors provide lots of dialogue to illustrate key points, and a series of videos on a linked website. They add personal reflections, as well as illustrations of the integration of motivational interviewing into electronic case records and its use in less familiar settings such as paediatrics. There is also a practical emphasis on how to teach and supervise motivational interviewing in the real world. Their enthusiasm for the subject was infectious and I was left in agreement that learning motivational interviewing should be a priority in medical education.

1.7.20 Waking Up: Searching for Spirituality without Religion

Matthew M Nour¹

date

2017-2

Contents

- *Waking Up: Searching for Spirituality without Religion*

Sam Harris has been waiting to write this book for over a decade. This may surprise some. The subject matter – dealing reverently with human spiritual experience – is at odds with Harris’ (in)famous public persona as a strident critic of religion. Yet, for the past 20 years Harris, who has degrees in philosophy and neuroscience, has been on a personal quest in search of ‘transformative insights about the nature of one’s own consciousness’.

Harris defines spiritual practice as the efforts people make, through meditation, use of psychedelics or other means, to fully bring their minds into the present. This practice leads to the insight that our sense of having a unified self is an illusion and that this illusion causes us much psychological suffering. Harris aims to convince his reader of this using philosophical thought experiments, discoveries of contemporary neuroscience and personal experience. He also encourages his reader to test these hypotheses about human consciousness ‘in the laboratory of your own mind’, through meditation practices inspired by Buddhist Dzogchen and Vipassana teaching. He argues that these spiritual insights can be accepted independently of the metaphysical baggage of traditional religion, and laments that until recently they have been under-investigated by an ‘impoverished’ neuroscience.

The resulting book is an ambitious mosaic: part memoir, part neuropsychology text and part meditation guide. A key strength is Harris’ clear, lively and personal writing style, which instils the prose with an endearing conversational air. Many readers will feel, however, that by focusing almost exclusively on solitary meditation practices and psychedelic drug-induced experiences, Harris has omitted important dimensions of human spiritual experience, such as the self-transcendence which may be arrived at when contemplating art or engaging in communal ceremonial practices. Moreover, the occasional barbed criticism of monotheistic religion will deter some readers, but play well to the Harris faithful.

Waking Up is a book for the general public and is not intended to have a clinical application. Why, then, is it being discussed in the pages of this journal? My answer is twofold. First, as psychiatrists we are interested in all dimensions of human experience. Consequently, the growing scientific interest in the mystical/spiritual experience and its potential therapeutic implications is of great importance for our specialty. Second, psychiatrists are humans and all humans may benefit from being reminded from time to time that our conventional sense of a unified self sitting some 2 inches behind the eyes is likely to be a pernicious illusion.

1.7.21 Deconstructing the OSCE

Deborah Cooper¹

date

2017-2

Contents

- *Deconstructing the OSCE*

This volume contests that it is possible to develop a generic way to approach different Observed Structured Clinical Examination (OSCE) scenarios, regardless of medical specialty. Perhaps surprisingly, it is not filled with possible exam scenarios, but rather looks at the underlying barriers to good performance. In this regard, it provides a behavioural and psychological schema for approaching the OSCE. The book makes no apologies for aiming at those who have already had a previous attempt at passing the OSCE, and given that pass rates for membership exams are generally around 50–60%, it is a resource available to a great number of doctors in training.

The initial chapters look at the common emotional and cognitive responses which typically follow an unsuccessful examination attempt – they do a good job of validating these experiences and feelings. Subsequent chapters aim to improve general exam strategy. These include the perhaps more neglected areas of good exam performance; for example, how to establish rapport with the actor or patient, and how to run a good study group and learning environment. An especially useful chapter is that which explores challenging scenarios such as ‘the angry relative’ or ‘the crying patient’. Although these passages are brief, practical tips are given to aid communication in these often difficult situations.

In addition, there are worksheets that support the doctor in understanding that the way they think about the exam influences their emotions and, ultimately, their exam performance. The psychiatry trainee will be no stranger to this process; however, I wonder whether trainees from other specialties might find the experience alienating.

This work undoubtedly highlights that poor exam performance is often not related to lack of knowledge, but to cognitive and emotional barriers. As a result, it may provide a good starting point for ongoing study where examination performance has proven problematic.

1.7.22 Schizophrenics can be good mothers too

Duncan Double¹

- *Schizophrenics can be good mothers too*

To protect her children the author of this book chose to publish it under a pseudonym, Q. S. Lam. However, it's easy to break her anonymity and she accepts it can only be partial. She is a British Bangladeshi artist who has had several psychotic episodes, including postpartum. She has been diagnosed with schizoaffective disorder but prefers to describe herself as having a different sort of brain.

Her friend Stephen Fry has described the book as 'brilliant' – an endorsement displayed on the book cover – and Alastair Campbell has tweeted the same. Artwork and poetry complement the narrative of the author's personal and family history, which includes episodes of psychosis, and the description of the dissociated parts of herself and how she recovers. She does not take antipsychotic medication.

She makes remarks – not always very complimentary – about each mental health practitioner that she has seen over the years, dating back to the time when she first sought help. Also discussed is the impact of her mental health problems on her husband and children. She moved to Brussels, as her husband works there.

The psychiatrist she has most identified with is Erik Thys, who is also an artist. He did not advise Q.S. not to have a second child; instead, he said it was 'doable'. Q.S. openly questions whether it was fair on her children that she became a mother and dedicates the book to them.

The strength of this book is its honesty. Q.S. has experienced multiple sexual assaults by men and considers whether her mental health issues are a sane response to an insane situation. She reveals her heart and mind, truthfully expressing what she feels and thinks, and I found the directness of the book attractive. As Q.S. notes, doctors generally don't like their authority to be challenged. However, in my opinion there needs to be an open discussion about the stigmatisation of mothers with mental health problems.

1.7.23 Epistemic injustice in psychiatry

Abstract

It has been argued that those who suffer from medical conditions are more vulnerable to epistemic injustice (a harm done to a person in their capacity as an epistemic subject) than healthy people. This editorial claims that people with mental disorders are even more vulnerable to epistemic injustice than those with somatic illnesses. Two kinds of contributory factors are outlined, global and specific. Some suggestions are made to counteract the effects of these factors, for instance, we suggest that physicians should participate in groups where the subjective experience of patients is explored, and learn to become more aware of their own unconscious prejudices towards psychiatric patients.

Epistemic injustice is a harm done to a person in her capacity as an epistemic subject (a knower, a reasoner, a questioner) by undermining her capacity to engage in epistemic practices such as giving knowledge to others (testifying) or making sense of one's experiences (interpreting). It typically arises when a hearer does not take the statements of a speaker as seriously as they deserve to be taken. The prime case of epistemic injustice is testimonial: the hearer deflates the level of credibility she gives the speaker because she is (often unconsciously) prejudiced against the social group to which the speaker belongs. Common examples include sexism and racism. In such cases the testimony of a woman or a person from an ethnic minority background will be given deflated credibility, based on the prejudicial associations between that group and negative stereotypes. The reason we chose this approach is that epistemic injustice provides an account for why, despite the best intentions, physicians often do not believe what psychiatric patients tell them. Clarifying some of the reasons for this common prejudicial stereotype of patient unreliability may make it possible to explore ways of overcoming the epistemic injustice that we suggest patients, and in particular psychiatric patients, are vulnerable to.

It is worth noting here that it is prejudicial or negative stereotypes, not stereotypes *per se*, which often give rise to epistemic injustice. We rely on stereotypes as heuristic aids in making credibility judgements because they are often empirically reliable generalisations. However, negative attitudes towards people with a mental illness may lead to negative stereotypes and to generalisations which are resistant to counter-evidence, owing to what philosopher Miranda Fricker calls an 'ethically bad affective investment'.¹ It is these kinds of stereotypes that may lead to epistemic injustice.

Epistemic injustice and psychiatric patients

Epistemic injustice is important in psychiatry because of the persistent negative stereotypes that affect people with mental disorders in particular and lead to a credibility deficit. The consequence is that patient testimonies and interpretations are not acknowledged as credible, and patients are thus undermined in their capacity as knowers and contributors to the epistemic effort to reach a correct diagnosis and treatment. We suggest that people with mental disorders are even more susceptible to epistemic injustice than those with physical illnesses, for reasons that are detailed below.

We have argued in the past that people with physical illnesses are vulnerable to epistemic injustice.^{2,3} Here we suggest that people with mental disorder may be susceptible to even greater epistemic injustice than people with physical illnesses. This is mainly owing to the high prevalence and great power of negative stereotypes of psychiatric illness. As a consequence, the patient may be telling the truth, but the doctor deflates the level of credibility which she gives to the patient ('credibility deficit') and thereby does the patient a distinctive kind of injustice, namely epistemic injustice, which undermines the patient specifically in her capacity as a giver of knowledge. This has detrimental effects on individual psychiatric patients, but also on the funding of psychiatric services and the public perception of mental disorder. Many people are influenced by negative stereotypes about mental disorders, are ill informed about their true nature, and have little understanding of how to treat them. Some measures to improve the current situation are suggested below.

Measures to counter epistemic injustice

The notion of epistemic injustice has been developed by Fricker.¹ She was interested in how social identity and power affects people's status as knowers. She gives the example of a White police officer who stops a Black car driver and asks him whether the car belongs to him. If the driver truthfully says that the car is his, but the policeman does not believe him because of racial prejudice, then he does the driver an injustice in his capacity as a knower.⁴

The main type of epistemic injustice that Fricker discusses is 'testimonial injustice'; it emerges from the fact that testifying, i.e. giving information to others, depends crucially on one's perceived credibility. If a person is seen as lacking credibility, her testimony will be ignored or treated with suspicion, or it might not be solicited at all. Of course, she may lack credibility for a good reason, for instance if she is a known liar. However, testimonial injustice occurs when a person suffers a 'credibility deficit' owing to some negative stereotype or prejudice associated with her social group (e.g. gender or race). This credibility deficit is unjustified and hence constitutes an epistemic injustice. Fricker analyses how negative racial and sexist prejudices unfairly deflate the credibility of people of Black and minority ethnic background and women, such that what they say is ignored, marginalised or otherwise excluded from epistemic consideration. Since being able to give information to others is essential to social life and agential action, testimonial injustice harms those who experience it.

Carel and Kidd have argued that people with physical illnesses are more vulnerable to epistemic injustice than healthy people.^{2,3} The testimonies of patients are often presumed to be irrelevant, unreliable, confused or otherwise lacking in credibility, owing to negative stereotypes associated with ill persons. Such stereotypes include viewing ill persons as cognitively impaired or emotionally compromised, owing either to their somatic condition or to their psychological reactions to it; or as existentially unstable, gripped by anxieties such that they 'cannot think straight'; or as psychologically dominated by their illness in a way that warps their capacity to accurately describe and report their experiences (e.g. 'the moaner' or 'the drama queen' stereotype). Because illness often evokes strong feelings in those affected, their emotions are often taken by health professionals to have a detrimental effect on patients' thinking, distorting the accounts they give of their illness. This pattern may be more acute in cases where subjective symptoms are driving the clinical encounter, such as unexplained breathlessness (see www.lifeofbreath.org), chronic pain, or other medically unexplained symptoms.⁵

Of course, the credibility of an individual is context dependent: if someone is talking about a subject on which she is an acknowledged expert then she is much more likely to be believed than if she is talking about something she is known to have little knowledge of.

Epistemic injustice – real-life situations

We are sufficiently aware of the existence of people's unconscious desires and beliefs to know that they can be mistaken about their own desires and beliefs, but it is also the case that they have exclusive access to many of their desires and beliefs. In the interests of epistemic justice, physicians should accept what people with mental disorders say about these matters as true unless there is good reason not to. Moreover, psychiatric patients who have experience of psychiatric services become reluctant to disclose psychotic symptoms because they know it might make them more likely to be diagnosed with a psychotic illness, and in some cases detained in hospital and medicated against their will. If they nonetheless disclose such symptoms, then psychiatrists might conclude that the symptoms are more severe in the sense that the patients are unable to inhibit their expression and/or that their executive function is also impaired.

Here we give three examples of epistemic injustice affecting psychiatric patients (Boxes 1, 2 and 3). Their purpose is to show that epistemic injustice can be a real problem in psychiatry, with possibly devastating effects on the individuals who are telling the truth. The personal details of the patients concerned have been altered to preserve their anonymity.

One of the important factors which can predispose to epistemic injustice is a widespread misunderstanding of the relationship between emotion and cognition, and the positive contribution made by emotional input to a broader conception of rationality.⁶ A consequence, in a medical and psychiatric context, is that the 'soft evidence' offered by patients is often met by credibility deflation. In practice this may lead to patient reports being ignored or discounted, especially when time pressure and other constraints are at play. Conversely, if the 'hard evidence' provided by objective investigation (e.g. blood tests) is regarded as more reliable, then the opinions of health professionals who can access and interpret that evidence may enjoy credibility inflation. In some cases it may be better for the doctor to try to treat on the basis of the symptoms reported by the patient rather than on the basis of an abnormal blood test result or an abnormal scan alone. An example of this is the PSA (prostate-specific antigen) test, which is a notoriously unreliable guide for the treatment of prostate cancer.

Box 1 Example of epistemic injustice in psychiatry 1

When one of the authors (P.C.) was a medical student in Munich, Germany, he saw a young man on an acute psychiatric ward who said he was a relative of the then Soviet leader. The responsible consultant took this to be a grandiose delusion, and therefore as evidence of a psychotic illness; it later turned out to be true.

Box 2 Example of epistemic injustice in psychiatry 2

The second example is of a woman in her early 50s, a former nun. The police contacted mental health services because they had been alerted by someone doing work on her house. They found evidence of smoke damage to the house, but not of fire damage. She was admitted to a psychiatric ward and detained under section 2 of the Mental Health Act. She claimed that she had been burning incense in the house for many years to drive away evil spirits. During the week she had spent on the ward there was no evidence of her trying to ward off evil spirits or attempting to start a fire, or of any psychotic symptoms. The mental health tribunal members concluded that her beliefs about incense and evil spirits were compatible with her religious faith, that there was no evidence of a psychotic illness, as had been claimed by the psychiatrist and one of the psychiatric nurses, and that section 2 should therefore be rescinded.

Box 3 Example of epistemic injustice in psychiatry 3

The third example is of a young man who was admitted to psychiatric hospital on section 2 despite the fact that he had agreed all along to be admitted and remain in hospital as a voluntary patient. He had been standing near the edge of a high cliff for about an hour until passers-by called the police. The staff involved in his care on admission did not believe that he could be trusted to remain in hospital on a voluntary basis and argued in the tribunal for the maintenance of the section. His community psychiatric nurse attended the tribunal, stating that he should never have been placed on a section, because he had had suicidal thoughts for many years, had gone to the same cliff many times in the past, had been admitted to hospital on several occasions as a voluntary patient, and had misgivings about the stigma attached to being placed on a section. All this had been documented in the hospital notes. She conceded that there would always be a risk of self-harm, but that it was a matter of managing the risk without compulsory detention and with the help of his friends and family. After hearing this evidence the tribunal members decided to rescind the section.

A psychiatric example is to do with making a diagnosis of epilepsy. Here a patient may have some epileptiform waves on the electroencephalogram (EEG), but unless there is also clinical evidence of altered consciousness and/or involuntary

movements which fit into a recognised pattern, a diagnosis of epilepsy cannot be made. An EEG can confirm but cannot exclude the diagnosis, which is essentially clinical.⁷

In very general terms, there are two types of contributory conditions for epistemic injustice affecting people with mental disorders: global and specific. Global factors are those that can affect any patient at risk of psychiatric disorder or those diagnosed as having psychiatric disorders. The fear of stigma among those at risk can make early intervention difficult and those who have been diagnosed may avoid service use and relapse more frequently.

Global contributory conditions for epistemic injustice

There are three global contributory conditions for epistemic injustice in psychiatric illness: problems associated with, and partly caused by, the mental disorder the higher value placed by health professionals on ‘hard’ or objective evidence compared with patient reports the entrenched negative stereotypes associated with mental disorders.

1. Problems related to mental disorder

Psychiatric patients are often disadvantaged – cognitively, socially and economically – and these disadvantages are frequently thought to be the patient’s fault. People with mental disorders are often badly educated because the illness has interrupted their education (‘dropouts’); they are often financially impoverished because the effects of the illness may make them unemployable (‘lazy’, ‘dependence culture’); and they are frequently socially isolated (‘loners’). They may become dependent on substances such as nicotine, alcohol and street drugs (‘lack of willpower’) and frequently experience physical illnesses. Causes of physical illnesses include substance misuse, self-neglect secondary to mental disorder and/or substance misuse, and psychotropic medication, such as atypical antipsychotics causing cardiovascular problems (‘down to lifestyle’).

People with mental disorders are thus often seen to have largely brought these disadvantages on themselves and are stigmatised and held responsible for them,¹ even though some conditions contributing to mental disorders, such as genetic factors and a dysfunctional environment, are outside the person’s control. To the extent that such negative stereotypes are shared by their voters, politicians, who often look to save public money, will not be motivated to redress the imbalance in mental health funding: in 2010/2011 mental health services were allocated only 10.8% of the National Health Service (NHS) budget, although mental disorders constituted nearly 22.8% of the disease burden in the NHS.⁹ Simon Wessely, the president of the Royal College of Psychiatrists, notes that despite rising demand, spending on adult mental health by NHS trusts has fallen by 8% since 2010.⁹ A recent parliamentary report advocates ‘whole person’ care, which includes mental and physical health, and highlights some of the barriers to parity of esteem for mental health.¹⁰

2. Hard v. soft evidence

Health professionals are trained to place higher value on ‘hard’ or objective evidence, namely the results of investigations, than on ‘soft’ or subjective evidence provided by patients. In fact, some such objective evidence (e.g. from X-rays or magnetic resonance imaging (MRI) scans) is heavily dependent on interpretation, for instance by a radiologist. This gives health professionals epistemic power, because only they have access to this evidence and have the training to interpret it. Montgomery¹¹ has argued that medicine is not itself a science but rather an interpretive practice that relies on clinical reasoning. A physician looks at the patient’s history along with the presenting physical signs and symptoms and juxtaposes these with clinical experience and empirical studies to construct a tentative account of the illness with what Montgomery calls ‘clinical judgment’. In psychiatry, there is virtually no hard evidence and diagnoses have to be made mainly on the basis of what patients say and how they behave. However, some psychiatrists regard their patients as objects of their epistemic enquiry rather than participants in an epistemic search for the correct diagnosis and best treatment. Anthropologist Tanya Luhrmann¹² argues that insurance companies exercise a more powerful influence over the content of healthcare than do doctors, in that they promote a biological approach to psychiatry because it yields explicit therapeutic rationales, targeted treatments and quantifiable outcomes that can be audited more easily.

Despite the lack of objective evidence in psychiatry, many psychiatrists are influenced by their general medical training and import this bias into the field. Although many acknowledge the biopsychosocial model of mental disorders, they often retain their biological orientation.¹³ Biological psychiatry has been dominant since the 1950s, when the first antipsychotic drugs were introduced, and there is little evidence that this is changing in any significant way. This is partly because the biological approach has practical benefits (e.g. psychiatrists can save time by focusing on drug treatments). Based on his experience working as a liaison psychiatrist in a large medical hospital, one of the authors (P.C.) believes that psychiatry itself is stigmatised within medicine and that some psychiatrists feel that they will be more respected by their medical colleagues if they approach mental disorders from a biological perspective. P.C. also senses that some patients might prefer this attitude, feeling exonerated if they are told that their mental disorder is caused by a 'chemical imbalance in the brain' which can be ameliorated by a drug.

3. Negative stereotypes

People with mental disorders are socially stigmatised and are frequently described with derogatory terms such as 'mad', 'crazy' or 'weird'. The term 'stigma' comes from the ancient Greek word denoting the mark made on slaves by a pointed instrument. Stigma involves negative associations that attach to a social group. Sociologist Erving Goffman¹⁴ argued that stigmatised people are considered abnormal by society and are not fully socially accepted. As a consequence, they constantly try to adjust their social identities. These additional cognitive and social burdens increase the pressures on stigmatised people, exacerbating their already difficult social and cognitive situation. Thornicroft¹⁵ points out that patients often describe the stigma they encounter as worse than the mental disorder itself. Stigma affects every aspect of their lives, including employment, accommodation, financial resources and sense of citizenship. It is a major problem throughout the world.

One of the negative stereotypes associated with mental illness is that people with a mental illness are responsible for their condition. For example, people diagnosed with depression are often told to 'get a grip' or to 'pull themselves together'. Illness, not only mental illness, is often seen as a mark of moral, social and epistemic failure (e.g. drug/alcohol dependence is sometimes seen as weakness of will). Such failures are shaped by group-specific values and commitments – for instance, certain religious groups regard depression as a punishment by God for their sins.¹⁶

However, in a legal setting, the poor insight of patients into their mental state may be recognised by the court as a factor which reduces the patient's responsibility for their actions. Although this diminishes their epistemic status, it also protects them, so recognition of their diminished responsibility may lead to them being treated in hospital rather than imprisoned.

Thus, those who are influenced by negative stereotypes about psychiatric patients may feel justified in cutting funding for mental health services because they think that many psychiatric patients are to blame for their mental health and other problems. In the case of depression, many people who have no personal experience of the illness tend to think that depressed people only need to think more positively for their depression to disappear.^{17,18} The fact that psychiatric services are more poorly funded than other services in the NHS suggests that negative stereotypes about mental disorders may have a role in funding distribution. These negative stereotypes are also influential in the broader context of widespread ignorance about the true nature of mental disorders and their treatment.

Types of stigma and their effects

General stigma

General stigma has negative effects on the prevention, early intervention and treatment of mental disorders. The formulation of a diagnosis has the advantage of making resources available for treatment, as well as providing the best available treatment. Moreover, there is evidence that early treatment improves the prognosis (e.g. in schizophrenia).⁷ On the other hand, having a diagnosis also leads to stigma and discrimination, which can act as a barrier to recovery, for instance making it more difficult to find employment and accommodation.¹⁵

Self-stigma

People with mental illness often accept and internalise negative stereotypes, and this in turn leads to low self-esteem, shame, demoralisation, confidence loss and giving up goals.

Structural stigma and discrimination

Patients typically report that they feel their views are not sufficiently elicited or considered by those who plan and organise psychiatric services.¹⁹ We have already seen that psychiatric provision for approaches other than the biopsychosocial model is severely under-resourced.

Specific contributory conditions

So far we have discussed global contributory conditions for epistemic injustice. In addition to these global conditions, there are specific problems which can lead to further kinds of epistemic injustice as a consequence of the particular nature of the mental disorder in question. Here are two examples, which illustrate how the symptoms of particular disorders may reduce the credibility of what patients report about their own experiences to an extent that constitutes epistemic injustice.

Dementia

The first example is dementia, an acquired impairment of cognitive function without impairment of consciousness. The central feature of its commonest form, Alzheimer's disease, is memory loss, especially of episodic memory, but there can be a wide range of other cognitive impairments as well. The main negative stereotype associated with dementia is the belief that the impairment of cognitive function is severe and global; that the person has or will rapidly and inevitably become a 'vegetable'. In fact, this is hardly ever the case, except perhaps in the final stage of the illness.²⁰

The personality of the individual and some cognitive functions are often well preserved. Thus, patients with mild to moderate dementia can be much more reliable informants than they are often thought to be. There is a need for careful neuropsychological assessment to establish the severity of the impairment. If a person's memory is badly affected, much can be gained by staying in the present in conversations, thereby minimising the occurrence of behavioural markers of epistemic incapacity that can exacerbate the risk of epistemic injustice.²⁰

Schizophrenia

The second example is schizophrenia. Perhaps the most common stereotype associated with it is that because of their delusional beliefs, people with schizophrenia are unpredictable and violent. This may diminish their status as truth-tellers because it may be concluded from one false (delusional) belief that none of their beliefs are credible. In fact, although violent behaviour can occur in schizophrenia, it is much rarer than is thought. There is a small but significant increase in violence in patients with schizophrenia (in any one year 8% of such patients will commit an act of violence compared with 2% of the general population). There is, however, a much stronger association between violence and substance misuse than with schizophrenia. The proportion of all violent acts committed by those with schizophrenia is 3–4%. This leaves 96–97% of all violent acts committed by people who do not have this disorder. The risk of an individual patient with schizophrenia committing homicide is less than 1 in 3000. Moreover, the rates of suicide are much higher than homicide rates in psychiatric patients as a whole.²¹ Thus, although the risk of violence is much higher in patients with schizophrenia than in the general population, the risk is lower than is suggested in the media.²¹ It also seems likely that other factors apart from the illness itself may play a part, such as the influence of alcohol and illicit substances at the time of the offence, and social factors.

Such negative stereotypes are problematic for several reasons, beyond their empirical inadequacy. They encourage unwarranted attitudes of suspicion and distrust towards people with schizophrenia, which, in turn, can contribute to

their social isolation; this is in itself epistemically impairing. Many of our epistemic practices are intrinsically social, such as testifying (giving information to others) and interpreting (making sense of one's experiences), and it is no coincidence that Fricker focuses her analysis of epistemic injustice on those two practices.¹ Social isolation and epistemic impairment can be mutually reinforcing.

In the case of schizophrenia, this problem takes on a specific form: it is integral to our social and epistemic agency that other people perceive us as a person – an agent – capable of engaging, in a sustained and reasonable way, in testifying, interpreting and other epistemic practices. A self is a locus of epistemic and social agency. Yet stereotypes about schizophrenia abide, typically the widespread but mistaken notion that schizophrenia is chiefly characterised by a personality split, as in the good Dr Jekyll and the evil Mr Hyde. The term 'schizophrenia' was coined by the psychiatrist Eugen Bleuler to capture a split between components of the mind – knowledge, emotion and will. This idea of a split has been abandoned in modern diagnostic criteria.²² However, the stereotype of 'split personality' is, of course, a perfect example of a fragmented epistemic self with whom one cannot effectively engage either socially or epistemically.

The rare cases of homicide by patients with schizophrenia are given intense coverage in the press. Examples include Christopher Clunis, who killed a stranger who happened to be standing on the same platform at Finsbury Park tube station in London in 1992; and Matthew Williams, who had a diagnosis of paranoid schizophrenia and killed a young woman in an act of cannibalism in 2014. This creates the impression that violence on the part of patients with schizophrenia is much more common than in fact it is, a phenomenon described by psychologist Daniel Kahneman as 'what you see is all there is', namely jumping to conclusions from limited evidence: another feature of prejudice that might lead to epistemic injustice.²³ Such jumping to conclusions on limited evidence can lead to prejudice ('people with schizophrenia are violent') and hence to epistemic injustice, if a patient says she does not have violent thoughts and is not believed.

As demonstrated in this section, the specific deficits found in dementia and schizophrenia can increase the susceptibility of such patients to epistemic injustice, in addition to the global factors which apply to all mental disorders.

Possible ways of overcoming epistemic injustice

One effective way to integrate the subjective perspective of patients into medicine and psychiatry may be changes in medical and psychiatric training with a view to emphasising the psychological aspects of patient care. 'Schwartz rounds', which allow health professionals to focus on the existential, ethical and personal aspects of a medical case, are growing in popularity in the UK. We suggest that this approach should not only be taught to medical students but should become part of clinical practice.²⁴ Regular interpersonal dynamic meetings with members of a multidisciplinary team, which create a forum for discussing problematic emotional contacts with patients, can enhance understanding of these aspects of patient care and reinforce their importance.¹³

Medical students should be taught to believe what psychiatric patients tell them, unless there is good reason not to do so. Students are frequently told to put patients first, but the experience of many patients is that they are often treated as cases rather than people, and that what is important to doctors is different to what is important to patients. By listening carefully to what patients tell them, doctors can make a conscious effort to imagine how things seem from the patient's perspective. In this way the relationship can become a genuinely collaborative one, rather than one in which the doctor decides what is in the patient's best interests.²⁵

Fricker¹ notes that hearers, in this case the physicians, need to practise giving more credibility to members of groups they fear they may be giving too low levels of credibility to: in this context, to psychiatric patients. Hearers may become aware of a cognitive dissonance: they may notice that on occasions they fail to live up to their belief that members of these groups are to be taken seriously, and then make a conscious effort to give them a higher level of credibility. The hope is that, with time, this corrective policy will become second nature.

Conclusions

We have suggested that there is even greater risk of epistemic injustice in psychiatry than in general medicine. There is a need for psychiatrists to be trained to listen carefully to what patients are telling them and to engage with them in collaborative decision-making, to allow patients to have a greater epistemic role and to overcome the risk of epistemic injustice. Changes are also required in the social and political arena. Media editors should reduce the stigmatisation of psychiatric patients in media reports, especially if epistemic failure (such as reliance on negative stereotypes) can be a cause of moral failure (such as treating persons with mental disorders in an unfairly hostile or suspicious manner). Similarly, politicians should ensure that there is a fairer distribution of healthcare resources, not merely to mitigate the economic cost of mental ill health.

Prejudices against people with mental disorders are entrenched in our society in what Fricker calls the ‘collective social imagination’.¹ They go unchecked because they operate below the radar of the conscious scrutiny of our own beliefs. Those who are in a position to influence public opinion have a special responsibility to oppose these prejudices. We hope that this editorial will increase awareness of the risks of epistemic injustice in psychiatry and thus contribute to this goal.

We are grateful to two anonymous referees for their helpful comments. Havi Carel is grateful to the Wellcome Trust for awarding her a Senior Investigator Award to support her research (grant number 103340).

1.7.24 Psychiatry and the geriatric syndromes – creating constructive interfaces

date

2017-4

Abstract

Integrating mental and physical healthcare is difficult to achieve because of professional and organisational barriers. Psychiatrists recognise the problems resulting from fragmentation of services and want continuity of care for patients, but commissioning and service structures perpetuate these problems. One way forward may be to follow the syndromic model employed by geriatricians as a means of avoiding over-emphasis on diagnosis above the pragmatics of implementing multi-component, co-ordinated care. Commissioners need to be made aware of the overlap and complementarity of skills possessed by old age psychiatry and geriatric medicine to create joint services for people vulnerable to dementia and delirium. A re-forged alliance between the two specialties will be necessary to turn integrated care for frail, elderly people from rhetoric into reality.

 - *Conclusion*

People with severe mental illnesses such as schizophrenia die younger than expected, losing an average 15 years of their lives to cardiovascular and other diseases. ¹ This has led to calls for a more integrated approach to care, with greater emphasis on physical health. In this article, we examine some current issues in the care of older people with severe mental illnesses such as dementia and delirium. We argue that existing systems compartmentalise care and lack the sophistication to deal with the complexity of these illnesses. We suggest that a more collaborative approach between old age psychiatry and geriatric medicine in both hospital and community settings could yield benefits.

Geriatric medicine occupies a position of unfashionable scepticism about the ‘medical model’ of care and its corollary of single-mode interventions. Under the banner of ‘comprehensive geriatric assessment’ attention is paid to function, mental health, and social and environmental factors as well as (usually multiple) acute and chronic medical diagnoses. Elements of prevention, rehabilitation, palliation and mental health models are used flexibly. Care often includes cessation of medicines, recognition of burdens placed on patients by medical intervention, and the prioritisation of comfort, rather than an expectation that death is delayed. ² Old age psychiatry can learn from geriatric medicine by embracing complexity, comorbidity and the ultimate inevitability of deterioration, signalling a return of old age psychiatry to its origins. ³

What is a geriatric syndrome?

Geriatric syndromes are states of ill health which occur with high frequency in older people but which do not fit into discrete disease categories. They are typically explained by a range of organ dysfunctions and diseases, have functional and social implications, and therefore require care that is complex and traverses traditional disciplinary boundaries. Delirium, falls, immobility and urinary incontinence have been described as geriatric syndromes, but the term is loose and may also include pressure sores and sarcopenia. Dementia and other mental health problems can be thought of in similar terms. ⁴

Dementia as a geriatric syndrome

Dementia is common towards the end of life; 6% of people who die aged 65–69 years and 58% of those who die aged 95 or over have dementia. ⁵ The aetiology of late-onset dementia is often multifactorial. ⁶ Dementia causes functional decline, and contributes to falls and incontinence. Multi-morbidity is usual ⁷ and the symptom burden in the last year of life of people with dementia exceeds that of people dying with cancer. ⁸ Dementia causes problems with safety awareness and loss of independence, and is a source of much carer strain. Crises are frequent, and usually have physical, mental, social or care-system contributors. People with dementia frequently transit between home, hospital and care home. These ‘unique and changing personal, psychosocial and physical needs’ are acknowledged in the Memory Services National Accreditation Programme, ⁹ but secondary care memory clinics are unlikely to be the only way to address them. ^{10,11}

A more comprehensive and accessible form of engagement is needed, in the form of primary care liaison psychiatry or

rapid response community mental health teams (CMHTs). CMHTs for older people led the way in delivering dementia care within communities (long before community geriatrics was a tangible entity).¹² These teams are under threat, with proposed merger into 'ageless' community teams. This would require increasing focus on psychopathology and behaviour, with a likely prioritisation of single (psycho)pathologies. Failure to recognise and appreciate the special needs of patients with dementia and the skills of CMHTs in addressing them risks diminishing patient care.¹³ At the same time, the need to address physical and functional comorbidity suggests that an overt alliance between old age psychiatry and geriatric medicine is needed.

Delirium as a psychiatric syndrome

Delirium and dementia frequently co-occur in older people in the general hospital. Dementia has achieved a high national profile in the UK. By contrast, delirium barely enters public discourse. Two-thirds of elders acutely admitted to hospital with delirium have underlying dementia^{14,15} and half of people with dementia in acute hospitals have delirium.¹⁶ Informant history is vital in identifying the two syndromes, but persistent, subacute and subsyndromal delirium is common and the syndromes can be difficult to distinguish, especially where prior dementia was undiagnosed, leading to the coining of the term 'cognitive spectrum disorders' to cover both.¹⁷ Between 10 and 20% of delirium in older people does not have an identifiable precipitant¹⁸ and the cognitive impact of delirium may persist for months or merge into the onset of a dementia syndrome.¹⁹ Some survivors develop post-traumatic stress disorder. Uncertainties also exist as to the division of clinical responsibility between geriatricians and psychiatrists. Arguably, neither specialty can do it well in isolation.

The development of health services in the UK over the past 20 years has seen psychiatrists focus on patients in the community while geriatricians have increasingly assumed responsibility for the acute medical intake, militating against collaboration. The diagnostic uncertainties and sequelae of delirium imply the need for systematic follow-up, which geriatric medicine is poorly placed to provide. Psychiatry has a role in working with the third sector and primary care to highlight the malign effects of delirium even in the context of successfully treated acute physical illness.

The publication of delirium guidelines from the National Institute of Health and Care Excellence (NICE) has been a major advance in the promotion of delirium management,²⁰ but evidence is weak that any specific intervention or programme of delirium care improves outcomes.²¹ Conversely, there is evidence that multi-component interventions aimed at preventing delirium can reduce its incidence and improve outcomes.^{22,23}

Establishing a role for delirium prevention in hospitals and community settings is a challenge given the low profile of delirium training in medical and nursing schools, poor recognition by clinicians, and competing imperatives for healthcare organisations. Conceptualising delirium as both a safety risk to individual patients and an organisational risk due to increased length of stay and adverse health outcomes provides an incentive for change. Old age psychiatrists, with their emphasis on the importance of assessing mental health alongside physical health, can valuably contribute to both delirium care and education.²⁴

Why is delirium prevention not taken more seriously in community psychiatry?

Prevalence studies of delirium in any setting are fraught with the problem of distinguishing delirium from dementia.²⁵ A Swedish study of very elderly people found that 52% of people with dementia had experienced delirium within the previous month compared with 5% of those without dementia.²⁶ Work in the Netherlands revealed a delirium prevalence of 9% in care homes.²⁷

The evidence for the value of delirium prevention programmes in care homes has yet to be established, but there is evidence that coordinated programmes to reduce the prescribing of culprit medications are effective in preventing delirium.²⁸ A trial of the effectiveness of multi-component delirium education in preventing the disorder in care homes is underway in the UK.²⁹

People with dementia who are living in their own homes and are in receipt of care from CMHTs are also at high risk of delirium. Behavioural and psychological symptoms in dementia (BPSD) are associated with morbid – ities that contribute to delirium, such as falls, nutritional deficits and polypharmacy. Delirium can cause a similar range of symptoms, which may become chronic and constitute BPSD.³⁰ Delirium is triggered by physical illness, injury,

medications or medication withdrawal, and rightly remains the domain of primary care and geriatricians, but unless psychiatry co-owns the delirium agenda, the cross-over of skills from the management of BPSD will fail to shape delirium prevention, assessment and management. The similarities between delirium prevention programmes and those for the non-pharmacological management of BPSD are striking.^{31,32}

Frailty

Frailty is a state of vulnerability to decline in the face of stressors, in the context of precarious multisystem physiology and social adversity.³³ Epidemiological evidence highlights the importance of frailty in elderly populations. It has proven difficult to operationalise, but recognisably overlaps with dementia in cross-sectional studies.³⁴ One view conceptualises it as the effect of cumulative deficits³⁵ and the other as a phenotype characterised by three or more of the following factors: unintentional weight loss, self-reported exhaustion, poor grip strength, slow walking speed and low physical activity.³⁶ However, geriatricians recognise that frailty will often manifest through geriatric syndromes – falls, immobility ('off legs'), delirium ('more confused'), urinary or faecal incontinence (often associated with delirium, dementia and immobility) and susceptibility to drug side-effects (antidepressants making a patient 'very drowsy').³⁷ The maturation of old age psychiatry as a specialty has been facilitated by the advent of specific therapies for Alzheimer's disease, but an emphasis on prescribing for Alzheimer's disease has selected against attendance by frail elders and those with non-Alzheimer pathology (particularly vascular dementia) and cognitive deficits outwith a full-blown dementia syndrome.

Comprehensive geriatric assessment aims to consider the full range of factors contributing towards frailty (*Table 1*). Its implementation is linked to better outcomes.³⁸ It has parallels with biopsychosocial assessment, although this does not have similar evidential weight behind it, and indeed has been criticised by the psychiatric profession as 'mere eclecticism'.³⁹ The accusation of vagueness laid against biopsychosocial assessment suggests that it needs to find a home within an operationally defined, evidence-based structure such as comprehensive geriatric assessment. The two processes differ only in the emphasis and differential expertise of the clinicians undertaking them. Geriatricians recognise that they tend to neglect the mental health dimension, which may be reduced to a brief cognitive assessment or screening test for depression. There is therefore a fertile opportunity for mutual learning between geriatrics and psychiatry in the area of the assessment of frailty.

Components of comprehensive geriatric assessment

Domains	Items to be assessed
Medical	Co-morbid conditions and disease severity
	Medication review
	Nutritional status
	Problem list
Mental health	Cognition
	Mood and anxiety
	Fears
Functional capacity	Basic activities of daily living
	Gait and balance
	Activity/exercise status
	Instrumental activities of daily living
Social circumstances	Informal support available from family or friends
	Social network such as visitors or daytime activities
	Eligibility for being offered care resources
Environment	Home comforts, facilities and safety
	Use or potential use of telehealth technology etc.
	Transport facilities
	Accessibility to local resources

Reproduced from Martin, 2010. ⁴⁰

Sustainable integration

The needs of older people with mental health disorders are not well served by a retreat to psychiatric specialisation, restrictive referral criteria or commissioning models based on activity alone. Geriatric medicine recognises and embraces complexity and uncertainty, and responds by flexibly utilising a variety of models, albeit at times with tensions between them. Old age psychiatry can learn from comprehensive geriatric assessment. Geriatric medicine needs to take mental health more seriously, to increase the depth and sophistication with which it assesses the mental state, and can learn from person-centred care and recovery models. The logical future for both disciplines is in collaboration and integration that transcends organisational and cultural barriers.

A sustainable integration of physical and mental healthcare for older people will require more than cooperation between clinicians. The joining of forces between psychiatrists and geriatricians can take place at an organisational level when mental health and community trusts merge. However, we also need a flexible, accessible, consultative model of psychiatry that seeks to empower a broad range of community practitioners and will be the means to generate influence on problems that are just too common and multi-morbid to be addressed solely by clinic-based approaches or a single professional discipline. This reinforces the need for CMHTs for older people, and highlights the need to change the commissioning model from one based on activity defined by clinic attendances. Crises in care homes, for example, often represent a complex interplay of medical, mental, social and environmental issues best addressed by timely multi-disciplinary input rather than transferring responsibility on to a single discipline. Accessible advice on a broad range of cases managed primarily by other teams ('liaisons') allows for teaching and upskilling while preserving specialty provision for patients with more severe, less tractable mental health problems. These teaching and support roles need a commissioning model.

CMHTs are in a good position to identify dementia and promote delirium prevention measures. Working alongside community geriatrics will strengthen old age psychiatry by allying it with the developing evidence base and increasing its workforce.

The Rapid Assessment Interface and Discharge (RAID) model developed in Birmingham has captured the attention of policy-makers through its widely publicised potential financial savings. But it also demonstrates the total immersion of mental health practitioners in the multi-professional melee that is acute hospital care. ⁴¹ Why not import this style of working into primary care and scale down the centralised psychiatric clinic? This has been tried in Gnosall, Staffordshire, where a model of primary care liaison psychiatry has created a well-received, effective service for people with dementia. ⁴²

Conclusion

Psychiatrists must lobby commissioners to recognise the plight of those frail, elderly patients who are not living well but dying with the multiple comorbidities of dementia within a healthcare system that fails to accommodate complexity. People with dementia are prone to crisis and comorbidity, necessitating attention to physical health (parity of esteem) equal to that developing for other severe mental illness. Emphasising geriatric syndromes (and the importance of sound mental health assessment within comprehensive geriatric assessment) is a good way to defend old age psychiatry while at the same time developing integrated physical and mental healthcare for older people. An invigorated liaison psychiatry, underpinned by a re-forged alliance between old age psychiatry and geriatric medicine, gives a pointer to how integration might work, and enables parity of esteem for mental and physical health.

1.7.25 Police liaison and section 136: comparison of two different approaches

Oliver Jenkins Stephen Dye Franklin Obeng-Asare Nam Nguyen Nicola Wright

Correspondence

Oliver Jenkins

date

2017-4

Abstract

Aims and method Two police liaison and section 136 schemes were developed alongside police services at different sites within the same NHS trust. In one, a mental health nurse worked with frontline police attending incidents related to mental health. The other involved nurses providing advice from the police control room. Section 136 detentions were measured over two 6-month periods (6 months apart) before and after practice change. Data analysed included total numbers of section 136 assessments, outcomes following subsequent assessment, and relevant diagnostic and demographic factors. Association of any change in section 136 total numbers and proportion subsequently admitted was investigated in both sites.

Results The model involving a nurse alongside frontline police showed significant reduction in section 136 numbers (38%, $P < 0.01$) as well as greater admission rates ($P = 0.01$). The scheme involving support within the police control room did not show any change in section 136 detention but showed a non-significant ($P = 0.16$) decrease in subsequent admission.

Section 136 of the Mental Health Act 1983 enables an individual police officer to remove any person found in a place to which the public have access appearing to have a mental disorder and to be in immediate need of care or control to a place of safety, such as a hospital, police station or a purpose-built section 136 unit. The section can only be used if the officer believes it is in the interests of that person or necessary for the protection of others. Although section 136 can be an important care pathway to enable an individual to receive appropriate support, it can also be a very distressing experience for them – some report feeling criminalised and punished for having a mental illness. ¹ Its use is also costly given that it requires the input of an approved mental health professional (AMHP) and two doctors for the assessment, plus police and often nursing time to manage the detained person and staff the place of safety.

Background and aims

The Mental Health Act Commission has highlighted the challenge of collating data on the use of section 136, ² but figures have only been gathered at a national level by the Health and Social Care Information Centre over the past 5 years. ³ These combine police and mental health records on section 136 detentions but have limited detail on outcomes. At a national level the rates of section 136 detentions to places of safety between 2010/2011 and 2014/2015 increased from 14 111 to 19 406. ³ Attempts to combine inconsistently recorded data have shown a steady upward trend at a rate greater than has been seen with use of the other Mental Health Act sections for detention. ⁴

Significant variation is seen regionally in section 136 use. Outcomes from such detentions, often seen as markers of how appropriately the detention has been applied, are also seen to vary from region to region: from areas where around 60% are admitted to hospital ⁵ to those where 68% are discharged. ⁶ While theories to explain these variations have included a rural/urban divide, police culture, socioeconomic deprivation and diagnostic factors, ⁷ the available data have been limited in both accuracy and detail.

In response to concerns about the growing use of this police power and regional variation, there has been a national drive to improve inter-agency working between police and mental health services. Both the Bradley Report ⁸ and the Crisis Care Concordat ⁹ placed emphasis on local agencies working more closely to improve the experience of individuals in a mental health crisis and to intervene as early as possible within the criminal justice system. Areas have responded differently to the challenge. This paper analyses various aspects of section 136 and changes observed with

different ways of inter-agency working within two areas of the same National Health Service (NHS) trust, in Ipswich and Norwich.

The local response in Ipswich has been a Commissioning for Quality and Innovation (CQUIN)-funded pilot scheme developed in partnership between Norfolk and Suffolk NHS Foundation Trust (NSFT) and Suffolk Constabulary. The scheme commenced in April 2014 and involves two experienced mental health nurses working on alternate shifts alongside frontline police officers, 7 days a week from 14:00 until 00:00, to help assess and appropriately divert members of the public who present with potential mental health-related emergencies. Accompanied by a police officer (individuals vary with police rota), they are seen as the initial point of contact for officers attending a potential mental health-related event. They are able to perform face-to-face assessments in a dedicated police car but can also provide advice to other officers over the phone.

Norwich was chosen as the control site as it was closely matched by size, ethnicity and measures of deprivation (*Table 1*). Norwich also established a police liaison service (funded by the police service) to address the same national concerns. It employed 4 mental health nurses on rotation providing support to the local police force between 8:00 and 22:00, 7 days a week. However, they were based in the police control room and offered telephone advice to police officers without face-to-face contact with the public.

2011 census data. ¹⁰

Ipswich, Suffolk Coastal, Babergh and Mid-Suffolk local authorities.

Norwich, North Norfolk, South Norfolk and Broadland local authorities.

Lower value indicates higher deprivation.

The aims of this study were to examine changes in and between Ipswich and Norwich regarding section 136 detentions and hospital admission rates of detained individuals. This would enable us to build on past research and consider what factors were driving the use of section 136 locally, and in turn better understand any impact the police liaison projects may have had.

Method

This retrospective study compared numbers and outcomes of section 136 assessments, characteristics of detained individuals and some follow-up data. Information was obtained prior to and following differing changed practices within the trusts for the two areas. Numbers of section 136 detentions were gained from local section 136 suite records and cross-referenced with data gathered at trust level in an attempt to capture all section 136 assessments in Ipswich and Norwich. Further data pertaining to each individual were then collected retrospectively from hospital records using electronic notes (Eplex in Ipswich and Carenotes in Norwich). Data were gathered for two 6-month periods: 1 June – 30 November 2013 and 1 June – 30 November 2014. This was to limit any impact on results of the preparation for and introduction of services. This also allowed for comparison of the same 6-month cycle (a year apart) pre- and post-intervention in both areas and between areas.

The project was viewed as service evaluation by the trust's research and development department and thus did not require ethics approval. The exact information gathered and hypotheses to be tested were agreed at the planning stage. Data were entered into Minitab (version 16) to allow for appropriate statistical analysis. The exact data collection questions can be found in *Box 1*.

Such a study set-up meant that each location had a control group prior to intervention and an experimental group post-intervention. Analysis was conducted pre- v. post-intervention in both locations and between the locations. Null hypotheses were that there were no differences between locations or between pre- and post-intervention. Population sizes covered by each section 136 suite were established by combining police force estimates of the locality from which officers were detaining people and the 2011 census local authority population sizes.¹⁰ Chi-squared statistical tests were used where appropriate. We used *t*-tests when comparing section 136 numbers per 100 000 population, Fisher's exact test for comparing proportions, and the Mantel–Haenszel procedure to identify possible confounding factors.

Results

Demographics

As seen in *Table 2*, there were no significant differences in the study participants' age or gender pre-intervention compared with post-intervention in either area individually or between the areas. There were no significant differences in ethnicity either, with the overwhelming majority of individuals assessed being of White British background.

Results of section 136 assessments in two study areas *a*

Numbers of section 136 assessments

There was strong evidence to suggest, over the total time periods, that Norwich had proportionately fewer section 136 assessments per 100 000 population than Ipswich ($P = 0.01$). This difference was greater in the pre-intervention period. Between the two 6-month periods there was a small, non-significant increase in those detained under section 136 in Norwich but a large reduction in section 136 assessments in Ipswich post-intervention ($P = 0.01$) (Table 2 and Fig. 1).

Fig. 9: Section 136 assessments and subsequent admissions.

Box 1 Survey questions

1. Pre- or post-intervention?
2. Ipswich or Norwich?
3. Date of assessment?
4. Time of assessment?
5. Gender?
6. Age?
7. Ethnicity?
8. Broad ICD-10 category?
9. Number of section 136 assessments the individual had in the previous 6 months?
10. Any contact with mental health services in past 2 weeks?
11. If so, what type of contact?
12. Main reason for section 136?
13. Any specified location?
14. Was the individual admitted?
15. If so, was this under detention?
16. If admitted, what was the length of admission?
17. If not admitted, was follow-up offered by secondary mental health services?
18. If so, was the first appointment complied with?
19. If not admitted, was the individual subject to a further section 136 assessment within the subsequent 4 weeks?

Admission

Over all the data collected, there was no significant difference in admission to hospital following section 136 assessment between Ipswich and Norwich. Prior to intervention, although admission was less likely in Ipswich than in Norwich, this was non-significant. In Ipswich there was a significant change in admission post-intervention ($P = 0.01$), with a higher conversion to admission. Post-intervention, there was a difference between Ipswich and Norwich ($P = 0.04$), with higher admission in the former. Thus the interventions were associated with a proportionate increase in admissions following section 136 in Ipswich. Although data suggested that the admission proportion decreased in Norwich, this was non-significant ($P = 0.16$).

Apart from weak, non-significant evidence to suggest that in Norwich those admitted post-intervention were more likely to have been detained than pre-admission ($P = 0.10$), there was no other association between detention under the Mental Health Act following admission and pre- and post-intervention status.

Contact with community mental health services

Any contact with community mental health services (CMHS) in the 2 weeks prior to section 136 assessment was measured. In Norwich, data provided strong evidence that in the pre-intervention period there were more individuals who had some contact with CMHS than in the post-intervention period ($P = 0.01$) and when compared with Ipswich ($P = 0.01$). In Ipswich there was no evidence of any difference between contact pre- v. post-intervention.

For those individuals who were not admitted to hospital following section 136 assessment, the proportion that had at least one subsequent 136 assessment in the following 4 weeks decreased in both sites, but the change was significant only in Norwich ($P < 0.01$ v. $P = 0.14$ in Ipswich).

In Ipswich there was moderate evidence to suggest that, if not admitted, people were more likely to be offered follow-up from secondary mental health services post-intervention than pre-intervention ($P = 0.04$). If follow-up was offered in Ipswich, there was strong evidence to suggest that the first follow-up contact was more likely to be kept post-intervention than pre-intervention ($P < 0.01$). In Norwich there was evidence that a person was more likely to be offered follow-up prior to as opposed to after the intervention ($P = 0.02$), but no evidence to suggest any difference between compliance rates pre- v. post-intervention.

Diagnosis

There was weak non-significant evidence to suggest that people assessed in Ipswich were more likely to have been deemed to have 'no mental illness' prior to the intervention compared with post-intervention ($P = 0.08$), but in Norwich there was strong evidence to the contrary ($P < 0.01$).

Counts of pre- and post-intervention broad ICD-10 categories of individuals assessed from each site are shown in *Fig. 2*.

Time of day

We were unable to obtain the exact time of implementation of the actual section 136 order for individuals. Time between implementation and assessment following the order is influenced by many factors. Trust policy states that this should happen within 3 hours.

In Ipswich the triage service was funded for 10 hours per day (between 14:00 and 00:00). As an estimate within this study, following implementation of the order, individuals who were assessed between 15:00 and 03:00 were deemed to have been assessed in a time period in which the triage service was operating. Within these time periods, the numbers assessed and numbers admitted are shown in *Table 2* (numbers admitted following assessment out of these time periods are also shown). Thus, a similar proportion were assessed within the triage hours both pre- and post-intervention (72.2% and 69.2%).

As stated above, admission following section 136 in Ipswich was more likely after the triage service commenced. On further analysis this effect was seen to be confounded by assessment within/outside triage times (Mantel-Haenszel odds ratio 5.44, $P = 0.02$) with a significant association in the triage times ($P = 0.05$). This indicated that the triage service intervention had most association with differing admission rates within the triage times.

Unfortunately, due to a large number of missing assessment time data in Norwich, a similar analysis was not deemed feasible.

Discussion

This retrospective study evaluated the impact of two recently developed police liaison schemes based in closely matched semi-rural areas within a single mental health NHS trust, with a focus on section 136 rates and outcomes before and after the projects were established.

The pre-intervention findings show that Suffolk Constabulary was detaining significantly higher numbers of people for assessment in the Ipswich area than the police force in Norwich. This difference matches the only data available prior to 2013/2014 on section 136 rates for the two regions, from 2005/2006, in which the Independent Police Complaints Commission (IPCC) analysed regional variation across England and found Suffolk to be a medium-rate user and Norfolk a low-rate user of section 136 detentions to police custody.¹¹

Well-matched local population demographics and demographic profiles of those detained would indicate that differences are not linked with variation in race, gender or age. The diagnostic profiles of those detained also show little variation between sites. These observations are significant given that a number of studies have identified common factors pertaining to those detained under section 136, such as Black men being over-represented, and the typical individual tending to be a young male, unemployed, with a psychiatric history and diagnosis of schizophrenia.¹²

As police officers are the sole implementers of S136 detentions, their attitudes and training around mental health can be considered an important variable. Qualitative studies have identified high rates of concern among police officers over inadequate training in relation to mental illness,¹³ and poor understanding of their role in relation to section 136.¹⁴ Informal feedback from the two police forces involved in this study indicates that mental health training is similar and thus would be an unlikely source of variation.

The IPCC report also observed that low-rate forces used alternative powers such as breach of the peace and that well-known 'suicide spots' such as seaside cliffs were observed in police force areas with high rates.¹¹ Data we have gathered on both police forces show a similar arrest rate (15 v. 16 per 1000 population) but a slightly higher crime rate (49.76 v. 43.98 per 1000 population) in Suffolk compared with Norfolk.¹⁵ However, there are also lower levels of policing per 1000 of population in Suffolk (3.11 v. 3.33).¹⁵ The impact of these slight differences is hard to interpret. Ipswich has a locally well-known 'suicide spot' but numbers of detentions relating to its locality were not significant.

Findings from the post-intervention data support the theory that a mental health liaison service to the police can have a significant impact on section 136 rates and also suggest which model is more effective. The Ipswich site showed a 38% reduction in the use of the police power during the post-intervention study period. In that time, there were no other significant changes to police or mental health policy or resourcing locally. This reduction is in contrast to the steady increase in the use of section 136 nationally.¹⁶ The Norwich site with support based solely in the police control room, by contrast, showed no significant change in overall numbers of section 136 detentions. The data provide some possible explanations for this observed difference between the sites.

It could be speculated that the impact of a liaison service with experienced mental health nurses in Ipswich, where rates were higher 10 years ago¹¹ and pre-intervention rates were high in this study, was to enable the local constabulary to achieve a greater level of confidence in dealing with mental health-related crises that is already present in Norwich. The detention outcome data in Ipswich may be seen to lend weight to this idea. Post-intervention we observed a proportionate increase in admission rates, an increase in offer of community support if discharged and a reduction in those deemed to have 'no mental illness'. These outcome measures can be interpreted as markers of a service better able to identify those with mental health needs and, combined with an increase in engagement, suggest it is better at signposting to appropriate services.

By contrast, the Norwich data post-intervention show a proportionate decrease in admission rates, decrease in follow-up being offered and increase in 'no mental illness' assessments despite overall numbers remaining approximately the same. It could be inferred that support based in the police control room is only effective for individuals known to mental health services, whereas members of the public unknown to services need to be assessed face-to-face to provide effective input from a specialist service. Our recording of those who had contact with mental health services in the 2 weeks prior to detention showed that for both areas approximately 50% were either known to or actively open to mental health services, which is lower than estimates from previous research of around 75–84%.¹² The near equal percentage of those in contact with mental health services prior to detention in Ipswich could further suggest that the face-to-face liaison service is able to affect detention rates for both those known to mental health services and those not known.

The data relating to time of assessments in Ipswich suggested that while the liaison service had a greater impact on conversion to admission rates during their working hours, there was a near-even drop in section 136 rates across all hours. This could indicate that multi-agency working has promoted an ability among the local police force to better identify those who should be detained for further assessment. Lending further weight to this perception is the fact that the service in Ipswich was only in operation 76% of the time due to planned leave and sickness.

A follow-up to the Bradley Report claims that similar schemes are producing positive results, including reduced section 136 rates.¹⁷ We believe that our study provides an evidence base for these as yet unpublished findings, and lends weight to the value and impact of closer inter-agency working between police and mental health services. The breadth of data and comparison of models available in this study may help to guide the development of future schemes and their refinement.

Limitations

Within this study we gathered data regarding individuals detained to places of safety under section 136 within the two main urban areas in Norfolk and Suffolk, namely Norwich and Ipswich. There will have been a few occasions where these sites were occupied and people were subsequently taken to other localities. Although we can say that both areas are equally resourced and from experience know these numbers to be small, this should be acknowledged as a weakness. Estimations of section 136 rates per population size in each area must be viewed with caution as the local authority boundaries do not equate to areas that the 136 suites serve, and it was difficult to achieve clarity on this. The study could not define the areas where the section 136 detention was made and this may have been outside the area covered by the triage services, which may have led to an underestimate of the impact of either service.

While this study builds towards a better understanding of the model that is most effective in police liaison work, it lacked a detailed analysis of the work done directly by the mental health nurses and police officers involved. Any future studies should include these data alongside qualitative feedback from relevant professionals and individuals to enable a fuller understanding of the impact of such a service.

1.7.26 Online media reporting of suicides: analysis of adherence to existing guidelines

reports of suicide from UK sources over the course of 1 month. Each article was assessed against guidelines for the responsible reporting of suicide produced by the Samaritans, a UK mental health charity.

Results We identified 229 articles, of which 199 failed to comply with at least one of the Samaritans' guidelines. Failure to mention support sources, excessive detail about the method used and undue speculation about the trigger for suicide were the most commonly breached guidelines. Significant differences were found between the quality of local and national media sources, with local media sources being broadly more compliant with guidelines.

Clinical implications This study highlights the urgent need for the implementation of responsible reporting guidelines in online media articles as a component of suicide prevention efforts.

Responsible media reporting of suicide is considered to be key to current international suicide prevention efforts.¹ Previous studies suggest that media reports of completed suicide can influence the rate of future suicidal acts and the method chosen.²⁻⁶

Guidelines to promote responsible reporting practices exist in a number of countries.⁷ Studies suggest that they can alter the content of media reports,⁸ although the general awareness and use of the guidelines has been found to be poor.⁹ In the UK, the 2012 Editors' Code of Practice from the Press Complaints Commission prohibits the reporting of suicide with excessive detail about the method used,¹⁰ but established responsible reporting guidelines tend to include additional features in an attempt to prevent copycat behaviour.¹¹

After a detailed literature review, no studies could be found comparing a significant number of contemporary UK media reports of suicide against responsible reporting guidelines, despite the fact that the media have been implicated in the phenomenon of 'suicide clustering' observed in the UK.¹² Other studies have focused on newspaper and television reports, and scant attention has been paid to online media sources, despite the fact that 84% of households in the UK have access to the internet and 55% of adults use the internet to access news.¹³ This is the most rapidly growing method of accessing news media, particularly for younger individuals,¹³ who may be more vulnerable to the content of media reporting.^{14,15}

This study sought to evaluate the compliance of online media reports of suicidal acts from UK-based sources with responsible reporting guidelines, and to identify the prevalence of the inclusion of other potentially harmful features of online media, namely comments sections and links to other internet features, for example pro-suicide websites.

Method

A search was performed on the Google News UK search engine using the keyword ‘suicide’ with the location filter set to include articles of UK provenance only. The analysis included reports which made reference to an attempted or completed suicide published by local and national media sources during 28 consecutive days in November 2014. Articles about suicide bombing and euthanasia were excluded, as were those behind a media paywall.

Each report meeting the inclusion criteria was assessed against an adapted version of the ‘Ten things to remember when reporting suicide’ contained in the document issued by the Samaritans.¹⁶ This is one of the more prominent and widely used sets of guidelines for journalists in the UK.¹⁷ As a direct search for articles was undertaken, it was not possible to assess whether each article was given undue prominence, for instance a homepage splash, so this criterion from the Samaritans’ guidelines was not used, leaving nine criteria for article comparison (*Box 1*).

Data were collected on compliance with each section of the guidelines and those meeting all criteria were considered to be compliant with responsible reporting of suicide. Analysis was undertaken to determine the overall compliance with guidelines, the frequency with which each guideline was breached, and whether there were any differences based on whether articles originated from a local or a national media source. Differences between local and national media sources in the proportion of articles breaching any guidelines were calculated using the chi-squared test. Data analysis was performed in STATA 11 for Windows XP.

Box 1 Guidelines for the reporting of suicide assessed in the study. Adapted from the Samaritans¹⁶

1. Leave out technical details about the method of suicide, such as describing the type of ligature used or the number and types of pills taken in an overdose. Never suggest that a method is quick, easy, painless or certain to result in death.
2. Language matters. Avoid dramatic headlines and terms such as ‘suicide epidemic’ or ‘hot spot’.
3. Include references to support groups and places where suicidal people can find help.
4. Treat social media with particular caution and refrain from mentioning websites or networks that promote or glamorise suicide.
5. Avoid dramatic or sensationalist pictures or video. Refrain from including content from suicide notes.
6. Do not give undue prominence to photographs of a young person who has died and avoid repeated use of images such as galleries.
7. Do not brush over the complex realities of suicide and its impact on those left behind.
8. Speculation about the ‘trigger’ for a suicide, even if provided by a close family member, should be avoided.
9. Use statistics with caution. Make sure you have the most recent data and are comparing like with like.

In addition to comparison against the Samaritans’ guidelines, the inclusion of user-generated comments, threads and internet links to other articles was noted.

Results

Overall, 229 articles met the inclusion criteria: 68 articles from local media sources and 161 articles from national media sources. The majority (214 articles) came from media organisations which offer both a print and online platform, with national publications such as the *Guardian*, the *Telegraph* and the *Daily Mail* making up the bulk of national media output, and an array of smaller local outlets each contributing a smaller number of articles to the total. Fifteen articles were found in a range of online-only outlets such as the International Business Times, Yahoo UK, The Huffington Post and Wales Online. Ten articles were found on the websites of media network providers such as the BBC, ITV and STV.

Compliance with the responsible reporting guidelines

Of the 229 online articles included for analysis, 199 (86.9%) breached at least one of the Samaritans' guidelines. The mean number of guideline breaches per article was 2.2, with only a small variation between local and national media sources (2.1 v. 2.2 breaches per article, respectively; $P = 0.08$).

The most commonly breached aspects of the guidelines were a failure to include reference to sources of support for those considering suicide (69.4%), the inclusion of excessive technical detail about the method used (31%) and undue speculation about the reasons for suicide (30.1%) (*Table 1*). The other guidelines were breached in less than 25% of articles, with just 2 articles mentioning organisations that promote suicide and 1 article using statistics irresponsibly, telling readers the proportion of people completing suicide after jumping from a well-known landmark.

Compliance with reporting guidelines

	All sources	Local	National	Difference between local and national <i>P</i>
Articles, <i>n</i>	229	68	161	–
1 breach, <i>n</i> (%)	199 (86.9)	55 (80.9)	144 (89.4)	0.08
Breaches per article, mean	2.2	2.1	2.2	–
Specific guideline breaches, <i>n</i> (%)				
1. Excessive technical detail about the method	71 (31.0)	25 (36.8)	46 (28.6)	0.22
2. Sensationalist or irresponsible language	38 (16.6)	20 (14.7)	28 (17.4)	0.04* <#TFN1>`_
3. No sources of support	159 (69.4)	48 (70.6)	111 (68.9)	0.81
4. Mentioning places that promote or glamorise suicide	2 (0.9)	0 (0)	2 (1.2)	0.36
5. Dramatic pictures, videos, content of suicide notes	41 (17.9)	6 (8.8)	35 (21.7)	0.02* <#TFN1>`_
6. Picture galleries	30 (13.1)	1 (1.5)	30 (18.6)	0.001** <#TFN2>`_
7. Narrative brushes over the complex realities of suicide	20 (8.7)	5 (7.4)	15 (9.3)	0.63
8. Undue speculation about the triggers	69 (30.1)	18 (26.4)	51 (31.7)	0.43
9. Irresponsible use of statistics	1 (0.4)	0 (0)	1 (0.6)	0.52

P < 0.05,

$P < 0.01$.

Additional features of online media

Sixty-four articles included additional features which could contribute to readers encountering unsuitable material, such as the inclusion of user-generated comments sections and links to other articles which may similarly be poorly adherent to reporting guidelines (Table 2).

Articles with additional adverse features

	All sources <i>n</i> (%)	Local <i>n</i> (%)	National <i>n</i> (%)	<i>P</i>
Articles with additional adverse features	64 (27.9)	11 (16.2)	53 (32.9)	*0.01
Links to other articles about suicide	37 (16.2)	5 (7.4)	32 (19.9)	*0.02
User-generated comment threads	39 (17)	7 (10.3)	32 (19.9)	0.08

$P < 0.05$.

Discussion

This study evaluated the compliance of 229 online reports of suicide with the guidelines issued by the Samaritans. To our knowledge, this is the first study looking at the content of online media reports of suicide and the first in the UK looking at a selection of contemporary media output. Of note, the majority of articles included in the study failed to meet the Samaritans' guidelines for the responsible reporting of suicide. The results support findings from the limited number of studies undertaken elsewhere in the world that suggest media reporting of suicide is poorly compliant with available guidelines.^{18–21}

Of particular concern is the finding that 69.4% of reports failed to include a reference to a potential source of support for those readers who may be experiencing suicidal thoughts themselves; this was consistent across local and national sources. Lack of responsible information awareness and signposting support undermines suicide prevention efforts and fails to provide an alternative perspective to the often distressing narrative of articles. The finding that most articles omit references to support groups has been replicated in other studies from around the world: just 1% of Indian newspaper sources,¹⁹ 3% of US sources²¹ and 8.6% of Chinese sources⁸ included a reference to a support group.

Our finding that 31% of articles contained an excessive level of detail about methods used to complete a suicide is a significant cause for concern. The experience in other countries supports the idea that publication of suicide methods can perpetuate attempts and trends in methods chosen by others in 'copycat suicides'.^{2–5,22} In the course of assessing media reports for this study, the inclusion of details about the blood concentration of cyanide to achieve death, and the exact location and time of suicides by train, as well as details of places where suicides by jumping were completed, were all noted.

The finding that 30.1% of articles engaged in speculation about the reason for suicide was also a cause for concern. The journalistic tendency to simplify the reasons behind a suicidal act or engage in undue speculation about the surrounding circumstances can have a damaging impact on the bereaved family¹⁷ as well as readers who may over-identify with the person mentioned in the article, potentially increasing the deleterious impact for vulnerable individuals. This tendency to make articles more 'readable' may also be reflected in the fact that 8.7% of articles brushed over the complex realities of suicide, often failing to mention the family left behind or the impact of the suicidal act on others.

That being said, only one report included the irresponsible use of statistics and only two reports directed readers towards pro-suicide websites.

A qualitative observation was that where a particular fact about a suicide attempt is known, it will usually feature in other articles from other outlets about the same act. For example, very specific details about a method used were usually re-reported in all articles discussing the same event without due regard for the reporting guidelines.

Local v. national media sources

When comparing reporting by national and local media sources, local sources were overall more compliant with guidelines, with significant differences in the use of sensationalist language, dramatic pictures, videos or the content of suicide notes and the use of galleries, as well as the use of additional features of online media. The exact reason for the broadly better compliance with guidelines among local sources is not fully understood, but it may be because local media sources are closer to the subject of the article and local reporters may be more sensitive to the feelings of the bereaved family and local community.

Additional features of online media

The unique additional features of online media (compared, for example, with newspaper articles or television reports) could also compound their negative impact on readers; 16% of articles included links to other reports of suicide. Our finding that a majority of articles about suicide fail to meet responsible reporting guidelines and that the mean number of guideline breaches is 2.2 per article raises the possibility that the negative impact of irresponsible reporting is likely to be amplified by the inclusion of links to other potentially non-compliant reports.

Previous findings that discussion forums can increase suicidality among younger users²³ suggest that the addition of comments sections which can facilitate discussion should be avoided with online reports of suicide. Despite this, 17% of analysed reports had a comments section for user-generated content, and concerning comments such as the deceased person being 'brave' or 'at peace now' were frequently a feature of these.

Policy considerations

There is an evident need to evaluate the reasons for journalistic non-compliance with the existing guidelines of suicide reporting in the UK. Given the increasing use of online media and the apparent poor quality of reporting, there is a need to focus efforts on increasing the compliance of reports with responsible reporting guidelines. Suitable measures should also be established for non-compliant and potentially harmful articles to be flagged for urgent review.

Limitations

Although a standardised tool was used to identify breaches of media guidelines, judgements about breaches were not cross-checked between researchers. In addition, although the search sought to capture publications over a period of time, this work cannot account for potential seasonal changes in data.

Next steps

The present study uncovers an urgent need to address the fact that the majority of online articles assessed do not comply with existing guidelines on the responsible reporting of suicide. It highlights a significant public health concern because potentially vulnerable people have access to material which may provoke suicidal behaviours and which does not signpost them to support resources. Given the increasing weight of evidence that media reporting can affect suicide rates, there is an urgent need for the implementation of responsible reporting guidelines in online media articles. We propose that work be done to clarify and publicise the guidelines, and to train and encourage journalists to use them, and that a strong consideration be given to the role of more formal regulation and monitoring.

1.7.27 Caregiver burden and distress following the patient's discharge from psychiatric hospital

Abstract

Aims and method Caring for someone with a mental illness is increasingly occurring within the community. As a result, family members who fulfil a caregiving role may experience substantial levels of burden and psychological distress. This study investigates the level of burden and psychological distress reported by caregivers after the patient's admission.

Results This study found that the overall level of burden and psychological distress experienced by caregivers did not differ according to the patient's legal status. However, the caregivers of those who were voluntarily admitted supervised the person to a significantly greater extent than the caregivers of those who were involuntarily admitted. Approximately 15% of caregivers revealed high levels of psychological distress.

Clinical implications This study may emphasise a need for mental health professionals to examine the circumstances of caregivers, particularly of those caring for patients who are voluntarily admitted, a year after the patient's admission.

One in four families worldwide is affected by mental illness.¹ With the onset of illness, a family member may assume a caregiver role for their unwell relative, which may result in positive and negative experiences for the caregiver.² While caregivers convey a sense of satisfaction and well-being from their caregiving relationship, they also report feeling burdened.³ Such burden may be characterised by both objective difficulties, such as being unable to leave the family home and work, and subjective difficulties, such as psychological distress.⁴

Should a patient become severely unwell, it is often the caregiver who intervenes to initiate emergency psychiatric treatment.⁵ Caregivers can experience significant obstacles in gaining the assistance of a mental healthcare team for their relative⁶ and involuntary admission in particular can be associated with high levels of caregiver burden.⁷ This is important, as the level of burden experienced by caregivers can significantly predict treatment adherence and outcome in the patient.⁸ Furthermore, caregivers who experience high levels of burden reveal an increased incidence of physical and mental health problems and health-related risk behaviours.⁸ However, less is known about the level of burden or psychological distress that caregivers experience in the period following admission. Additionally, the limited research to date has focused on caregivers of involuntarily admitted patients and there is very little known about the caregivers of those admitted voluntarily.

For this reason, we aim to determine the level of burden and psychological distress reported by caregivers approximately 18 months after the patient's admission to an acute mental health unit. We also aim to determine whether clinical (specifically legal status) and demographic factors were associated with the level of burden and psychological distress reported by caregivers.

Method

Participants

Participants consisted of caregivers of either involuntarily or voluntarily admitted patients. Caregivers were recruited from two concurrent studies: the Service Users' Perspectives of their Admission (SUPA) study⁹ and the Prospective Evaluation of the Operation and Effects of the Mental Health Act 2001 from the Viewpoints of Service Users and Health Professionals study. The former was conducted in south-east Dublin and North Wicklow and involved both involuntarily and voluntarily admitted patients. The latter was conducted in Galway and Roscommon and included involuntarily admitted individuals and individuals who were brought to hospital under the Irish Mental Health Act, 2001, but were not subsequently involuntarily detained (i.e. they accepted a voluntary admission).

As patients were recruited before caregivers in these studies, our inclusion and exclusion criteria for caregivers stemmed from those applied to patients (*Fig. 1*). Patients were excluded if they could not provide informed consent, had a diagnosis of dementia or had a moderate to severe intellectual disability that rendered them unable to participate in the study. Patients who received a sole diagnosis of a personality disorder or substance misuse were also excluded from participating, as these individuals cannot be admitted involuntarily under the Irish Mental Health Act, 2001. Caregivers who were younger than 18 at the time of interview or who had a moderate to severe intellectual disability that impeded their ability to consent were similarly excluded from participation in the study.

Informed consent

Informed consent was obtained from all individual participants included in the study. The consent process consisted of three steps. First, patients were asked to consent to their caregiver being contacted and informed of the study approximately 1 year after their discharge. Second, caregivers were contacted by telephone by a researcher who introduced the study and arranged a time of interview. Finally, informed consent was sought from caregivers at interview.

Psychometric instruments

The Involvement Evaluation Questionnaire (IEQ) was employed as a measure of caregiver burden and caregiving.¹⁰ It consisted of 27 core items divided into four sections: urging, supervision, tension and worrying. Scores on the IEQ ranged from 0 to 108, with larger figures representing a higher level of caregiver burden. The IEQ is a reliable instrument, with Cronbach's alpha 0.74–0.85 for each subscale and 0.90 for the total score.¹¹ The IEQ also included a short, 12-item General Health Questionnaire (GHQ-12) that measured psychological distress. Scores on the GHQ-12 ranged from 0 to 12, with higher scores indicating that the caregiver was experiencing emotional difficulties.¹² The GHQ-12 is a reliable measure of psychological distress with an alpha coefficient of 0.87.¹³ Finally, diagnostic and clinical information pertaining to the patient was taken from a Structured Clinical Interview for DSM-IV-TR Axis I Disorders (SCID).¹⁴

Setting

The study included caregivers of individuals admitted to an acute mental health unit in one of five hospitals in Ireland that covered a combined urban and rural catchment population of over 590 000 individuals.

Ethical approval

The study received ethical approval from the governing ethical committees in all of the study sites: St John of God Hospitaller Order Provincial Ethics Committee, Newcastle Hospital Ethics Committee and University Hospital Galway Ethics Committee.

Statistical analysis

All data were entered into a Microsoft Access database and analysed using SPSS Version 22 for Mac. As the data were not normally distributed, multiple Mann–Whitney U and Kruskal–Wallis tests were used to determine whether burden and psychological distress scores differed between caregivers of involuntarily and voluntarily admitted individuals, and according to clinical and demographic factors. Effect sizes (r) were used to measure the magnitude of differences between scores. A small, moderate or large effect size corresponded with values equal to or less than 0.10, 0.30 and 0.50, respectively.

Results

Demographic and clinical characteristics

Sixty-five caregivers participated in the study; 42 (65%) were female. The mean age of caregivers was 54 years (s.d. = 15). The majority of caregivers were married ($n = 49$, 75%), 5 (8%) were single, a further 5 (8%) were divorced and the remaining 6 (9%) were widowed. Most caregivers were the person's parents ($n = 37$, 57%), 11 (17%) were spouses or partners, 8 (12%) were siblings, 6 (9%) were children and 3 (5%) were other relatives. The mean length of time between caregiver and patient interviews at baseline was 584 days (s.d. = 165). The median duration of the index admission was 34 days (interquartile range (IQR) 17.5–50) and 24 (36.9%) patients were readmitted within 1 year of the index admission.

Forty-six (71%) individuals were involuntarily admitted and 19 (29%) were voluntarily admitted. The majority were male ($n = 33$, 51%). The mean age of patients was 39 years (s.d. = 12). The majority of patients were single ($n = 41$, 63%), 16 (25%) were married and the remaining 8 (12%) were divorced.

Caregiver characteristics across legal status are given in *Table 1*.

Comparison of caregiver characteristics across legal status

Characteristic	All caregivers	Caregivers of involuntarily admitted patients	Caregivers of voluntarily admitted patients	Statistical test	<i>P</i>
Age, years: median (IQR)	54 (43–67)	54 (43–66)	54 (39–68)	$U = 340$	0.94
Gender, <i>n</i> (%)					
Male	23 (35)	14 (30)	9 (47)	$\chi^2 = 1.7$ d.f. = 1	0.19
Female	42 (65)	32 (70)	10 (53)		
Marital status, <i>n</i> (%)					
In relationship	49 (75)	34 (74)	15 (79)	$\chi^2 = 0.2$ d.f. = 1	0.67
Not in relationship	16 (25)	12 (26)	4 (21)		
Education, <i>n</i> (%)					
Primary/secondary	16 (30)	12 (33)	2 (13)	$\chi^2 = 2.8$ d.f. = 1	0.09
Tertiary	37 (70)	24 (67)	13 (87)		
Household, <i>n</i> (%)					
Living together	37 (57)	23 (50)	14 (74)	$\chi^2 = 3.1$ d.f. = 1	0.08
Living separately	28 (43)	23 (50)	5 (26)		
Relationship, <i>n</i> (%)					
Parent	34 (71)	25 (78)	9 (56)	$\chi^2 = 2.5$ d.f. = 1	0.12
Partner	14 (29)	7 (22)	7 (44)		

IQR, interquartile range.

Caregiver burden

The median level of burden in the sample was 13.00 (IQR 6.00–22.00). The median level of burden in caregivers of involuntarily admitted patients was 11.50 (IQR 6.25–20.75) and in caregivers of those voluntarily admitted it was 18.00 (IQR 5.00–34.00). Caregivers' overall scores of burden did not significantly differ ($U = 328$, $P = 0.18$, $r = 0.17$). However, caregivers of voluntarily admitted patients supervised the person to a greater extent than caregivers of involuntarily admitted patients (median IEQ supervision scores 2 v. 0, $U = 258$, $P < 0.001$, $r = 0.38$). The particular items of the subscale of supervision on which caregivers of voluntarily admitted individuals scored higher were ensuring that the person had enough sleep ($P = 0.02$) and that they did not drink too much alcohol ($P = 0.05$).

Factors associated with caregiver burden

There was no significant association between the level of caregiver burden and the caregiver's gender, patient's gender, diagnosis, level of functioning, relationship to caregiver or living in the same household as the patient (*Table 2*).

Involvement Evaluation Questionnaire (IEQ) and General Health Questionnaire (GHQ-12) scores according to demographic and clinical characteristics

	IEQ

GAF, Global Assessment of Functioning; IQR, interquartile range.

P 0.05. On applying a Bonferroni correction, no variable reached significance.

Psychological distress

Nine caregivers (15%) reported high levels of distress (defined as a score of 4 on GHQ-12). The median score of psychological distress was 1.00 (IQR 0.00–2.50): 1.00 (IQR 0.00–3.00) in caregivers of involuntarily admitted patients and 0.00 (IQR 0.00–1.00) in caregivers of voluntarily admitted patients. Caregivers of involuntarily or voluntarily admitted patients did not significantly differ in their levels of psychological distress ($U = 302, P = 0.19$).

Factors associated with psychological distress

No significant association was found between the caregiver's level of psychological distress and the caregiver's gender, patient's gender, diagnosis, level of functioning, relationship to caregiver or whether they lived in the same household as the patient (*Table 2*).

Post hoc analysis

We hypothesised that subsequent admissions from the index admission could affect the burden and psychological distress of caregivers and therefore further analysis examining this was performed. Caregiver burden was higher when the patients had been readmitted (16.0 *v.* 9.5, $U = 281.5, P = 0.04$) and there was a trend for a higher level of distress (1.0 *v.* 0.0, $U = 277, P = 0.06$). Legal status for the index admission was not associated with readmission ($\chi^2 = 0.28, n = 61, P = 0.60$).

Discussion

Summary of findings

The findings indicated that overall levels of burden and psychological distress did not differ between caregivers of involuntarily and voluntarily admitted patients at approximately 18 months after discharge from an acute mental health unit. However, caregivers of voluntarily admitted patients engaged in significantly higher levels of supervision than caregivers of those involuntarily admitted. Such supervision focused on, for example, ensuring that the patient slept sufficiently. *Post hoc* analysis also suggested that caregiver burden is associated with readmission to hospital.

Comparison with previous research

To our knowledge, no study to date has examined whether differences in the patient's legal status at admission accounted for differences in caregiver burden (objective and subjective) at more than 1 year follow-up. Our findings, however, support those of Boydell *et al.*,⁷ who also emphasised that overall burden was not linked to involuntary admission in caregivers of patients with first-episode psychosis. Our scores of burden and psychological distress are substantially lower than those reported by other authors.¹¹ Thus, the similarity in scores between caregivers in this sample may be due to a reduction in overall caregiver burden following the person's admission to hospital regardless of legal status.¹⁵

Implications

The finding that caregivers of voluntarily admitted individuals supervised the person to a greater extent is interesting and warrants discussion. It is possible that this additional supervision is a positive experience and that it results in an earlier detection of warning signs and prevents potential relapses from progressing to an involuntary admission. This finding highlights the need for caregivers of both voluntarily and involuntarily admitted individuals to receive support and psychoeducation. Interestingly, the *post hoc* analysis suggests that it may be the frequency of admissions that results in higher burden, as opposed to the legal status of the admissions. Furthermore, a longitudinal replication of this study assessing burden at various time points may provide us with a clearer picture of the caregiver's experience of burden.

Strengths and limitations

The study encompassed a number of strengths and limitations. Our sample included caregivers of involuntarily and voluntarily admitted individuals from both rural and urban geographical locations. Another strength of the study was that the caregivers did not self-select to the study. Nonetheless, our process of consent may have introduced bias, as those who consented for their caregiver to be interviewed may have had closer family relationships. Additionally, there was a significant gap between the index admission and the caregiver interviews, which introduces a number of potential confounders, such as readmission to hospital.

We thank Alastair Fetherston for designing the database for this study.

1.7.28 Unlocking an acute psychiatric ward: the impact on unauthorised absences, assaults and seclusions

Abstract

Aims and method The acute psychiatric in-patient service in Christchurch, New Zealand, recently changed from two locked and two unlocked wards to four open wards. This provided the opportunity to evaluate whether shifting to an unlocked environment was associated with higher rates of adverse events, including unauthorised absences, violent incidents and seclusion. We compared long-term adverse event data before and after ward configuration change.

Results Rates of unauthorised absences increased by 58% after the change in ward configuration ($P = 0.005$), but seclusion hours dropped by 53% ($P = 0.001$). A small increase in violent incidents was recorded but this was not statistically significant.

Clinical implications Although unauthorised absences increased, the absence of statistically significant changes for violent incidents and a reduction in seclusion hours suggest that the change to a less restrictive environment may have some positive effects.

 - * *Strengths and limitations*
 - * *Final consideration*

The locking of psychiatric institutions is an important topic because detention involves significant restrictions on human rights, enshrined in the Universal Declaration of Human Rights. However, studies that have evaluated the impact of unlocking a psychiatric ward are rare; we were only able to identify four such studies spanning 7-decade-long assessing in this area. Lang *et al*¹ evaluated a policy change that resulted in a ward changing from being largely locked for 6 months to being largely open for 6 months and found that negative outcomes were more common during the closed time period. Other studies are considerably older^{2,3} and were largely positive in their findings, with the exception of the study by Molnar *et al*,⁴ which reported an increase in the frequency of ‘elopement’ (unauthorised absence) from 2.5 to 7% of admissions in the context of changing ward policy to allow a largely unlocked environment.

Any consideration of locked psychiatric wards must be viewed in the context of emerging policy that recommends minimising the use of locked psychiatric wards⁵ and emphasises a duty to provide psychiatric care in the least restrictive environment. A desire to provide least restrictive care created the impetus for our local psychiatric service to shift from an acute in-patient environment consisting of two locked wards and two unlocked wards to four largely unlocked wards. It also provided the opportunity to evaluate the impact of the change through reporting of long-term data detailing adverse events, such as unauthorised absences, ward violence and rates of seclusion, prior to and following the changes in ward environment.

Method

Data for this study were taken from the acute in-patient service in Christchurch, New Zealand. The service is the sole provider of acute in-patient services to adults aged 18–65 in the city of Christchurch, outlying towns and rural areas, with the exception of forensic patients, patients with an intellectual disability and in-patients requiring planned detoxification from substances, who are admitted elsewhere. The acute in-patient service receives admissions from community and emergency psychiatric services when care in the community is no longer feasible, with a typical case mix consisting of patients with affective disorders, psychotic disorders and personality disorders.

The service underwent major architectural change in 2013. Before, the service was configured with two locked wards (totalling 20 beds), two wards (totalling 44 beds) that were predominantly unlocked except overnight, and a seclusion area with 3 seclusion rooms. In response to service development initiatives and the desire to provide less restrictive care, the wards were reconfigured into 4 largely unlocked 16-bed wards (except overnight when the wards remain locked). At the end of each ward is a zone called the ‘high care area’, which is quieter than the general ward and provides care for up to three of the more unwell patients. Each high care area is continuous with its adjacent ward and can be designated ‘high care’ when doors are closed or locked, or be regarded as part of the general ward when extra clinical input is not required. The décor and bedrooms of the high care area are identical to the adjacent ward, but an

additional lounge, bathroom and courtyard are provided in order for the high care area to act as a self-sufficient unit when required. All wards, including the high care areas, are intended to be unlocked as much as possible but each ward or high care area can be locked separately in order to detain a patient if this is deemed necessary. The high care area bedrooms were not outfitted for seclusion but the seclusion area remained unaltered and could still be used if required. *Figure 1* presents details of the ward layout. If the ward or a high care area is locked, it is recorded in the restraint register as an environment restraint, and is therefore available for review.

In addition to these structural changes, nursing staff numbers increased, from 27 nurses routinely rostered on the wards to 34 nurses. However, if a nurse was required to provide one-to-one supervision after the change, this needed to occur within existing staff levels, whereas previously this was not the case. The frequency of one-to-one supervision pre- and post-change was not systematically recorded and is not readily available for review.

The acute in-patient service routinely records data on unauthorised absences, seclusions and violent incidents. Unauthorised absences include patients who are under involuntary mental health legislation and leave the ward without permission or fail to return from authorised leave, and voluntary patients who leave the ward outside of their agreed treatment parameters or fail to return from agreed leave. Nursing staff follow procedures when absences occur, including filling out a form documenting the absence which is then collated in a central database.

Violent incidents are assessed clinically and categorised into a number of subcategories including verbal abuse, threats of violence and assaults; all are recorded and collated centrally.

Seclusion is initiated by nursing staff as an intervention of last resort for managing a situation of imminent or actual violence. In response to international and New Zealand initiatives,⁶ seclusion reduction initiatives became embedded into the routine care environment of the acute in-patient service from 2010 and the goal of reducing seclusion occurred alongside the plan to provide a less restrictive environment through the ward redevelopment. Although seclusion rates are likely to be reduced by the seclusion reduction initiatives, the change in ward environment had the potential to hinder or assist the goal of reducing seclusion. As a consequence, we report seclusion rates which are collated centrally on a database and are therefore available for review.

The AWOL (absent without leave), violent incidents and seclusion databases have all collected data over an extended period. In de-identified form, they provided the opportunity to examine rates of unauthorised absences, seclusions and violent incidents for 18 months prior to the change in ward configuration and compare this to 18 months following the change. The mean rates and standard deviations of the monthly adverse events were calculated for the pre- and post-change 18-month intervals. As the data were non-parametric in nature, the Mann-Whitney *U*-test was used to compare the 18 months prior to the change with the 18 months following the change. The change in ward environment was staggered during June and July 2013; this time period was therefore not included in any data analysis as our goal was to examine a longer-term impact of the policy change as opposed to short-term effects during and following the transition.

We also report frequency and duration of the use of environmental restraint to clarify whether or not the intended change to a largely unlocked environment was successful or resulted in frequent locking of the newly configured wards. The frequency of Safety Assessment Code (SAC) 1 and 2 incidents (adverse events involving serious, major or extreme harm to patients) involving psychiatric in-patients is also provided pre- and post-change and examined for the possibility of a change in more serious adverse events that would not be detected by previous methods.

Ward occupancy data are routinely collected by means of a census taken at midnight every 24 hours. Admission data to the acute in-patient service and the forensic service are also recorded daily. Forensic in-patients are predominantly admitted from forensic out-patient services, courts and prisons, and not from general out-patient services. However, we examined admission and occupancy data for these services to test for the possibility that changes in outcome data were confounded by variations in occupancy or transfer to the more secure environment of the forensic service. The rate of monthly admissions pre- and post-change was compared using the Mann-Whitney *U*-test.

Although this was a study of group data and individual files were not accessed, ethics approval was sought and granted by the local University of Otago ethics committee (reference number HD 14/21).

Results

Longitudinal data on monthly unauthorised absences are presented in *Fig. 2*. The mean rate for the 18 months prior to the new ward configuration (December 2011-May 2013) was 16.9 (s.d. = 7.7) compared with 26.7 (s.d. = 11.2) for 18 months following the change in ward configuration (August 2013-January 2015). This represented a mean increase of 9.7 unauthorised absences per month and a percentage increase of 58% that was statistically significant ($P = 0.005$). As some literature suggests unauthorised absences may be seasonal, means were also calculated for the year pre- and post-change to ensure identical calendar months were compared, and the results were similar (16.6 (s.d. = 9.1) v. 29.6 (s.d. = 7.5), respectively).

Violent incidents were examined through the extraction of data recorded under the category of aggression, which includes verbal abuse, verbal threats, physical threats and physical assaults. Specific data were also extracted on physical assaults to assess for more significant violence. *Figure 3* shows the longitudinal data for all violent incidents and the mean monthly rates for 18 months pre- and 18 months post-ward changes, which were 72.3 (s.d. = 34.5) and 78.2 (s.d. = 43.1), respectively. This represented a mean increase of 5.9 violent incidents/month, or an 8% increase in incidents, which was not statistically significant ($P = 0.696$). With regard to physical assaults, the mean difference of 2.8 assaults/month, from 11.5 (s.d. = 5.9) before to 14.3 (s.d. = 10.1) after, was also not statistically significant ($P = 0.628$) (*Fig. 3*).

Another assessed variable was the longitudinal data on monthly seclusion hours over the study period as well as the mean rates of monthly seclusion (hours/month) (*Fig. 4*). The mean length of seclusion prior to the change was 391.5 (s.d. 203.0) compared with 185.2 (s.d. 135.6) following the change. This represented a mean drop of 206 hours/month or a percentage drop of 53% that was statistically significant ($P = 0.001$).

Occupancy was recorded according to bed nights/month and converted to a percentage of available bed nights. Occupancy varied between 80 and 101%, with a mean occupancy of 91% over the study period. It is likely that the single month that experienced more than 100% occupancy was very busy and included extra persons in rooms (e.g. partners, who do not routinely stay) being entered in the census data. Percentage occupancy data were largely stable over the study period and were without systematic trends that could account for the significant increases in unauthorised absences or significant reduction in seclusion hours. In keeping with the occupancy data, the rate of new admissions to the acute in-patient service was also largely stable over the study period (mean monthly admissions for the 18 months pre-change 100.4 compared with 107.8 for the 18 months post-change, $P=0.071$). The mean number of monthly admissions to the forensic service increased from 3.1 before the new ward configuration to 4.4 after; however, the increase was not caused by in-patients from the acute in-patient service as a total of 3 patients were transferred from the acute in-patient service to the forensic service for the 18 months prior to the ward change compared with 4 patients in the 18 months following the change.

The frequency of environmental restraint (locking of the high care areas or whole wards) revealed that, on average, there were 16 times per month when either a high care area or a whole ward was locked following the change in ward configuration. This meant that on average, each of the four wards had 4 periods each month in which part or the whole of the ward was locked. The frequency of locked periods/month varied from 0 for some wards to a maximum of 19, when the high care area of one ward was locked on multiple occasions in response to a single patient's multiple attempts to leave. In 37% of the environmental restraints, just the high care areas were locked as opposed to whole wards (affecting only 1–3 patients at a time). The mean time an area was locked was 120 minutes, and the range varied from 1 minute to 920 minutes. These results can be compared with the period prior to the new ward configuration, which had two wards (affecting up to 20 patients) constantly locked and occasional periods when the two open wards were locked in response to clinical pressure.

The total number of SAC1 and SAC2 events involving in-patients was 14 over the study period. Of these, 10 occurred before the change in ward configuration, 0 occurred during the transition period, and 4 occurred after the changes were made. For SAC1 incidents resulting in the death of a patient, 7 occurred prior to the ward changes (4 deaths occurred on the ward, 2 while patients were on granted leave, and 1 while on unauthorised absence from the ward) and 4 deaths occurred following the ward changes (3 on the ward and 1 while on granted leave). No SAC2 incidents occurred for patients who were on leave in the community or during an unauthorised absence.

Discussion

This study examined a range of adverse indicators over an extended time period in order to clarify whether or not a change in ward environment from two locked and two unlocked wards to a largely unlocked environment was associated with an increase in adverse events. The principal finding was that a significant increase in unauthorised absences occurred. However, significant decreases in the use of seclusion and non-significant increases in violent outcomes were also observed, although the reduction in seclusion occurred alongside national and local initiatives to minimise the use of seclusion.

The new ward configuration still made provision for the locking of wards. However, this was only done for relatively short periods (mean 120 min) and less often than prior to the ward redevelopment, when 2 wards affecting 20 patients were continuously locked. In addition, in 37% of the occasions when locking occurred, only a high care area was locked, meaning that 3 or fewer patients were affected. These numbers suggest that the unlocking of two wards and the change in ward environment did not result in wide-spread or prolonged locking of the new ward configuration.

The occupancy and admission data were without systematic trends to explain the changes noted. In addition, there was minimal flow of patients from the acute in-patient service to the forensic service, suggesting that more difficult patients who may be over-represented in adverse incident data were not transferred to forensic services after the wards were reconfigured.

Previous studies of unauthorised absences from psychiatric wards have raised concerns about rare but serious adverse events that have occurred while patients are absent.⁷ Although the low base rate of these events makes analysis difficult, it is reassuring for those considering a transition to the provision of a largely unlocked environment that of the 14 SAC1 and SAC2 events occurring over the study period, 10 occurred prior to the ward change and only 4 occurred afterwards. In addition, of the adverse events resulting in the death of a patient, 7 occurred before the ward changes and 4 afterwards. Although total numbers of unauthorised absences increased, there was only one death involving a patient who had left the ward without being granted leave, and it occurred prior to the ward change. All other community deaths over the study period involving in-patients occurred for patients who had been granted leave.

Strengths and limitations

One strength of the study was the routine collection of outcome data by hospital staff who were unaware that the data would later be used for study purposes. As a consequence, changes in reporting behaviour could not arise as a result of study influences because of the retrospective nature of the study conception and design. A further strength is the longitudinal nature of the data-set that allowed us to make before-and-after comparisons and consider longer-term effects, as opposed to solely focusing on the transition period during which staff are adapting to changes. These longer-term effects were thought to be more important in evaluating the impact of the change in environment and can be taken into account by service leaders in other locations considering similar changes. Although the longer-term outcomes were our primary area of interest, it is also reassuring that the transition period did not coincide with any SAC1 or SAC2 events, or a spike in the other adverse events evaluated by the study.

Our main limitation was that the study design was not experimental in nature. As the study was uncontrolled, our methodology allows comments to be made on associations between adverse events and the ward changes, but demonstrating causation is not possible. In particular, there was a service initiative to reduce seclusion that started prior to the study period. There were also increases in the numbers of routinely rostered nursing staff on the acute in-patient service after the ward change. This means that the relative influences of the change in ward configuration, the seclusion-reducing initiatives and the changes in nursing numbers on the adverse event rates are hard to quantify. It is therefore possible that increases in seclusion might have been observed if the changes in ward configuration had occurred in isolation. However, it is also reassuring to note that no such increases were seen in the presence of the seclusion reduction focus and nursing number changes that also occurred over the study period.

Final consideration

Studies such as ours that have evaluated the impact of unlocking psychiatric wards are rare. We were only able to identify 4 previous studies over 7 decades in our literature review. These studies were largely supportive of unlocking psychiatric wards, although the Molnar *et al*⁴ study also identified an increase in unauthorised absences following changing ward policy. However, after the initial increase, the rate subsequently decreased following an intervention to better manage risk and absconding.⁴

As stated, the unlocking of our in-patient ward should not be viewed in isolation. Although the findings were mixed with respect to adverse outcomes, we suggest that clinical attention and adaptations to nursing practice and clinical care have the ability to mitigate adverse outcomes when changes in environment occur. This conjecture is supported by the ability of some psychiatric units to markedly reduce seclusion rates⁸ in the presence of administrative and clinical support, and scrutiny of seclusion practice. It is likely that the reduction of seclusion hours demonstrated in this study occurred largely as a result of nursing and management strategies already in place to reduce seclusion in our service. However, seclusion hours continued to fall despite the change in ward configuration, meaning that the less restrictive environment did not have a negative impact on seclusion rates or supported the continued reduction of seclusion. Further support for the ability of service improvement initiatives to minimise adverse outcomes is given by the studies of Bowers *et al*,^{9,10} who trialled anti-absconding interventions in acute psychiatric wards with positive results, and the study by Nijman,¹¹ who demonstrated a reduction in aggressive incidents through a systematic focus on aggression alongside an intervention to reduce aggression. These studies suggest the importance of nursing practice interventions in addition to any environmental measures for reducing rates of absconding and aggression.

Adverse outcomes varied after the change to a largely unlocked environment, with increases in absconding, reductions in seclusion and non-significant increases in violent incidents. The real-world nature of this study does not allow clear inferences to be made regarding whether or not the unlocking of the ward was causally linked to these changes in adverse outcome rates. However, the longer-term nature of the database, with the ability to scrutinise the adverse outcomes pre- and post-change in ward configuration, strengthened the ability of this study to examine the change. The change to a largely unlocked environment was stimulated by a desire to provide care in the least restrictive way possible. Our findings constitute a cautious endorsement of this approach. Although unauthorised absences increased, other adverse outcomes were stable or improved. Thus, providing acute in-patient psychiatric care in a largely unlocked environment appears feasible, particularly in the presence of other service improvement strategies.

1.7.29 Psychiatry trainees' experiences of cognitive-behavioural therapy training in a UK deanery: a qualitative analysis

Abstract

Aims and method To explore core psychiatry trainees' experiences of cognitive-behavioural therapy (CBT) training by using interpretative phenomenological analysis of semi-structured interviews conducted with seven core trainee psychiatrists in Yorkshire and the Humber Deanery.

Results Four key themes emerged: (1) barriers to training; (2) guidance, with emphasis on the importance of supervision groups; (3) acquisition of new skills and confidence; (4) personal influence on the training experience.

Clinical implications Many trainees in Yorkshire have a positive experience of CBT training; however, some also experience barriers to acquiring the relevant skills. Further research should build on the positive factors and barriers identified here, with a view to guiding improvements in training nationwide.

In 2009 the Royal College of Psychiatrists revised the curriculum for psychiatric training to include specific psychotherapy elements within the core curriculum for all psychiatry trainees.^{1,2} The curriculum outlines general and specific competencies.² To achieve these competencies, trainees must complete a psychotherapy Assessment of Clinical Experience (ACE) as a workplace-based assessment (WPBA), attend case-based discussion (CBD) groups and undertake two psychotherapy cases in two modalities.² This revision was an attempt to ensure that core trainees get sufficient experience of psychological treatments to be able to utilise them accurately, evaluate their effects intelligently and, where appropriate, deliver them competently. Cognitive-behavioural therapy (CBT) is one of the recommended modalities of psychological treatments. Psychiatry trainees are expected to be competent to deliver CBT effectively, and CBT is a valuable skill that enriches and informs their practice.³⁻⁵

The current literature suggests that prior recommendations for training in psychotherapies have not been widely implemented,⁶⁻⁸ despite trainees expressing an interest in acquiring such skills.⁸ Historically, trainees have been unaware of new curriculum guidelines⁷⁻⁹ and barriers to the training have been identified. These include lack of supervision,¹⁰ limited availability of suitable cases for training,⁹ and lack of protected learning time.^{4,11-16} A small study¹⁷ suggested working with low-complexity patients in the primary care setting as a way of overcoming these barriers, with protected time to do so. However, this has not been trialled on a wider scale, and limited data are available about whether this is a preferred route of training.¹⁷ Indeed, little qualitative research exists on the experiential accounts of psychiatric trainees undergoing the current training programme.

Aims

This study aims to explore the experiences of CBT training, delivery and supervision in core trainee psychiatrists who have trained in Yorkshire and the Humber Deanery. This work aims to identify barriers that lead to negative experiences of CBT training and identify the factors that facilitate a positive training experience. We also hope this study will guide improvements to CBT training for core trainee psychiatrists to enable trainees to meet the Royal College of Psychiatrists' objectives and, ultimately, become more competent and psychologically minded psychiatrists.

Method

This was an exploratory, qualitative study. Semi-structured telephone interviews and face-to-face interviews were used for data collection, and interpretative phenomenological analysis (IPA) was employed. IPA is a qualitative tool that enables the exploration of an individual's perception of events and how they 'make sense' of experiences.^{18,19} Approval for the study was granted by the Research and Development Department, Faculty of Medicine and Health, University of Leeds.

Recruitment

Twelve core trainee psychiatrists in Yorkshire who had recently completed CBT cases under supervision were invited to participate in the study via email. One trainee declined participation as they were no longer working in the area and four trainees did not respond to the recruitment emails. Seven participants consented to take part in the study.

Participants

The participants were a small, purposeful sample of seven core trainee psychiatrists (CT2 and CT3). Three participants were male. Two participants had worked in a psychotherapy post and one expressed an interest in specialising in psychotherapy.

Procedure

The semi-structured interviews were guided by a review of the pre-existing literature concerning psychotherapy training experiences. This was piloted and amended as necessary. The questions concerned core trainees' experiences of CBT training and the generalisability of acquired competencies, the feasibility of training, the impact of supervision, the emotional aspects of training, and understanding of the College's curriculum. The interviews lasted between 12 and 24 min and were recorded. The recordings were transcribed verbatim to produce the raw data for the study.

Analysis

The process of IPA¹⁹ was conducted by both interviewers, who listened to interview recordings and read and re-read the transcripts to familiarise themselves with the data. Initial interpretations of the data (descriptive summaries and points of interest) were entered as annotations in the margins of the transcripts. Emergent themes were then drawn and recorded in a table after cross-checking them against the transcript. This process was repeated for each transcript. Initially, the researchers searched for connections between the themes within the transcripts, and then between the transcripts. Thematic connections were identified and emergent themes were clustered, and a list of subordinate themes was compiled. Subordinate themes were clustered into superordinate themes. The superordinate themes and sub-themes were verified against the transcripts to ensure that they were grounded in evidence and then they were organised into a master table (*Table 1*). Last, quotations which best encapsulated each theme were identified.

Themes

Superordinate themes	Subordinate themes
1. Barriers	<ul style="list-style-type: none"> a. Time b. Cases c. Patients d. Access to learning resources
2. Guidance	<ul style="list-style-type: none"> a. The role of supervision b. Learning from peers c. Sticking to the curriculum
3. Acquisition	<ul style="list-style-type: none"> a. Gaining new skills b. Models of mental illness c. Personal influence d. Confidence

Results

Three superordinate themes were identified, with three or four subordinate themes each, and are described below.

Barriers

Barriers to CBT training and the impact that this had on learning was a prominent theme across all of the interviews. Some participants had personally experienced barriers to training and others described the impact that barriers had had on their peers.

Time

The impact of insufficient time for learning was a theme that occurred across all seven interviews. Participants disclosed how shift work caused disruption to their CBT training.

‘if we were on-call that day or on nights or on leave, um, you ended up missing some of the sessions because of that and I think because CBT is quite structured, so you learn one thing in one session and then progress on to the next bit in the next session, so if you miss a bit I think it becomes a bit more difficult to get your head around it’ (participant 2).

One participant described the challenges encountered in maintaining protected learning time amidst other work commitments: “‘Because I was working in the ward [...] it’s quite difficult to get out of that to get supervision and do other things’ (participant 6).”

Conversely, another participant perceived that colleagues respected protected learning time, suggesting that trainees’ experiences varied depending on where they were working: “‘There’s no problem getting time away from your day job to go [to] the CBT training’ (participant 7).”

One participant, who had worked in a psychotherapy job, acknowledged that this job provided more time for training than other jobs: “‘I did a psychotherapy job in my last 6 months, so I was able to spend a lot more time and pick up a

lot more cases than perhaps other people have experienced' (participant 4)."

One participant expressed concern that lack of time may prevent the use of CBT in future practice: "depending on the workload you're not always able to provide the adequate time per patient' (participant 2)."

The time delay between beginning CBT training and being allocated a patient case was identified as a barrier.

Cases

Participants felt that there was a shortage of CBT cases available for trainees and this had a significant impact on their CBT training.

'I think the barrier is there is a big waiting list and that is a problem, like you have to wait to get a case [...] and obviously if there [aren't] enough patients [...] you [won't] get a case and there's loads of trainees and this is kind of a mandatory thing, everybody has to have a case' (participant 3).

Participants felt that it would be beneficial to have more than one case: "I would say if we had at least two cases that might be better but again it is very difficult to get a CBT patient because we have got loads of trainees and, um, not a lot of CBT we do, we get for trainees because [...] if it is not simple for trainees they do not consider it, to give it to us, and there is a long waiting list, I think you know that, there is a big waiting list for CBT, so like I had to wait for nearly ... more than a year actually' (participant 3)."

A participant who had worked in a psychotherapy post observed that one case would not have provided sufficient CBT experience: "I work in psychotherapies so I have had more than one case and [I] have had good exposure to CBT. I just don't know whether if I hadn't had this job, this exposure would be enough' (participant 1)."

Patients

Six of the participants discussed the impact of the patient on their experience of CBT. First, participants felt that completing a CBT case was more challenging if the patient did not engage. Second, they discussed the impact of patients not attending sessions or discontinuing with treatment; this was perceived to be a substantial barrier to training that was not taken into account by the College's curriculum.

'if the patient doesn't engage or doesn't complete therapy – this could potentially be a problem. In fact [the trainee] might not have the time to undertake another case and complete it' (participant 7).

However, participants acknowledged that the impact of the patient on CBT training was a factor that is difficult to control.

'It's totally up to the [patient] whether he or she will continue or not and if she leaves before you complete the full therapy then you have to wait for the next patient so that is a problem but I don't know the way to change it because it's totally up to the patient if they will continue or not' (participant 3).

Conversely, one participant acknowledged that a good doctor-patient relationship could have a positive impact on the experience of CBT training.

'seeing results from patients as well has been really good' (participant 4).

Access to learning resources

Participants expressed concern about keeping skills up to date as time elapsed.

‘I think the Royal College [of Psychiatrists] run a CBT module, but it’s all things that you have to pay for [...] and I think that most people feel like they pay for enough exam material [and] for the Royal College exam, and probably don’t have [a] mountain of spare cash to be spending on more e-learning stuff, so it might be good if the trust wanted to sort of do something with CBT, or if the Royal College will give out [an] e-learning module – I think that would be quite useful, and for people who are not seeing cases that regularly – I think it might kind of just update you with CBT’ (participant 4).

Conversely, others thought that the time and experience was ‘ample’: “‘I’ve been given adequate texts to read and stuff in my spare time. I have ample opportunity to discuss any complications that arise with my case so [...] all in all it’s been really good’ (participant 2).”

Guidance

The participants perceived that supervision was an important feature within their experience of CBT training. The superordinate theme of guidance was identified across all interviews, with the subordinate themes of supervision, peer learning and curriculum.

The role of supervision

There was an overall satisfaction with supervision from all the participants, who felt that they had continued support and advice. Feedback and reassurance from supervision encouraged the trainee to gain confidence and it was highlighted that the participants felt able to ask their supervisor for advice.

‘I would say that the supervision was really good, it was tailored down to trainees’ need [...] the supervisor was approachable’ (participant 5).

‘there were quite a few things that needed improvement and I felt that supervision enabled me to identify these areas and work on improving these sets of things’ (participant 1).

It appeared that the expertise of the supervisor themselves was respected and was useful to the majority of the participants. All of the participants had a consultant psychiatrist as their supervisor.

‘expert opinion on where you are going with your cases, so you feel like you do a good job with the patient’ (participant 4).

‘has a lot of experience on this ground so that was quite helpful’ (participant 3).

In terms of emotional support, there appeared to be a consensus that, if required, emotional support from supervision would be present.

Interviewer: ‘And, do you feel like you had enough emotional support if needed during your training?’

Participant: ‘I suppose I would, yes. It was never an issue, but I would imagine that if I had felt stressed I would have found support’ (participant 1).

Learning from peers

Three of the participants discussed how helpful peer learning was in their training, in particular as regards case supervision conducted in group sessions.

‘Well, I actually used to love and look forward to [...] supervision, because every time – because our supervision was a group sort of supervision – I learn not only from my case, but [I] also learn from other people’s cases. Because people have different aspects they need supervision [for], so I will kind of learn quite generally because it’s quite enjoyable to keep on listening to different cases, including mine – and following it up through week after week. So I really enjoyed it’ (participant 6).

Sticking to the curriculum

In contrast to the optimism surrounding supervision, the participants did not consider the College curriculum to be a sufficient source of guidance.

I: ‘Also, how aware were you of the Royal College guidelines before you started your CBT training?’

P: ‘Um ... not very.’

I: ‘And do you feel that there is any way in which they could be accessed more easily?’

P: ‘I wouldn’t even know how you access them now to be honest.’

I: ‘Okay, that’s okay. Okay.’

P: ‘I’m assuming that you look on the Royal College website but I never have’ (participant 7).

This lack of awareness of the Royal College of Psychiatrists’ curriculum guidelines was found in other participants, who reasoned that the guidelines are too extensive and incomprehensible. However, it transpired that six participants had acquired the competencies outlined in the curriculum despite the fact they were unaware of what these were.

‘The curriculum for core training is huge and extremely vague mostly – so you need to trawl through that document, probably most people haven’t’ (participant 4).

P6: ‘I’ve been able to explain to the patient what CBT is and what it is used for and also, sometimes I’ve been able to use the skills I’ve learnt in CBT, to offer treatment to the patient.’

I: ‘Do you feel like you are able to deliver CBT?’

P6: ‘I think I feel that way’ (participant 6).

One participant relayed that the curriculum needed to be more flexible owing to the nature of the therapy itself being unpredictable and time consuming.

‘I do think they need to be a bit flexible, because say if a patient drops out of therapy and say you have done 10 sessions that now doesn’t count as a case!’ (participant 4).

Acquisition

The participants felt that they acquired a great deal via their CBT training, in terms of gaining specific CBT skills, but also in learning generic skills that could be applied to psychiatric practice and learning which patients would be suitable for CBT. They acquired a new insight into models of mental illness and learnt to conceptualise mental illness in accordance with the CBT model. Trainees also discussed their personal influence on their experience and thus their acquisition of CBT skills. Last, they grew in confidence as they gained experience working with their CBT case.

Gaining new skills

The trainees felt that they gained a great deal from their CBT training, in terms of both specific CBT skills and also broader transferable skills that could be applied to their psychiatric practice.

‘I enjoyed it. I think basically it’s really important [...] for [a] psychiatric trainee or for a psychiatrist to have experience in CBT’ (participant 1).

Most of the participants felt that they gained a greater understanding of what CBT entails and how it works. This enabled them to confidently explain CBT to patients.

‘it gave a clear understanding for me of what exactly CBT involves and how it has a beneficial effect on patients’ (participant 5).

Three participants described how the training helped them to identify which patients would be suitable for CBT. They felt confident in referring patients for CBT. However, others felt that they needed more experience to accurately assess patients for CBT.

‘I mean, now like when I will refer patients for psychotherapy I would now know what are the categories that I need to check before referring and whether the patient is suitable for CBT or not because I have practical experience of doing it and I know that I’ve some idea whether the patient [would benefit] from CBT or not’ (participant 3).

Some of the participants felt confident using CBT techniques. However, they acknowledged that they had limited experience and that they were not fully equipped to deliver formal CBT.

‘And do you feel like you would be able to deliver it as well?’ P: ‘Delivering, to be honest – no. Because, I think, err, having done only one short case of CBT, without any supervision, I won’t be able to take up a case on my own I guess ...’ (participant 5).

Although not all of the participants felt confident in delivering CBT, they felt that they had gained transferable skills that could be used elsewhere in their psychiatric practice.

‘Sometimes in my session now [...] I see people with [...] anxiety and other disorders; I am able to use the very same skills I used in my CBT session to kind of handle the situation around me’ (participant 6).

The participants hoped that they would continue to use the skills that they had gained. However, some expressed concern about losing skills over time, particularly if they did not use CBT regularly in their job.

‘if you’re not in touch then you may lose some skills. That may be a problem in the future because you’re not going, not actually keeping doing it, practising it, yeah, so maybe it can impact on practice in the future’ (participant 3).

Models of mental illness

Six participants talked of the training causing a shift in their understanding of mental illness, moving them away from the diagnosis exclusively, and focusing on the wider problems for their patient, allowing them to reach the criteria of the curriculum and develop their emotional intelligence.

‘what I found out is that [pause] maybe some of these people do not have defined mental illness but they definitely have a problem, and just basically move me away from having to diagnose a patient with something, so [I was able to] focus on the problem rather than the diagnosis, and sometimes the problem did not correspond to an ICD-10 diagnosis, and I think this is really useful because, eh, usually in everyday life, people have problems – rather than psychiatric diagnosis’ (participant 1).

‘Well it has given me the insight into looking at the behaviour and thoughts, in terms of how people are affected, and how to help them – that’s not what I was thinking before, because before I was thinking in terms of the medical model, and now I’m thinking more about other things like their thoughts and their

behaviour, and their emotion – and how all of that is part of their illness, and how to use that to treat their illness’ (participant 6).

The trainees described how this increased awareness affected the management of their patients.

‘it does change your thinking about your practice, and you know – what else is out there, other than, you know, medication and that kind of thing, there are other ways that people can benefit from secondary care’ (participant 4).

‘having done CBT training [pause] it helped me to identify that there are some mental disorders which need both medications and psychotherapy’ (participant 5).

The benefits of having time to reflect as part of psychotherapy training gave trainees a different perspective on the patient that they were treating.

‘and I think when you’re using CBT to make them think differently about their illness and their actions it makes you think differently about it as well [...] and you certainly see patients’ difficulties from a different point of view [...] and it gives you time to figure that out’ (participant 2).

Personal use of this new way of looking at models of mental illness was cited; the participants described how this changed how they see themselves.

‘within myself, it changed me in such a way, the way I am able to kind of evaluate my behaviour, with what I do and what I think – so I use it on myself quite a bit. If I find myself in a difficult situation, even in day-to-day life – I use the same principle on myself to kind of look at how things are done, and change things differently. So I think that’s how personally CBT has influenced me’ (participant 6).

Personal influence

Several of the participants acknowledged that they had a particular interest in CBT. Two had worked in a psychotherapy post and one hoped to specialise in psychotherapy. Furthermore, the participants acknowledged that their personal interest may have affected their experience of CBT training and they may have gained more from the training as a result.

‘Personally, I am interested in psychotherapy anyway, so I wanted – I want to be able to use CBT [pause] later on in my career, so [pause] so that’s one of the reasons why I think it was really useful’ (participant 1).

Confidence

The majority of the participants talked of increased confidence during their training and afterwards. This is in regards to their own skills and understanding, as well as recognition of when to refer a patient for CBT.

‘since my first case, [I] have got a lot more fluent [than] in the beginnings of therapy’ (participant 4) .

One participant expressed a lack of confidence in referring patients for CBT because their CBT supervision was still ongoing at the time of the study: “‘I don’t think I’m confident at the minute because I suppose I’ve been given a patient, I’ve not assessed someone for it as such but, um, I’m continuing to have CBT supervision [...] so I think by the end of it I will be able to, yes, to figure out who would benefit from it’ (participant 2).”

Overall, there was a positive association between experience and confidence.

‘Do you know, I feel much more confident about CBT ... because I know what it is, so I feel much more confident’ (participant 3).

Discussion

A number of barriers that affect trainees' experiences of CBT training have been identified here; chiefly a lack of protected learning time, a shortage of available cases for training purposes and difficulties arising due to problems with patient engagement and therapy completion.

Having protected time for CBT training was high-lighted as crucial for psychiatry trainees, who reasoned that the difficulty in completion and the formulaic structure of CBT require a regularity and dedication to carry it through. The 'inevitability' of work disruptions and shift patterns were the main source for these disruptions recognised in this study. As previous work suggests, there was variability within this, dependent on where one is a trainee and what jobs one is assigned. Trainees in a dedicated psychotherapy post were more positive about their ability to complete and transfer their CBT skills. We propose that this may be due to the trainee having a personal interest in 'talking therapies' in addition to the granted protected time to acquire these skills in a psychotherapy post, a proposition which resonates with previous work in this area.⁴ This variation resulting from chance permeates to the level of patient allocation as well – as each trainee is allocated a different patient, standardisation of experience becomes problematic. One aspect that helped with this was peer-group learning, insofar as the experience of each trainee is shared and hence multiple cases are acquired instead of just the one that each trainee has had. This echoes previous recommendations to utilise novel ways, such as peer-group learning, to assist CBT supervision and skills acquisition.³ Thus, ensuring that protected learning time is provided and that it is a feasible task is likely to improve the trainees' experience.

Concerning the shortage of cases, further enquiry would be beneficial to explore the feasibility of targeting the long waiting lists for both the patients and the trainees by enabling trainees to take on a broader range of patient cases. A larger study would be beneficial in exploring this, continuing with the idea to source cases from primary care.¹⁷ This could help to relieve the pressure for the trainee to complete one 'ideal' CBT case, and thus the patient being a barrier to learning could have less impact. It was also suggested that it could be beneficial to provide a follow-up course that can be accessed freely to ensure that skills are maintained over time. Furthermore, the training experience could be improved if the Royal College of Psychiatrists' curriculum took into account the effect of patients discontinuing with therapy and allowed a degree of flexibility for cases in which almost all sessions had been completed. Moreover, as prior literature suggests, further dissemination and accessibility of the College curriculum is still warranted.

A number of factors that facilitated a positive experience of CBT training in Yorkshire were identified. Supervision was highly valued and deemed to be an important facilitating factor during the training. Further research could be useful in order to elucidate how the benefits of supervision are mediated and thus enable similar supervision to be conducted elsewhere.

In accordance with the College curriculum, this study suggests that psychiatric trainees in Yorkshire report enhancements in their emotional intelligence and being able to refer for CBT accurately and evaluate its effect intelligently after the training. A broad positive association was relayed from the participants between exposure to CBT and confidence in recognition and delivery of skills learned. However, although trainees' overall confidence about psychotherapy increased, further experience is deemed necessary for the trainees to feel able to deliver CBT competently. On the whole, trainees gained a broader perspective of models of mental illness and learned transferable skills, which have now influenced their clinical practice.

Although a robust study design was employed and triangulation of the data was used to increase the validity of the findings, the qualitative nature of the study has inherent limitations.²⁰ Nonetheless, the study provides a valuable insight into the experiences of psychiatry trainees in Yorkshire and paves the way for further research in other deaneries across the UK in order to gain a clearer insight into the experiences of core trainee psychiatrists in general, with the aim of improving CBT training and ultimately enabling psychiatrists to become more emotionally aware, competent and confident.

1.7.30 Antipsychotic prescribing of consultant forensic psychiatrists working in different levels of secure care with patients with schizophrenia

date

2017-4

Abstract

Aims and method To detect any differences in the antipsychotic prescribing practices of consultant forensic psychiatrists working in different levels of secure care with patients diagnosed with schizophrenia, and to identify potential reasons for any differences. Prescribing data were collected from four secure hospitals within one National Health Service trust. A questionnaire was sent to consultant forensic psychiatrists working at those hospitals as well as those working in the trust's community forensic services.

Results Consultants working in high security prescribed more oral antipsychotics than consultants working in medium and low security, who prescribed more depot antipsychotics, as established via the prescribing data. The questionnaire provided insight regarding the reasons for these preferences.

Clinical implications There were differences in the antipsychotic prescribing practices of consultant forensic psychiatrists working in different levels of secure care, and, overall, the rate of depot antipsychotic prescribing was lower than might be expected. Although it was positive that the rate of polypharmacy was low when compared with earlier studies, the lower-than-expected rate of depot antipsychotic prescribing has clinical implications.

Schizophrenia is an enduring mental illness characterised by remissions and relapses. Treatment is available in the form of psychosocial interventions but the mainstay of effective management is antipsychotic medication.^{1–3} Antipsychotic efficacy is reduced by poor adherence and it is estimated that the risk of relapse is 2 to 6 times greater for patients not taking antipsychotic treatment.¹

Forensic psychiatrists working in secure hospitals are likely to have case-loads with high levels of comorbidity, non-adherence and risk;^{4,5} a history of aggression has been found to predict the use of high-dose antipsychotic treatment (total antipsychotic doses totalling greater than 100% maximum *British National Formulary* dose).¹

Paton *et al*⁶ reported on an in-patient census. Most (97%) of the 53.2% diagnosed with psychosis were prescribed an antipsychotic. Polypharmacy (the prescription of more than one antipsychotic agent) was common. Of those prescribed a regular antipsychotic, 51.6% were prescribed a first-generation agent, 11.3% were prescribed clozapine and 33% were prescribed a depot agent (80% of these patients had a psychotic illness). High-dose prescribing was more common when a depot agent was prescribed.

No previous studies have examined the prescribing patterns of forensic psychiatrists working in differing levels of security. It is important to identify such patterns to build on existing knowledge and to identify areas requiring change.

Aims

To detect any differences in the antipsychotic prescribing practices of consultant forensic psychiatrists working in different levels of secure care within a National Health Service (NHS) trust, and to identify potential reasons for any differences. We hypothesised that there would be no significant differences in prescribing patterns in this clinician group.

Method

Settings and sample

Covering a vast geographical area, the NHS trust studied is one of the largest in England and provides services in a variety of settings. Its secure hospitals feature one high secure hospital, two medium secure hospitals and one low secure hospital. Information on antipsychotic prescribing was collected on all in-patients with schizophrenia in these four hospitals in July 2014. A questionnaire was sent to the 34 consultant forensic psychiatrists based at the hospitals and 3 community-based consultant forensic psychiatrists working within the same trust.

Procedure

Prescribing patterns

In July 2014, the electronic healthcare records were used to produce a list of all current in-patients at the trust's four secure hospitals. The clinical records (electronic and paper healthcare records, and pharmacy records) were then used to ascertain which of these patients had schizophrenia. Further information was collected about patients with schizophrenia (gender, age, ethnicity, length of stay, antipsychotic medication prescribed), to produce an anonymised data-set detailing the percentage of patients diagnosed with schizophrenia at each hospital, and the proportion of patients with schizophrenia prescribed different types of antipsychotic medication.

Consultant questionnaires

Owing to the absence of a validated instrument, a semi-structured self-report questionnaire was developed to assess forensic consultants' attitudes to the prescription of oral and depot antipsychotic medications. The questionnaire was designed to take less than 5 min to complete. Consultants were asked in which level of security they worked and then three further questions: Disregarding the special case of clozapine, when treating a patient with schizophrenia do you have a general preference for either oral or depot antipsychotic medications? (Yes/No) Please indicate the strength of any preference on the scale below (0–100 anchored Likert scale: 0 – oral, 100 – depot). What are the reasons behind any stated preference? ((a) Improves adherence, (b) Better clinical outcome, (c) More convenient for the patient, (d) More convenient for the clinical team, (d) The next level of security/community team would expect/prefer it). There was also space for a free-text response. The three community consultants were asked two further questions: How important is the route of antipsychotic administration in your considering whether to accept a patient on to your caseload? (0–100 anchored Likert scale: 0 – very important, 100 – not at all important). How likely are you to accept a patient currently prescribed an oral antipsychotic (not clozapine)? (0–100 anchored Likert scale: 0 – very unlikely, 100 – very likely). The Likert scale is an ordinal psychometric assessment of attitudes or opinions, typically lacking concrete answers to accommodate neutral or undecided feelings. It was selected for this questionnaire owing to the speed and ease of completion, low cost, ease of distribution, and providing results amenable to analysis.

The Likert scale has been criticised for failing to measure the true attitudes of respondents, as it gives only 5 to 7 options of choice, and also for the space between each choice in reality possibly not being equidistant. In view of this, and in an attempt to further maximise freedom on behalf of the responder and to avoid railroading respondents into giving polarised responses, the Likert scale was amended to include some characteristics of an analogue scale.

The questionnaire was sent, with a cover letter, to all forensic consultants working in the four secure hospitals and in community forensic services in the NHS trust. After 3 months, the questionnaire was sent again to encourage non-responders. All data were supplied anonymously.

Ethical considerations

The project proposal was reviewed by the trust's research and innovations department and approved as service evaluation; research ethics approval was therefore not required. Patient anonymity was preserved throughout the study.

Analytic strategy

SPSS version 21 (Windows 10) was used for data analysis. Chi-square and ANOVA were used where appropriate. All tests were two-tailed and $P < 0.05$ was used to determine statistical significance.

Results

Demographic information

In July 2014, there were 556 patients detained at the four secure hospitals; 265 (48%) were diagnosed with schizophrenia. The sample characteristics are summarised in *Table 1*.

Sample characteristics of in-patients at each of the four secure hospitals

	High secure hospital	Medium secure hospital 1	Medium secure hospital 2	Low secure hospital	<i>P</i>	<i>a</i>
Total number	339	69	85	63	–	
Schizophrenia, <i>n</i> (%)	139 (41)	53 (77)	33 (39)	40 (63)	**	: $\chi^2_{sup:2} = 38.52$, d.f. = 3
Ethnicity, <i>n</i> (%)						
White British	100 (72)	41 (77)	21 (64)	17 (42)	**	: $\chi^2_{sup:2} = 15.23$, d.f. = 3
White other	5 (4)	0 (0)	1 (3)	2 (5)	0.500	: $\chi^2_{sup:2} = 2.34$, d.f. = 3
Black/Black British	19 (14)	3 (6)	4 (12)	11 (28)	**	: $\chi^2_{sup:2} = 9.25$, d.f. = 3
Asian/Asian British	9 (6)	5 (9)	2 (6)	3 (7)	0.902	: $\chi^2_{sup:2} = 0.58$, d.f. = 3
Mixed/other ethnicity	6 (4)	4 (8)	5 (15)	7 (18)	**	: $\chi^2_{sup:2} = 9.42$, d.f. = 3
Age, years						
Mean (s.d.)	40.0 (9.8)	36.9 (8.7)	36.5 (8.8)	38.1 (10.3)	0.100	ANOVA $F_{(3,261)} = 2.10$
Median (range)	38.6 (21.9–66.3)	37.2 (19.6–60.0)	35.2 (21.8–58.2)	35.9 (19.8–62.0)	–	
Length of stay, years						
Mean (s.d.)	6.4 (4.5)	2.1 (1.9)	1.9 (1.4)	3.0 (3.9)	**	ANOVA $F_{(3,261)} = 26.86$
Median (range)	5.9 (0.1–21.4)	1.5 (0.1–8.0)	1.4 (0.03–5.6)	1.5 (0.3–18.2)	–	
Female patients, <i>n</i> (%) <i>b</i>	5 (3.6)	0 (0)	1 (3.0)	4 (10.0)	0.093	: $\chi^2_{sup:2} = 0.58$, d.f. = 3
Age, years: mean (s.d.)	43.1 (5.9)	–	–	41.7 (13.4)	0.373	ANOVA $F_{sub: (2,7)} = 1.14$
Age, years: median (range)	41.1 (36.9–54.3)	–	–	39.7 (25.7–62.0)	–	
Length of stay, years: mean (s.d.)	4.9 (2.4)	–	–	1.1 (0.4)	0.053	ANOVA $F_{sub: (2,7)} = 4.62$
Length of stay, years: median (range)	6.5 (1.3–6.8)	–	–	1.1 (0.5–1.6)	–	

Bold denotes significance ($P < 0.05$).

As medium secure hospital 2 had only 1 female in-patient, means and medians for age and length of stay have not been calculated.

Medium secure hospital 1 provides a male-only service. The high secure hospital and medium secure hospital 2 have wards specialising in the care of patients with personality disorder, whereas medium secure hospital 1 and the low secure hospital do not, hence the differences in the rate of schizophrenia. The proportion of patients from Black and minority ethnic (BME) groups was high when compared with the general population ⁷ (29% v. 14% respectively). The rate was highest for the low secure hospital (53%). This significant finding mirrors an earlier study ⁸ which found an overrepresentation of BME groups admitted to low secure services across the UK.

There was little difference in mean patient age between the four hospitals, and expected differences in the mean lengths of stay.

Pattern of prescribing

Of all patients with schizophrenia, 3% ($n = 8$) were not prescribed antipsychotic medication and 12% ($n = 33$) were prescribed antipsychotic medication constituting polypharmacy. The most common polypharmacological combination was clozapine augmented with a second-generation oral antipsychotic. Data regarding the prescription of antipsychotic medication are summarised in *Table 2*.

Antipsychotic prescribing for patients with schizophrenia at the four hospitals

	High secure hospital	Medium secure hospitals	Low secure hospital			
Regular first-generation antipsychotic only, n (%)						
Oral	6 (4)	2 (4)	0 (0)	2 (2)	2 (5)	10 (4)
Depot	17 (12)	7 (13)	8 (24)	15 (17)	9 (22)	41 (15)
Regular second-generation antipsychotic only, n (%)						
Oral	59 (42)	8 (15)	10 (30)	18 (21)	11 (27)	88 (33)
Depot	1 (1)	9 (17)	0 (0)	9 (10)	6 (15)	16 (6)
Clozapine only, n (%)	33 (24)	18 (34)	10 (30)	28 (33)	8 (20)	69 (26)
Total, n	139	53	33	86	40	265

Excluding clozapine.

Clozapine was prescribed to 26% of all patients, with the highest prescription rate observed in medium security hospitals (33%).

Excluding polypharmacy and clozapine use, more patients were prescribed a second-generation oral agent than a first-generation oral agent (33% v. 4%); this was true for all four hospitals. In general, this pattern was reversed for depot agents, with more patients being prescribed a first-generation depot agent than a second-generation depot agent (15% v. 6%). 70% of patients with schizophrenia in high security were prescribed an oral antipsychotic only (including clozapine), compared with 56% of patients in medium security and 52% of patients in low security (*Table 2*). It emerged that 13% of patients with schizophrenia in high security were prescribed a depot antipsychotic only, compared with 28% of patients in medium security and 37% of patients in low security. Owing to the relatively small sample sizes, data from the two medium secure hospitals and one low secure hospital were combined for statistical analysis, as shown in *Table 3*.

Oral and depot antipsychotic prescribing for schizophrenia in high security and the other hospitals

	High secure hospital	Other hospitals <i>a</i>	Total, <i>n</i>
One type of regular oral antipsychotic only, <i>n</i> (%)	98 (70)	69 (55)	167
One type of regular depot antipsychotic only, <i>n</i> (%)	18 (13)	39 (31)	57
Other, <i>b n</i> (%)	23 (17)	18 (14)	41
Total, <i>n</i>	139	126	265

Medium secure hospital 1, medium secure hospital 2, low secure hospital.

More than one type of antipsychotic prescribed regularly, no regular antipsychotic prescribed.

Chi-square testing revealed a significant difference in the rate of prescribing of oral and depot antipsychotic medication between the high secure hospital and the other hospitals ($\chi^2 = 12.78$, d.f. = 2, $P < 0.01$). The data suggest that more oral medication was used in high security and more depot medication was used in the other hospitals. *Table 4* shows the route of medication administration for patients with schizophrenia broken down by ethnicity. When medication was prescribed (i.e. excluding the 'no antipsychotic prescribed' category), chi-square analysis showed a statistically significant difference between the ethnic groups ($\chi^2 = 6.90$, d.f. = 2, $P < 0.05$); depot antipsychotics appear to be used more frequently for patients from BME groups.

Medication administration for patients with schizophrenia by ethnicity

	Regular depot antipsychotic only	Regular oral antipsychotic only	Regular depot and oral antipsychotic	No antipsychotic	Total
BME patients, <i>n</i> (%)	23 (29.5)	48 (61.5)	5 (6.4)	2 (2.6)	78
White patients, <i>n</i> (%)	34 (18.2)	142 (75.9)	5 (2.7)	6 (3.2)	187
Total	57	190	10	8	265

Consultant questionnaires

The questionnaire was sent to the 34 consultant forensic psychiatrists based at the four secure hospitals in the trust (19 at the high secure hospital, 10 at the two medium secure hospitals and 5 at the low secure hospital), as well as to the 3 forensic consultants working in community forensic services within the same trust. The overall response rate was 78% (74% high secure, 80% medium secure, 80% low secure and 100% community). Limitations in the data collected leave us unable to comment on any differences (e.g. gender, age, years of experience) between consultants who did and did not respond.

Of the hospital-based consultants responding to the questionnaire, 35% expressed a preference for oral medication and 42% expressed a preference for depot medication; 23% did not express a preference. The mean score on the 0–100 scale, where 0 indicated a preference for oral and 100 for depot medication, was 37 (s.d. = 20) for respondents from high security and 74 (s.d. = 22) for respondents from other settings (medium security and low security); ANOVA demonstrated a significant difference between the two groups ($F_{(1,24)} = 19.759$, $P < 0.01$). Thus, those working in high security preferred oral medications and those working in other settings preferred depot medications.

Most (89%) expressing a preference for oral medications worked in high security. The following reasons were given: convenience for patient, adherence, safety, less invasive, improved engagement, increased patient responsibility and improved therapeutic relationship. Most (73%) expressing a preference for depot medications worked in medium or

low security, and their reasons were: adherence, clinical outcome, expectation from next level of security, reduced side-effects, reduced tension between patient and team, easier risk management in community, 'mental health review tribunal'/'Ministry of Justice' reassurance, and reduced adverse events.

All of the community-based forensic consultants expressed a preference for depot medication; stated reasons included adherence, clinical outcome and convenience for the patient.

Community-based forensic consultants were asked two further questions (see Method). It emerged that route of administration was important for consultants when considering whether or not to accept a patient (mean rating for question 1, where 0 was 'very important' and 100 was 'not at all important', was 31 (s.d. = 17)). Considering question 2, consultants were also likely to accept patients currently prescribed an oral antipsychotic (not clozapine) (mean rating 72 (s.d. = 21), where 0 – very unlikely, 100 – very likely).

Discussion

Findings

This study demonstrates a similar rate of antipsychotic prescribing (97%) as a previous study; ⁶ 3% of patients were not prescribed antipsychotic medication. Consultant psychiatrists may opt not to prescribe antipsychotic medication in the context of a drug-free trial related to diagnostic uncertainty or severe side-effects, or because a patient has refused to take such medication.

This study reveals significant differences in the antipsychotic prescribing practices of consultants working in different levels of secure care. Consultants in high security were found to prescribe more oral antipsychotics, and those in medium and low security were found to prescribe more depot antipsychotics. It may be that the likelihood of high secure patients having an extended period of supervised care ahead of them reduces the bearing of adherence on antipsychotic selection.

The overall rate of depot antipsychotic prescribing was lower than that found by Paton ⁶ and also lower than that quoted in the Maudsley guidelines. ⁹ Polypharmacy was less prevalent than in Paton's study; ⁶ this finding was welcome but perhaps unsurprising as over a decade later the risks associated with polypharmacy are better understood and many trusts have guidelines restricting polypharmacy. The Care Quality Commission also actively discourages polypharmacy. The most common combination of clozapine augmented by a second-generation oral antipsychotic is in keeping with usual approaches to treatment-resistant schizophrenia.

BME patients with schizophrenia were significantly more likely than their White counterparts to be prescribed a depot antipsychotic. This finding builds upon existing research. ^{10,11}

Significant differences in the opinions expressed by consultants were found: consultants working in high security preferred oral antipsychotics and consultants working in other settings preferred depot antipsychotics. Overall, 31% of all respondents expressed a preference for oral antipsychotics and 89% of these worked in high security, whereas 48% of respondents expressed a preference for depot antipsychotics and 79% of these worked in medium and low security and the community. Comments from community consultants suggest there is no expectation that patients should be prescribed a depot antipsychotic before they are deemed suitable to be managed by community services.

It is noteworthy that the presence of a community forensic team may mean that the area served by the NHS trust in this study is not typical of other areas in England and Wales. Community forensic services are not available countrywide and it may be that general adult psychiatrists accepting patients from secure services hold different views than their forensic colleagues.

Adherence

Both consultants preferring oral antipsychotics and those preferring depot antipsychotics listed 'adherence' as a reason for their preference. For patients with schizophrenia, poor adherence can be related to forgetfulness, disorganisation, complexity of regime, cost, lack of insight, ambivalence, poor relationship with therapist, stigma, side-effects and lack of perceived efficacy.^{3,12} Higher rates of non-adherence have been reported in patients with schizophrenia prescribed oral medication than those prescribed depot medication¹³ and patients treated with depot medication have been found more likely to continue medication, and to continue it for longer, than patients treated with oral medication. It has been suggested that improved adherence is likely to lead to better clinical and functional outcomes.¹⁴

Stone & Niz¹⁵ found that non-adherent patients with schizophrenia were more likely to enter the criminal justice system and suggest that consideration be given to using depot antipsychotics (or clozapine) as a first-line treatment for offenders with schizophrenia. Arango *et al*¹⁶ studied patients with schizophrenia and a history of violence. Of those who were violent again, those prescribed oral antipsychotics were violent sooner, and more frequently, than those prescribed depot antipsychotics. The authors link improved adherence to reductions in violence. It may therefore appear counterintuitive that the forensic population studied were prescribed less depot medication than patients in an earlier, mixed population, study⁶ and the rates quoted in the Maudsley guidelines.⁹

Efficacy

Reviews comparing the efficacy of oral and depot antipsychotics^{12,17} report that mirror-image and some large cohort studies have favoured depot preparations but randomised controlled trials (RCTs) have not.

Lafeuille *et al*¹⁸ compared outcomes in patients who relapsed on an oral medication and were then 'switched' to a depot antipsychotic with those who remained on an oral medication. 'Switched' patients had fewer readmissions and fewer emergency presentations. Johnson¹⁹ found that 33 months after being discharged from hospital, 40% of patients prescribed depot antipsychotics relapsed, in comparison with 60% of patients prescribed oral antipsychotics. David & Adams' review³ of non-forensic patients with schizophrenia identified little difference between oral and depot antipsychotics in terms of relapse rates or side-effects, but depot formulations were found superior in bringing about 'important global change'. Leucht *et al*²⁰ present a systematic review and meta-analysis of 10 RCTs carried out between 1975 and 2010; there were significantly fewer relapses in out-patients prescribed depot medication than in those prescribed oral medication.

Psychiatrist attitude

Haddad *et al*²¹ report that 50% of psychiatrists said that their use of depot antipsychotics had reduced in the previous 5 years, and 23% said that their use had increased (the 5-year time-span included the introduction of second-generation depot agents). Despite 89% opining that depot administration was associated with better adherence, and 98% opining that depot administration was associated with reduced relapse rates, only 4% said that depot was their 'first choice' route of administration for patients requiring long-term treatment. The findings from the current study may go some way in explaining the possible cognitive dissonance demonstrated by Haddad *et al*'s findings, i.e. consultant psychiatrists may consider many things other than adherence when deciding on antipsychotic treatment.

Potkin *et al*²² reviewed prescriber-patient conversations and found that depot antipsychotics were discussed only half of the time when a patient prescribed an oral antipsychotic wished to discuss a change in medication.

Advantages and disadvantages of depot antipsychotic medication

Previous studies have commented on perceived advantages and disadvantages of depot medications.^{1,3,12–14,19,22,23} Advantages have included a more constant plasma level, improved bioavailability, reduced availability of medication for overdose, improved adherence, more time to intervene when non-adherence is identified, reduction in family conflict and reduced treatment costs. Studies assessing patient attitude towards depot medication have revealed generally positive attitudes.^{3,22}

Disadvantages have included concern about side-effects, effect on therapeutic relationship, risk of high-dose prescribing, inappropriateness of use post-neuroleptic malignant syndrome, less flexibility and delayed response (i.e. mental state improvement on initiation, side-effect reduction on discontinuation). Potkin *et al*²² found that the usual reason for a patient declining depot medication was needle phobia.

This study adds to the existing literature by providing a forensic perspective on the advantages and disadvantages of depot medication.

Limitations

This study encountered a number of limitations which restrict the generalisability of the findings to wider forensic and indeed non-forensic settings. These include the small sample size, particularly with regard to the community consultants, the use of a non-validated questionnaire, and not including patients in the private sector (who in 2007 accounted for 35% of patients in England).²⁴

Clinical implications

Community teams caring for forensic patients with schizophrenia do not seem to have an expectation that patients should be prescribed a depot antipsychotic medication before they are deemed suitable for their service. It could be argued that given the relatively low rate of depot antipsychotic prescribing found in this study, and the superiority of depot preparations in terms of adherence, readmission and relapse rates, ‘important global change’ and, notably, risk of violence revealed through this literature review, consultants working with forensic populations should consider taking steps to increase their use of depot antipsychotic medications.

Directions for future research

Future research could attempt to evaluate the opinions of a more representative sample of consultant forensic psychiatrists, or the opinions of general adult psychiatrists and non-medical practitioners, particularly nurses,³ who may be expected to receive the handover of patients formerly known to forensic services. It would also be interesting to establish whether or not the perceived effectiveness of different types of antipsychotics influences prescribers’ choices. Future research could further explore the finding that BME patients are more likely to be prescribed a depot antipsychotic than their White counterparts. It may also be useful to undertake a follow-up study, where patients stepped down from high or medium security are followed up some time after discharge and any changes in antipsychotic prescription are identified and investigated.

We are grateful to Dr Chris Clark, Dr Simon Gibbon, Dr Najat Khalifa and Sarah Brennan for their help and advice.

1.7.31 Niemann–Pick type C disease – the tip of the iceberg? A review of neuropsychiatric presentation, diagnosis and treatment

Correspondence

Will Evans (willefans@nhs.net)¹

date

2017-4

Abstract

Niemann–Pick type C (NP-C) disease is a rare neurodegenerative lysosomal storage disorder. It is highly heterogeneous, and there is limited awareness of a substantial subgroup that has an attenuated adolescent/adult-onset disease. In these patients psychiatric features, often a psychosis, may dominate the initial impression, although often there is an associated ataxia and cognitive impairment. Typically, patients experience a substantial diagnostic delay. In this review we highlight the importance of early recognition and discuss the pathophysiology, neuropsychiatric presentation and recent changes in the investigation and work-up of these patients, and treatment options.

(usually an enzyme), leading to altered intracellular synthesis and catabolism.¹ IEMs are individually rare but collectively common. Most are diagnosed during childhood, but there is increasing awareness of later-onset variant forms that may present in adults, often with a mix of both cognitive and psychiatric problems.²

Niemann–Pick type C (NP-C) disease is a neurodegenerative, pan-ethnic, globally occurring lysosomal storage disorder. Lysosomal storage disorders are a subgroup of nearly 60 IEMs that also includes Gaucher's disease, Tay–Sachs disease and the mucopolysaccharidoses. Although the lysosomal storage disorders are individually rare, their collective prevalence is 1:5000;³ they are usually the consequence of an enzyme deficiency and follow an autosomal pattern of inheritance. NP-C is rare, with a 'classical' clinical incidence of approximately 1:100 000.^{4–7} It follows an autosomal inheritance pattern, the result of mutations in one of two genes: *NPC1* (chromosome 18q 11-12) or *NPC2* (chromosome 14q 24.3),⁸ with *NPC1* accounting for 95% of cases.^{4,6} However, unusually, neither of these genes encodes an enzyme; they encode intracellular transporter proteins: *NPC1*, a late endosome/lysosomal transmembrane-bound protein and *NPC2*, a soluble protein.⁹

NP-C, like many other IEMs, has historically been considered a severe neurological and systemic disease of children, but this does not reflect the wide range of its presentations and severities. In a substantial subgroup of patients the illness has an adolescent/adult onset, with cognitive decline and neuropsychiatric symptoms predominating and survival that can extend even into their 7th decade.¹⁰ Most of these patients never receive an accurate diagnosis and for those who do, it is often after many years' delay with frequent misdiagnoses.^{1,4,10–12}

This is a timely review of adult- and adolescent-onset NP-C. A recent publication suggests that the frequency of this late-onset disease may be far higher than the 1:100 000 'classical' incidence.^{4–7,13} Wassif *et al*⁶ predicted a prevalence as high as 1:19 000–36 000, based on exome sequencing data of known disease-causing mutations. With easier and more readily available diagnostic tests, a disease-specific treatment⁴ and ongoing clinical trials, there has never been a more important time for a heightened awareness of NP-C.

Pathophysiology

The lysosome is an intracellular organelle, often termed the recycling centre of the cell. It has an acidic interior containing hydrolytic enzymes (hydrolases). These hydrolases, together with the integral transporter proteins (such as NPC1 and NPC2), traffic, break down and recycle cellular products. A defect in these results in the accumulation of partially metabolised substrates and a shortage of other lysosomal products. This 'traffic jam' leads to a complex chain of events, resulting in cell dysfunction and death and the consequent disease phenotype.

NP-C was described more than 100 years ago by Albert Niemann as an infantile disorder with hepatosplenomegaly and neurodegeneration,⁹ but the exact function of the NPC1 and NPC2 proteins has still to be fully elucidated. We know that a loss of function of either results in an identical clinical phenotype, suggesting a shared pathway for the two proteins. NPC1, a large transmembrane protein of the late endosome/lysosome and NPC2, a soluble lysosomal protein,⁸ work cooperatively to traffic intracellular lipids. Loss of function in either protein leads to the accumulation of cholesterol and a range of sphingolipids in the late endosomal/lysosomal intracellular compartment. This disrupts lysosomal calcium homeostasis, resulting in a host of secondary cellular trafficking defects.¹⁴ The neuropathological sequelae of these defects include Alzheimer's-like neurofibrillary tangles, neuronal degeneration, neuroaxonal dystrophy and demyelination.^{6–18} Also, as endogenously synthesised cholesterol is necessary for axonal membrane maintenance and repair, white matter tracts are severely affected, with the corpus callosum showing the most striking axonal loss.^{18,19} Purkinje cells of the cerebellum, basal ganglia and thalamus are characteristically vulnerable in NP-C, leading to the often pronounced cerebellar dysfunction and ataxia in NP-C patients.¹⁵

Neuropsychiatric presentation

An organic cause can be found in a sizeable proportion of patients presenting with psychosis. For example, Johnstone *et al*²⁰ showed that a causative organic disease could be found in 6% of patients with a first episode of psychosis. Several IEMs are known to cause both psychoses and cognitive decline in adults. A recent systematic review² highlighted six metabolic disorders that should be considered in adult patients with psychosis: homocysteine metabolism disorders, urea cycle disorders, Wilson's disease, acute porphyrias, cerebrotendinous xanthomatosis and NP-C.

NP-C can vary widely in both age at onset and symptoms. A useful classification system subdivides NP-C into four groups based on the onset of neurological disease: early infantile/late infantile/juvenile/adolescent/adult onset.⁴

Typically, the earlier the onset of neurological disease, the more aggressive the disease process (*Fig. 1*).^{4,21,22}

Patients with adolescent/adult-onset NP-C have a neuropsychiatric disease involving varying degrees of cognitive decline, psychiatric and neurological symptoms.⁴ At presentation, psychiatric symptoms often dominate the clinical impression, and a substantial period may pass before neurological symptoms develop or are recognised by treating clinicians.²² In many patients this delay is confounded by early neurological features, commonly an ataxia misinterpreted as a side-effect of psychotropic medication, and the challenge of eliciting subtle cognitive decline in a depressed or psychotic patient.^{22,24} This diagnostic delay is often measured in years or sometimes even decades,^{10,24} with patients frequently receiving a range of incorrect neurological and psychiatric diagnoses before NP-C is confirmed. Incorrect diagnoses made in patients with NP-C include:¹² psychotic syndromes/Alzheimer's disease and frontotemporal dementia/progressive supranuclear palsy/Parkinson's disease/parkinsonism/spinocerebellar ataxia/Wilson's disease/multiple sclerosis/Creutzfeldt–Jakob disease/Wernicke encephalopathy.

Cognitive decline

The neurodegenerative disease leads to dementia in almost all NP-C patients. NP-C is sometimes referred to as 'childhood Alzheimer's'. Although this is used as an easy identifier rather than for its accuracy, the two diseases share some neuropathological features.

In patients with adult/adolescent onset, cognitive decline features to a greater or lesser extent in almost all cases. If found in combination with other disease features, further investigations should be performed.²⁵ To highlight a possible diagnosis, the three most useful clinical features are: cognitive decline, psychosis and progressive ataxia. Consequently, these have been utilised in a patient group-initiated awareness campaign 'Think again, think NPC' (<http://think-npc.com>). This clustering of symptoms to help identify patients has been further investigated by Wijburg *et al*²⁵ who have developed 'The NP-C Suspicion Index'. This index attributes scores to different clinical features to identify the likelihood of a patient having NP-C, with pre-senile cognitive decline (< 40 years) considered a strong indicator.²⁵

The cognitive profile in adult patients with NP-C usually starts with problems in word fluidity, working memory and executive dysfunction.^{4,8,26} There may also be a frontal lobe syndrome with perseveration and loss of interpersonal distance that manifests as excessive familiarity.²⁶ At this early stage of cognitive impairment, the Mini-Mental State Examination (MMSE) often fails to identify deficiencies in these areas. However, with disease progression, a more global impairment of function develops, meeting the diagnostic criteria for dementia.^{4,5,21,22}

Psychiatric symptoms

Psychiatric symptoms associated with NP-C can vary. In juvenile- and adolescent-onset patients, intellectual disability, behavioural problems and attention-deficit hyperactivity disorder (ADHD) have been reported.^{4,11,22} Many of these patients receive further psychiatric diagnoses at a later stage.⁴ One case report describes a patient with an autism spectrum-like disorder preceding a schizophrenia-like illness before eventually receiving their final diagnosis of NP-C.²⁷

In adult patients both affective disorders and psychoses are reported.^{4,5,22} An NP-C case series describes general psychiatric symptoms in 38% of early adult-onset patients,²² with the literature suggesting that a schizophrenia-like disorder

is found in 25–40% of adolescent- and adult-onset NP-C patients.^{4,22} This psychiatric disease may initially be indistinguishable from schizophrenia, with auditory hallucinations, delusions and disorders of thought and behaviour; however, certain features are suggestive of an organic cause: neurological or visceral features, cognitive impairment, treatment resistance or even a paradoxical worsening of psychosis with drug therapy, visual hallucinations, unusual in classical forms of schizophrenia.⁴

Although the psychosis may be resistant to therapy, atypical antipsychotics can be useful, but caution should be taken to avoid worsening of any pre-existing dystonia.^{4,18}

Other major psychiatric illnesses described in NP-C include: depression generally susceptible to selective serotonin reuptake inhibitor (SSRI) therapy,⁴ bipolar disorder, often sensitive to mood stabilisers such as sodium valproate,^{4,18} obsessive–compulsive behaviour, catatonia, often in younger patients and sometimes resistant to treatment, although electroconvulsive therapy (ECT) has been used successfully.^{4,18}

Neurological features

Adolescent- and adult-onset NP-C patients almost always have some neurological features at presentation, although these may at first be subtle and eclipsed by psychiatric features. In the more aggressive late infantile/juvenile-onset group, patients are often first described as being clumsy and struggling at school. This then progresses to the development of frank neurological disease that may include limb and gait ataxia, seizures, gelastic cataplexy (the loss of muscle tone with emotional stimuli), dysarthria, dystonia, dysphagia and dementia. Prognosis in these patients is poor, with death from the consequences of their advanced neurological disease typically in their late teenage years or early adulthood.^{4,7}

Adolescent and adult patients share some of these disease features, but in their case the illness is more insidious in its onset and slower in progression. Cerebellar dysfunction, especially ataxia, is the most commonly identified neurological feature, although dysarthria and dystonia are also frequently present.^{4,18,22} Interestingly, epilepsy, common in infantile and juvenile disease, and cataplexy (20% of classical NP-C patients), are both rarely seen.²²

The most important neurological sign in NP-C, as it is both highly prevalent and specific, is a vertical supranuclear gaze palsy (VSGP).^{4,7} VSGP is seen in only a limited number of other neurodegenerative diseases and rarely so early in their disease process. In NP-C it nearly always heralds the onset of the neuropsychiatric disease, regardless of the patient's age.^{4,22}

The gaze palsy, initially in the vertical plane, progresses to also involve horizontal eye movements as the brainstem pathology advances. Initially, the VSGP is subtle and may be missed. It involves vertical voluntary saccadic movements only, especially of downward gaze, and at this stage slow pursuit eye movements are preserved.⁴ If saccadic eye movements are not tested, the initial VSGP will be missed. Saccadic eye movements are easily tested by requesting the patient to look up and then down in quick repetition. (See <http://think-npc.com/could-it-be-np-c> for a video demonstrating saccadic eye movement testing in NP-C.)

Systemic features

NP-C is a neurovisceral disease, but in adolescents and adults the visceral component is rarely of clinical significance, although splenomegaly with or without hepatomegaly is usually present.⁴

In the perinatal and early juvenile forms, systemic manifestations may be pronounced, with severe and sometimes fatal liver and pulmonary disease.⁴ Interestingly, regardless of the patient's age, visceral disease, when present, always precedes neuropsychiatric features, often by years or even decades. The severity of this visceral disease offers little insight into the likely onset or severity of the patient's later neurological disease.^{4,5} There are cases of patients with paediatric liver disease who only develop neuropsychiatric features many decades later in adulthood.¹²

In adolescent- and adult-onset patients, hepatosplenomegaly – although frequently present – is often unrecognised. When present it is usually less pronounced and nearly always asymptomatic.⁴ The proportion of patients with hepatosplenomegaly in one case series was 85%, but within the adolescent/adult cohort it was reported lower, at nearer to

50%.⁵ However, another group reported that splenomegaly (with or without hepatomegaly) was found on abdominal ultrasound in closer to 90% of patients, regardless of the patient's age.^{4,22} Because of this, Bonnot *et al*² incorporate an abdominal ultrasound scan into their diagnostic 'work-up' algorithm for IEMs causing a schizophrenia-like illness.²

A patient with splenomegaly (especially in the absence of liver disease) with a co-existent neurodegenerative or psychiatric disorder is strongly suggestive of NP-C⁴ and should be appropriately investigated. A history of paediatric liver disease in such patients should also raise clinical suspicion.

Investigation and diagnosis

Rapid advancements in gene sequencing and liquid chromatography/tandem mass spectrometry (LC-MS/MS) have led to significant change in the available approaches to diagnosing NP-C, with both easier and more affordable tests available or in development.²⁸

Bonnot *et al*² suggest an algorithm for the work-up of a patient with a schizophrenia-like illness and a possible IEM. They suggest that with initial suspicion, a clinical and ophthalmological assessment and a cerebral magnetic resonance imaging (MRI) scan should be performed. Subsequent investigations should be performed based on these findings, with an abdominal ultrasound scan to identify hepatosplenomegaly if NP-C is considered. If this is positive, then disease-specific NP-C tests can be performed.² However, this pragmatic approach has some limitations: not all patients with NP-C have hepatosplenomegaly,^{4,5,22} and with easier plasma diagnostic tests available these should be performed earlier in the diagnostic process.

Historically, the diagnosis of NP-C was made histopathologically, by both cholesterol esterification studies and filipin staining of cultured skin fibroblasts,⁴ with most patients receiving a combination of different tests performed prior to this good, but costly and difficult, definitive investigation. These tests may have included: chitotriosidase measurements, white cell enzyme studies to exclude other lysosomal storage disorders, and fluorescent and electron microscopy of both bone marrow aspirate and liver biopsy specimens.²⁸ Because of the difficulties with the filipin staining test, the most widely performed and accessible definitive diagnostic test is now the sequencing of the *NPC1* and *NPC2* genes. Next-generation sequencers make this far easier to perform, especially if the genes concerned are included on a multi-gene panel appropriate for patients presenting with a certain disease phenotype – such as neonatal cholestatic jaundice.²⁹ But this approach is not without some limitations either. In 10% of patients only a single pathogenic mutation can be identified, and in some patients new mutations of uncertain clinical significance may be identified.

More recently, highly specific and sensitive oxidative cholesterol metabolites for NP-C have been identified.³⁰ This 'oxysterol test' can be performed on a plasma sample and is now used as the first-line diagnostic test with subsequent genetic confirmation at one of the principal UK reference laboratories for lysosomal storage disorders. Although it has a positive predictive value of > 97% in an NP-C enriched population such as infants with cholestatic jaundice,²⁸ its accuracy as a screen in broader populations is still being clarified. With the recent advances in LC-MS/MS, other candidate metabolites for diagnostic tests are being identified, with several in the pipeline. These are likely to be available in the near future as cheaper and widely accessible plasma or urine diagnostic tests.²⁸

Treatment options

Disease-specific treatments

Miglustat, a small iminosugar molecule, is licensed in the European Union for the treatment of the progressive neurological manifestations of NP-C in both adults and children.⁴ It reduces the accumulation of the downstream toxic metabolites, glycosphingolipids (GSL), by competitively inhibiting the first step in their synthesis.³¹ It has been shown to stabilise certain key neurological manifestations in a randomised controlled trial (RCT), a retrospective cohort study and in clinical experience.^{4,32,33} However, in adults it may take a year or longer to identify a discernible clinical benefit.⁴

Multiple other therapies are currently under clinical investigation for NP-C, of which two studies are at the Phase 2b/3 pivotal trial stage: arimoclomol, a small molecule that induces the heat shock protein response – a normal cellular stress response³⁴ cyclodextrins, ring-like sugar molecules that reduce lipid storage and in animal models have both substantially reduced the burden of disease and greatly prolonged lifespan.^{35,36}

Symptomatic treatments

Complex neuropsychiatric diseases have a profound effect on the patient, their family and carers. Consideration of the patient's nutritional status, swallow safety and toileting/bowel function, as well as their mobility and safety, is important, with a multidisciplinary team involved and access to appropriate agencies as needed. Timely discussions around issues of capacity, care and end-of-life planning are also necessary.

Cognitive impairment

Appropriate support services should be involved. Although miglustat may stabilise the cognitive decline, there is no evidence that cognitive-enhancing drugs such as cholinesterase inhibitors have a beneficial role.⁴

Psychiatric illness

Psychosis usually responds to antipsychotic medications, but some NP-C patients are resistant to treatment or even show (paradoxical) worsening with the initiation of drug therapy (a useful diagnostic red flag in unidentified NP-C). Atypical antipsychotics should be used and frequent neurological assessments performed to identify worsening of any pre-existing dystonia. If it occurs, dose reduction or an alternative antipsychotic may be used, supplemented if necessary with sodium valproate.⁴ Depression typically responds well to SSRIs,³⁷ and in some patients, when effectively treated, this leads to improvements not only in their mood but also their cognition and neurological disease. Bipolar disorder in NP-C has responded to mood stabilisers such as sodium valproate and catatonia has been treated successfully with ECT.^{4,18} Sleep disturbance in NP-C may manifest as sleep inversion, narcolepsy or obstructive sleep apnoea and can be treated with melatonin and continuous positive airway pressure ventilation (CPAP).⁴

Neurological disease

Patterson *et al*⁴ have published recommended treatment strategies for a range of different NP-C neurological complications.

Prognosis

Accurate prognostic predictions in NP-C are difficult. There is poor genotype-phenotype correlation in disease course, with affected siblings not infrequently following different disease trajectories. The extent and severity of visceral disease offers little insight into the severity of later neurological disease, an additional challenge when counselling parents of a newly diagnosed infant with liver disease.

The most useful prognostic indicator is the age at neuropsychiatric disease onset.

Summary

The largest subgroup of NP-C patients is likely to be an undiagnosed/misdiagnosed adult population with a neuropsychiatric disease. Consequently, NP-C highlights the need for continual diagnostic review in patients with psychosis, especially if there is coexistent cognitive decline and/or ataxia.

1.7.32 The mini-PAT as a multi-source feedback tool for trainees in child and adolescent psychiatry: assessing whether it is fit for purpose

Gill Salmon Lesley Pugsley

date

2017-4

Abstract

This paper discusses the research supporting the use of multi-source feedback (MSF) for doctors and describes the mini-Peer Assessment Tool (mini-PAT), the MSF instrument currently used to assess trainees in child and adolescent psychiatry. The relevance of issues raised in the literature about MSF tools in general is examined in relation to trainees in child and adolescent psychiatry as well as the appropriateness of the mini-PAT for this group. Suggestions for change including modifications to existing MSF tools or the development of a specialty-specific MSF instrument are offered.

 - *Does the mini-PAT suit the needs of trainees in child and adolescent psychiatry?*
 - *Conclusions*

Multi-source feedback (MSF) can motivate doctors to improve and change their practice.^{1,2} It gives doctors an overview of how others see them and compares this with their own view as well as the results of their peer group.³ MSF evolved in Canada and the USA out of a public demand for accountability to patients as well as an acceptance that assessments examining clinical decision-making and medical expertise do not address other essential competencies, such as interpersonal skills, professionalism and communication.³ MSF tools were originally designed to be formative, that is, to lead to awareness of and improvements in performance through feedback. More recently, however, they are being used for summative purposes, namely to provide information for revalidation and the annual review of competence progression (ARCP) which determines whether a trainee is considered fit to proceed with their training. As such, MSF tools need to be sufficiently reliable and valid. Reliability refers to the reproducibility of assessment measures or scores over repeated tests under identical conditions, and validity refers to the degree of confidence that an assessment measures what it is intended to measure. An associated term, feasibility, is a measure of whether an assessment instrument is practical, realistic and sensible given the circumstances and context.⁴

Research on the use of MSF for doctors

Ramsey *et al*⁵ published a landmark study showing that it was feasible for internal medicine physicians to obtain peer assessments about their humanistic qualities, clinical practice and communication skills. They also came to important conclusions about the reliability of MSF – for example, that 11 peer ratings were needed to ensure a reliability coefficient of 0.7 (the minimum acceptable for workplace-based assessments (WPBAs)) and that the results were not substantially affected by the relationship between the rater and the person being rated nor by the method used to select the raters. The findings of this study also suggested that a doctor's medical knowledge (determined by examination marks) was not predictive of how peers subsequently rated their interpersonal relationships or communication skills.

The finding that reliable and valid MSF questionnaires can be developed and be feasible to use for assessing doctors has been replicated across settings and specialties.^{2,6-9} A number of systematic reviews have also been published, all of which conclude that MSF as a method of assessing communication skills, collegiality, humanism and professionalism in doctors has high reliability, validity and feasibility.¹⁰⁻¹⁵

The mini-PAT as an MSF tool

The mini-PAT is used by the Royal College of Psychiatrists as an MSF instrument for trainees. It is well known because of its widespread use in the Foundation Programme.^{16,17} The mini-PAT was derived from the Sheffield Peer Review Assessment Tool (SPRAT) following a mapping exercise against the foundation curriculum,⁶ thus ensuring its content validity. The SPRAT contains 24 questions assessing a doctor's competencies and professional attributes, and it maps directly on to General Medical Council (GMC) standards of good medical practice,¹⁸ again establishing its content validity. These standards include good clinical care, maintaining good medical practice, teaching and training, appraising and assessing, relationships with patients and working with colleagues. The SPRAT was the first MSF tool validated in the UK for use by paediatric consultants as part of their appraisal.¹⁹ It has also been shown to be reliable, needing as few as four raters to determine whether a doctor is in difficulty or not (more in borderline situations), and feasible, taking only 5–6 minutes to use with good return rates (more than 70%).²⁰ It can also discriminate between the more and less experienced trainee.²¹

In developing the mini-PAT, nine questions which did not map on to the curriculum for the Foundation Programme were removed from the SPRAT. These included questions relating to the management of complex patients and leadership. One question about probity and health was added while the free-text element and six-point scale (where 1 indicates 'very poor' and 6 indicates 'very good') remained unchanged.⁶ The resulting mini-PAT was thought to reflect the importance for foundation doctors of developing communication skills, team work and other humanistic qualities in relation to patient care in addition to their medical knowledge.³

In his critical analysis of the mini-PAT, while accepting its content validity and feasibility, Abdulla stated that it 'lacks sufficient field evaluation and has not gone through any stringent criteria that are required for the validation of an assessment tool'.³ Data on the reliability and validity of 693 mini-PAT assessments on 553 foundation year 1 and 2 (F1/F2) doctors have subsequently been published.⁶ The mean scores of the two groups were found to be significantly different when using the same criterion standard (i.e. expectation for F2 completion), with 19.6% of F1s and 5.6% of F2s being assessed as borderline or below the expectations for F2 completion. This was used as evidence of internal standardisation and construct validity, as was the finding that the trainees scored higher in the domains of working with colleagues and relationships with patients compared with the clinical skills domains. Overall, 53% of F1 doctors and 74% of F2 doctors could have been assessed by no more than 8 assessors based on their mean scores. Factor analysis revealed that the two main factors were humanistic qualities and clinical performance. The authors concluded that the mini-PAT was a valid and reliable MSF tool for assessing foundation doctors.

Use of the mini-PAT in child and adolescent psychiatry training

In child and adolescent psychiatry, the process when using the mini-PAT is as follows: twice a year, the trainee provides contact details of between 8 and 12 co-workers who see them on a frequent basis in a range of situations. These people and the trainee then complete the mini-PAT online. Presumably based on the findings of Archer *et al*,⁶ it is suggested that at least 8 forms must be completed to ensure the assessment is reliable. There is, however, no research specifically related to the mini-PAT on the minimum number of assessors required to give a valid result.³ The form uses a 6-point Likert-type rating scale. Trainees are rated according to the standard expected at each stage of training. A score of 4 corresponds to the expected standard, with higher or lower scores suggesting the trainee's performance is better or worse.²² The responses are analysed centrally and a report is then sent to the trainee's educational supervisor who delivers the feedback in person.²³

Potential issues with using MSF tools

Several issues that have been identified in relation to the use of MSF tools for medical practitioners in general are also relevant to their use in child and adolescent psychiatry. One is the trainee's choice of rater. Although several authors have found that MSF assessment is not necessarily biased by allowing the doctor to select their own raters,^{5,24,25} others have found that factors such as the seniority, gender and profession of raters can significantly influence the assessment. For example, Archer *et al*²¹ found that consultant raters using the SPRAT gave significantly lower mean scores to paediatric trainees than more junior doctors did; similarly, Bullock *et al*²⁶ found that consultants and senior nurses were more likely to give 'concern' ratings when assessing junior doctors than were peers or administrators. Thus, there is a trend for assessors to be more critical with increasing seniority. When considering the mini-PAT, Archer *et al*⁶ found that assessors' scores were affected by their occupation, the length of time the trainee had been working with them, and the working environment. They suggested standardising the number of consultants used as raters by each trainee. These findings support the need for more detailed guidance in rater selection from the Royal College of Psychiatrists. Trainees are currently only advised that raters be chosen from a broad range of co-workers.⁴ In addition, Abdulla³ suggests that selection bias can be reduced if the list of raters is discussed and agreed on beforehand with the trainee's supervisor.

Measurement errors, such as the central tendency and halo effect, can also occur and are particularly likely when behaviours which cannot be easily observed are being assessed.²⁷ A particular issue for non-doctor raters is knowing what standards they should expect for a doctor at that stage in their training. In an attempt to reduce measurement errors, Abdulla³ suggests better education for mini-PAT raters. This could be provided by the Royal College of Psychiatrists as part of their online mini-PAT package.

It has been shown that doctors' self-assessments do not correlate well with peer or patient ratings.^{7,28} Violato & Lockyer²⁹ studied psychiatrists, internal medicine physicians and paediatricians, and found that all were inaccurate in assessing their own performance. Those psychiatrists who were rated by peers to be in the bottom quartile saw themselves as 'average', whereas the psychiatrists in the top quartile significantly underrated themselves. This indicates that poorly performing doctors often lack insight, not always accepting negative feedback from others and querying its validity.³⁰ Overeem *et al*³¹ advise that trained facilitators should encourage trainees to reflect on MSF results and help them set concrete goals for improvement. Offering coaching to help trainees identify their strengths and weaknesses may help facilitate changes in performance.³² Making the feedback highly structured can help trainees acknowledge feedback from all sources rather than just the medical scores which they tend to value more.^{5,33-35} Although taking the mean of the scores may be the most reliable approach,³⁶ attention should also be given to the free-text comments which might highlight specific performance issues and which may also make the feedback more acceptable.³⁵ These findings highlight the importance of the MSF feedback process, which should include the development of a relevant action plan in collaboration with the doctor.

It has been proposed that a single, generic MSF tool be used in the UK.³⁷ Research supporting this includes Violato & Lockyer's^{29,38} study of the use of one MSF tool for internal medicine physicians, paediatricians and psychiatrists. Although they found no specialty differences in response rates or reliability, it is of note that of the items clustered into the same four factors across the specialties, for psychiatry the most discriminating factor was communication whereas for the other two specialties the most important was patient management. By contrast, Mackillop *et al*³⁹ evaluated the

use of a generic MSF tool across specialties and concluded that, although the generic content was appropriate for most specialties, some would benefit from specialty-specific content.

Does the mini-PAT suit the needs of trainees in child and adolescent psychiatry?

In child and adolescent psychiatry, the mini-PAT is currently used to assess trainees. Although the mini-PAT has content validity for foundation doctors, having been mapped against their curriculum, this does not necessarily mean it is also a valid tool for other grades or for use across specialties. In the making of the mini-PAT, some questions were removed from the SPRAT, namely those relating to management of complex patients and leadership.⁶ However, these items are highly relevant to trainees in child and adolescent psychiatry. Davies *et al*⁴⁰ modified the SPRAT for trainees in histopathology following a blueprinting exercise against the histopathology curriculum to establish content validity. They concluded that specialty-specific MSF is feasible and achieves satisfactory reliability. A similar approach blueprinting the SPRAT against the child and adolescent psychiatry competency-based curriculum⁴¹ could therefore be considered. The SPRAT also requires fewer raters than the mini-PAT in order for the results to be sufficiently reliable,⁶ thus adding to its potential suitability for child psychiatry trainees who often work in small teams.

Alternatively, a specialty-specific MSF instrument for child and adolescent psychiatry trainees could be developed, to reflect the differences in their practice compared with other specialties and the greater importance placed on communication, interpersonal skills, emotional intelligence and relationship building.⁴ Tools taking these attributes into account have been developed for use with consultant psychiatrists and have been found to be feasible to use as well as being reliable and valid.^{42,43} The child and adolescent psychiatry competency-based curriculum⁴¹ gives details of intended learning outcomes (ILOs), which are either mandatory or selective, some of which tap into these areas. The ILOs range from those that are predominantly clinical (e.g. managing emergencies (mandatory), paediatric psychopharmacology (mandatory) and paediatric liaison (selective)) to those that focus on more humanistic skills (e.g. professionalism (mandatory) and establishing and maintaining therapeutic relationships with children, adolescents and families (mandatory)). The ILO on professionalism includes: 'practicing Child and Adolescent Psychiatry in a professional and ethical manner; child and family centred practice; understanding the impact of stigma and other barriers to accessing mental health services and inter-professional and multi-agency working'.⁴¹ Some of the necessary associated skills which trainees are expected to attain include: supervising junior psychiatric staff, working with colleagues within the team and with other agencies to put the child's needs as central, and acting as an advocate for the child. There is scope to develop this area of the curriculum even further; the American Board of Pediatrics (ABP) published guidelines for the teaching and evaluation of professionalism in paediatric residency programmes⁴⁴ as well as standards of professional behaviour against which paediatricians, including those in training, can be evaluated.⁴⁵ Both are of relevance to child and adolescent psychiatrists.

If developed, a child and adolescent psychiatry specialty-specific MSF instrument would need to map on to the relevant ILOs. It could also include feedback from patients and families (which is not currently routinely collected as part of the WPBAs) to reflect the need to balance the views of the child (who is the patient) with those of their carers.

Conclusions

MSF tools such as the mini-PAT can provide reliable and valid information on areas of a trainee's performance such as communication skills and other humanistic qualities affecting patient care for which other forms of assessment, such as written examinations, are unhelpful. MSF tools have their predominant strength when used for formative assessment and were generally designed for this purpose. They are most appropriately used within a portfolio of other WPBAs and can help in making decisions about a doctor's fitness to practice or to continue training.⁴⁶ Rater bias and measurement error could be reduced by offering more detailed guidance to trainees in their choice of rater as well as to raters in the use of the tool. Measurement error could also be reduced by encouraging trainees to obtain a larger number of returns than the minimum of eight recommended by the Royal College of Psychiatrists.³ The quality of the feedback to the trainee is also important and educational supervisors would benefit from training in this area.

Although the mini-PAT is used widely across specialties, it has only been properly evaluated for use with foundation doctors. Interested researchers, clinicians or educationalists might now want to consider developing a modified version of the SPRAT or a specialty-specific MSF tool that is more appropriate for the needs of trainees in child and adolescent

psychiatry. This would reflect the differences in their day-to-day practice compared with that of other trainees but would obviously need to be mapped to the curriculum and evaluated in practice to ensure content validity and reliability.

1.7.33 James Patrick Watson MD, FRCP, FRCPsych

: Formerly Professor of Psychiatry, King's College London and Honorary Consultant Psychiatrist, South London and Maudsley NHS Trust

- *James Patrick Watson MD, FRCP, FRCPsych*
 - : *Formerly Professor of Psychiatry, King's College London and Honorary Consultant Psychiatrist, South London and Maudsley NHS Trust*

James (Jim) Watson, who died after a stroke on 3 August 2016 aged 80, was among a small band of British psychiatrists who trained in the 1960s and 70s to take psychiatry out of the asylums and establish robust services in general hospital and community settings. They were also responsible for developing a wide range of specialist mental health services. Jim was deeply committed to improving the standards of clinical care, from early implementation of behavioural therapy through in-patient group therapies and the understanding and management of behaviour on hospital wards. He championed the relationship between staff and patient as key to recovery in psychiatry, deploring the move to ever fewer acute beds, reductions in staffing levels and organisational changes that resulted in fractured continuity of care and consequent erosion of the essence of good mental healthcare.

His clinical interest was reflected in his research, which included evaluations of community mental health, telemedicine and treatments for psychosexual disorders, for which he established one of the earliest specialist multidisciplinary clinics and training programmes in Britain. With his personal style, he led a vibrant, outward-facing, creative and very happy department, in which a serious commitment to excellence went along with a refreshing lack of pomposity and a keen sense of work being enjoyable. This was in no small part due to Jim's dedication to improving the quality of psychiatric services, not least by ensuring excellence in the education and training of psychiatrists and by making sure that medical students had a varied and stimulating exposure to psychiatry.

Under his leadership, Guy's Hospital Medical School had the enviable reputation of having the highest proportion of medical students opting for a career in psychiatry. In the postgraduate field, he was an inspirational leader of the South East of England training scheme for psychiatry, chairman of the Royal College of Psychiatrists' Specialist Training Committee and chairman of the Association of University Teachers of Psychiatry. In the mid-1990s he launched an MSc in mental health studies – a programme directed at professionals from all disciplines involved in delivering mental health services. This course was extraordinarily successful: consistently oversubscribed, with unprecedented numbers of applicants. Its success spawned further collaborations with university departments overseas, notably in Egypt and the Middle East, where he worked with colleagues to develop a diploma in psychiatric practice for wider dissemination across the region. His determination to improve mental healthcare led him to a lengthy involvement with mental healthcare in Pakistan. From the early 1990s, he collaborated with colleagues there, visiting regularly and helping to train staff for mental health clinics in rural settings that have now expanded to more than 15 centres, some of which are co-located with a mosque and madrasa. Jim was also connected with several other international projects involving, among other countries, Greece and the former Yugoslavia.

Jim was the eldest of three sons. His father was a teacher and his mother a doctor. He attended the Roan School for Boys in Greenwich, where he excelled academically and in sport. He studied medicine at Trinity College, Cambridge,

where he was a senior scholar. In 1957 he transferred to King's College Hospital Medical School for clinical studies, qualifying in April 1960. It was there that he met his fellow student and future wife Christine Colley – they were married in April 1962.

After training in psychiatry at the Bethlem Royal and Maudsley Hospitals and Institute of Psychiatry, he was appointed as consultant and senior lecturer in psychiatry at St George's Hospital London in May 1971. He was appointed to the Chair of Psychiatry at Guy's Hospital Medical School in September 1974, steering his department through the union with St Thomas's Hospital in 1982 and onward to the final merger with King's College in 2000. In addition, he served as honorary consultant psychiatrist to the British Army from 1980 to 2000 and was the vice-president of the Royal College of Psychiatrists from 1998 to his retirement.

After retirement, Jim continued to contribute actively to the field, providing teaching and mentorship to psychiatrists in the Sussex Partnership NHS Foundation Trust. He maintained his collaboration with colleagues in Pakistan, advising on setting up a new School of Nursing as well as the development of a service and training resource for children with learning disabilities and autism. He took part in continuing education meetings with colleagues in Cheltenham, chaired a patient support group in a local general practitioner practice and was trustee of the Soundwell Music Therapy Trust which provides music therapy for people suffering from mental ill health.

Jim enjoyed a very happy family life, having four sons whose diverse careers in music, international school teaching, hospital medicine and clinical psychology were a great source of pride and affection. In 2002, he and Christine exchanged London life for a Cotswold home where he could indulge his enthusiasm for vegetable gardening – a throwback to his maternal ancestors who had traded as market gardeners, supplying mustard and cress to Queen Victoria.

Jim's passing will be felt as a great loss to psychiatry and by the many clinical and academic colleagues who had the privilege of knowing and working with him.

1.7.34 Irving Gottesman

: American psychologist and behaviour geneticist who radically changed traditional views of schizophrenia

Peter McGuffin

date

2017-4

Contents

- *Irving Gottesman*
 - : *American psychologist and behaviour geneticist who radically changed traditional views of schizophrenia*

The research and writings of the clinical psychologist and behaviour geneticist Irving Gottesman, who has died aged 85, radically changed the way psychologists and psychiatrists think about schizophrenia and, more generally, about

what Irv called the ‘origins of madness’ (which was the subtitle of his 1991 book *Schizophrenia Genesis*).

His path to becoming a dominant figure in psychiatric genetics began at an international conference in 1961 when, as a psychology lecturer at Harvard University, he was introduced to Eliot Slater, director of the Medical Research Council (MRC) psychiatric genetics unit at the Institute of Psychiatry in London, and the doyen of psychiatric genetics of his day.

Slater agreed that Irv might join his unit provided he brought his own funding. Irv duly won a three-year grant from the US National Institutes of Health (NIH) and arrived in London in 1963. Slater was an austere and imposing figure and the building that housed his unit was equally austere, a makeshift postwar prefabricated building, affectionately known by staff as ‘the hut’, on the fringe of the campus of the Maudsley hospital in Camberwell. Although its physical environment was poor, the unit had much intellectual capital, provided by Slater himself, his deputy director Valerie Cowie, a psychiatrist trained in the new techniques of cytogenetics, and a brilliant if self-effacing senior research assistant, Jerry Shields.

The hut also housed another world-class asset, the Maudsley Twin Register. Begun by Slater in 1948, it contained the names of all patients entering the Maudsley and Bethlem Royal hospitals who had been born a twin. Irv’s successful NIH proposal was for a study of schizophrenia using the register and Slater paired him with Shields to carry out the work.

The principle of the classic twin method is straight-forward. Identical or monozygotic (MZ) twins share all their genes, whereas fraternal or dizygotic (DZ) twins share half their genes. MZ and DZ twins usually share the environment in which they are raised. Therefore if a disorder such as schizophrenia shows greater co-occurrence (‘concordance’) in MZ versus DZ twins this is evidence of a genetic effect. Similarly, absence of 100% concordance in MZ twins is evidence of environmental effects. The Gottesman-Shields Twin Study (1967) clearly confirmed the proposition that both genes and environment play a role in schizophrenia (at a time when theorists in the US and Britain were blaming parents, particularly mothers, for ‘causing’ the disorder).

One of Irv and Jerry’s major contributions was to propose a plausible mode of inheritance for schizophrenia. One of the big puzzles about familial common diseases at the time was that none (including physical disorders such as heart disease, diabetes, some cancers) showed the simple ratios of affected:unaffected within families predicted by Mendel’s laws.

The most widely accepted solution for schizophrenia was Slater’s model invoking the idea of a dominant gene with ‘incomplete penetrance’ (some people carry the gene but do not show the disorder). Irv and Jerry boldly proposed an alternative polygenic model, derived from the work of the Edinburgh mathematical geneticist DS (Douglas) Falconer, in which liability to develop schizophrenia has a normal ‘bell-shaped’ distribution in the population (like height or weight) contributed to by many genes. But, unlike height or weight, there is a threshold effect, so that only the 1% or so of the population with the highest liability show the disorder.

The Gottesman-Shields polygenic model of schizophrenia eventually gained ascendancy, even though the final clinching piece of evidence emerged only in 2014 with the publication of a huge genome-wide molecular study of tens of thousands of subjects showing that more than 100 genes are involved.

Another far-reaching conceptual innovation was their idea of ‘endophenotypes’. Irv and Jerry proposed in their 1972 book, *Schizophrenia and Genetics*, that the genetic basis of psychiatric disorders could be better understood, and specific genes more readily identified, by the discovery of biological characteristics that lie a step closer to DNA than the clinically observable symptoms and signs, the ‘exophenotypes’, by which disorders are defined. Irv continued to elaborate the endophenotype concept over ensuing years and it provoked thousands of papers by others, a sort of Higgs boson for biological psychiatry. Unlike the Higgs particle, the existence of endophenotypes has yet to be proved experimentally for any of the major disorders.

Irv was born in Cleveland, Ohio, to Hungarian-Romanian Jewish emigre parents, Bernard, an insurance agent, and Virginia (nee Weitzner). He was a science enthusiast from an early age and began a physics degree while serving as an officer in the US navy, later switching to psychology. He completed his PhD at the University of Minnesota on the genetics of personality but initially had great difficulty in getting his findings published because of the prevailing orthodoxy in US academia in the late 1950s that behaviour was entirely due to nurture and nothing to do with nature.

After his postdoctoral fellowship in London, Irv returned in 1966 to the biology-friendly department of psychology in

Minneapolis and set up one of the first behaviour genetics training programmes in the US. He thereafter held chairs in Washington University in St Louis (1980–85), where I first came under his mentorship as a visiting MRC fellow, and at the University of Virginia (1986–2001), where he set up a clinical psychology doctorate, before returning to Minnesota, where he remained for the rest of his career.

He won many plaudits and prizes worldwide but retained particular affection for and gratitude to the UK, where his recent awards included honorary fellowship of the Royal College of Psychiatrists and King's College London.

Irv is survived by his wife, Carol (nee Applen), whom he married in 1970, and their sons, Adam and David, and grandchildren, Josh, Ava and Fiona.

1.7.35 The Other Side of Silence: A Psychiatrist's Memoir of Depression

Tom Brown¹

date

2017-4

Contents

- *The Other Side of Silence: A Psychiatrist's Memoir of Depression*

Linda Gask is an eminent academic psychiatrist with an outstanding international reputation. I state this upfront because it is none too obvious from this book – owing to her self-effacing style – and in my opinion, it is very relevant. I should also declare an interest as Linda and I were in the same year at Edinburgh University's medical school and I have heard small snippets of this story from her over the ensuing years.

In this excellent book Linda Gask shows what may be achieved despite living with a recurrent depressive illness; hope emerges even from her darkest moments and this work should encourage many. It is striking for its frankness and honesty – no small achievement given that she clearly must have known it would be read not only by colleagues, but by patients past and present, some of whom would have known little about her. She even mentions her failure to pass the MRCPsych exam at the first attempt and describes her – surprising to some! – experience of how sensitive and supportive a very senior academic colleague was at this time.

The book chronicles her life and career and the impact of her illness, including thoughtful reflections on its roots (in her early life). She teaches us about depression through the mirror of her own illness and that of her patients, and brings this to life through the use of clinical vignettes. She emphasises the importance of both biological and psychosocial factors in the origins of this illness and her description of treatments is both fair and accurate. Her accounts of her interactions with patients are particularly helpful and should be of value to any doctor, whether trainee or senior. I especially valued her comments on those whose failure to improve is ascribed to personality disorder, which is, alas, an all too common tactic of many psychiatrists.

This is an exceptional book and should be read by many, both doctors and patients. The high-profile endorsements on the cover are entirely deserved. Some years ago Linda wrote another excellent book entitled *A Short Introduction to Psychiatry*. I gave it to many medical students to read. I will give this to many more.

1.7.36 Mentalisation-Based Group Therapy (MBT-G): A Theoretical, Clinical, and Research Manual

Gwen Adshead¹

date

2017-4

Contents

- *Mentalisation-Based Group Therapy (MBT-G): A Theoretical, Clinical, and Research Manual*

This book presents a challenge for a reviewer because it is both a theoretical text and a technical manual. The technique in question is mentalisation-based group therapy (MBT-G) and one of this book's functions is to assist supervisors of MBT-G in rating therapists on quality of technique and adherence to the MBT-G guidelines. So, at first sight, you might not be drawn to this publication unless you are a group therapist – and trained in MBT-G.

However, I encourage people who are not psychotherapists or trained in MBT to consider this manual as a useful introduction to the concept of mentalising. Mentalisation is an old concept in psychology and refers to our human ability to understand ourselves as agents who make choices and form intentions. This ability includes an understanding and perception of *other* people as having minds that form intentions, which are real and distinct from our own.

All psychiatrists need a valid and reliable model of mind with which to work clinically, and the concept of mentalisation fits the bill. Mentalising capacities are crucial to our social existence, across the lifespan; failure to mentalise successfully is a feature of all mental disorders. The healthy mind is constantly mentalising, with odd lapses in reasoning and dialogue that are neither too severe nor too frequent. When the mind is disordered – through any cause – mentalising fails and immature modes of thinking dominate, often with catastrophic results in terms of social identity and function. The restoration of mentalising then becomes a crucial aspect of all psychiatric treatment.

There are several books on mentalising and mentalisation-based therapy by Karterud's collaborators in the UK (Peter Fonagy and Anthony Bateman) and the USA (Jon Allen). I found this particular book of interest because it approaches mentalising from a philosophical perspective: that of hermeneutics and how we interpret the world. Karterud suggests that the way we interact with and interpret others comes before our experience of our own minds; that the social self is

primary in developmental terms. Such a relational approach to mind is a vital complement to models of mind that are either atomistic or mechanical. We have no evidence that the mind works like a machine, but there is growing evidence that the mind is organic and dynamic, responding, developing and evolving in response to the environment – which, for human beings, is the experience of other minds.

MBT is recommended by the National Institute for Health and Care Excellence for the treatment of borderline personality disorder and treatment trials of MBT for antisocial personality disorder are ongoing. But understanding mentalising is a broader objective which all psychiatrists need to achieve. This work is obviously essential reading for trained MBT-G therapists, but it is a useful introduction to mentalising in its own right.

1.7.37 The Narcissist Next Door. Understanding the Monster in Your Family, in Your Office, in Your Bed – in Your World

Jon Patrick¹

date

2017-4

Contents

- *The Narcissist Next Door. Understanding the Monster in Your Family, in Your Office, in Your Bed – in Your World*

I find myself split in my thinking about this book. On the one hand, I can see its appeal as an airport read; requiring little effort to get through, and full of celebrity and political commentary as well as easily digestible chunks of scientific evidence.

At that level, it's enjoyable. Especially so when it allowed me to neatly project all my ugly narcissism into reports about Kanye West and Sarah Palin. Perhaps a first for them to be mentioned in the *Bulletin*, no doubt adding to their narcissistic satisfaction, should they or their agents be subscribers.

At another level – and this is where I'm split – it is an exercise in quite contemptuous character assassination. Kluger's portrayal of his example subjects is cold and sneering at times. Furthermore, he often seems to conflate the concepts of narcissism and psychopathy, leading to a sense that the more narcissistic of us are one step away from becoming serial killers or workplace tyrants.

There are only brief mentions of how the presentation of narcissism might be related to inner vulnerability, and this left me wondering if Kluger might have been looking at the mirror crack'd. Even as I write this I wonder if I too am succumbing to the narcissistic appeal to feel superior to what we read – this is hard to contain when I am a UK reader and the author mentions former prime minister 'Malcolm Browne' (referring to Gordon) and the football team 'Aston Vista'. Such mistakes feel sloppy, arousing my narcissistic contempt; perhaps a response to feeling as though the author does not care enough about the UK to check facts properly.

Coming from a psychoanalytic tradition, where this subject has been a preoccupation of clinicians since Freud's 1914 *On Narcissism: An Introduction*, Kluger's view on the dilemma of the narcissist saddened me. We are all narcissists to

some degree; it's what allows us to get out of bed in the morning and feel like we are good people who might be loved. The pathological narcissist is someone who has found their early experiences to be lacking and who has lost their trust in acceptance by others. To manage this insufferable situation, they create an outer self that is contemptuous of need and full of itself, and project away their dependent, vulnerable selves onto others. Sometimes, they are contemptuous and dismissive of needy people. Sometimes, if society is lucky, and the person more creative, they will look after others who are vulnerable – to repair the damage they feel inside themselves.

1.7.38 The Vegetarian

Ginevra Read¹

date

2017-4

Contents

- *The Vegetarian*

This short novel, winner of the Man Booker International Prize 2016, is translated from Korean and tells the story of Yeong-hye, a young woman in modern day South Korea. It is a fascinating and thought-provoking narrative that starts with Yeong-hye choosing to become vegetarian. This seemingly unremarkable and straightforward choice turns out to be nothing of the sort – vegetarianism is almost unheard of in Korea but, more importantly, Yeong-hye is on the verge of serious mental illness. Yeong-hye's stance is challenged by all of those around her, but she remains steadfast. It transpires that becoming vegetarian is the prodromal seed of an all-encompassing psychosis which will take Yeong-hye on a journey from being vegetarian to believing that she is vegetal in nature and therefore food is superfluous to her needs.

Clinicians will be acquainted with the somewhat perplexing process by which this intricate and emotive story develops. Information appears not in neat chronological order but in a tangle that needs some work to unpick. Yeong-hye's story is told in three parts. We hear first from her husband, then her brother-in-law and finally her sister, all the while following the unravelling of Yeong-hye's internal and external world, in a tale that deepens in complexity and darkness as it unfolds. Interspersed italicised monologues allow us a brief glimpse of Yeong-hye's muddled (and muddling) mind. By portraying thoughts that mingle with dreams and memories in a way that confuses the reader as to what is real and what is not, Kang elegantly conveys something of Yeong-hye's mental state. We don't hear much about Yeong-hye's premorbid adult life, other than through her husband, who says she was 'ordinary' and functioned to his liking. We can, however, sense the weight of the oppression she is subject to and guess that although becoming vegetarian may have marked an important transition point in her illness, it is unlikely to have been the beginning of it. The husband's account of Yeong-hye's condition reveals, through the lens of his own narcissism, a shocking lack of concern for his wife beyond her role in satisfying his immediate needs. He views Yeong-hye as an object and a possession, and this is most apparent in his remorseless and matter-of-fact description of raping her. A meal with her husband's boss tells us something about society's inflexible expectations and demonstrates that the lack of compassion experienced by Yeong-hye is multifaceted. We see Yeong-hye's father in action and learn a little about her upbringing; as a result, the degree

to which she has been repressed and forced to endure throughout her life becomes clearer, and the powerful, subversive resistance enacted through her illness begins to make sense.

The second part of the book is equally disturbing and leads us to the brother-in-law, a less than successful video-artist who becomes obsessed with Yeong-hye's pre-pubertal appearance and whose paraphilic behaviour uncomfortably exposes her vulnerability.

In the final part of the book, several years later, we join Yeong-hye's sister In-hye as she visits her in a psychiatric hospital. In-hye now faces the repercussions of preceding events and the resulting family disintegration. We hear more about the sisters' childhood and the abuse which they experienced; we learn that In-hye continues to suffer her own anguish as a corollary and that she in some way envies her sister's position.

This is an astonishing book. Strange, surreal and beautifully written. The idea that people could find themselves surrounded by such brutal inhumanity and lack of connection that they reject their current existence and instead opt for transformation into a life form that does not involve thought or feeling is indescribably sad, but probably not beyond imagination for most psychiatrists. Readers will find that they must piece together the jigsaw of Yeong-hye's life, and as hard as they try, the image is not clear and the final pieces can never be found – an experience to which most of us surely relate.

1.7.39 The Psychedelic Policy Quagmire: Health, Law, Freedom, and Society

Adam G. Van Hagen¹

2017-4

Contents

- *The Psychedelic Policy Quagmire: Health, Law, Freedom, and Society*

The resurgence of psychedelic research has opened up a new realm of possibilities in consciousness research. However, public policy surrounding the use of psychedelics has struggled to acknowledge that they may be effective therapeutic treatments or tools for enhancing self-awareness and exploring consciousness. Highlighting the need for redress, this anthology argues that current international public policy is not scientifically or culturally informed and is thus divorced from the empirical evidence that is supposed to inform its construction and implementation.

The book examines the complex policy issues surrounding psychedelic-based healing modalities and calls for an urgent shift in policy regulating the research and application of psychedelic substances. At its core, it is a scathing criticism of legal frameworks and regulatory policies that control the use of and research on psychedelics, and goes so far as to suggest that current structures and mechanisms impose a status quo of consciousness, thereby preventing people from fully enacting their right to freedom of religion, thought and conscience. At the very least, policy makers and ethicists need to give due attention to medical and psychotherapeutic research on psychedelics and the role they have in facilitating direct spiritual experiences. This includes acknowledging the transformative effect that experience may have on the self, as well as the right of all people to freedom of religion, thought and conscience.

Any book that rates these substances highly as a connection between the individual, society and the human race as a whole will find its detractors. That being said, *The Psychedelic Policy Quagmire* presents a strong case for the notion that psychedelics have transcended seemingly outdated legal, academic, cultural and spiritual paradigms. Although – by the editors’ own admission – this volume is by no means definitive, it will undoubtedly prove to be a lightning rod in the academic community. With its focus on research and policy that maximise the benefits of the use of psychedelics, reduce the potential dangers of misuse and remove impediments to achieving these ends, it is inevitable that this book will be a catalyst for lively and robust debate. Recommended to academics and researchers in various fields, including psychology, psychiatry, anthropology and the arts, this work should challenge many long-held assumptions about these fascinating substances.

1.7.40 Spirituality and Narrative in Psychiatric Practice: Stories of Mind and Soul

Paramabandhu Groves¹

- *Spirituality and Narrative in Psychiatric Practice: Stories of Mind and Soul*

Telling stories is probably as old as human culture. Our ancestors used storytelling to entertain, instruct and make sense of their experience. A psychiatric history, when well taken, should be more than a fact-finding mission to provide a diagnosis and treatment plan. To be effective in providing treatment, helping with healing and promoting recovery, we need to know what matters to our patients. This includes the realm of belief and practice encompassed by the broad term spirituality. A book then that explores both spirituality and narrative is welcome.

Spirituality and Narrative in Psychiatric Practice, like the term spirituality, is broad in its scope. On the one hand, we have agnostic atheist Jeremy Holmes describing in his chapter “Meaning without ‘believing’ ” the spiritual nature of mentalising. As he puts it, ‘an intensely practical and loving pathway to spiritual aliveness’. On the other hand, there are writers from a theistic background, such as mental health chaplain Beaumont Stevenson, who considers how God or a higher power may manifest in the everyday stories of patients, providing a greater frame of reference than the story of self that often limits a human’s potential. The early chapters give a range of perspectives on narrative. With characteristic clarity Andrew Sims indicates how through careful psychopathological appraisal from attending to the patient’s story, it is possible to distinguish between spiritual experiences and psychiatric symptoms. Later chapters explore narrative and spirituality in a wide variety of themes such as affective disorders, offending behaviour, psychosis and the end of life.

The subtitle of the book is *Stories of Mind and Soul* and it is the stories that really shine. To preserve anonymity some are composite – made up from several people’s histories or typical examples – and therefore feel somewhat artificial; nevertheless, they engage the reader and serve didactic purposes well. Others are the words of individuals who have been willing to share their stories, and these have a greater ring of authenticity. In particular, the chapter by Jo Barber stands out as an honest and moving account of someone who has struggled with mental health problems and for whom

spirituality has been important – at times problematic but often a resource that has supported her ongoing journey of recovery.

As the editors note in their concluding chapter, pressures on service delivery may get in the way of the time and space to listen well to patients' narratives. However, for good psychiatric practice, not taking a good history is a short-cut we can ill afford. This work is a timely reminder of the importance of the fundamental tool of psychiatry and a welcome enjoiner to attend to what is significant to our patients.

1.7.41 Big data in mental health research – do the *ns* justify the means? Using large data-sets of electronic health records for mental health research

Abstract

Advances in information technology and data storage, so-called 'big data', have the potential to dramatically change the way we do research. We are presented with the possibility of whole-population data, collected over multiple time points and including detailed demographic information usually only available in expensive and labour-intensive surveys, but at a fraction of the cost and effort. Typically, accounts highlight the sheer volume of data available in terms of terabytes (10^{12}) and petabytes (10^{15}) of data while charting the exponential growth in computing power we can use to make sense of this. Presented with resources of such dizzying magnitude it is easy to lose sight of the potential limitations when the amount of data itself appears unlimited. In this short account I look at some recent advances in electronic health data that are relevant for mental health research while highlighting some of the potential pitfalls.

Recent advances

The most extensive electronic health data available for research in the UK are collected in primary care. For example, the Clinical Practice Research Datalink (CPRD) covers approximately 5 million active patients, with longitudinal records going back to 1987. This in turn is now linked to hospital episode statistics (HES) and mortality data, providing one of the world's largest longitudinal health data-sets. ¹ As with any big data project much depends on the quality of the data. This may be enhanced in primary care, as general practitioners (GPs) have a financial incentive to accurately record certain treatments and outcomes under the quality and outcomes framework (QOF). ²

While there is no national equivalent for psychiatric care, HES data provide at least some information about psychiatric in-patient stays nationally. There are also examples of local schemes providing comprehensive psychiatric data for research use, often on a very large scale. For example, the Case Register Interactive Search (CRIS) system covers the full clinical record of over 250 000 patients from the South London and Maudsley (SLAM) catchment area. ^{3,4} This can be linked with neighbourhood census data, primary care records, HES data and educational data from the National Pupil Database (NPD). A feature of CRIS is that it comprises the entire clinical record so that much of what is available is in the form of free text which, through recent advances in the use of natural language processing (NLP) techniques, is now accessible for large-scale research. ⁴ For example, a recent project used free-text-mining algorithms to extract information about cannabis use to investigate the relation with clinical outcomes for just over 2000 patients with first-episode psychosis. ⁵ Another recent study supplemented coded diagnostic and treatment data with data extracted from free text to look at delays in treatment and diagnosis for patients presenting with bipolar disorder. ⁶

With over 50 publications to date using this data-set, CRIS has proved particularly useful for research into mortality outcomes for people with severe mental illness, ^{7,8} hard-to-reach groups such as homeless people ^{9,10} and, more recently, services for people in the early stages of psychosis. ^{11,12}

These examples are, however, still limited to either specific geographical regions or a relatively small subsample of the population. We have, of course, recently come close to a universal data-set of health records with the, ultimately ill fated, care.data proposal. Originally intended to link primary care data with existing hospital records, this would have provided whole-population data for research use. Arguably, this was unsuccessful because it was presented in a way that failed to reassure the public their data would be safe. ¹³ While this has now been scrapped, it is still the government's aim that something similar is implemented. ¹⁴

Allowing whole-population health data to be made available for research has, however, long been an accepted part of life in Nordic countries. For example, since 1968 all Danish citizens have had a unique personal identification number allowing data linkage across a range of health, welfare, employment and education data. ¹⁵ This arguably represents a gold standard for mental health research, with all psychiatric in-patient admissions (since 1969) and all out-patient contacts (since 1995) providing longitudinal data for the entire population over nearly five decades. ¹⁶ Because of the scale of longitudinal data collected, register-based studies using data such as these have proved particularly useful for aetiological research into relatively rare disorders such as schizophrenia. For example, a number of landmark papers have highlighted urban/rural differences in psychosis incidence ^{17,18} and also documented the increased risk of psychosis for migrants and refugees. ^{19,20}

Do big data mean high-quality data?

All these developments in the resources available for research are to be welcomed. However, simply having the ability to access data on this scale is not enough. What we gain through the sheer volume of data and breadth of coverage could be offset by ill-informed analysis and interpretation that fails to account for the limitations of the data. One fundamental limitation is that almost all examples of what we think of as big data are collected for purposes other than research. Health records, just like any bureaucratic product, are shaped by administrative convenience rather than the search for scientific truth. For example, if we look at the way that depression is recorded in primary care, it would be a mistake to take this at face value.^{21,22} For some time, recording a diagnosis of depression on the electronic record has triggered a series of prompts and demands on the clinician, which many saw as unnecessarily burdensome. This became a disincentive to code a formal diagnosis and instead alternatives, such as 'low mood', would be entered, although treatment itself remained unaffected. This has meant that GP records can show an exceptionally low prevalence of depression compared with what we know from national survey data.^{23,24} In this case, a failure to understand what statisticians term the data-generating process would lead to a fundamental misinterpretation of what these data represent. Furthermore, the quantity of data collected here makes no difference to the validity of our conclusions. In fact, having more data is likely to help reinforce any erroneous claims.

Looking at health informatics more broadly, a classic example of what can go wrong if we fail to understand the data-generating process is that much cited example of big data, Google flu trends. Here, the frequency and location of a selection of Google search terms, based on health-seeking behaviour, were used to predict where and when the next flu epidemic would occur.²⁵ This was shown to more accurately predict epidemics compared with previous epidemiological studies and was therefore held up as an exemplar of the ascendancy of big data in health research.²⁶ That is, until Google flu trends stopped predicting accurately and eventually proved no better than estimates based on flu prevalence from a few weeks before.²⁷ This was in part a result of changes Google had made to their search engine, including the introduction of the auto-complete feature that meant searches no longer worked in quite the same way as when the algorithm was first devised. This problem was further exacerbated as the original search terms were never actually made public so could not be externally validated. Clearly, electronic health records are not subject to the same technical issues as a search algorithm. However, as we outline above, changes in the data-generating process, such as how diseases are coded, could make an important difference to results. In some ways, Google flu trends is the perfect example of the hubris associated with big data; as one of the early evangelical accounts confidently stated, 'society needs to shed some of its obsession with causality in exchange for simple correlations: not knowing why but only what'.²⁶ Although this might make sense if we are simply mining data looking for patterns, this approach alone has little to offer in the way of research evidence.

Are the data we routinely collect aligned with research agendas?

A further limitation of research using administrative data is that we rarely have any control over what is collected and therefore risk the research agenda being set by what data are available. One field in which there have been major advances in recent years is ethnicity and mental health, partly due to the availability of electronic health records where patients' ethnicity is now routinely coded. In particular, large-scale case registers have been used to document the increased incidence of psychosis among Black and minority ethnic groups, as well as exploring possible risk factors to explain these differences.²⁸⁻³¹ These findings have been validated using other methodologies. However, there is a risk that we now focus research attention on what are often fairly crude categories, while neglecting other forms of minority status or more nuanced definitions of ethnicity simply because of the available data. For example, it is likely that other forms of marginalised status may also be relevant as risk factors where individual characteristics (such as sexuality, social class or marital status) are at variance with what is usual in a locality.^{32,33} However, these are typically not recorded in register data and are therefore unlikely to receive as much research attention. Where relevant risk factors are not being recorded, research has the potential to inform the data collection process to not only benefit research but also enhance clinical care.

How complex is the analysis of big data?

Another inherent danger is in the way we analyse these data. Often, the more data we have to analyse the more likely it is that we miss patterns in the data that could confound the associations we are interested in. For example, there might be temporal patterns in longitudinal data, such as long-term disease trends, that make it difficult to distinguish effects in before-and-after study designs. Short-term events such as the shift from ICD-9 to ICD-10 in the 1990s could confound our results when comparing changes in rates of diagnosed psychiatric disorders. Data might also be spatially patterned, with different environmental risk factors operating in different areas. This might be further patterned by administrative structures where, for example, differences in mental health outcomes in particular areas may reflect the performance, and reporting practices, of different mental health trusts. Considerable advances have been made in recent years in the tools available for analysing data patterned in this way. In particular, multilevel modelling and Bayesian analysis techniques allow us to simultaneously account for effects operating at temporal, individual, spatial and administrative levels. However, these are still not easily accessible to many researchers, or research consumers, although their use and accessibility are increasing. Implicit in these methods is a fundamentally different approach to that of small-scale studies, such as randomised controlled trials, where the aim is to remove complexity from the data through random allocation. With big data we can no longer rely on random assignment and rely instead on being able to model the complexity inherent in the data to account for possible confounding effects.

Do big data mean more or less transparency?

Admittedly, complex data of this kind can be difficult to analyse, but it also presents an ever-increasing number of choices about how the analysis could be conducted. We might use different diagnostic categories, we could follow our sample over different time periods and look at a variety of different subgroups. We might use different statistical methods for the same analysis and we could also adjust for different sets of covariates. This growing array of possibilities also increases the opportunities to pick and choose our analysis until we find the most impressive-looking *P*-value. This tendency, often termed *P*-hacking or *P*-fishing, can be found in any statistical analysis, unless of course the method is predetermined and published in an advance protocol. However, big data exacerbate this tendency by increasing the possibilities for analysis. Often this means that statistically significant effects, which appear to show something important, cannot then be reproduced and our analysis is ‘over-fitted’ to our data. The US statistician Andrew Gelman describes this potential as the ‘garden of forking paths’.³⁴ He argues that this need not necessarily mean deliberate deception on the part of the analyst, but is often the result of unconscious bias as reasonable analysis decisions are made but they are contingent on the data. The accumulation of these decisions, at different stages in the analysis, ultimately leads to a statistically significant result being more likely. What is required, argues Gelman, is greater transparency so that we are able to retrace the steps made in the analysis to assess for ourselves the significance of findings. A related problem with large data-set analysis is that often very low, highly statistically significant *P*-values can be found for what amount to clinically insignificant effects. It is argued that these tendencies have led to what has been described as a ‘reproducibility crisis’ in science.³⁵ In response, the American Statistical Association recently issued a statement calling for greater transparency in the reporting of results and a move away from simply reporting *P*-values below a certain threshold ($P < 0.05$).³⁶

Complementary methods

Clearly, there are some inherent problems in the analysis of large-scale health records data, both for the unwary and for the unscrupulous. However, there is nothing either inherently good or bad about the use of these kinds of data for mental health research. Ultimately, this comes down to understanding the human story behind how the data were created, having the analytical skills to best interpret the data and being transparent in the way results are reported. What big data can then give us is one version of the truth to complement what we are able to discover using other methods. In fact, one of the best examples of big data that we have in UK mental health, CRIS, also includes a parallel community survey component, the South East London Community Health Study (SELCoH).³⁷ This is intended both to provide a parallel sample of community controls to match the case register and to yield detailed information about individual circumstances and attitudes otherwise absent from medical records.

There are of course a number of well-established national community survey resources, such as the Adult Psychiatric Morbidity Survey and the annual Health Survey for England, that are not dependent on health service use or subject to the diagnostic bias that occurs in health records data.^{38,39} We must also not forget the potential for qualitative research to address many of the questions in mental health research that are beyond the reach of statistical analysis. With the increased emphasis on evidence-based medicine, qualitative methods have increasingly been sidelined. For example, the *BMJ* recently announced that, in future, qualitative studies would have a low priority in the journal.⁴⁰ In response, 76 senior academics from 11 countries wrote an open letter calling for the journal to reconsider.⁴¹ They cite the complementary role that qualitative research can have, particularly where there is a failure to reproduce the results of analyses of large-scale health data-sets.

Last, let us not forget that the research we do is only meaningful in that it relates to the, essentially individual, experience of mental disorder. Whatever volume of data we analyse, whether we look at $n = 100$ or $n = 1\,000\,000$, ultimately we are interested in what this can tell us about the experience of $n = 1$.

The author would like to acknowledge the contribution of Justin Lock, who provided the inspiration for the title of this editorial.

1.7.42 Vitamin D deficiency in adolescents in a tier 4 psychiatric unit

Neil F. Stewart Simon N. Lewis

Correspondence

Simon N. Lewis (slewis9@nhs.net)¹

date

2017-6

Abstract

Aims and method To review the current clinical practice and guidelines for testing and treating vitamin D deficiency in adolescents admitted to a tier 4 adolescent psychiatric unit in north London. The blood test results of 56 patients admitted between 2012 and 2014 were examined to determine whether vitamin D levels had been tested. For those individuals who were tested for vitamin D, results were analysed by gender and ethnicity.

Results Of 56 patients admitted, 48% were tested for vitamin D deficiency and in 81.5% of cases we uncovered deficiency or severe deficiency; 18.5% had the minimum levels of vitamin D for bone health as per our trust guidelines.

Clinical implications Adolescents within tier 4 adolescent mental health services may be at higher risk of vitamin D deficiency and so assessment of vitamin D levels should be considered as part of a standard physical health review for this group of young people.

It is well known that vitamin D plays a role in bone health. In addition, vitamin D receptors have been found in several areas of the brain and are reported to be involved in neuroimmuno-modulation, neuroprotection, neuro-plasticity and brain development.¹ Given that some of these receptors are found in brain areas implicated in mental illnesses such as depression,¹ it is plausible that vitamin D and/or vitamin D deficiency have a role in the pathogenesis of mental illness.

Existing guidelines identify risk factors for vitamin D deficiency²⁻⁴ (details available from the authors on request), although there is little that relates specifically to adolescents or individuals within mental health settings. We hypothesised that patients in a tier 4 adolescent psychiatric unit in north London may be at increased risk of vitamin D deficiency, potentially having had reduced exposure to sunlight as a result of their psychiatric presentations. Linked to this, according to data from the UK National Census in 2011,⁵ there is a higher proportion of individuals with increased skin pigmentation (black and minority ethnic (BME)) compared with the national average within inner London schools, which may reflect general population trends in urban areas.

Aim

We examined the blood test results of all patients admitted to Simmons House, a tier 4 adolescent psychiatric unit, to review our management of individuals with vitamin D deficiency, make recommendations for future practice and identify areas where further study is needed.

Method

The blood test results of patients admitted to the unit between 2012 and 2014 were examined after a clinical observation that a number of patients had vitamin D deficiency. Patient notes were checked to determine gender, ethnicity, whether they were tested for vitamin D levels and the result of the test. The results were classified according to local laboratory reference ranges at the Whittington Hospital NHS Trust in London: <25 nmol/L severe deficiency, 25–50 nmol/L deficiency and 50 nmol/L minimal vitamin D levels for bone health. The results were also mapped to other guidelines, such as National Institute for Health and Care Excellence (NICE) guidelines (<25 nmol/L ‘low vitamin D status’) and those outlined by the Endocrine Society and Society for Adolescent Health and Medicine (>75 nmol/L ‘adequate’).^{4,7}

Results

Of 56 patients on the unit between 2012 and 2014, 48% ($n = 27$) were tested for vitamin D deficiency. According to local laboratory reference ranges (Whittington Hospital NHS Trust), 81.5% ($n = 22$) were deficient or severely deficient (40.7% deficient and 40.7% severely deficient) and 18.5% had the minimum levels for bone health. Applying the NICE guidelines, 40.7% of patients had low vitamin D status. No individuals tested had levels of >75 nmol/L (a level recommended in other guidelines).^{4,7} The results are summarised in *Table 1*.

Vitamin D levels in the tested patient sample

	Pa- tients <i>n</i>	Tested for vitamin D levels (%)	D efficient or severely deficient (%)	Minimum level of vitamin D for bone health (%)	Vitamin D at $>$ 75 nmol/L
Male	14	8 (57)	6 (75)	2 (25)	0 (0)
Fe- male	42	19 (45.2)	15 (79)	4 (21)	0 (0)
White	39	18 (46.1)	13 (72.2)	5 (27.8)	0 (0)
BME	17	9 (52.9)	9 (100)	0 (0)	0 (0)
To- tal	56	27 (48)	22 (81.5)	5 (18.5)	0 (0)

BME, Black and minority ethnic.

<50 nmol/L

>50 nmol/L

Results by ethnicity

Nearly half of adolescents who were White were tested (46.1%, 18/39), and 72.2% ($n = 13$) were deficient or severely deficient in vitamin D. In individuals from BME groups, who were potentially at higher risk of vitamin D deficiency due to increased skin pigmentation, 52.9% (9/17) were tested for vitamin D levels and 100% were deficient or severely deficient. There was no significant statistical association between ethnicity and vitamin D deficiency ($\chi^2 = 3.07$, $P = 0.136$ (Fisher's exact test)).

Results by gender

Three-quarters of the sample were female ($n = 42$); 14 were male. Of the 57% ($n = 8$) males tested, 75% ($n = 6$) were deficient or severely deficient in vitamin D, whereas of the 45.2% ($n = 19$) females tested, 79% ($n = 15$) were deficient or severely deficient in vitamin D. There was no statistical association between gender and vitamin D deficiency ($\chi^2 = 0.05$, $P = 1.000$ (Fisher's exact test)).

Discussion

Are adolescents at risk?

There is emerging evidence that the adolescent population in general is at risk of vitamin D deficiency.⁸ Although risk factors may vary, depending on geographical location, seasonal changes, latitude and variations in ultraviolet light levels, there has also been a suggestion of a worldwide re-emergence of rickets in the paediatric population.⁹ The Royal College of Paediatrics and Child Health identifies adolescents as having an ‘increased need’ for vitamin D,¹⁰ and the draft NICE guidelines⁶ stated that young people undergoing rapid periods of growth are at an increased risk of vitamin D deficiency, although this did not appear in the final guideline.²

Which guidelines to use?

An update to the NICE guidelines regarding vitamin D deficiency was published in November 2014 with the aim of increasing vitamin D supplement use among at-risk groups.² The guidelines include the findings of the *National Diet and Nutrition Survey* showing that 8–24% of children (depending on age and gender) may have vitamin D deficiency (details available from the authors on request). It is also noted that up to 75% of Asian adults may be deficient in vitamin D. The groups at risk of vitamin D deficiency, including adolescents, are: people who have low or no exposure to the sun, for example those who cover their skin for cultural reasons, those who are housebound or confined indoors for long periods, and people with darker skin, for example people of African, African-Caribbean or South Asian origin.

There appears to be a lack of consensus between various guidelines in defining a biochemical vitamin D deficiency. NICE guidelines² give a level of <25 nmol/L as low vitamin D status, but local laboratory reference ranges and recommendations made in other guidelines vary. For example, the Endocrine Society⁴ and the Society for Adolescent Health and Medicine⁷ provide different recommendations regarding required vitamin D levels, which appear to be higher than those in the NICE guidelines.² *Table 2* summarises the guidelines.

Vitamin D levels by guideline

	Whittington Hospital NHS Trust laboratory interpretation	NICE guidelines	Endocrine Society and SAHM interpretation
< 25 nmol/L	Severe deficiency	Low vitamin D status	Deficiency
25–50 nmol/L	Deficiency	n/i	Deficiency
>50 nmol/L	Minimal levels for bone health	n/i	Recommended or ‘adequate’ level

SAHM, Society for Adolescent Health and Medicine; n/i, no interpretation offered in the guideline.

Prevention and treatment

Vitamin D deficiency can be treated with oral or intramuscular supplementation, usually in the D₃ form (cholecalciferol), as this may be more effective than vitamin D₂ in raising serum 25(OH)D levels.¹¹ NICE guidelines outline the daily vitamin D intake requirements to minimise the risk of deficiency in various age groups, with 400 IU for ‘at risk’ adults. Similar requirements have been suggested for adolescents.⁸ Medical causes of vitamin D deficiency, other than reduced sunlight exposure, should also be considered, for example reduced parathyroid hormone levels or malabsorption disorders such as coeliac disease. No single treatment recommendation for vitamin D deficiency is given in national guidelines.

How much sun exposure is recommended?

A recent NICE guideline, published in February 2016, outlines the risks and benefits of sunlight exposure.¹² It recognises that advice on sunlight exposure to date has been available from many sources and that the information has often been ‘inconsistent and potentially confusing’.¹² Young people and their parents/carers could be confused, worrying about balancing advice to limit sun exposure, because of the increase in incidence of skin cancer and other skin disorders, with a need to have sun exposure for vitamin D production.^{13,14} The new NICE guideline acknowledges that, with a proviso that ‘a simple definitive message telling different groups how often and how long they can be exposed to sunlight to ensure minimum risk but maximum benefit’ is not possible because of the multiple biological, social and environmental factors that contribute towards an individual’s risk-and-benefit profile.¹² Specific risk factors for skin cancer such as a family history of the disease should always be considered when giving sun exposure advice, and the NICE guideline also mentions groups who should take ‘extra care to avoid skin damage and skin cancer’. This includes young people.¹²

It is suggested that skin colour charts may be helpful in making judgements about sun exposure advice. Individuals with naturally very light skin (skin types I and II) are at greater risk of sunburn and skin cancer and require shorter times of sun exposure to synthesise vitamin D compared with those with darker skin types (types V and VI), who are at increased risk of vitamin D deficiency in the UK.¹²

Advice should be tailored for the time of year and the time of day. For example, in the UK between March and October and between 11 am and 3 pm, short periods of sun exposure to the forearms, hands or lower legs are required to synthesise vitamin D, whereas longer times are required between 3 pm and 11 am.¹² Between October and March, there is ‘very little of the ultraviolet B wavelength the skin needs to make vitamin D’.¹²

With so many factors to consider, it is perhaps not surprising that the general advice given in the NICE guideline remains equivocal, with an emphasis on providing consistent, balanced messages regarding the risks and benefits of sunlight exposure for each individual. It is suggested that: ‘short (less than the time it takes for skin to redden or burn), frequent periods of sunlight exposure are best for vitamin D synthesis. In addition, this type of exposure is less likely to result in skin cancer’.¹² This advice is broadly similar to advice published in a multiagency consensus document in 2010 (<https://www.cancerresearchuk.org/sites/default/files/vitaminD-consensus.pdf>).⁷

Study recommendations

If it were assumed that all of the individuals in our study who were not tested – deliberately or by accidental omission – had ‘optimum’ vitamin D levels, then 39.3% ($n = 22$) of the total sample had vitamin D deficiency. However, it seems unlikely that all of the non-tested patients had optimal levels given that, for example, 8 BME patients were not tested and 100% of those who were tested were deficient or severely deficient in vitamin D.

Factors influencing whether patients on Simmons House Adolescent Unit were tested for vitamin D before 2015 have not been explored in this project. The apparent idiosyncrasy of testing is beyond the scope of the present study but was one of the reasons for the study and subsequent recommendations detailed in the *Appendix*.

The results could suggest that all individuals within Simmons House at risk of vitamin D deficiency were identified and their levels tested accordingly. Alternatively, it may be that a proportion of the 52% of individuals not tested had an undetected vitamin D deficiency, particularly those from BME backgrounds given that 100% of the BME patients who were tested had deficiency or severe deficiency. As increased skin pigmentation is identified as a specific risk factor for vitamin D deficiency in the NICE guidelines, it could be that all adolescents with increased skin pigmentation admitted to a tier 4 adolescent psychiatric unit should have their vitamin D levels checked. This may be particularly relevant in units with culturally diverse populations. Specific recommendations made for Simmons House are detailed in the *Appendix*.

Perhaps any adolescent with a mental illness of a severity that requires in-patient admission is at risk of reduced sun exposure and consequent vitamin D deficiency, no matter their ethnicity. It could be suggested that all patients within tier 4 adolescent psychiatric units should be considered at high risk of vitamin D deficiency and tested, unless there was clear evidence to the contrary, such as a confirmed history of adequate sun exposure and theoretically sufficient dietary intake.

Choosing a particular treatment regime depends on clinical need and consideration of local guidelines. Recommendations given in various London NHS trusts guidelines (St Bartholomew's and The London NHS Trust, Royal Free Hospital NHS Trust and The Whittington Hospital NHS Trust; details available from the authors on request) range from treating a deficiency with oral cholecalciferol in doses of 2000 to 6000 IU per day, or once-weekly doses of 20 000 IU, all for a minimum of 3 months before rechecking vitamin D levels. Once the serum 25(OH)D level has been normalised, the recommended maintenance doses range from 400 to 1000 IU of cholecalciferol per day, with NICE suggesting 400 IU per day as a prophylactic dose for those at risk of deficiency. Therefore, at the very least, it seems that prophylactic supplementation of 400 IU of vitamin D₃ per day should be considered for adolescents at risk of vitamin D deficiency, or treatment of a confirmed vitamin D deficiency initiated after discussion with the adolescent and/or their family/carers. Treatment regimens should be in line with local guidelines until a sufficient evidence base is established to provide national guidelines.

More research is needed into the prevalence of vitamin D deficiency in all age groups, both in the general population and in hospital settings (general and psychiatric hospitals). The topic is likely to appear in the medical literature frequently in years to come, with hypothesised links between vitamin D deficiency and a multitude of medical conditions ranging from cancer to psychosis,¹⁵ multiple sclerosis¹⁶ and the possibility of a worldwide re-emergence of rickets in the paediatric population.⁹ The relationship between vitamin D and mental illness is not known. A meta-analysis¹⁷ published in the *British Journal of Psychiatry* in 2013 supported an association between low vitamin D concentrations and depression, mostly based on observational studies. However, the nature of the association is not yet known to be causal and the paper also noted that the quality of evidence in this particular area to date is poor; no randomised control trials have been performed.¹⁷

If an association between depression and vitamin D deficiency were to be confirmed through future study, vitamin D supplementation could potentially be a cost-effective treatment adjunct with minimal adverse effects. In the meantime, the beneficial effects of vitamin D on bone health have been clearly demonstrated. Future research might include a nationwide project through the Royal College of Psychiatrists' Quality Network of Inpatient CAMHS Units (QNIC; qnic.org.uk) to which almost all tier 4 units in the UK are allied for appraisal and accreditation. Additionally, consideration of whether the child and adolescent population attending tier 3 child and adolescent mental health services (CAMHS) should be tested for their vitamin D status requires further thought.

1. All admissions to Simmons House should be considered at high risk of vitamin D deficiency, especially individuals with increased skin pigmentation or with a history suggestive of a lack of sun exposure. Therefore, vitamin D levels should be included as part of the routine physical assessment.
2. If blood tests are refused or clinically inappropriate, prophylactic treatment should be considered with 400 IU cholecalciferol (vitamin D₃) orally once daily, assuming informed consent is gained.
3. If a vitamin D deficiency is detected, baseline corrected calcium levels should be tested, plus a full bone mineral profile and testing of parathyroid hormone levels, along with routine admission blood tests (e.g. full blood count, urea and electrolytes, liver function tests, random blood glucose, thyroid function tests and lipid profile).
4. Treatment of a vitamin D deficiency should consist of high-dose cholecalciferol (vitamin D₃) (5000–6000 IU) orally daily for 3 months. Vitamin D levels and corrected calcium levels should then be checked again and a maintenance dose of cholecalciferol (vitamin D₃) 400 IU commenced once daily when vitamin D levels have normalised. Continuation of treatment should be tailored to each individual, based on severity of the deficiency and ongoing risk factors for vitamin D deficiency. Longer-term management of supplementation should be discussed with primary care colleagues.
5. Patients and/or their families/carers should be made aware of potential side-effects of treatment i.e. vitamin D toxicity or hypercalcaemia, which may present with anorexia, weight loss, vomiting and polyuria.
6. Ongoing examination of blood test results (serum vitamin D levels) should take place and internal audit on clinical practice should continue.

1.7.43 Adherence to NICE guidance on lifestyle advice for people with schizophrenia: a survey

Abstract

Aims and method The STEPWISE trial (STRUCTURED lifestyle Education for People With Schizophrenia, schizoaffective disorder and first episode psychosis) is currently evaluating a lifestyle education programme in addition to usual care. However, it is difficult to define what constitutes 'usual care'. We aimed to define 'usual care' for lifestyle management in people with schizophrenia, schizoaffective disorder and first-episode psychosis in STEPWISE study sites. Ten National Health Service (NHS) mental health trusts participated in a bespoke survey based on the National Institute for Health and Care Excellence (NICE) guidance.

Results Eight trusts reported offering lifestyle education programmes and nine offered smoking cessation support. Reported recording of biomedical measures varied.

Clinical implications Although recommended by NICE, lifestyle education programmes are not consistently offered across UK NHS mental health trusts. This highlights missed opportunities to improve the physical health of people with psychotic illness. Our survey benchmarks 'usual care' for the STEPWISE study, against which changes can be measured. Furthermore, future studies will be able to identify whether any progress in clinical practice has been made towards achieving the NICE recommendations.

The prevalence of overweight (body mass index (BMI) >25 kg/m²) and obesity (BMI>30 kg/m²) in adults with schizophrenia is approximately twice that in the general population and while it has increased in both groups in the past 30 years, the rate of increase is greater in people with schizophrenia. ¹ Weight gain often occurs after initiation of antipsychotic treatment: over 50% of individuals gain more than 7% of their initial body weight within the first 12 months of treatment, with up to 86% gaining weight with some types of antipsychotic. ² Compared with the general population, people with schizophrenia consume more fat and refined carbohydrates and fewer vegetables, ³⁻⁵ are less physically active and experience higher levels of deprivation, ⁴⁻⁷ all of which are associated with obesity. The National Institute for Health and Care Excellence (NICE) recommends that people with psychosis or schizophrenia, particularly those taking antipsychotics, should be offered access to a combined healthy eating and physical activity programme to aid in the prevention of weight gain and its related comorbidities, leading to improved quality of life. ⁸ They should be supported by clinicians to make choices about antipsychotic medication, informed by discussions of likely benefits, possible side-effects, such as weight gain and metabolic disturbance, and impact on other aspects of their physical health. For those who smoke, help should be offered to stop smoking. ⁸

The STEPWISE study (STructured lifestyle Education for People WItch SchizophrEnia, schizoffective disorder and first episode psychosis; ISRCTN19447796) was commissioned to evaluate the extent to which a structured lifestyle education programme can support weight loss, compared with usual care, when delivered to adults with schizophrenia, including those with schizoffective disorder or first-episode psychosis, in a community mental health setting. In pragmatic trials, practitioners are often allowed ‘considerable leeway in deciding how to formulate and apply’ the treatment in a control arm defined as ‘usual care’. ⁹ While the result may be reflective of the care received by patients outside the trial, there is often variation in care in an active control arm, which may be difficult to document. ^{10,11} For this reason, study teams often try to capture the active content of the control arm of their trials. ¹² In this paper we describe a survey of ‘usual care’ for the management of weight and other lifestyle factors in people with schizophrenia, schizoffective disorder and first-episode psychosis in the ten participating study sites.

Method

Research tool

The survey instrument consisted of 14 questions, which were a combination of closed and open design, with the aim of eliciting information about the implementation of the recent NICE guidance on psychosis and schizophrenia at National Health Service (NHS) mental health trusts in the UK, and consequently what is offered as 'usual care'. The survey was developed for the research study, based on the physical health aspects of the NICE recommendations in clinical guideline 178.⁸ Questions followed the baseline assessment tool published alongside the NICE guidance. The instrument was piloted with one study site investigator (J.M.) on two occasions, and each led to substantial changes to the tool. For instance, the second iteration revised questions to ascertain proportions of patients to whom certain criteria apply, rather than closed questions such as 'Are patients referred to a healthy eating programme?' The final version of the tool also clarified which questions related to all patients with schizophrenia, schizoaffective disorder and first-episode psychosis, and which questions related to patients with first-episode psychosis only (the questionnaire is included in the *Appendix*). This is in line with the additional recommendations specified in the NICE guidance for patients with first-episode psychosis who have recently been prescribed antipsychotic medication; these additional questions were not applicable to the management of patients with established mental illnesses.

Survey structure

Trusts were initially asked whether they offered a healthy eating and physical activity programme. Subsequent questions asked for more information about these programmes, including whether they were combined or separate for healthy eating and physical activity; how patients accessed them; and how often patients were referred to such services. Additional information was sought on the availability of smoking cessation services in this population and whether discussions took place between patients and clinicians prior to antipsychotic treatment initiation, including benefits of treatment, interactions with other substances and other possible side-effects.

In addition, NICE recommend that a number of physiological measures should be recorded both prior to the patient starting antipsychotic medication and annually thereafter. Respondents were asked to comment on how likely it was that each measure would be recorded at both of these time points in their trust and how often patients on antipsychotic medication have their weight recorded.

Sample selection

The STEPWISE trial has ten centres in a variety of urban, suburban and rural locations across England: Sheffield Health and Social Care NHS Foundation Trust, Leeds and York Partnership NHS Foundation Trust, Bradford District Care NHS Foundation Trust, Greater Manchester West Mental Health NHS Foundation Trust, South London and Maudsley NHS Foundation Trust, Sussex Partnership NHS Foundation Trust, Southern Health NHS Foundation Trust, Devon Partnership NHS Trust, Somerset Partnership NHS Foundation Trust and Cornwall Partnership NHS Foundation Trust. A representative from each centre was invited to complete the survey.

Respondents

The principal investigators at each of the ten centres for the STEPWISE trial were initially approached. Some of them completed the survey themselves, while others delegated to trust physical health leads or equivalent as they were better placed to answer the questions. Contact was made via email in the first instance, with an invitation to attend a teleconference with the STEPWISE research assistant (L.S.) to complete the survey. Those who did not provide a response to the invitation within 4 weeks were contacted again by reminder emails and/or by telephone. Six of the ten sites' surveys were completed through discussion via teleconference. The remaining four sites' surveys were completed independently by a trust representative and written responses were provided to the STEPWISE research assistant.

No sites required more than one reminder email/telephone call in order to arrange completion of the survey. As the survey information was requested from members of a research team, a favourable ethical opinion from an NHS Research Ethics Committee was not sought and consent was unnecessary. Responses provided organisational data only and did not include any personal data. Responses from all sites were received between 22 May and 28 October 2015.

Analysis

Descriptive statistics in the form of counts were produced for quantitative variables. Supporting information provided by respondents and information yielded from qualitative questions was summarised in narrative form.

Results

Healthy eating and physical activity programmes

Eight respondents reported that their trust offered programmes on healthy eating and physical activity, which were mostly separate programmes. Supplementary information indicated that provision was *ad hoc* and interventions were rarely standardised. Most respondents reported routinely inviting patients to access services such as discounted local gym memberships, cooking groups and activity groups delivered by local authorities and third-sector organisations. Two trusts reported offering one-on-one advice sessions with healthy living advisors or health trainers, but the sessions were usually advice-giving and often more clinically focused rather than looking at the patient's physical well-being.

Those trusts that offered trust-led programmes reported that these were available in principle to all of their patients rather than specific groups based on diagnosis. However, interventions were often accessed only by certain groups of patients, usually through particular clinicians or clinics. One trust estimated that 70% of their eligible patients are referred to such services by mental health professionals, based on recent Commissioning for Quality and Innovation (CQUIN) results; other respondents were unaware of routine data from which they could quantify referrals. Six trusts reported offering lifestyle advice through open-ended group courses, three through courses delivered over a fixed period and four through drop-in sessions.

Smoking cessation advice

Six respondents indicated that patients who smoke were offered help to stop some of the time, three reported help was offered all of the time, and one said this was not offered at all. Respondents who selected 'some of the time' were unable to quantify this, but felt that this occurred most of the time. Although it varied whether smoking cessation services were offered by the trusts or external services, most offered a combination of the two. Seven trusts reported offering trust-led smoking cessation services, while others had trained smoking cessation advisors but had no formal trust-offered service. Most trusts reported signposting outpatients to external services, some of which were managed by primary care, with advice leaflets available within the trust.

Antipsychotic treatment initiation

Table 1 shows the reported levels of discussion about likely benefits of treatment, as well as potential weight gain, diabetes and metabolic side-effects and any other possible side-effects, across all respondents. Most trusts who reported that the recommended discussions took place 'some of the time' felt that this would be most of the time, but there was a lack of evidence to support this. One site reported that discussions would be dependent on the clinician, but that resources were available to clinicians to support the discussions. Another site suggested that such discussions may be part of an ongoing process rather than all happening in one session, depending on the patient's level of capacity.

Discussions with patients when deciding on antipsychotic treatment ($n = 10$ NHS trusts)

	All of the time	Some of the time	Not at all
Topic			
Likely benefits	7	3	0
Weight gain	5	5	0
Diabetes and metabolic side-effects	3	7	0
Other possible side-effects	5	5	0
Other substances			
Alcohol	5	5	0
Tobacco	2	8	0
Other prescribed medications	3	7	0
Non-prescribed medications	0	10	0
Illicit drugs	3	7	0

Table 1 also shows how often respondents reported discussions taking place regarding the use of alcohol, tobacco, prescribed and non-prescribed medications and illicit drugs, at the time of antipsychotic treatment initiation.

Table 2 shows how likely trusts considered that physiological measures would be recorded prior to treatment initiation.

Recording of physiological measures prior to antipsychotic treatment initiation ($n = 10$ NHS trusts)

	Very likely	Likely	Neither likely nor unlikely	Unlikely	Very unlikely
Weight	3	4	1	2	0
Weight plotted on a chart	1	3	1	3	2
Waist circumference	0	2	3	3	2
Pulse	3	4	1	1	1
Blood pressure	4	2	1	2	1
Fasting blood glucose	0	5	1	2	2
Random blood glucose	2	4	0	3	1
HbA1c	2	2	1	2	3
Blood lipid profile	2	4	0	2	2
A sassessment of any movement disorders	2	4	2	0	2
A sassessment of nutritional status, diet and level of physical activity	3	3	1	3	0

Ongoing monitoring of weight and other physiological measures

It was clear from the responses that there were variations in recording patients' weight at the time points recommended by NICE (first at 6 weeks post-treatment initiation, then at 12 weeks, at 1 year and annually thereafter), both between trusts and within trust services. Some confusion exists regarding responsibility for annual patient reviews in the community and whether these should be completed by the general practitioner (GP) or the trust. Half of those surveyed reported that it was neither likely nor unlikely that patients would have their weight recorded weekly for the first 6 weeks, with three other trusts reporting that this was very unlikely. There was an even spread across all response categories as to whether weight was recorded at 12 weeks, but at 1 year four of those surveyed reported that patients were very likely to have their weight recorded. Six respondents reported that weight was likely or very likely to be recorded annually thereafter, although this was where the confusion arose regarding responsibility for these reviews.

Table 3 shows trusts' consideration as to how likely it was that physiological measures would be recorded at least annually in patients taking antipsychotic medication. One site felt they were unable to answer this question, so we present data reflecting responses from nine trusts.

Recording of physiological measures at least annually for patients on antipsychotic medication ($n = 9$ NHS trusts)

	Very likely	Likely	Neither likely or unlikely	Unlikely	Very unlikely
Weight	3	4	0	2	0
Weight plotted on a chart	0	3	3	2	1
Waist circumference	0	2	2	3	2
Pulse	2	4	1	1	1
Blood pressure	3	4	1	1	0
Fasting blood glucose	1	2	5	1	0
HbA1c	2	2	4	1	0
Blood lipid profile	2	1	4	2	0
A assessment of any movement disorders	1	4	3	1	0
A assessment of nutritional status, diet and level of physical activity	3	1	3	2	0

There was no correlation between which of the recommended physiological measures were recorded by trusts prior to antipsychotic treatment initiation or annually thereafter, although generally those trusts who were likely to record particular measures prior to treatment initiation were also likely to record the same measures at least annually thereafter.

Discussion

Principal findings

It was clear from this survey that there was great variation between different NHS mental health trusts in the provision of healthy eating and physical activity interventions routinely offered to patients, as well as variation between clinicians within the same trust, with interventions often accessed only through particular clinicians or clinics. Commonly, trusts reported signposting or referring patients to programmes offered by external services, such as gym memberships and activity classes.

Most patients had access to a smoking cessation service should they require it, and referrals to such services were reported to occur most if not all of the time at nine out of the ten trusts surveyed, regardless of whether the service was offered within the trust or run externally.

When deciding on antipsychotic medication with newly diagnosed patients, there was also variability in the reported discussions that took place across trusts. All trusts reported that the likely benefits, weight gain, diabetes and metabolic and other possible side-effects were discussed with the patient at least some of the time; the possible interference of other substances with prescribed antipsychotic medication was also discussed.

Although at the early stages in the course of antipsychotic treatment it was reported unlikely that trusts would record a patient's weight, as recommended by NICE, by 1 year after treatment initiation a larger proportion of trusts reported weight recording, with an increase for annual reviews thereafter, despite the uncertainties regarding responsibility for undertaking annual reviews in the community.

Study strengths and limitations

A strength of this survey was that its design was based on the NICE guidelines to which mental health trusts should be adhering. This meant that trusts' compliance with these recommendations could be assessed, allowing us to elicit information on what programmes (if any) trusts were offering in usual practice and how these compared with what is recommended by NICE. This also allowed us to try to define 'usual care' in relation to the STEPWISE study, using a standard approach across all trusts.

The survey was, in principle, a suitable method to elicit the same information from all respondents; however, it was clear from the responses that owing to the variability of services offered it was often difficult to provide a succinct account using this survey tool. The narrative information provided by the respondents proved more useful in gaining a fuller picture of their usual care than the descriptive statistics, which in some cases were a best guess, as clear data were not always available.

Furthermore, responses were based on one member of staff's knowledge of usual care in practice, and although this person was usually best placed to answer the questions, from the survey responses received knowledge may have been limited, especially as some interventions offered were particular to a specific clinic or clinician and usual care may vary within and between community mental health teams in any given NHS organisation. In addition, how representative 'usual care' is in comparison with NHS trusts not taking part in the STEPWISE study remains unknown.

The levels of detail regarding the content of available services also varied, perhaps indicating that the respondent had more involvement with some programmes than others. Therefore, it was considered likely that additional interventions may have been offered within trusts of which the survey respondent was unaware.

In relation to implementation, a weakness in the survey was highlighted when some responses were received through telephone discussion while others were completed by the respondent and returned to the researcher. No systematic differences between telephone and paper copy responses were identified, although more supporting information was often provided through telephone responses, as these were elicited through more of a conversational discussion. This difference in response methods may have caused questions to be perceived differently, although all telephone participants had a copy of the questionnaire available to them at the time of completion. Perceptions of appropriate levels of detail can change with different methods of completion, which may lead to variation in results. However, as such

variation was evident between practices offered as ‘usual care’ in the ten trusts surveyed, the impact of these differences in completion method is considered likely to be small.

The variability in the information elicited has not allowed for a common picture across all sites, as although a type of programme is recommended by NICE, a particular standardised programme is not available across all trusts. However, the survey did provide sufficient baseline information to allow any changes in usual practice during the course of the STEPWISE study to be monitored at a trust level, rather than across all study sites as a whole. This will enable assessing at the end of the STEPWISE study the extent of potential contamination between the intervention and control arms of the trial, based on changes in practice reported in the survey.

Context

Although there may be an increased awareness of the potential benefits of some treatments, this does not ensure that such treatments are implemented effectively. Evaluations and methods of improving the implementation of NICE guidelines often have limited attention.¹³ A systematic review undertaken by Berry & Haddock¹³ noted that the research around the implementation of NICE guidelines on schizophrenia is relatively limited, suggesting that these patients have poor access to psychological interventions such as cognitive-behavioural therapy (CBT). Some barriers to implementation of NICE guidelines were reported, such as insufficient support from trust management and the needs of organisations. The paper also highlights that whereas NICE considers randomised controlled trials (RCTs) to be the gold standard when developing an evidence base for its guidelines, RCTs have also been criticised for their poor ability to reflect the ‘real world’. The authors suggest that targeting these barriers is key to facilitating successful implementation of the guidelines.¹³

It is therefore important to identify which aspects of the guidance are not currently being followed, in order to target these areas for implementation and improve clinical care. Not only is it important to consider the implementation of guidance relating to monitoring of biomedical measures, but there is also likely to be a limited effect unless this is combined with sufficient intervention in behaviour or treatment. Similarly, the mere fact of guidance or a trial does not necessarily lead to substantive changes or better outcomes. Repeating the survey annually will allow identification of any substantive, systematic changes within the organisations, both since the introduction of the NICE guidelines and throughout the duration of the STEPWISE trial.

From a research perspective, the reported variation also has implications for our study when defining ‘usual care’. If all trusts adhered to all recommendations in the NICE guidelines, we could be sufficiently confident that contamination between trial arms would be minimal. However, as different levels of compliance with different recommendations were evident, this does not allow for standardised ‘usual care’ across the study. This does mean that usual practice can be compared over time within each trust individually, in order to assess how much ‘usual care’ has changed throughout the course of their participation in the STEPWISE study.

The Royal College of Psychiatrists’ National Audit of Schizophrenia includes standards on the monitoring of physical health in patients with schizophrenia. The audit report in 2014 noted that the provision of interventions is poor when there is evidence of physical health risks.¹⁴ It highlighted barriers to intervention, such as availability of staff time, facilities and equipment, the need for formal systems to conduct annual reviews, and the need for more formal arrangements regarding responsibility for physical health between primary and secondary care.¹⁴ Standard 5 in the audit specifically looks at interventions offered for particular physical health risks. The overall results show that intervention for BMI > 25 kg/m² was evident in 71% of patients, while interventions for smoking were reported in 59% of patients.¹⁴

For the ten trusts surveyed, the audit reported a range of 47–83% of patients receiving intervention for elevated BMI, and 33–67% receiving intervention for smoking. Overall, the audit also showed wide variation in the monitoring of physical health risk factors. For example, the range across all participating trusts for monitoring of BMI was 5–92% of patients and 16–99% for the monitoring of glucose control. This is supportive of the information yielded from the study survey and highlights variability in services offered across trusts.¹⁴

Implications for stakeholders

This survey indicates that the ten sites surveyed are not fully compliant with NICE physical health recommendations on the management of patients with schizophrenia. However, as the guidelines were published in March 2014, this is not surprising, because services require time to commission and set up. In some respects, this alleviates the concerns that the ‘usual care’ arm of the STEPWISE trial may converge with the intervention arm, as there are no reported standardised programmes offered across any of the trusts surveyed. However, there is such variability observed that it becomes clear that ‘usual care’ is not the same for all participants in the trial or in the wider population group.

We have not tried to assess the success or potential effect of any one aspect of the physical health programme in comparison with others. Although it may be argued that smoking cessation could have a greater effect on physical health than healthy eating or physical activity programmes, despite the lower compliance with NICE guidance, any discussion is likely to be subjective. Furthermore, NICE does not prioritise any one element, coming from an understanding that all aspects are important and contribute to improved physical health.

As a future direction, it may be useful to try to identify patients at higher risk of cardiovascular events, using recording of cardiovascular disease risk factors in combination with risk engines to calculate risk accurately. This identification process could then drive intervention. This may be of interest to trusts as a method of offering a physical health intervention to those patients who are likely to receive the most benefit clinically. A suitable risk engine to calculate this would be the PRIMROSE cardiovascular disease algorithm,¹⁵ as this has been developed specifically for people with severe mental illness. The PRIMROSE model includes additional variables for psychiatric diagnosis, psychotropic medication, harmful use of alcohol, antidepressants and social deprivation score, unlike similar prediction models used in the general population. This is perhaps why PRIMROSE performed better than some other available published risk models, which may overpredict the risk of cardiovascular disease in this population.¹⁵

Further research

The survey will be repeated with the same ten NHS trust representatives at 12 and 24 months after the first iteration. This will allow the STEPWISE study team to consider how trusts are implementing the NICE guidelines and, consequently, whether convergence has occurred between the two arms of the STEPWISE trial at an individual trust level. As STEPWISE progresses, the participating NHS organisations may become more aware of the need to undertake physical health interventions and so ‘usual care’ may improve, potentially diminishing the effect of the STEPWISE intervention.

We acknowledge the STEPWISE research group: Katharine Barnard, University of Southampton; Michael Bradburn, University of Sheffield; Marian Carey, University Hospitals of Leicester NHS Trust; Heather Daly, University Hospitals of Leicester NHS Trust; Melanie Davies, University of Leicester; Christopher M. date

2017-6

Abstract

Aims and method To examine gender differences in self-reported depression and prescribed antidepressants (ADs). The Hospital Anxiety and Depression Scale was used to assess depression, and information on prescribed ADs was obtained from the Swedish Prescribed Drug Register.

Results Depression was reported by 11.7% of the participants (12.3% men and 11.2% women). ADs were prescribed for 7.6% of the participants (5.3% men, 9.8% women). Among men, 1.8% reported depression and used ADs, 10.5% reported depression but did not use ADs, and 3.6% used ADs but did not report depression. The corresponding figures for women were 2.6%, 8.6% and 7.2%.

Clinical implications Men report depression to a greater extent than women but are prescribed ADs to a lesser extent, possibly a sign of under-treatment. Women are prescribed ADs without reporting depression more often than men, possibly a sign of over-treatment. Although the causes remain unclear, diagnostic and treatment guidelines should benefit from considering gender differences in these respects.

* *Summary of findings*

Depression is currently considered one of the largest and fastest growing health hazards.¹ Although only a small percentage of all those with mental health problems contact healthcare professionals and obtain a diagnosis, depression is one of the most common causes of sick leave and disability.^{2–5} Diagnosed depression was relatively unusual 20 years ago, but the incidence has increased remarkably with the introduction of new diagnostic guidelines and antidepressant drugs. What was previously considered psychological distress was then interpreted as a disease, with the risk of over-diagnosis and over-treatment.^{6–10} The point prevalence of depression in the general population is now estimated as 3–9%.^{1,11,12} There is an explicit gender impact on diagnosed depression, with a 2:1 ratio of women/men; about one in four women and one in ten men will develop depression severe enough to require treatment at some time in their lives.^{1,2,11,12} Moreover, depression may present differently in women and men. Women may be more prone to somatic symptoms of depression, whereas men appear to have more melancholic symptoms and to be more susceptible to drug misuse and aggressive behaviour.^{13–17} To date, however, there is no clear understanding of what causes these gender disparities in depression. They are considered likely to be a combination of several factors: biological, social and behavioural.^{18,19}

Depression is a long-lasting and, if left untreated, often chronic condition. Treatment usually lasts at least 6–12 months, and includes pharmacological therapy with antidepressants (ADs).²⁰ The use of ADs has increased dramatically in recent years.²¹ According to the national Swedish Prescribed Drug Register (SPDR), almost 9% of the Swedish population was prescribed ADs in 2014, and 65% of these ADs were prescribed for women.²² Similar patterns have been found in other countries.^{23–25} The explanation for this escalation, especially seen in women, remains unclear, but has sometimes been interpreted as a sign of inappropriate use.^{8,9} Nevertheless, despite the widespread use of ADs, depression has repeatedly been shown to be inadequately treated in the general population. Some studies have found that fewer than one in four patients with depression are prescribed ADs and that the duration of treatment is often shorter than recommended.^{26,27}

The ADs prescribed are primarily selective serotonin reuptake inhibitors (SSRIs), although others, for example serotonin–noradrenaline reuptake inhibitors (SNRIs), tricyclic antidepressants (TCAs) and monoamine oxidase inhibitors (MAOIs), are also used depending on illness severity, the patient's age and various adverse drug reactions.^{20,28,29} Gender impact has been observed not only on the number of ADs prescribed but also on their type. For example, women are prescribed SSRIs more often than men.³⁰

We examined gender differences in the relationship between self-reported depression and prescribed ADs, in the prevalence of self-reported depression, and in the number and type of prescribed ADs.

Method

Participants

A questionnaire was sent to a random sample ($n = 16\,000$, aged 18–84 years) of the Swedish population (totaling 9.5 million); responses were received from 7725 people (48.3%), as presented in *Fig. 1*. The study complies with ethical research requirements, as approved by the Regional Ethical Review Board in Uppsala, Sweden (Dnr 2012/073). Participation in the study was voluntary and information about its purpose was sent out with the questionnaire. Filling in and returning the questionnaire was considered to be equivalent to the respondent giving their agreement to participate in the study.

Assessment of depression and prescribed antidepressants

Self-reported depression was assessed using the Hospital Anxiety and Depression Scale (HADS).³¹ Of the 7725 available participants, 7618 (3435 men, 4183 women) filled in the HADS form (*Fig. 1*) and all analyses were based only on these participants. The HADS was developed to detect patients with high levels of psychological distress and does not include assessment of somatic symptoms. It contains two subscales, one each for anxiety and depression, each consisting of 7 items (score range 0–21) capable of distinguishing between these diagnoses. Higher scores indicate higher levels of psychological distress. Each subscale has three categories based on the score: 0–7 (normal), 8–10 (borderline) and 11–21 (abnormal). In this study, a cut-off level of +8 was used on the depression scale; this level indicates at least mild depression and provides an optimal balance between sensitivity and specificity.³²

Information on depression obtained from the HADS was linked (through the participants' identification number, a unique lifetime personal identifier given to all Swedish citizens) to prescription data. Prescribed ADs were obtained from the SPDR, a national register held by the National Board of Health and Welfare, which gathers data on all dispensed prescriptions for patients in ambulatory care from the entire Swedish population.^{22,33} We collected information on ADs 0–6 months prior to the HADS evaluation. SPDR drugs are classified according to the Anatomical Therapeutic Chemical (ATC) classification system.³⁴ The ADs (N06A) were categorised as TCAs (N06AA, e.g. amitriptyline, imipramine), SSRIs (N06AB, e.g. citalopram, fluoxetine), 'others' (N06AX, including SNRIs (e.g. venlafaxine) and tetracyclic antidepressants (TeCAs, e.g. mirtazapine)), and monoamine oxidase inhibitors (MAOIs; N06AF, N06AG, e.g. moclobemide). The MAOIs were excluded due to few users.

Analyses

The Statistical Analysis System software (SAS9.2, Cary, North Carolina, USA) was used to perform chi-squared tests (χ^2, P) to examine gender differences in the relationship between self-reported depression and prescribed ADs, and in prevalence of self-reported depression, prescribed ADs, and type of ADs prescribed. Logistic regression analysis (odds ratios (OR) with 95% confidence intervals) was used to examine gender differences in self-reported depression, controlling for age.

Results

In total, 11.7% of the study population (12.3% men, 11.2% women; ², n.s.) was classified as having self-reported depression. Logistic regression analysis showed that the difference between men and women was statistically significant, i.e. men reported depression more often than women (OR 1.226 (CI 1.062–1.414)). According to the SPDR, 7.6% of the study population had been prescribed at least one AD during the 6 months prior to the HADS evaluation. Significantly more women than men were prescribed ADs: 5.3% of the men and 9.8% of the women were prescribed at least one AD ($P < 0.0001$).

Table 1 presents gender differences in the relation between prescribed ADs and self-reported depression in the study population. Among the men, 1.8% reported depression and used ADs, 10.5% reported depression but did not use ADs, and 3.6% used ADs but did not report current depression, while 84.1% were neither depressed nor used ADs. The corresponding figures for women were 2.6%, 8.6%, 7.2% and 81.6%. The gender difference was statistically significant (² $P < 0.001$) in all age groups except the youngest, and was most marked in the groups aged 45–64 and 65–74 years.

Relation between self-reported depression (assessed using the HADS) and prescribed antidepressants (ADs) in the study population ($n = 7618$), Sweden 2012/2013

	Men	Women									
18–34	593	1.7	8.9	2.0	87.4	831	1.8	9.8	3.6	84.8	N.S.
35–44	475	1.9	11.8	2.3	84.0	576	3.1	8.7	6.8	81.4	<0.01
45–64	1277	1.8	10.6	4.6	82.9	1537	3.3	9.0	8.3	79.4	<0.001

Total	3435	1.8	10.5	3.6	84.1	4183	2.6	8.6	7.2	81.6	<0.001

² analyses comparing men and women.

The participants who had received at least one prescribed AD during the 6 months studied ($n = 592$: men $n = 182$, women $n = 410$) were analysed with respect to the type of AD prescribed (*Table 2*). SSRIs were the most commonly prescribed ADs for both men (62.8%) and women (71.0%), although women were prescribed them more often than men, particularly in the age group 45–64 years (² $P < 0.05$). By contrast, there was no statistically significant gender difference for the TCAs (men 14.8%, women 10.2%), except for in the age group 45–64 years. Further, men were prescribed ‘other’ ADs (e.g. SNRIs and TeCAs) significantly more often than women (men 39.3%, women 28.1%; ² $P < 0.01$).

Types of antidepressant (ATC classification) among participants prescribed at least one antidepressant ($n = 592$), by age and gender, Sweden 2012/2013

	Users, n	SSRIs (N 06AB)	TCAs (N 06AA)	Others (N 06AX) ^a								
18–44	144	42	102	69.1	73.5	NS	9.5	5.9	NS	38.1	29.4	NS

ATC, Anatomical Therapeutic Chemical; NS, not significant; SSRIs, selective serotonin reuptake inhibitors; TCAs, tricyclic antidepressants.

For example, serotonin–noradrenaline reuptake inhibitors, tetracyclic antidepressants.

² analyses comparing men and women.

Discussion

The present study found that the relationship between self-reported depression and prescribed ADs differs by gender. As in several other studies,^{26,27} the majority of those who reported depression in our study did not use ADs, and overall, men used ADs to a lesser extent than did women, although they reported depression to a greater extent. This could have been caused by several factors. Many people, especially men, prefer not to seek healthcare.³⁵ Women are clinically diagnosed with depression far more often than men, probably not only because they are more depressed but also because they are more likely to seek healthcare, thus increasing the chance that their depression will be detected.³⁶ Also, diagnostic criteria for depression originate from a female norm and symptoms provided by women, leading to an increased likelihood that depression in women will be diagnosed.¹⁵ Depression in men has a different presentation than the classic depressive symptoms more often than in women, and this could lead to men's mental health problems not being recognised and therefore being under-treated.^{13,35}

In contrast to diagnosed depression, previous studies using HADS to assess depression have mostly found no gender differences or, like our study, found a higher prevalence of depression in men.^{37,38} Since men experience more melancholic symptoms and women more somatic symptoms (e.g. increased appetite and weight, and hypersomnia),¹³⁻¹⁷ the reversed gender differences in depression assessed with HADS compared with clinically diagnosed depression could be due to the fact that HADS's focus is more on melancholic rather than somatic symptoms. Whether the HADS might be more sensitive than other scales in detecting depression in men is as yet unclear.

Other factors that could explain the relatively low use of ADs in our study among the sample with depression might be that the depressed participants may have been reluctant to accept treatment with ADs, a choice that is possibly more common among men; they may not have needed drug treatment, perhaps because other treatments were used (in mild depression psychotherapy is considered as effective as drugs); or they may not have had the prescribed drug dispensed. Many patients do not adhere to treatment instructions, for example do not even obtain their prescribed drugs (primary non-adherence), and prior studies have suggested that both gender and illness severity affect adherence.³⁹⁻⁴²

In our study, it was twice as common for women as for men to use ADs when not currently depressed. This could indicate that their depression was in remission, but it could also mean that women are being over-treated with ADs. Several studies have found AD use to be higher among women, and the increased prescription of ADs in recent decades is especially notable among women.^{23-25,30,43} The higher level of AD prescribing to women may in part be attributed to the greater consumption of healthcare among women in general.^{36,44} Apropos of this, there are studies that show that women are more likely than men to receive a prescription during their medical visits.⁴⁵ The lower threshold for prescribing ADs has led to a debate about the possibility of over-prescription or of ADs being sometimes prescribed where alternatives would be better.⁷⁻⁹ It seems that even mild symptoms are now considered indicative of disease and treated with medications, although the efficacy is often limited in mild to moderate depression.^{7,46,47} Further, an expanding number of indications (e.g. neuropathic pain, anxiety disorders, eating disorders and sleep disorders) seen more often in women than in men are contributors to the increasing trend to prescribe ADs, and this could explain some of the AD use without depression seen in our study.^{9,48}

As in other studies, the SSRIs were the main drugs in our study.^{28,30} Because of gender differences in the pharmacokinetics and pharmacodynamics of ADs, and because depression may present differently in women and men, it has been suggested that men and women could differ in their response to treatment and that pharmacological treatments should therefore be chosen by gender.⁴⁹⁻⁵¹ The women in our study used SSRIs more often than the men. It could be that somatic symptoms respond better to SSRIs than to TCAs. Another cause might be gender differences in adverse drug reactions. However, supporting data are limited and sometimes conflicting, and current treatment guidelines do not take gender into account.^{49,50,52} Regardless, it is important to continue to examine any differences between men and women concerning pharmacotherapeutic efficacy and adverse drug reactions.

Limitations

The SPDR offers complete data on all dispensed drugs; however, it does not give information on actual usage. Also, ADs during the 6-month period were analysed without distinguishing whether the drugs had been used for a long or a short time. Moreover, ADs are sometimes prescribed for indications other than depression, which we could not control for. However, previous studies have reported that depression remains the main indication for AD use.⁵³ Participation in the study was voluntary and there may have been selection biases. For example, non-responders were more likely to be men than women. It is also possible that people with current symptoms of depression would be less likely to respond, introducing further bias to participant selection. Depression assessed using the HADS (in the previous week) was not directly linked to prescribed ADs via the SPDR (0–6 months prior to the HADS evaluation). However, depression is often a prolonged state, and problems in this respect that were encountered in the previous week were probably not temporary. Finally, it is important to emphasise that a cross-sectional design does not permit evaluation of causality to be derived from the results.

Summary of findings

The relationship between self-reported depression and use of ADs differed by gender. Overall, men were prescribed ADs to a lesser extent than women, although they reported depression to a greater extent. By contrast, women were prescribed ADs without reporting depression more often than men. This may be a sign for under-treatment among men and over-treatment among women. Further, men and women were prescribed different types of ADs, possibly because of gender differences in treatment outcomes and adverse drug reactions. Although the causes of these findings remain unclear, diagnostic and treatment guidelines should benefit from considering gender in these respects.

1.7.45 An analysis of whether a working-age ward-based liaison psychiatry service requires the input of a liaison psychiatrist

Abstract

Aims and method This article presents a 12-month case series to determine the fraction of ward referrals of adults of working age who needed a liaison psychiatrist in a busy tertiary referral teaching hospital.

1

Results The service received 344 referrals resulting in 1259 face-to-face contacts. Depression accounted for the most face-to-face contacts. We deemed the involvement of a liaison psychiatrist necessary in 241 (70.1%) referrals, with medication management as the most common reason.

Clinical implications A substantial amount of liaison ward work involves the treatment and management of severe and complex mental health problems. Our analysis suggests that in the majority of cases the input of a liaison psychiatrist is required.

Contents

- *An analysis of whether a working-age ward-based liaison psychiatry service requires the input of a liaison psychiatrist*
 - *Method*
 - * *Involvement of a liaison psychiatrist*
 - *Results*
 - * *Referrals which required the involvement of a psychiatrist*
 - *Discussion*

Liaison psychiatry services in England have recently seen considerable expansion, following the positive evaluation of the Rapid Assessment Interface and Discharge Team (RAID) service in Birmingham.¹ The independent evaluation suggested that this well-staffed multidisciplinary liaison psychiatry service returned considerable cost savings for people with mental health problems in that general hospital and those attending the emergency department.

The 2015 annual survey of liaison psychiatry in England demonstrated that many services are too poorly resourced to be delivering benefits to patients as envisaged by the RAID study,² while the recent *Guidance on Developing Models for Liaison Psychiatry Services* has shown great variability in service provision.³ The relative lack of consultant psychiatric input suggests that the specialist skills offered by consultant liaison psychiatrists may be poorly understood. To examine the multidisciplinary liaison psychiatry team, we aimed to determine the proportion of referrals to a ward-based liaison service which required the involvement of a psychiatrist in a busy tertiary teaching hospital in England. This project was carried out as part of a registered audit (Audit Project 2125) with Manchester Mental Health and Social Care Trust.

There are many descriptions of the activity of liaison services, but we believe this is the first time the role of a psychiatrist has been addressed in depth. We hope our findings will help inform decisions regarding staffing and the configuration of multidisciplinary liaison psychiatry teams. We focused on a ward-based liaison service for adults of working age.

Method

We carried out a case series of the electronic records of consecutive referrals to a ward-based liaison service at a large teaching hospital in Manchester, over a 12-month period from 18 June 2013 to 17 June 2014. The hospital has approximately 750 beds, with a large renal and critical care unit. There is also a maternity unit on site, with over 8500 deliveries per annum, and an eye hospital. Our liaison service reviews referrals covering an age range of 16–65 by the next working day. Routine alcohol referrals, covered by two specialist nurses, may also be received by our service.

The following details were recorded for each referral: age, gender, number of face-to-face contacts carried out by the team, amount of time the team had ongoing contact with the patient (days), reason for referral, referrer type, psychiatric diagnosis using clinical judgement according to ICD-10 criteria,⁴ employment of the Mental Health Act 1983, and disposal.

Involvement of a liaison psychiatrist

To determine the proportion of patients who required the input of a psychiatrist, we developed criteria for contacts or interventions that required medical input and could not be undertaken by a non-psychiatrist. We deemed the involvement of a psychiatrist would be necessary in any of the following scenarios: Mental Health Act employed, rescinded or considered; medication management; treatment with psychotropic medications commenced in the general hospital; complex diagnostic matters; behavioural disturbance in physically unwell patients where advice about appropriate sedation is required; complex capacity assessments; and a specific request for a consultant psychiatrist opinion. Each case was reviewed and rated by a member of the team. *Box 1* provides detailed criteria for each of these scenarios. We recognise that there are many other kinds of interventions a psychiatrist may carry out as part of liaison work, but we wished to focus solely on interventions which could not be carried out by someone other than a psychiatrist. Many of the interventions therefore require some kind of expertise involving medical knowledge or prescribing of psychotropic medication in patients who are physically unwell.

Summary scores for normally distributed data are presented as means and standard deviations (s.d.). The activity data were not normally distributed, so summary scores are presented in the form of medians and interquartile ranges (IQR). Comparisons of continuous activity data were carried out using non-parametric statistical tests. Mann-Whitney *U*-tests were used to compare continuous data. As in some cases we had few activity data, with only one or two patients in each group, groups with very small sizes (two patients or fewer) were not included in the statistical analyses.

Results

The service received 344 referrals over the study period and carried out 1259 face-to-face contacts with patients. The average number of 'face-to-face' contacts per patient was 3.7 (s.d. = 5, range 1–33). The median age of patients seen was 48 years (IQR 36–59), and 184 (53.4%) were female. At any one time, between 8 and 15 patients were under review by the team. The majority of referrals were from physicians (all medical departments) ($n = 227$, 66.0%), 59 (17.2%) were from surgery, 31 (9%) from the maternity hospital and 23 (6.7%) from the critical care unit. One referral came from the eye hospital and a further 3 were from the liaison service for older adults, but these patients were best managed by the adults of working age team.

Table DS1 in the online supplement provides a snapshot of the patients under the care of the service on one day in May 2014, and is typical of the kind of patients who are under review by the service at any given time. Five patients had severe mental illness (four had schizophrenia and one had bipolar disorder). Two had been treated under the Mental Health Act and there was a possibility that one more person may have needed treatment. One person was on a community treatment order (CTO). Four patients had voiced recent suicidal ideas, two had complex organic mental disorders, and three had psychological reactions to physical illness or difficulties with their behaviour in an acute hospital setting.

Referrals which required the involvement of a psychiatrist

Table 1 illustrates the number of referrals which needed a psychiatrist. Of the 344 referred patients who saw a psychiatrist, we deemed on the basis of our criteria that a psychiatrist was required for 241 patients (70.1%). Patients who required a psychiatrist needed more face-to-face contacts than those who did not require a psychiatrist (median 2 (IQR 1–5) v. median 1 (IQR 1–2)), and were under the liaison service for a greater period of time (median 7 days (IQR 1–14) v. median 1 day (IQR 1–7)).

Referrals and service workload depending on whether patient required a psychiatrist or not

		Face-to-face contacts	Days in contact with service, median (IQR)	
Requires psychiatrist	241 (70.1)	1039 (82.5)	2 (1–5)***	7 (1–14)***
Does not require psychiatrist	103 (29.9)	220 (17.5)	1 (1–2)	1 (1–7)
Total	344	1259	2 (1–5)	4 (1–13)

IQR, interquartile range.

$P < 0.001$ (requires v. does not require a psychiatrist).

According to our criteria, the most common reason for psychiatric input was medication management (*Table 2*): 77 patients (32.0%) required input regarding their current psychotropic medication use. Of interest, 10 of these patients were referred for clozapine management which required over 100 face-to-face contacts from the team. 56 patients were started on treatment for their mental health problems while they were in hospital (i.e. patient started on psychotropic medication). There were complex diagnostic issues in 38 patients and the Mental Health Act was considered in 23 patients, but only actually implemented in 18. In 14 cases the patient required a complex capacity assessment, 10 patients presented with challenging behaviour requiring advice about sedation, and a specific consultant opinion or involvement was requested in 6 patients. The categories are not mutually exclusive.

The number of patients who required a psychiatrist according to the categories in the study

Clinical categories	<i>n</i>	Percentage of total requiring psychiatrist
Medication management	77	32.0%
Treatment with psychotropic drugs	56	23.2%
Complex diagnostic issues	38	15.8%
Mental Health Act	23	9.5%
Management of severe mental illness	17	7.1%
Complex capacity assessments	14	5.8%
Management of behavioural disturbance	10	4.1%
Specific liaison consultant review	6	2.5%

Box 1 Definitions of categories used to determine whether the involvement of a liaison psychiatrist was required

- Mental Health Act: situations where the Mental Health Act has been applied or its potential use has been seriously considered
- Medication management: consultation in which there was a specific issue about psychotropic medication the patient was taking due to a change in their physical health. This may involve stopping, switching or another action.

- Management of behavioural disturbance in the general hospital: involving advice about medication, where a psychiatrist has provided assessment, advice and guidance about using sedating medication. The psychiatrist will have considered the patient's underlying physical health problems (e.g. renal failure) in making the decision regarding type and dosage of medication. Other non-pharmacological aspects for management of acute behavioural disturbance in physically unwell patients are not considered here, as they are not exclusively carried out by liaison psychiatrists
- Complex diagnostic matters: diagnosis or understanding of a clinical problem which required knowledge of specific medical disorders
- Capacity: requests for medically complex capacity assessments, where the patient has a history of a psychiatric condition which may be interfering with their judgement to give informed consent to potentially life-saving treatment
- Treatment with psychotropic medications commenced in the general hospital: treatment with a psychotropic agent that was commenced in the general hospital by the liaison team, in a patient who had ongoing physical health concerns
- Specific request for consultant liaison psychiatrist opinion: the referring consultant specifically requested a consultant psychiatric opinion or involvement

Box 2 Categories of clinical scenarios where we judged a psychiatrist was required (examples)

- **Mental HealthAct:** Female (age range 50–60) with diagnosis of schizophrenia. Admitted with a ruptured oesophagus. Clozapine had been stopped prior to admission as she had refused to take it. Her psychosis had relapsed and she was floridly psychotic in hospital. Following repair of her oesophagus she required 6–8 weeks bed rest for the repair to heal. She was treated under Section 3 of the MHA with covert medication (clozapine). Her mental state returned to normal. She had a good physical and mental health recovery. She later agreed to continue to take clozapine on a voluntary basis.
- **Medication management:** Female (age range 30–40) admitted following collapse and found to have very low sodium. Diagnosis of schizophrenia. In discussion with medical team, all psychotropic medication was stopped. Haloperidol started cautiously. Usual medications re-started after physical recovery. Discharged to CMHT.
- **Management of behavioural disturbance:** Male (age range 40–50) who was admitted with delirium, barricaded himself and 3 other patients in a 4-bedded side room. History of hydrocephalus and other abnormal neurological signs. Input required sedation to manage the current situation and to facilitate medical investigations including brain MRI.
- **Diagnosis:** Male (age range 50–60) admitted from nursing home with a history of severe weight loss. History of schizophrenia and extrapyramidal side-effects attributed to neuroleptics. Huntington's chorea diagnosed by consultant psychiatrist.
- **Capacity:** Male (age range 50–60) with history of schizophrenia. Jumped off a bridge when 22 years of age, paraplegic following this. Psychosis treated well for years on clozapine. Developed bowel obstruction, multi-organ failure. Clozapine stopped. On regular haemodialysis. Chronically psychotic. Refusing dialysis. Complicating factors, low mood, chronic psychosis (at times he believes he is Christ and can be resurrected).
- **Treatment with psychotropic drugs commenced in the general hospital:** Male (age 60–70) admitted after stabbing his wife in the back and then stabbing himself 4 times in the abdomen. Diagnosed with depressive disorder. Treatment started with antidepressants while receiving medical treatment on ward. Mood improved.
- **Specific request for consultant liaison psychiatric opinion:** Male (age range 40–50) with a history of gastric problems and feeding difficulties. Had had gastrectomy and had been started on TPN. Had been in hospital for over a year. Staff suspected that reliance on TPN was far more than clinically indicated but all efforts to reduce it failed. Patient was aggressive on occasions with staff, made frequent complaints about staff and at times threatened self-harm. Consultant opinion was specifically sought regarding the risks of moving to home with TPN feeding.

CMHT, community mental health team; MHA, Mental Health Act; MRI, magnetic resonance imaging; TPN, total parenteral nutrition.

Table 2 shows the number of patients who required a psychiatrist according to the categories developed for this study.

Clinical illustrations of actions or interventions which were judged to require the involvement of a psychiatrist, according to each category, are provided in *Box 2*.

Table 3 shows the number and percentage of patients who required input from a liaison psychiatrist according to the most common psychiatric diagnoses. Patients with bipolar affective disorder, schizophrenia, Korsakoff's psychosis, amnesic syndrome and somatoform disorder required the involvement of a psychiatrist in over 80% of all cases, whereas for patients with anxiety/panic disorder, adjustment disorder or dementia the requirement was much lower.

Patients who required input from a liaison psychiatrist according to diagnosis

Psychiatric diagnosis	Required psychiatrist (% of total seen)
Somatoform disorders	9 (100.0%)
Bipolar affective disorder	23 (92.0%)
Amnesic syndrome	11 (91.7%)
Korsakoff's psychosis	11 (91.7%)
Schizophrenia	42 (82.4%)
Depression	100 (74.1%)
Miscellaneous including eating disorders, intellectual disability	5 (71.4%)
Personality disorder	9 (69%)
Substance misuse	11 (68%)
Delirium	15 (65.2%)
Anxiety/panic disorder	6 (50.0%)
Dementia	2 (33.3%)
No diagnosis	8 (32.0%)
Adjustment disorder	2 (20.0%)

Discussion

Our findings suggest that a ward-based liaison psychiatry service for working-age adults in a large teaching hospital requires the input of liaison psychiatrists. We deemed that a psychiatrist was essential in the assessment or management of approximately 70% of all referrals to the service, whereas approximately 30% could be reviewed by other members of a liaison team. We based this judgement on clear, definable actions or aspects of care that necessitated the involvement of a psychiatrist. A consultant liaison psychiatrist would of course have many other roles, but for the purposes of this study we limited our focus to interventions or actions where the role of a psychiatrist was unequivocal.

Many of the patients seen by the service had complex physical and mental health needs. Table DS1 provides a snapshot of the work, and illustrates that it is necessary to involve a psychiatrist in the management of a large proportion of referrals. Out of the 12 patients under the care of the team on one day in May 2014, 9 required the input of a psychiatrist.

Certain patients with diagnoses such as adjustment disorder and dementia were unlikely to require psychiatric input, whereas high rates of psychiatric involvement were required for patients with severe mental illness and somatoform disorders. Psychiatric input was also needed in the management of patients with Korsakoff's psychosis, because locally a formal diagnosis from a psychiatrist is required in order to access particular kinds of Social Services support.

This study has three major limitations. First, data were based on routine clinical entries made using a National Health Service (NHS) electronic record system. It is possible that this may have led to an underestimation of the numbers of patients requiring psychiatric input due to a lack of recording certain data (e.g. details about psychotropic medication). It is very unlikely that it would have led to an overestimate of our findings. Second, this study was undertaken in a teaching hospital, with a large critical care unit, a large renal unit, a very busy maternity hospital and other specialist centres. It may not reflect the work of a liaison service in a district general hospital, but it emphasises the need to take account of local variations in acute hospital services when planning a liaison service. Third, this liaison service is a ward-based service only. Approximately a third of liaison services run out-patient clinics for complex cases requiring psychiatric time. Clinics can take psychiatrists away from acute ward cover and require different planning and staff resources compared with a ward-based liaison service.

The methods we employed, however, can easily be used by other services to estimate the requirement for input from a liaison psychiatrist, and this is likely to vary depending on the setting and age range of patients seen. As this research team consisted entirely of psychiatrists, we may have overestimated the need for the skills of our own discipline when creating the criteria and applying them. However, we have provided clinical examples to illustrate our decision-making process and thus expose it to critical examination.

Our results suggest that liaison psychiatrists have a pivotal role in ward-based liaison services for adults of working age, and this may be particularly important in a teaching hospital setting. Our work also provides support for the recent commissioning guidance for liaison psychiatry services in England developed by the Department of Health, which suggests that liaison psychiatry services in a teaching hospital/inner city setting may require additional consultant psychiatric input.⁷

1.7.46 Civil and forensic patients in secure psychiatric settings: a comparison

Abstract

Aims and method To evaluate differences between male patients in secure psychiatric settings in the UK based on whether they are detained under civil or forensic sections of the Mental Health Act 1983. A cohort of patients discharged from a secure psychiatric hospital were evaluated for length of stay and frequency of risk-related incidents.

Results Overall, 84 patients were included in the study: 52 in the forensic group and 32 in the civil group. Civil patients had more frequent incidents of aggression, sex offending, fire-setting and vulnerability, whereas forensic patients had more frequent episodes of self-harm.

Clinical implications Secure hospitals should ensure treatment programmes are tailored to each patient's needs. Civil patients require greater emphasis on treatment of their mental illness, whereas forensic patients have additional offence-related treatment needs. Regular liaison between forensic and general adult services is essential to help ensure patients can return to appropriate settings at the earliest opportunity in their recovery.

Further to the closure of the asylums and subsequent rare but high-profile failures in community care, forensic psychiatry in the UK has rapidly expanded, with the development of high, medium and low secure in-patient services across the country as well as specialist forensic mental health teams in the community.¹ Alongside its expansion, an ongoing debate related to its interface with general psychiatry has persisted.² In England and Wales, the forensic v. general psychiatry divide extends to the subdivision of in-patients detained under the Mental Health Act 1983 into those affected by civil and forensic sections. Patients detained under Part II of the Act are termed 'civil patients'. They can be detained under Section 2 for assessment and treatment for up to 28 days where there is suspicion of a mental disorder. Section 2 can be converted to Section 3 for further treatment. Alternatively, patients can be admitted directly under Section 3 when there is a known mental disorder. Patients detained under Part III of the Act are termed 'forensic patients', given their involvement in the criminal justice system through the courts and prisons.

While forensic units have expanded, there has been an overall reduction of in-patient bed numbers in the UK, which have fallen from 155 000 in 1954 to just 18 166 as of 31 March 2014. The number of patients detained in all settings under civil sections during 2013/2014 was 32 781, of which 25 300 were under Section 2 and 7481 were under Section 3. During 2013/2014 there were 1847 detentions under forensic sections: 99 under Section 35 or 36, which is admission for assessment or treatment via the courts; 763 under Section 37 hospital orders, allowing detention in hospital instead of a prison sentence; and 457 under Section 47, which allows transfer of a serving prisoner to hospital.^{2,3}

Secure psychiatric hospitals are generally geared towards providing assessment, treatment and rehabilitation for forensic patients, since they are the majority group in such hospitals. In particular, Coid *et al* found that 69% of patients

//creativecommons.org/licenses/by/4.0/), which permits unrestricted re-use, distribution, and reproduction in any medium, provided the original work is properly cited.

The Authors own the copyrights to the individual articles.

in medium security were detained under forensic sections.⁴ Despite this discrepancy in distribution, research into whether there are differences between these groups is limited. The only study we could identify was that by Reed (2004),⁵ who evaluated the differences between civil and forensic in-patients in a low secure intellectual disability setting and found, surprisingly, that the forensic patients were less likely to be aggressive or use weapons but more likely to harm themselves.⁵ It is not known whether these findings are isolated to intellectual disability settings. Therefore, we present findings from our evaluation of male patients discharged from a secure psychiatric hospital (excluding intellectual disability – the hospital does not cater for such patients) and suggest recommendations on how to meet the differing clinical needs identified in each group.

Method

The study was conducted as part of a service evaluation into length of stay at St Andrew's Healthcare, Birmingham, and registered with the St Andrew's Clinical Audit Team. In keeping with previous similar evaluations, ethical approval was not required as the study evaluated retrospective, non-patient-identifiable data from health records as part of service evaluation.⁵ Data were retrospectively collected for all discharges from the two medium and three low secure wards since the opening of the hospital in March 2009 to the study end point of 30 December 2014. The source of data were patients' electronic health records, including medical reports, Historical Clinical Risk Management-20 (HCR-20) assessments, Care Programme Approach records, electronically recorded risk incident logs and discharge summaries.

Summary statistics were calculated for all patients evaluated. Patients were then grouped by whether they were initially detained under a civil or forensic section at the start of their admission to St Andrew's Birmingham. In order to evaluate illness severity between the two groups, Health of the Nation Outcome Scales for Users of Secure and Forensic Services (HoNOS-secure) assessment scores taken at admission and discharge were noted.⁶ A power calculation was not performed but all available data were used in the analysis. The average length of stay was calculated for each group. SPSS version 16 for Windows was then used to calculate independent *t*-test statistics to examine any between-group associations and frequency of various types of incidents.

Results

In total, 93 male patients were discharged from the hospital during the data collection period; 9 patients were excluded from the study: 7 were excluded as their admission was less than 3 months and unlikely to be representative of the treatment phase being evaluated, and discharge would also have occurred prior to the standard Care Programme Approach meeting held 3 months after admission, where a formal diagnosis would have been made. One patient was excluded as they were informal during the course of their admission and one was excluded due to death from natural causes. Therefore, 84 patients were included in the study, with 32 in the civil group and 52 in the forensic group. In the civil group, 16 patients were admitted from general adult services, 1 from a police station, 7 from low secure services and 8 from medium secure services. The legal status of patients in the civil group remained unchanged during the course of their admission, apart from one patient who became informal in the days prior to discharge. None of the patients in the civil group switched to being forensic patients following convictions in court. Regarding the forensic group, 4 patients were admitted from general adult services, 3 from low secure services, 16 from medium secure services, 28 from prison and 1 from a high secure hospital. In this group, 14 patients changed their legal status prior to discharge; 11 changed from being sentenced prisoners under Section 47/49 to being detained under a notional Section 37, as they had gone past what would have been their automatic release date from prison. Two patients switched from being remanded prisoners under Section 48/49 to being sentenced under a Section 37 hospital order at court and one patient switched from Section 48/49 to a Section 37/41 hospital order with restrictions after sentencing at court.

Table 1 outlines the baseline characteristics of each group, including diagnosis, age, ethnicity and Mental Health Act status on admission. All patients were male, with a mean age of 37 years (range 20 to 63 years). *Table 2* shows the mean length of stay, HoNOS-secure scores on admission and discharge, and frequency of risk-related incidents.

Discussion

The study found no significant difference in length of stay or severity of illness based on HoNOS-secure scores at the start or end of admission between the civil and forensic groups. However, it should be noted that HoNOS-secure is not a specific measure of mental state, since it also evaluates behavioural functioning and a range of security measures. This study identified that civil patients in secure settings have more frequent incidents of aggression, sex offending, fire-setting and vulnerability, whereas forensic patients have more frequent episodes of self-harm. This finding challenges the preconception that forensic patients are more ‘dangerous’ and difficult to manage.² One explanation for this may be that the civil patients in this study represent a cohort of general adult patients that have been placed in forensic services due to their frequency of aggressive and difficult to manage behaviours, whereas the more stable forensic patients have been admitted due to severe but more isolated offences.

The higher frequency of incidents in the civil group may make engaging with specialist treatment programmes practically more difficult for this group, which may in turn become a factor that limits their motivation to engage. Secure hospitals should be aware that civil patients, due to higher frequency of risk incidents, may have differing needs to forensic patients. Therefore, we suggest that civil patients who present with a high frequency of incidents will benefit from a greater emphasis on treatment of their mental illness combined with behavioural interventions, with less of a requirement to engage in specialist treatment programmes or to complete formal psychological therapy programmes that are often required in forensic settings. Further research is needed to explore whether the higher frequency of incidents among civil patients affects the therapeutic milieu on the ward and has an adverse impact on outcomes for forensic patients engaging in specialist treatment interventions. The higher frequency of vulnerability incidents among civil patients highlights the difficulty they experience in forensic settings and suggests a greater need for vigilance and robust safeguarding for this patient group, who may be at risk of reprisal assaults by their forensic peers. The findings of our study must also be considered in light of the Schizophrenia Commission report,⁷ which comments that patients

stay too long in secure services, and highlights funding cuts and acute bed closures in general adult services as part of the problem.

We conclude that our study supports the need to focus more on preventive interventions, such as avoiding delays in assessment, ensuring early treatment and supporting alternatives to admission such as crisis and home-based treatment teams, to help avoid admissions. Regular liaison between forensic and general adult services is essential to help ensure patients can return to appropriate settings at the earliest opportunity in their recovery. This may only be possible with careful consideration when commissioning services at all levels of care.

The finding that forensic patients have a greater frequency of self-harm incidents should be treated with caution as the numbers in this study are small and self-harm is a rare outcome. One possibility is that forensic patients may find the criminal justice system and their conviction distressing, leading to a greater risk of self-harm and potentially suicide. We suggest that clinical teams should be aware of this risk in these patients and ensure careful monitoring, risk management and support for patients during criminal proceedings.

Limitations

This study has a number of limitations. Most significantly, it is a comparison of forensic and civil patients conducted in a secure mental health hospital and the findings cannot be used to compare differences between forensic and general adult patients in non-secure settings. In addition, the civil patients in the study are likely to represent patients with greater treatment resistance whose aggressive behaviours have led to them being transferred to secure settings. It remains possible that the section status assigned to the patient on admission may be misleading, as quite often patients who commit offences when unwell are not prosecuted.⁸ The study is reliant on accurate recording of risk incidents in patients' records. Although some degree of inaccuracy in recording of incidents may have occurred, it is anticipated that this would have occurred evenly between both groups and thus not affected the validity of the results. This study, in line with previous work, evaluates data for a cohort of discharged patients in order to evaluate comparable groups. It is possible that the study may underestimate the severity of risk incidents, since the most challenging patients would not have been included in the analysis as they have not yet been discharged from hospital. It is anticipated that the impact of this factor would be evenly distributed between each group.

Practice recommendations

Secure hospitals should ensure all treatment plans are based around the individual. There should be an emphasis on managing the mental illness of civil patients and tailoring treatments based on this goal, which will help reduce risks and hopefully shorten length of admission. Forensic patients are more likely to have additional offence-related treatment needs which would require specific interventions. Regular liaison between forensic and general adult services is essential to help ensure patients can return to appropriate settings at the earliest opportunity in their recovery. This can only be possible with careful consideration when commissioning services at all levels of care.

We thank Catherine Clarke, Psychology student at the University of Birmingham, for her help in the study.

1.7.47 Known unknowns and unknown unknowns in suicide risk assessment: evidence from meta-analyses of aleatory and epistemic uncertainty

Abstract

Suicide risk assessment aims to reduce uncertainty in order to focus treatment and supervision on those who are judged to be more likely to die by suicide. In this article we consider recent meta-analytic research that highlights the difference between uncertainty about suicide due to chance factors (aleatory uncertainty) and uncertainty that results from lack of knowledge (epistemic uncertainty). We conclude that much of the uncertainty about suicide is aleatory rather than epistemic, and discuss the implications for clinicians.

Contents

- *Known unknowns and unknown unknowns in suicide risk assessment: evidence from meta-analyses of aleatory and epistemic uncertainty*
 - *Can knowing about suicidality reduce uncertainty about suicide?*
 - *Can knowing about a wider range of risk factors reduce uncertainty about suicide?*
 - *Implications of the limits to epistemic uncertainty*

Uncertainty is the psychological state of being unsure, of having doubt, of not fully knowing. Uncertainty is central to modern medicine, where its recognition drives diagnostic efforts and leads to the pursuit of evidence-based practice. All medical decision-making occurs under conditions of varying uncertainty about diagnosis, optimal treatment and prognosis. This is true in the assessment of suicidal patients.

Uncertainty has two underlying components: epistemic uncertainty that results from a lack of knowledge, and aleatory uncertainty that results from random or chance events.¹⁻³ In medical practice, both types of uncertainty are at play. A teenage tobacco user might or might not develop cancer later in life. This is mostly a matter of chance, a chance that will increase with heavier and longer tobacco use. This longitudinal cancer risk is probabilistic, akin to the throw of a die, and further knowledge might not greatly reduce uncertainty about what will eventually happen. In middle age, the same smoker might develop haemoptysis. A chest X-ray would reduce uncertainty about the presence or absence of lung cancer, but it might be more clearly resolved by a biopsy. Uncertainty in this case is not probabilistic – the smoker either has or does not have cancer. This is now a question that can be resolved with more information. Chance is no longer playing a part.

It is generally considered that uncertainty in suicide risk assessment can be greatly reduced by a detailed assessment of the patient's suicidal thoughts, plans and actions, and attention to other demographic and clinical factors. Suicide risk assessment guidelines and relevant peer-reviewed publications often contain long lists of questions to ask and factors to consider.⁴⁻⁷ This approach assumes that more substantial knowledge of the patient, their illness, circumstances and intentions will reduce the epistemic uncertainty in the assessment. Few would doubt that chance also plays a major part in suicide. The course of underlying illness, the vagaries of individual decision-making and impulsivity, and the patient's future circumstances are all sources of aleatory uncertainty.

In this article we consider the uncertainty surrounding suicide using the framework of epistemic and aleatory uncertainty. In order to do this, we use recent meta-analytic research to interrogate the proposition that uncertainty about

suicide risk can be reduced by knowing more about suicidal thoughts and behaviours, or by the knowledge of a wider range of suicide risk factors.

Can knowing about suicidality reduce uncertainty about suicide?

No small number of references could begin to do justice to the importance that suicidal ideation and behaviours have assumed in suicide research. Several recent systematic meta-analyses have synthesised the quantitative peer-reviewed literature on the statistical relationship between suicidality and suicide. Each of these meta-analyses has cast doubt on the notion that knowing more about suicide ideas, or suicidality more broadly, reduces uncertainty about suicide.

Two meta-analyses published in 2011, one examining risk factors for suicide by psychiatric in-patients⁸ and the other examining risk factors for suicide by recently discharged patients,⁹ found that the association between suicidal ideation and suicide was statistically weak, with diagnostic odds ratios (OR) of less than 3. In 2015, Chapman *et al*¹⁰ published a meta-analysis finding that suicidal ideation was significantly associated with suicide among patients with schizophrenia spectrum conditions. However, suicidal ideation was not significantly more likely to lead to suicide than no suicidal ideation among patients with mood disorders (OR = 1.49, 95% CI 0.92–2.42).

A 2016 meta-analysis¹¹ examined the broader question of whether self-injurious thoughts and behaviours deserve their status as strong predictors of future suicidal behaviour. This study found that self-injurious thoughts and behaviours are only weakly associated with later suicide attempts (OR = 2.14, 95% CI 2.00–2.30) and death from suicide (OR = 1.54, 95% CI 1.39–1.71). The authors concluded that assessments of suicidality provided an improvement in prognostic accuracy that was only marginally above chance.

Another 2016 meta-analysis examined the psychometric properties of both individual risk factors and suicide risk assessment scales (the Beck Hopelessness Scale, Suicide Intent Scale and Scale for Suicide Ideation) among populations of people who self-harm.¹² The authors found a modest statistical association between previous self-harm and suicidal intent and later suicide, concluding that individual risk factors are ‘unlikely to be of much practical use because they are comparatively common in clinical populations’. With respect to use of suicide risk scales they considered that they ‘may provide false reassurance and [are], therefore, potentially dangerous’.

Thus, five recent meta-analytic summaries of the peer-reviewed literature have each reached similar conclusions – knowing about suicide thoughts and behaviours can only reduce uncertainty about future suicide to a modest extent.

Can knowing about a wider range of risk factors reduce uncertainty about suicide?

If enquiries about our patients’ suicide ideas, plans and actions do not help very much, what else should mental health professionals do to reduce uncertainty? The most common and obvious answer is to consider a comprehensive range of other suicide risk factors. Again it is simply not possible to describe the full range of articles, guidelines and peer-reviewed papers that consider the range of potentially important risk factors for suicide. A weakness of this literature is that although very large numbers of risk factors for suicide have been identified, there is no widely accepted way in which this information can be combined to improve the predictive strength of suicide risk assessment. Further, despite widespread recommendations for a comprehensive consideration of suicide risk factors, there are doubts as to whether combining risk factors can ever produce clinically useful predictive models. More than 30 years ago, Pokorny¹³ concluded his paper describing a landmark prospective suicide prediction study with the statement that it ‘is inescapable that we do not possess any item of information or any combination of items that permit us to identify to a useful degree the particular persons who will commit suicide, in spite of the fact that we do have scores of items available, each of which is significantly related to suicide’.

We recently published a meta-analysis that further examined the dilemma posed by Pokorny.¹⁴ We synthesised the results of all the published longitudinal prospective studies that used multiple risk factors to model future suicide among cohorts of psychiatric patients. We included experimental studies that employed multiple regression or survival analysis and studies that validated suicide risk prediction instruments. Our main outcome measure was the odds of suicide in high-risk patients compared with lower-risk patients. One of the aims of the meta-analysis was to determine if the observed between-study variability in this OR could be explained by the number of risk factors used in the predictive modelling. The results were very clear. We found a pooled OR of 4.84 (95% CI 3.79–6.20) derived from 37 studies

and 53 samples of patients. This indicates that the rate of suicide among high-risk patients can be expected to be about 5 times the rate of suicide of low-risk patients. While this sounds like it might be a clinically useful finding, these odds do not meaningfully improve on the pooled ORs of about 4 that are associated with some individual suicide risk factors among psychiatric patients – factors such as depression, hopelessness and prior suicide attempts.^{8,9} The meta-analysis also found that 56% of suicides occurred in high-risk groups (sensitivity) and 44% occurred among the lower-risk group. Over an average follow-up of 5 years, 5.5% of high-risk patients, but 1% of low-risk patients, died by suicide. This 5.5% suicide mortality over a period of 5 years means the probability of suicide of high-risk patients over clinically important durations is extremely low. For example, the weekly probability of suicide of a high-risk patient over the 5-year follow-up can be estimated at $0.055/(5 \times 52) = 0.0002115$ or 1 in 4700 people. In practical terms, what this means is that if a patient is deemed at higher risk of suicide because of the presence of one or more risk factors (recall that the number of risk factors seems unimportant), our best estimate of the incidence of suicide in the following week is about 1 in 4700. Even if there was a hypothetical dynamic risk factor that transiently increased the next-week risk of suicide by 10 times, strict supervision of almost 500 high-risk people for 1 week would be needed to prevent one suicide – assuming that such supervision were 100% effective.

Relevant to the present paper, the meta-analysis found that the predictive models that used more suicide risk factors had no more statistical strength, and no better discrimination between high-risk and lower-risk groups, than studies that used fewer factors (slope 0.007, 95% CI 0.016 to 0.03, $P = 0.53$). In fact, studies that employed two factors had a similar predictive strength to studies that employed ten or more factors. *Figure 1* plots the diagnostic odds with 95% confidence intervals effect size of models using 2 or 3 factors (8 samples), 4 or 5 factors (11 samples), 6 or 7 factors (7 samples), 8 or 9 factors (5 samples) and 10 or more factors (22 samples) with obviously overlapping confidence intervals. We concluded that multivariate models offered little advantage over single risk factors and that multivariate models that relied on more suicide risk factors performed no better than those that use fewer risk factors.

Implications of the limits to epistemic uncertainty

The findings of these recent meta-analytic studies undermine one of our profession's main assumptions about suicide risk assessment. Suicidal ideation,¹⁰ suicide behaviour^{11,12} and more complex modelling¹⁴ offer predictive advantages only a little better discrimination than chance. Hence, most of our uncertainty about suicide risk is aleatory; knowing more does not help because epistemic uncertainty plays only a minor part.

So what should clinicians do? First, we believe that this fundamental problem with suicide risk assessment needs to be acknowledged. We need to acknowledge our powerlessness to usefully classify individuals or groups of patients according to future suicide risk. We need to acknowledge this to ourselves, and communicate this to health departments, to the courts, and most importantly, to our patients and their families.

Second, we need to provide a more universal standard of care, involving a complete and sympathetic assessment of every patient, their illness and their circumstances. Such assessment is needed to guide individualised treatment plans, and might also have the intrinsic benefit of reducing suicidality.¹⁵ Where modifiable risk factors are found, we need to try to modify them. For example, patients who present with suicidal ideation when intoxicated should not be summarily discharged when sober and denying suicidal ideation, but should be offered access to addiction services that have some prospect of reducing suicide risk and improving their lives, irrespective of their overall risk category.

Third, we need to be very sparing in our use of involuntary treatment as a reaction to suicide risk. It is likely that very few patients who we admit to hospital would have died by suicide as out-patients over the period of time usually associated with a contemporary length of stay. Patients making ongoing immediate threats might still be admitted to hospital, as such threats are a crucial communication and legitimate focus of care without recourse to notions of probability. However, suicide risk is simply not a sufficient warrant for making paternalistic decisions about involuntary hospital care. Equally, we should be careful not to automatically deny low-risk patients voluntary in-patient treatment when they want it. Many suicides are by low-risk patients and we should not pretend we are able to peer into their future any more than we can discern the future of a higher-risk patient.

1.7.48 Drug information update. Unconventional treatment strategies for schizophrenia: polypharmacy and heroic dosing

Abstract

The majority of patients respond to antipsychotic monotherapy at standard doses, but a subset of patients will require more heroic measures that include antipsychotic polypharmacy and high-dose monotherapy. Indeed, research has shown that roughly 30% of patients with psychosis are prescribed multiple antipsychotic medications. We discuss the potential benefits and challenges of these approaches and provide a rationale for why and when they should be utilised.

– *Summary*

Schizophrenia is one of the most challenging psychiatric disorders faced by clinicians today, affecting roughly 1% of the population.¹ Many out-patient clinics and virtually all in-patient facilities manage these often complex clinical cases. Since the introduction of the first-generation antipsychotics (FGA) and subsequent development of the dopamine hypothesis, blockade of dopamine 2 (D₂) receptors has been the primary goal of pharmacological intervention. Even with the development and proliferation of the second-generation antipsychotics (SGA), D₂ blockade remains central to effective control of positive symptoms whereas serotonin 2A (5-HT_{2A}) plays an important but secondary role in the modulation of dopamine, theoretically improving negative symptoms while reducing the risk of extrapyramidal symptoms.²

The term ‘dopamine hypothesis’ of schizophrenia is slowly being phased out, as more sophisticated imaging studies have identified the nature of the dopamine dysfunction and its locus within the striatum. The striatum is a major component of the basal ganglia, and is divided functionally into the dorsal sensorimotor portion, the central associative striatum, and the ventral limbic striatum. Recently it has been found that the best correlation between positive symptoms of psychosis in schizophrenia and levels of D₂ activity is in the rostral caudate, a portion of the central associative striatum.^{3,4} We thus have *in vivo* confirmation of excessive D₂ neurotransmission and the relationship to the positive symptoms of schizophrenia. In the limbic striatum low dopamine release is directly related to the severity of negative symptoms; the lower the dopamine levels, the greater the negative symptom severity.³

While the goal of treatment is normalisation of D₂ neurotransmission in the striatum, a subset of patients do not respond to traditional treatment algorithms which include antipsychotic monotherapy at dosing levels defined in registrational trials. Consequently, many patients continue to exhibit uncontrolled positive and negative symptoms as well as manifesting aggressive and impulsive behaviours.⁵ It has been argued that ‘unconventional’ strategies for better management of treatment-resistant psychosis should be employed.^{6–8} The two primary methods we discuss in the following pages include antipsychotic polypharmacy and high-dose monotherapy.

Why do standard treatments sometimes fail?

To effectively treat the positive symptoms of schizophrenia it is important to achieve at least 60% striatal D₂ blockade with antipsychotics.⁹ The exception is clozapine, which has been shown to have some antipsychotic effect at as little as 20% blockade.¹⁰ Beyond 80% D₂ occupancy, risk of extrapyramidal side-effects (EPS) increases, leading to non-adherence and treatment failure. Therefore, the ‘sweet spot’ of D₂ receptor blockade for most patients is between 60 and 80%.⁶ However, in some treatment-resistant cases, particularly when aggression and impulsivity are of concern, moving beyond 80% may be necessary.^{6,8,11–14} Moreover, there is significant evidence from the literature that a substantial portion of patients tolerate plasma antipsychotic levels consistent with >80% D₂ occupancy.

One of the early imaging studies from 1997 noted that a large fraction of patients stabilised on low-dose oral haloperidol had plasma levels associated with >80% D₂ occupancy;¹² however, prior clinical studies found that even at a plasma haloperidol level of 6 ng/ml (predicted 90% D₂ occupancy), only 30% experienced adverse effects.¹³ A similar pattern is seen with risperidone. The pivotal trials studied doses of 10 mg and 16 mg, which correlate with a plasma active moiety level of 70 ng/ml and 112 ng/ml, respectively.¹⁵ The plasma level of 70 ng/ml would correspond to a D₂ occupancy of 85%;¹⁴ however, despite this high level of predicted D₂ occupancy, the proportion of patients on 10 mg who required anti-Parkinsonian treatment was only 31%.¹⁶

Pharmacokinetic failure

Pharmacokinetics is the umbrella term that covers drug absorption, bioavailability, distribution, metabolism and excretion. The role of pharmacokinetics in antipsychotic treatment failure is relatively simple. Through abnormal pharmacokinetic processes such as poor absorption, rapid metabolism and enzymatic polymorphisms, antipsychotic plasma levels do not reach the threshold associated with 60% striatal D₂ occupancy. This leads to continued psychotic symptoms. It also leads to frustration and confusion for clinicians in that the patient does not sufficiently respond to standard treatment algorithms.

Pharmacodynamic failure

Pharmacodynamics encompasses receptor binding and sensitivity, postreceptor effects, and chemical communication. Pharmacodynamic treatment failure with regard to antipsychotics is the inability to provide significant amelioration of psychotic symptoms in spite of achieving plasma levels associated with at least 60–80% D₂ occupancy.¹⁷ Although adequate drug plasma levels are achieved, patients with treatment-resistant psychosis present with continued positive, cognitive and aggressive symptoms. The treatment failure associated with pharmacodynamic influences is hypothesised to be related to lack of D₂ receptor sensitivity or hypersensitivity. When patients manifest a lack of extrapyramidal adverse effects or akathisia, increasing drug doses to achieve plasma levels that are associated with >80% D₂ blockade may be necessary to provide symptom control.^{18–20} The overriding principle is that there are a subset of patients who both tolerate and require high levels of D₂ antagonism for symptomatic relief.

The importance of being patient

While recent studies have demonstrated that minimal response after 2 weeks on a particular antipsychotic dose portends a low likelihood of week 6 response on that dose, the full therapeutic effects of adequate D₂ receptor blockade in schizophrenia may not be apparent until many weeks or months later.⁷ Therefore, patience in pharmacological treatment of psychosis is critical when a patient exhibits partial response.^{7,11} For example, Robinson and colleagues found that in a sample of 118 first-episode patients with schizophrenia or schizoaffective disorder only 20% responded to treatment at 4 weeks. The picture was quite different at 52 weeks; roughly 87% responded to treatment.²¹ Other studies of ziprasidone, risperidone and olanzapine have shown continued improvement over several months of treatment.¹¹

Strategies to use prior to heroic measures

We believe polypharmacy and high dosing should not be the initial approach to treating schizophrenia. However, considering that roughly 30% of patients with psychosis are on multiple antipsychotics, the practice is far from rare.^{22,23} In an effort to address the growing practice of antipsychotic polypharmacy and high dosing of antipsychotics in spite of little support in the literature, Stahl provides 12 case-based recommendations.⁷ We review several below.

Utilise monotherapy first to include clozapine

Sequential trials of at least two SGAs are recommended. If both trials fail, consideration of an FGA is appropriate. Also, it is important to not overlook clozapine as monotherapy. The efficacy of clozapine in treatment-resistant schizophrenia, particularly with regard to aggression and violence, is well documented.^{24–26} However, some clinicians may be hesitant to initiate a trial of clozapine owing to fear of side-effects such as agranulocytosis.

Monitor blood levels

Securing drug plasma levels is the only way to know whether treatment failure is due to a pharmacokinetic issue such as rapid metabolism or a cytochrome P450 polymorphism, or simply poor adherence with oral therapy. Likewise, blood levels can alert you to pharmacodynamic abnormalities which occur when treatment response does not correlate with adequate dosing. Blood level monitoring of both FGAs and SGAs can provide the clinician with important information which can guide the treatment plan for patients with treatment-resistant psychosis. This is supported by the recent work of Lopez & Kane as relevant to haloperidol, fluphenazine, perphenazine, risperidone, olanzapine and clozapine.²⁷

Time may not be on your side

As noted above, it takes some patients longer than others to respond to antipsychotic treatments. Granted, it may not be possible to wait several weeks (and certainly not months) in acute settings or when a patient's behaviour is potentially harmful to self or others, but when possible, allowing adequate time for full response may be all that is needed when a patient has exhibited a partial response. The result of impatience is that a second antipsychotic may be prescribed or a single medication may be dosed in an unnecessarily aggressive manner.

Double-check the diagnosis

It is common practice to rethink the primary diagnosis if the treatment plan appears ineffective. Once pharmacokinetic, pharmacodynamic or time-course failures have been ruled out, the presence of substance misuse or a personality disorder or neurological illness should be considered.

Antipsychotic polypharmacy

Although a number of published treatment guidelines for schizophrenia are available, some of which conflict with each other, it is clear that clinicians should utilise a monotherapy approach to antipsychotic medication use.²⁸ Multiple trials of antipsychotic medications, generally SGAs to include clozapine, are recommended. In fact, divergence from this sequential clinical progression has historically been met with scepticism, caution and outright criticism.^{29–36} It is certainly understandable why this is the case. The literature is replete with evidence supporting the efficacy of monotherapy for schizophrenia. Furthermore, the pitfalls associated with combining antipsychotics are well documented. Increased side-effects, higher medication costs, scant information supporting efficacy, and suboptimal outcomes are all problematic with regard to antipsychotic polypharmacy.^{29–36} So, why the need to even review the topic? The reality is that patients included in research studies are generally those who are able to give consent, exhibit less violence and less impulsivity, have lower rates of chemical dependency, and are less likely to have histories of sequential trials of antipsychotics at documented therapeutic levels.^{7,8} In other words, consistent with much of psychiatry research, they are healthier and not mirror images of the patients seen in clinical practice. Therefore, we believe a strict adherence to a treatment guideline based on highly selective samples does not necessarily translate well to community-based out-patient clinics and in-patient facilities.

We acknowledge that antipsychotic monotherapy is sufficient for the majority of patients with schizophrenia and that adherence to established guidelines should generally occur. Indeed, recent studies support this position. A 2004 study by Suzuki and colleagues revealed that when patients with schizophrenia were switched from multiple antipsychotics to monotherapy, roughly half maintained gains whereas a quarter showed improvements. Another quarter of the sample decompensated.³⁷ In a similar study by Essock and colleagues it was found that patients switched to monotherapy maintained gains, but also showed improvement in metabolic effects assumed to be caused by antipsychotic polypharmacy. It should be noted that approximately a third of patients required multiple antipsychotics.²³ However, some evidence supports the use of antipsychotic polypharmacy. A recent meta-analysis of randomised controlled trials comparing antipsychotic monotherapy and polypharmacy highlighted that polypharmacy may be superior to monotherapy in certain clinical cases.³⁸

In addition to achieving adequate D₂ occupancy, antipsychotic polypharmacy also exploits other receptor-binding properties that could lead to improvement in other schizophrenia symptom clusters. For example, serotonergic, noradrenergic and histaminergic binding theoretically ameliorate depression, anxiety, insomnia, impulsivity and aggression. On the flip side, however, the patient is potentially exposed to adverse side-effects from multiple receptor binding or excessive binding via similar properties shared by antipsychotics (e.g. excessive histaminergic binding leading to daytime sedation or appetite stimulation and weight gain). Consequently, combining antipsychotics should be done rationally based on their binding profiles. One clear example is the need to avoid combining the partial D₂ agonism of aripiprazole with antipsychotics with full D₂ antagonism. The binding interference may lead to a worsening of symptoms due to aripiprazole's high affinity for the D₂ receptor, and the fact that even low doses such as 10 mg achieve 83% D₂ occupancy, and thus may displace full antagonists.⁶

High dosing of antipsychotics

Antipsychotic polypharmacy is not the only means of addressing the more complex and treatment-resistant cases of schizophrenia. High-dose monotherapy is a viable option as well. In fact, it has been argued that if the goal is to occupy a greater degree of D₂ receptors in order to address treatment-resistant positive and aggressive symptoms, high-dose monotherapy is the preferred option when compared with polypharmacy. High-dose monotherapy does, however, come at a greater financial expense and the risk of increased metabolic and other potential treatment-limiting side-effects.¹¹

It is impossible to know what dose of a particular antipsychotic is required to achieve the intended outcome. Therefore, the prudent action is to start low within the US Food and Drug Administration (FDA)- and British National Formulary (BNF)-approved guidelines for the particular medication. The medication can be gradually increased outside the FDA-approved dosing window until therapeutic response occurs or the patient develops intolerable side-effects. It is important that informed consent is obtained and treatment rationale is well documented when this occurs. Below we discuss the typical dosing ranges and special considerations for high dosing of the antipsychotics. A more detailed analysis can be found in Stahl & Morrissette's review of the topic.¹¹

Clozapine

Clozapine is typically only recommended after subsequent trials of other antipsychotics have failed. This is primarily owing to its side-effect profile. At typical dosing of 300–450 mg/day, clozapine binds to less than 50% of D₂ receptors, but as noted earlier, the antipsychotic benefits with this medication can be seen at as low as 20% occupancy.¹⁰ A meta-analysis by Davis & Chen revealed that patients on high levels of clozapine responded more frequently than those on low levels.³⁹ Clozapine can be dosed as high as 900 mg/day, but seizure risk does increase with higher plasma levels, so titration to this dose should be done slowly. Furthermore, due to the diverse binding profile of clozapine, improvement in multiple symptom clusters is possible.

Quetiapine

Quetiapine has a relatively weak affinity for D₂ receptors and often requires high dosing to achieve intended outcomes. Only at the upper range of 400–800 mg/day are the antipsychotic properties of the medication seen. It is generally believed that a dose of 1200 mg/day is no more effective than the typical dosing range and carries greater incidence of metabolic effects; however, clinical practice has shown that 1800 mg/day may be useful in treating violent patients.^{2,5,39}

Olanzapine

Doses of olanzapine between 10 and 20 mg/day equate to 60–80% D₂ occupancy. Higher doses of 40–60 mg daily appear to be more effective, particularly with aggressive patients and in some forensic settings.^{2,32,40,41} A note of caution is that as plasma levels increase the risks of anticholinergic and metabolic effects also increase.^{5,10}

Risperidone/paliperidone

Risperidone reaches 70–80% of D₂ occupancy at doses between 2 and 6 mg/day. The risk of EPS is positively correlated with dose. Doses above 8 mg/day are generally not considered beneficial for most patients, but in some, the side-effects may not appear until higher dosages.⁵ As noted previously, even at 10 mg/day only 31% of patients required anti-Parkinsonian medication in the pivotal trials, again providing evidence that a subgroup may both require and tolerate higher dosages and plasma levels.¹⁶ Risperidone's active metabolite paliperidone has less chance of drug–drug interactions as it is not metabolised by the liver. Similar to risperidone, paliperidone carries increased risk of EPS as the dose increases.¹¹

Ziprasidone

Data support the use of high doses of ziprasidone, particularly in forensic settings at 360 mg/day.^{2–5,40,41} It can be difficult to achieve adequate plasma levels with ziprasidone in out-patient settings as food is required to increase absorption. It has been reported that ziprasidone has historically been under-dosed due to concern about increased agitation and QTc prolongation.

Aripiprazole

Aripiprazole has a different mechanism of action compared with the 'first wave' of SGAs. Contrary to its predecessors, high doses of aripiprazole may not result in increased efficacy in schizophrenia. This is due to its partial agonist properties and high affinity for D₂ receptors.¹¹ Doses of 40 mg/day are associated with 96.8% D₂ occupancy, so further increases will not have an impact on D₂ neurotransmission to any considerable extent.

Asenapine, iloperidone, and lurasidone

Asenapine, iloperidone, and lurasidone are newer atypical antipsychotics. Consequently, there is limited information that supports their use in high doses. Although doses of asenapine of 30–40 mg/day may be effective for some treatment-resistant cases, there are virtually no data supporting use at these higher doses, and the buccal absorption of asenapine declines significantly for each 5 mg increase in the dose. As with asenapine, there are limited to no data supporting the use of iloperidone at high doses. One treatment-limiting issue with iloperidone is orthostatic hypotension. Lurasidone is approved up to 160 mg/day for schizophrenia, but higher dosages have not been studied for efficacy, only for safety (e.g. thorough QT studies up to 600 mg). Similar to ziprasidone, lurasidone should be taken with food to increase absorption.¹¹

Summary

Schizophrenia is a relatively common psychiatric disorder but it is often difficult to treat. Although antipsychotic monotherapy at standard dosing levels is sufficient for the majority of patients, a subset will require ‘unconventional’ approaches such as antipsychotic polypharmacy and higher than normal dosing. If done cautiously and rationally, these approaches can provide much-needed benefit for those most in need of relief.

1.7.49 Should compulsory admission to hospital be part of suicide prevention strategies?

Daniel Wei L. Wang Erminia Colucci

2017-6

Abstract

The World Health Organization report *Preventing Suicide: A Global Imperative* provides governments with guidance for comprehensive suicide prevention strategies. However, it does not mention the role that compulsory admission to hospital of psychiatric patients should have in policies for suicide prevention. This was a missed opportunity for international discussion and guidance about a measure that, although widely used, is becoming increasingly controversial in light of the existing evidence and human rights norms.

Contents

- *Should compulsory admission to hospital be part of suicide prevention strategies?*
 - *Compulsory admission to hospital for suicide prevention*
 - *Compulsory admission to hospital: trade-offs and human rights*
 - *The need for guidance*

Legal and policy approaches to suicide have been changing significantly in the past decades. Notably, the decriminalisation of suicide attempts in many countries has been followed by an increasing recognition that the stigma around suicide must be grappled with and that adequate social and healthcare policies can reduce the rate of suicide in the population. In other words, the focus has shifted from criminal punishment and moral condemnation to awareness, support and prevention.¹

The 2014 World Health Organization (WHO) report *Preventing Suicide: A Global Imperative*¹ is an important step in this direction. It draws attention to the discrepancy between the magnitude of suicide as a health problem worldwide

and the low priority it is given by national governments. The report also describes the risk and protective factors in suicide prevention based on state of the art research and offers guidance for comprehensive strategies for suicide prevention. The central message in the document is that suicides are preventable but this requires actions such as restricting access to the means of suicide, reducing excessive use of alcohol, collecting and collating good-quality data about suicide and suicide attempts, providing training for gatekeepers, improving the quality of mental healthcare services, and promoting responsible reporting of suicide by the media. The report is also clear that taboo, stigma, shame, guilt and discrimination surrounding suicide hamper effective suicide prevention policies as they discourage vulnerable people from seeking help.

However, despite its emphasis on the need for comprehensive strategies for suicide prevention, the compulsory admission to hospital of people at risk of suicide was not discussed in the WHO report. This should not come completely as a surprise given that compulsory admission to hospital was also ignored in the previous United Nations (UN) and WHO documents on which this report was built.²⁻⁴ Moreover, the literature on suicide prevention rarely lists compulsory admission to hospital among the measures for suicide prevention, and those who do normally do not distinguish between voluntary and compulsory admission.⁵⁻⁷

This gap in international guidelines and in the scholarly literature needs to be addressed. Compulsory admission to hospital is widely used as a measure for suicide prevention, but the trade-offs involved and the human rights implications make it a topic in which guidance and further discussion are urgently needed.

Compulsory admission to hospital for suicide prevention

Compulsory admission to psychiatric hospitals or psychiatric wards is allowed in many countries as a measure to prevent self-harm.⁸ In England and Wales, for instance, the Mental Health Act 1983 (MHA) provides the legal framework for the compulsory admission and treatment of patients with mental disorders of a nature or degree that warrants their detention in a hospital and who ought to be so detained in the interests of their own health or safety or with a view to the protection of other persons. Whether the patient has capacity to decide on their stay in hospital and has objected to it will not affect the legality of a detention under the MHA. A recent publication shows that there were over 63 000 detentions under the MHA in the period from 1 April 2015 to 31 March 2016.⁹ Considering the body of literature associating suicide with mental disorders^{6,10} (see, however, Hjelmeland *et al*¹¹) and that statistically people with mental disorders are at a higher risk to themselves than to others,¹² it is plausible to assume that prevention of self-harm is a common reason for compulsory admission to hospital.

Some would interpret this authorisation to detain as actually a duty to detain when there is a high and immediate risk of a person taking their own life. A failure to do so can be considered medical negligence and may also be a breach of human rights. In the case of *Rabone & Anor v Pennine Care NHS Foundation Trust* [2012],¹³ the Supreme Court unanimously held that the failure of the hospital staff to detain Melanie, a voluntary psychiatric patient who hanged herself from a tree after being allowed to spend the weekend with her family, was a breach of her right to life under Article 2 of the European Convention on Human Rights. According to the Court, given her history of depression and self-harm, including a previous suicide attempt, the hospital staff should have used their powers to detain Melanie under the MHA to protect her from the 'real and immediate risk of suicide' when she demanded to leave the hospital.

Even though this precedent applies to the UK only, it shows that a national strategy for suicide prevention may be incomplete without a policy for compulsory admission to hospital. In hindsight, it is clear that the deaths of people like Melanie could have been avoided were they admitted to hospital and put under close observation, treated, managed and prevented from having access to the means to take their own life.

Compulsory admission to hospital: trade-offs and human rights

When looking at individual cases of suicide and at the data from population-based studies there is evidence that compulsory admission to hospital saves lives.^{14,15} However, this does not answer the question of how, when or whether it should be used to prevent suicide. Compulsory admission to hospital involves trade-offs and has human rights implications that need to be considered in clinical, policy and legal decisions about its role in strategies for the prevention of suicide.

There is now compelling evidence that suicide, being a low-frequency event, is very difficult to predict. The clinical methods for predicting suicide among patients have a very poor predictive capacity.^{16–20} A recent meta-analysis revealed that, over an average follow-up of 5 years, almost half of all suicides are likely to occur in patients considered at low risk, and that 95% of high-risk patients will not die by suicide.²¹ This creates a trade-off between the need to be sensitive to the risk of suicide to reduce the chance of false negatives and the need to be specific to avoid false positives that may lead to unnecessary detentions. Assuming that it is impossible to predict whether a person is going to take their own life and that the best we can do is to estimate that 1 out of X people in a certain cohort will die by suicide, then a society that allows compulsory detention of people at risk of suicide has to admit that to save one person it will have to unnecessarily detain $(X - 1)$ people.

There are also concerns about whether compulsory detention may increase the risk of suicide in some cases. First, some people may not seek treatment because they are fearful of being forced to accept treatments not of their choice or of being detained for prolonged periods.²² This would go against the WHO recommendation that a national effort to prevent suicide should encourage people to seek help. Second, there is an association between suicide and psychiatric admission to hospital, as suicide risk peaks in the period immediately after admission to hospital and shortly after discharge.^{5,6,14,23,24} This association can be explained in part by the fact that individuals with higher risk of suicide are more likely to be admitted to hospital,²⁵ but some argue that admission to psychiatric in-patient care might actually increase the risk of suicide. The stigma, discrimination, impact on employability, trauma, isolation and the feeling of dehumanisation caused or augmented by compulsory admission to hospital may contribute to the extremely high risk of suicide in the first few days of admission and after discharge.^{17,22,26,27} Although further research is necessary, this hypothesis does not seem farfetched given that people who are detained, disconnected from their social circle and experience trauma, abuse and emotional distress are at a higher risk of suicide.¹ Hence, it is possible that some of the $(X-1)$ people unnecessarily detained will in fact die by suicide as a result of compulsory admission.

The trade-offs and tragic choices in compulsory admission to hospital have clear human rights implications. Health systems and professionals who are under pressure to be sensitive to the risk of suicide to avoid breaching a patient's right to life will do so at the expense of specificity. This leads to an increase in unnecessary detentions, which interferes with the right to freedom of movement, autonomy, bodily integrity and private life of those detained. It may also affect the right to life of those whose risk of suicide increased as a result of their stay in hospital. Therefore, the rules and practices regarding the compulsory admission to hospital of people with mental disorders to prevent suicide are always choices between different rights and rights-holders.

There are also concerns about whether compulsory admission to hospital is inherently discriminatory against people with mental disorders as it denies them the right to decide about their own treatment. This concern is reflected in the discussions about whether compulsory admission to hospital is compatible with the UN Convention on the Rights of Persons with Disabilities (CRPD), in particular Article 14, which establishes that 'the existence of a disability shall in no case justify a deprivation of liberty'. The UN Committee on the Rights of Persons with Disabilities,²⁸ for instance, affirms in its guidelines on Article 14 of the CRPD that the 'legislation of several States parties, including mental health laws, still provide instances in which persons may be detained on the grounds of their actual or perceived impairment, provided there are other reasons for their detention, including that they are deemed dangerous to themselves or others. This practice is incompatible with Article 14 [...]'. Others, however, worry about how the prohibition of compulsory detention and treatment for people with mental disorders will affect the protection of other rights of people with disabilities, such as their rights to health and to life.²⁹

The need for guidance

In conclusion, four things can be said about compulsory admission to hospital as a measure for suicide prevention. First, it can save the lives of those who, without the care, treatment and management received in hospital, would have taken their own life. Second, owing to the poor suicide predictive capacity of the existing methods, false positives will occur and this results in unnecessary hospital admissions, which can be aggravated if legal accountability encourages defensive clinical practice. Third, there is the possibility that compulsory admission to hospital is partially responsible for the suicides of those who failed to seek help owing to the fear of involuntary detention or for whom the experience of being admitted to hospital contributed to the decision to take their own life. Fourth, it is still unclear how and if compulsory admission to hospital of people on the basis of their mental impairment and the risk of danger to themselves can be reconciled with the CRPD.

The trade-offs involved and the need for measures for the prevention of suicide to be compliant with human rights make the creation of guidelines concerning their use challenging, but necessary. The WHO is a forum in which an evidence-informed, international, multi-stakeholder discussion can shed light on the role (if any) that compulsory admission to hospital should have in a national policy for the prevention of suicide. It is unfortunate that the otherwise commendable 2014 report missed this opportunity. It may be uncomfortable for those advocating policies to prevent suicide to discuss compulsory admission to hospital as this is a measure in which the line that separates protection and harm can be very thin, and there is controversy about where it lies. However, as those working in the area of suicide prevention already know, avoiding a difficult issue is never the best way to deal with it.

1.7.50 Improving the quality of mental health services using patient outcome data: making the most of HoNOS

Mike J. Crawford Mo Zoha Alastair J. D. Macdonald David Kingdon

Abstract

Efforts to assess and improve the quality of mental health services are often hampered by a lack of information on patient outcomes. Most mental health services in England have been routinely collecting Health of the Nation Outcome Scales (HoNOS) data for some time. In this article we illustrate how clinical teams have used HoNOS data to identify areas where performance could be improved. HoNOS data have the potential to give clinical teams the information they need to assess the quality of care they deliver, as well as develop and test initiatives aimed at improving the services they provide.

 - *Discussion*
 - * *Challenges to widespread HoNOS use*

A commitment to improving the quality of healthcare is central to the aims of the National Health Service (NHS).¹ This commitment involves developing and evaluating new interventions and treatments, obtaining feedback from patients and learning from mistakes.² It also involves monitoring and improving patient outcomes. Despite repeated calls for greater use of patient outcome measures in mental health, available evidence suggests that very few services use them to monitor change over time.³ There are a number of important barriers which make it difficult to implement systems for monitoring patient outcomes, including access to reliable and valid measures, the need to protect patient confidentiality and the time and money needed to collect, analyse and report data.^{4,5}

While many initiatives aimed at improving the quality of NHS services have been ‘top-down’, it is widely acknowledged that front-line clinicians have a key role in efforts to improve service quality.^{6,7} However, unless clinical teams have access to information about patient outcomes, they cannot assess their performance or identify areas where performance could be improved.

For the past 20 years the Health of the Nation Outcome Scales (HoNOS) have provided a means of assessing the health and social functioning of people who use mental health services.⁸ HoNOS is a clinician-rated outcome measure comprising 12 scales covering symptoms, functioning, social relationships and environmental issues. Each domain is rated by the treating clinician on the scale of 0 to 4: 0 means no problem, 1 means a problem that probably requires no intervention and 2, 3 and 4 correspond to ‘mild’, ‘moderate’ and ‘severe’ problems. They are rated by staff using all available information – not as a questionnaire or interview – based on the worst state in the reference period, usually 2 weeks. There is a glossary, and training in their use is generally recommended.⁹ Although it is possible to calculate a total HoNOS score for a patient, individual scores on each of the 12 scales provide a better guide to the problems they are experiencing and targets for future interventions and treatments. Originally developed to measure the health and social functioning of working-age adults with severe mental illness, the scales have been modified to assess mental health of older adults (HoNOS65+),¹⁰ children and adolescents (HoNOSCA),¹¹ people with intellectual disability (HoNOS-LD),¹² in secure settings (HoNOS-Secure)¹³ and with acute brain injury (HoNOS-ABI).¹⁴

Use of HoNOS in mental health services in England was patchy until work started on the development of a commissioning tariff based on a Mental Health Clustering Tool, which needed HoNOS scores to be completed on all patients who are in scope of the mental health tariff.¹⁵ While these plans are still in development, this initiative has led to widespread use of HoNOS throughout the country. In recent years clinicians have begun to consider how these data might be used to assess and improve the quality of care they provide. In the next section we present how clinical teams in three trusts have used HoNOS data to identify problems with the care they provide and plan ways to improve it.

HoNOS use – examples of application

Example 1: using HoNOS to examine reasons for admission

Reasons for admission to hospital or to crisis resolution/home treatment (CRHT) teams are poorly understood yet very important in terms of ensuring that available resources are used effectively. As the number of beds decreases, thresholds for admission are becoming increasingly important to assess at a service level.

A team in Southampton used routine HoNOS data to explore mental health problems (such as psychotic symptoms, suicidality and aggression) experienced by adults who were admitted to in-patient units and people referred to CRHT services. They compared the proportion of people who had problems requiring intervention (a score of 2 or more on different HoNOS items) among 3409 people admitted to hospital and 2991 referred to local crisis teams (*Table 1*). The most prevalent problems among people referred to either service were suicidality and agitation, with levels of agitation higher among those admitted to hospital. Nonetheless, clinicians were surprised to see that only around half of patients admitted to hospital and 39% taken on by crisis teams scored as requiring intervention for suicidality and/or agitation. Even when people with significant problems with psychosis or accommodation status were included, a significant minority did not appear to have major problems requiring intervention.

HoNOS scale differences between hospital and crisis team admissions

Scores > 2 on HoNOS items	Hospital <i>n</i> = 3409 %	Crisis team <i>n</i> = 2991 %
1: Agitation	29	16
2: Suicidality	22	27
3: Accommodation	6	5
4: Delusions and hallucinations	13	9
1 or 2	47	39
1 or 2, 3 or 4	66	53

When these findings were discussed within teams, clinicians raised the possibility that people may be being referred to in-patient or CRHT services because of a combination of different problems at less severe level or that staff were under-scoring these items. It also led to discussions about the level of severity at which people were being referred to these services. Discussions based on this information led to a review of in-patient services (numbers of beds in the area were higher than in other comparable catchment areas),¹⁶ and a review of thresholds for access to CHRT services.

Example 2: outcomes of patients treated by assessment and brief treatment teams

Community mental health teams in central London used routine data from HoNOS to examine outcomes of treatment. Changes in mean HoNOS scores were calculated for patients under the care of assessment and brief treatment teams between April 2013 and September 2014 by comparing the mean severity from initial review with that from a follow-up. Scores of 3 (moderate) or 4 (severe) were categorised as 'high' and scores of 0 (absent), 1 (minimal) or 2 (mild) were categorised as 'low', and proportions of people moving between low and high scores were plotted (*Fig. 1*). In *Fig. 1* differences in severity of each subscale of HoNOS are presented for people in clusters 1–5 (single non-psychotic episode), clusters 6–8 (enduring non-psychotic) and clusters 10–15 (psychosis). The data showed that a smaller proportion of people in clusters 6 to 8 had made progress during their time with teams; among people in clusters 6 to 8, fewer who had high scores at baseline had lower levels at follow-up, especially compared with people in clusters 10 to 15. When data were examined from four other sector services in the trust a similar pattern emerged, with a greater proportion of patients in clusters 6 to 8 failing to show evidence of improvement or problems becoming more severe between the two time points compared with people in clusters 10 to 15.

When these data were presented to front-line staff they commented that it can be difficult to help meet the needs of people in clusters 6–8 (predominately people with personality disorder) through the types of interventions available to staff working in assessment and brief treatment teams. Although staff working in these services are able to refer patients to a local specialist personality disorder service, many do not want the group-based psychological treatment offered by this service or are too chaotic and poorly motivated to engage in psychological treatment. Discussions prompted by a review of these data led to the development and piloting of a six-session brief intervention package for people with personality disorder offered by members of the local specialist team (details available from the authors on request). This package of treatment is based on National Institute for Health and Care Excellence (NICE) guidelines¹⁷ and focuses on psychoeducation and skills training. It is hoped that some people who initially reject the offer of longer-term psychological treatment can be engaged through this extended assessment and that others will benefit more from this approach than they do from the care they are currently receiving.

Example 3: comparing outcomes of older adults admitted to in-patient units

Staff working on an in-patient mental health unit for older adults with dementia and other organic conditions used routine HoNOS65+ data to examine outcomes of people admitted to their service. It was noted that over a 3-year period the mean percentage improvement in scores on the depression scale of the HoNOS65+ declined (*Fig. 2*). Outcomes can only be properly understood with reference to context and interventions. These data were therefore compared with those from a similar unit in the same trust with the same operational policy, lengths of stay, diagnostic and demographic characteristics, and initial severity scores. Data from this unit showed that mean percentage improvement on the depression scale over the same period was approximately 50%. The team did not have and still do not have direct data on interventions, but in 2001 there was a pilot study of the systematic recording of care plans, and these data were linked to outcomes data. It transpired that in the unit with the poorer outcomes, all patients with dementia were automatically given night-time benzodiazepine hypnotics. Furthermore, there was a strong association between being given night-time benzodiazepines and poor outcomes. During discussion with the teams it was agreed that routine use of benzodiazepines was a plausible explanation of poor outcomes and this policy was revoked. Over the course of the next year mental health outcomes of patients admitted to the unit improved (*Fig. 2*).

Discussion

The examples given above illustrate how front-line clinical teams have used routinely collected HoNOS data to examine and to try to improve the outcomes of the patients they treat. While changes to mental health services will continue to be made in response to new national policy directives, new research findings and new technologies, we believe that one of the most effective ways to improve service quality is ‘bottom-up’: through local teams using local data to drive change. However, front-line clinicians face a number of significant challenges when trying to assess and improve the quality of the care they provide. Chief among these are limited time and other resources needed to collect data on patient outcomes. We are aware of numerous occasions when clinical teams have made changes to the services they provide but have not had the resources to examine whether these changes led to improvements in patient care. In other instances, baseline audits are conducted that identify problems in a service that teams try to correct, but staff have not had time to assess whether these changes benefited patients. To fulfil the NHS promise to patients to continuously work to improve service quality, clinical teams need to be able to access data on patient outcomes. Yet the experience of participants in the UK Routine Clinical Outcomes Network (www.ukrcom.org) suggests that very few services provide outcomes data to their teams. Embarking on new efforts to collect patient- and staff-rated outcomes is expensive and time consuming. By contrast, routinely collected HoNOS data in England provide an important source of clinician-rated patient outcomes that do not require additional resources to be spent and can be used to assess and improve the quality of care that teams provide.

Challenges to widespread HoNOS use

While the vignettes above illustrate how HoNOS data have been used by front-line clinical teams, a number of obstacles need to be overcome if this approach is to become more widespread.

First, concerns have been raised about the quality of routine HoNOS data.¹⁸ Available evidence suggests that if staff are provided with appropriate support and training, HoNOS can be used to generate reliable information that can be used to compare different services and examine changes in patient outcomes over time.¹⁹ Second, IT systems in trusts need to be able to generate reports on outcome data in a form that clinical teams find useful. Third, data from HoNOS and other routine outcomes scales need to be interpreted cautiously. Random variation and subtle changes in practice and case-mix may have led to changes in patients outcomes over time. Separating real and spurious differences can be difficult.²⁰ Finally, teams need to be given time and space to examine their data, learn from them and use them to evaluate their efforts to improve service quality. If staff are supported to generate reliable data and systems are available to deliver data to front-line clinical teams, then these data have the potential to be used in clinical audit and in alternative models for improving service quality, such as Plan–Do–Study–Act cycles.²¹ The latter approach may have some advantages over traditional audits because it allows the impact of changes in practice to be examined more frequently and provides a more iterative approach to developing changes aimed at improving patient outcomes.^{22,23}

At present, most staff see collecting outcome data as an ‘invisible task’, in which time is spent collecting and entering data for no purpose.²⁴ If systems can be implemented that deliver feedback to staff on service-level patient outcomes, staff are more likely to value collecting these data. For instance, in South London and Maudsley NHS Foundation Trust and Central and North West London NHS Foundation Trust, clinicians have organised meetings for staff in which HoNOS data are presented and discussed. Feedback from staff attending these meetings has shown they value getting this information and their comments have been used to refine the way that data are collated and presented (most staff indicated a preference for the categorical change model presented in *Fig. 1* rather than changes in total HoNOS scores).

While HoNOS scores collected through the current mental health payment initiative¹⁵ provide a rich source of routine data on patient outcomes, the timing of assessments is unlikely to be optimal for evaluating the impact of treatments and services. Further work is needed to establish when outcome assessments are best undertaken in different settings to compare services and assess the impact of quality improvement initiatives.

HoNOS data are not the only form of evidence that mental health services collect. For instance, psychiatric in-patients are asked to complete the ‘friends and family test’ (a two-item short patient-rated experience measure).²⁵ However, there is very little evidence that these data are being fed back to clinicians to allow them to reflect on differences in levels of patient satisfaction over time or between different teams.²⁶ Such data also have the potential to stimulate bottom-up efforts to assess and improve service quality if steps are taken to use them in this way. One of the great

strengths of HoNOS data is that they provide a summary of mental health, behavioural problems and social factors. Although this means that HoNOS can be used under circumstances where poor mental health or impaired cognition may limit the value of patient-rated data, there are drawbacks to relying solely on clinician-rated outcomes. The possibility that outcome data could be used to pay services based on patient outcomes could paradoxically reduce their value as a means to assess and improve service quality.²⁷ This is commonly known as Goodhart's law after the British economist Charles Goodhart: 'When a measure becomes a target, it ceases to be a good measure'.²⁸

Mental health trusts in England are currently collecting large amounts of outcome data using HoNOS. We believe that efforts by mental health services to use HoNOS data and other routinely collected patient outcomes have the potential to make better use of available resources and engage front-line clinicians in efforts to improve patient outcomes.

1.7.51 Personalisation and social care assessment – the Care Act 2014

Deb Barnes Billy Boland Kathryn Linhart Katherine Wilson

date

2017-6

Abstract

The Care Act 2014 represents a significant change in legislation in England. For the first time it brings together various aspects of adult social care into a single statute succeeding earlier acts and policy. Given its importance to the lives of service users and carers, clinicians need to have a clear understanding of its implications. We provide an overview of why it was developed, its underlying principles and international comparisons, as well as implications for assessments, interventions and outcomes. The impact on the lives of patients and carers is discussed, as well as dilemmas and challenges the Act presents. While it addresses other important aspects of social care, including safeguarding, Mental Health Act section 117 aftercare and duty of candour, we focus on personalisation because of the opportunities it provides to enhance management plans for people experiencing mental health problems.

Why was the Care Act 2014 developed?

The Care Act 2014 represents the latest evolution in current attitudes to care. It was asserted by Norman Lamb MP, Care and Support Minister in the UK coalition government, as ‘the most significant reform of care and support in more than 60 years’.¹ Think Local Act Personal (TLAP, a partnership of more than 50 organisations, including the National Health Service (NHS), ‘committed to transforming health and care through personalisation and community-based support’ (www.thinklocalactpersonal.org.uk/About-us/)) sees it as representing a significant change in legislation, of importance to service users and carers in England and Wales because ‘for the first time it puts them in control of their care and support. It also makes clear what kind of care they should expect’ (www.thinklocalactpersonal.org.uk/Browse/careact2014/).

Social care law can be seen to have begun with the National Assistance Act in 1948 that contained provisions for the basis of the modern welfare state. Direct payments as a method of personalisation were introduced in 1996 by the Community Care Act. More recent updates, such as the Carers and Disabled Children Act 2000 and the Health and Social Care Act 2001, broadened and refreshed these approaches. Separately, safeguarding of adults from abuse was dealt with by the Department of Health in *No Secrets*.² The Care Act 2014 succeeds earlier acts with a single statute. The golden thread running through the Act is the promotion of individual well-being (*Box 1*): “‘The general duty of a local authority, in exercising a function under this Part in the case of an individual, is to promote that individual’s well-being.’ (Care Act 2014 section 1(1)) ‘As a service user who has in the past been a carer to a diverse group of individuals, I feel that had a lot of these changes been made in the past, many people’s lives would have transformed sooner rather than later. That being said, we are now moving forward to enable individual lives to be more fulfilled.’ (Deb Barnes)”

Box 1 Scope: purpose of the Care Act (adapted from the Care Act 2014)

- a. To reform the law relating to care and support for adults
- b. To reform the law relating to support for carers
- c. To make provision about safeguarding adults from abuse or neglect
- d. To make provision about care standards
- e. To establish and make provision about Health Education England
- f. To establish and make provision about the Health Research Authority
- g. To make provision about integrating care and support with health services

Box 2 Care Act specified outcomes

The specified outcomes as defined in the Act are: managing and maintaining nutrition maintaining personal hygiene managing toilet needs being appropriately clothed being able to make use of the adult's home safely maintaining a habitable home environment developing and maintaining family or other personal relationships accessing and engaging in work, training, education or volunteering making use of necessary facilities or services in the local community including public transport and recreational facilities or services, and carrying out any caring responsibilities the adult has for a child.

What are the international comparisons?

In establishing the Care Act, a cap on spending for long-term social care was originally proposed to be introduced in April 2016. However, this has now been postponed until at least 2020. In 2014, The King's Fund reviewed international comparisons for health and social care provision.³ It highlights that The Netherlands introduced a 'universal' (i.e. available to all) system of insurance for long-term care in 1968. In the 1990s it introduced caps in response to rising costs, but this led to long waiting lists and the caps were abolished. Latterly, they have raised the threshold to access social care and outlined aspects of care that are expected to be delivered by families. Sweden established the right to tax-funded legislation in 1982/1983, whereas countries including Germany, France, Japan and South Korea all have mandatory long-term care insurance schemes.

Assessment under the Care Act

Assessment of needs, both for service users and their carers, is a core aspect of the Care Act. The process is divided into three stages: identifying needs, assessing eligibility and care planning.⁴ Each of these should be viewed not only as a gateway to support but as an intervention in itself.

Stage 1: identifying needs

The Act places a statutory duty on local authorities to provide assessments for any adult, including carers, appearing to have a need for care or support, regardless of the local authority's view of the level of that need or the individual's financial resources (section 9–10). It is important to note that in some areas this responsibility may be delegated by the local authority to partner organisations, such as NHS foundation trusts, and that assessment may be carried out by a range of professionals, including healthcare professionals. This assessment should address the person's needs in relation to the specified outcomes as defined in the Care Act (*Box 2*). It aims to identify the impact of these needs, the person's desired outcomes, and whether the provision of care and support services will be effective in contributing to the achievement of these outcomes (section 9(4), 10(5)). For clarity, we have used the term 'specified outcome' as a technical definition to refer to those outcomes specified in the Care Act (*Box 2*) and 'personal outcome' to describe all possible outcomes individuals may see as important.

It is crucial that the individual, their carer and any other person the individual requests be fully involved in the assessment process. Consideration should also be given to the most appropriate kind of assessment. Options for supported self-assessment, telephone assessment, joint assessment with other agencies or a combined assessment of the needs of, for example, the individual and their carer, may be appropriate (Care Act section 6(3)). In addition, in cases where the individual has significant difficulty in representing themselves at assessment and has no suitable advocate, the local authority is required to provide an independent advocate regardless of the individual's capacity under the Mental Capacity Act 2005.⁵

Stage 2: assessing eligibility

At the eligibility stage, the Care Act replaces previous Fair Access to Care (FACS) guidance on eligibility criteria^{6,7} with a national eligibility threshold based on the causes, extent and impact of the individual's needs (~Box 3). It should however be noted that local authorities are able, where considered appropriate, to meet non-eligible needs and may choose to do so, for example, in order to prevent further deterioration.

Well-being, individual personal outcomes and eligibility

In order to judge eligibility, impacts and contexts of needs are relevant: individual needs must be considered against the specified outcomes to determine whether or not they can be met, and reasons for this should be understood. Some social needs are not addressed by the Care Act, for example housing and debt. A homeless person would not be eligible purely by virtue of their homelessness, but the reasons for homelessness may make them eligible. For example, becoming homeless solely through relationship breakdown would not be considered potentially eligible. However, homelessness through an inability to manage a tenancy due to the impact of severe mental illness (i.e. impaired 'ability to maintain a habitable home' as defined in the specified outcomes) may well be eligible.

Furthermore, the impact on well-being is a personalised assessment and an individual perception, so that two people with the same needs in relation to specific outcomes could end up with a different assessment of eligibility. For example, obsessive-compulsive disorder could manifest in repetitive behaviours which affect an individual's ability to maintain family relationships and employment. These two specified outcomes may be fundamental for one person and significantly affect their well-being. Another person may have very different priorities or personal outcomes that they want to achieve; their well-being is not significantly affected and they would not be eligible.

The word 'significant' is not defined in the legislation, rather it is a judgement made by the local authority after considering the person's needs and what is important to them. However, well-being is a broadly defined and holistically assessed concept, relating to areas such as: personal dignity; physical and mental health and emotional well-being; protection from abuse and neglect; control by the individual over day-to-day life; participation in work, education, training or recreation; social and economic well-being; domestic, family and personal relationships; suitability of living accommodation; and the individual's contribution to society.⁵

Box 3 The National Eligibility Threshold (Regulation 2(1)14)¹¹

An adult's needs meet the eligibility criteria if – the adult's needs arise from or are related to a physical or mental impairment or illness; as a result of the adult's needs the adult is unable to achieve two or more of the outcomes [...] and as a consequence there is, or is likely to be, a significant impact on the adult's well-being.

The key to assessment under the Care Act is understanding what personal outcome (personal aim, wish or goal) the individual is looking for and what their needs are, before considering how these needs can be met. Person-centred assessment focuses on the individual and the difficulty they have in achieving personal outcomes, balanced with their strengths and support network; it does not start with service provision. For example, the assessment does not begin with 'the person needs residential care', but rather may find that 'the person is unable to wash, dress and feed themselves. This is having an impact on their personal dignity and their ability to continue to live safely in their own home'.

The local authority must consider what strengths, resources and capabilities the person has themselves and within their support networks and wider community. This strengths-based approach to assessment and care planning can maximise opportunities for utilising assets found within communities and normative support networks, thereby reducing dependence on service provision by meeting people's needs in more innovative and creative ways.

Stage 3: care planning

In developing and delivering preventive approaches to care and support, local authorities should ensure that individuals are not seen as passive recipients of support services, but are actively encouraged and supported to participate and are able to design care and support based around achievement of their goals. All assessments and subsequent care and support plans should be person-centred and genuinely engage the person and people involved in their care throughout.

Support plans should consider the broader needs identified by the assessment as well as the personal outcomes associated with the specified outcomes the individual is looking to achieve to maintain or improve their well-being. The person's own capabilities, assets and strengths and the potential for improving their skills, as well as the role of any support from family, friends or others that could help them to achieve what they wish for, should be incorporated into the plan. A person's independence should be maximised across these networks before any statutory service provision is considered to meet the desired personal outcomes.

Any person who requires ongoing support and has eligible needs is entitled to have these needs met through a personal budget. The Care Act 2014 has given parity to carers, who are now entitled to have their own eligible needs met through a carer's personal budget. A personal budget is an amount of money allocated for a person's support; this can be managed with or on behalf of the individual by the local authority or a broker, or can be paid to the individual as a direct payment. Person-centred care and support planning means that a person can receive part or all of their personal budget as a direct payment. Direct payments aim to enable a person to exercise the maximum possible choice over how they are supported, who they are supported by and where they are supported. The person must understand how much money is likely to be required to meet their eligible needs and have clear and realistic expectations of what is available locally. People who self-fund are entitled to receive necessary information, advice and support with support planning.

The third national TLAP survey⁸ demonstrated that over three-quarters of personal budget holders reported a positive impact of personal budgets on their lives. People with mental health difficulties were more likely than other groups to report a positive impact on relationships with carers, family and friends. However, older people were less likely than other cohorts to report a positive impact on mental health.

Review

Plans may be revised as a scheduled review or in response to changing needs or circumstances. The review should be a positive opportunity to consider whether the plan is enabling the person to meet their needs and achieve their desired personal outcomes. At this point it can be considered whether the support provided is working (be this through a carer, the community, through a direct payment or a commissioned service through a personal budget), whether new personal outcomes need to be defined, or whether any changes need to be made to care and support to achieve improvement.

Responsibilities of professionals

The Care Act places a responsibility on the local authority to inform the individual of their eligibility determination and produce a written record of whether any of their needs meet the eligibility criteria, and the reasons for this decision. Where an individual does not have eligible needs, the local authority must also provide information on what support may be available in the wider community, or what preventive measures might be taken to prevent or delay the condition progressing. This will require professionals responsible for eligibility decision-making to clearly evidence the reasons for their decisions and present these in an accessible format for the person concerned.

Implications for service users and carers

The Care Act 2014 has changed the ability that a service user or carer has to influence assessment of their own needs and eligibility. Whereas the FACS criteria ⁷ considered the needs of the individual, they did not consider their whole well-being and how this fits into their everyday lives, meaning that some service users may not have completely fitted into the specified categories. The criteria that the Care Act 2014 looks at focus on the individual in context, so that the impact on their well-being cannot now be overlooked or misjudged.

This holistic approach is mirrored by the TLAP 'I' statements, which make their markers for change much simpler to understand across a diverse range of individuals (*Box 4*). These statements complement the Care Act in allowing the individual service user to take control of everything that supports their specific needs and requirements. 'I' statements are presented in the form of first-person statements, for instance, 'I have the information and support I need in order to remain as independent as possible'.

'A service user or carer can automatically feel comfortable in all the statements as they are very clear and acknowledging. They allow you to take control of everything that supports your needs and requirements. The implications are quite dramatic; you feel worthwhile and not a burden to anyone and it allows you to take greater control of your own personal needs.' (Deb Barnes)

Box 4 Think Local, Act Personal 'I' statements ⁹

- Information and advice: having the information I need, when I need it
- active and supportive communities: keeping friends, family and place
- flexible integrated care and support: my support my own way
- workforce: my support staff
- risk enablement: feeling in control and safe
- personal budgets and self-funding: my money.

Dilemmas and challenges

The Care Act 2014 has introduced some major statutory changes to the way social care is delivered nationally, and as such presents a number of dilemmas and challenges to service users, carers and service providers.

Assessment as intervention

Assessment under the Care Act should be an intervention in itself rather than merely a process by which individuals are granted or denied access to funded services. This presents challenges both for local authorities as a whole and for individual professionals in a number of areas, including the necessary provision of reliable and up-to-date information about local services, and management of the time and resources required to ensure that assessments can be completed in a full and holistic manner.

Provision of appropriate and proportionate assessment

Assessment under the Care Act 2014 requires local authorities to become more flexible in administering assessments and to develop assessment processes which allow for this both internally and in collaboration with other organisations.

Measurement of efficacy

Whereas the Care Act 2014 defines specified outcomes for service users and carers, the way in which these are met will be highly specific to each individual service user and may create challenges in the ways local authorities monitor and measure the efficacy of service delivery.

Provision of services

Local authorities are expected under the Care Act to promote and shape the local market so as to achieve diverse provision of care and support in their area. This carries with it budgetary implications with regards to commissioning, funding and fee-setting, which must be considered not only in terms of local authority budgets but also in relation to providers' sustainability.¹⁰

Carer support

The Care Act broadens previous definitions of the carer role and requires assessment of support needs for anyone who feels that they fulfil this role.⁶ The challenge for local authorities is to provide sufficient information to all potential carers on their rights to assessment and possible financial support, while managing the potentially increased demand for these assessments and provisions.

Conclusion

Time will tell whether the aspirations of the Care Act are achieved. The emphasis is clear that care should be holistic and empowering; promotion of well-being is at its core. It is hoped that it will develop services that are inclusive, work in a person-centred way, and achieve specific outcomes. The introduction of the Care Act makes this way of working a statutory duty that public services will be measured by. It will be through individual lives and stories that success will be realised.

1.7.52 Dr Robert George (Rob) Jones FRCPsych

: Formerly Honorary Professor of Old Age Psychiatry, University of Nottingham

Tom Denning Tom Arie

Contents

- *Dr Robert George (Rob) Jones FRCPsych*
– : *Formerly Honorary Professor of Old Age Psychiatry, University of Nottingham*

For over 30 years Rob Jones, who died recently at the age of 69, was a pillar of old age psychiatry in Nottingham and beyond. Qualifying in Manchester in 1970, he trained there in psychiatry and was particularly impressed with David Jolley's work in old age psychiatry. Following research with David Goldberg, he moved in 1980 to Nottingham as senior lecturer in psychiatry in the department of Health Care of the Elderly that Tom Arie had newly set up. This comprised physicians, psychiatrists and other health professions – Rob worked opposite John Bendall, the senior lecturer

in medicine, and was a key figure in the ambitious 1-month combined attachment in old age medicine and psychiatry for all medical students. The novel joint department attracted wide interest, visitors and attached workers coming from home and abroad. Courses in psycho-geriatrics sponsored by the British Council or the World Health Organization brought workers from more than 30 countries to Nottingham and Nottingham staff were often invited abroad. Rob also contributed to a British Council course in Warsaw.

Rob's research included studies of outcomes for care home residents and of community provision; he also participated in major national studies and published widely. He was involved in collaborations that have shaped the practice of old age psychiatry across the UK and internationally. These included the DOMINO-AD clinical trial,¹ which has shown that continuing anti-dementia drugs in people with moderate to severe Alzheimer's disease is worthwhile and does reduce the likelihood of entering a care home at least for a few months.

His most important research was around the care and services for older people with dementia, including, with Ian Rothera and others, a study of life expectancy after entering residential care.² More recently, he provided the psychiatry input into the Medical Crises in Older People programme led by John Gladman. This documented just how many very elderly, frail and vulnerable people are admitted to hospital.³ His later work included studies of care for people with dementia living at home and at the time of his death he was involved in the NIHR Programme Grant PrAISED: Promoting Activity, Independence and Stability in Early Dementia, led by Rowan Harwood.

Rob was a busy clinician and led a district service for older people which served some of the most socially deprived parts of Nottingham, whenever possible taking services to people's own homes. He retired from clinical work in 2013 but continued to be a trustee of the local Radford Care Group, reflecting his passion for the well-being of people living at home, particularly those with dementia. He continued also to work for the university, heading the teaching programme in Health Care of the Elderly until his full retirement in October 2015. Of course, this was not the last we saw of him! He carried on with his research interests, as well as work on public involvement in dementia research – he organised the monthly Centre for Dementia seminars at the Institute of Mental Health. His contributions were recognised by the university with an honorary professorship.

Rob Jones was born in Paignton, Devon, into a family of proud Welsh ancestry. His father edited the local newspaper and this doubtlessly contributed to his insatiable lifelong interest in current affairs. At home he was permanently tuned into BBC Radio 4 and his colleagues were often deeply impressed by his detailed knowledge of world news and politics, to say nothing of lower league football (Torquay United in particular). In Manchester he met Diane and they married in 1971.

Rob was a man of warm and generous personality. He was regarded with respect and affection by all who knew him. His enthusiasm and commitment to the cause of older people was inspiring. For the last 20 years of his career he led academic old age psychiatry in Nottingham, as well as the Trent Dementia Research Network from 2004 until the establishment of the Nottingham Centre for Dementia in 2014. A particular mission was to keep us psychiatrists in close alliance with our colleagues in geriatric medicine, notably through the combined medical student programme. He was especially noted for bundles of papers in carrier bags, festoons of keys and lanyards at his neck, and his characteristic hearty laugh.

Notwithstanding his interest in people, he was quite private. For example, nobody he worked with was aware that Rob had been living with multiple sclerosis for 15 years. Indeed, he completed numerous half marathons during this time. He was definitely not one to complain. After he suffered a myocardial infarction in 2015, we were able to welcome him back to work. It is no surprise, therefore, that his sudden death on 23 May 2016 from a cerebellar haemorrhage came as a blow to all.

He leaves his wife Diane, and his children Haydn, Rhian, David and Siân, along with nine grandchildren.

- *Mental Health in the Digital Age: Grave Dangers, Great Promise*

Technology has always been a double-edged sword: there are associated risks and benefits. As a practising psychiatrist I increasingly rely on technology at work, using next-generation electronic medical records and at times recommending appropriate smartphone-based applications as additional therapy for my patients.

In contrast to numerous other titles about technology and its impact on healthcare – which have emerged as a result of the massive technical advances in the past decade – *Mental Health in the Digital Age* does not focus only on the benefits of the use of technology in mental healthcare. It offers a timely balanced perspective by also providing an in-depth analysis of the risks.
